The **rr-filter** command creates a reflection policy for the route reflectors.

The **undo rr-filter** command removes the configuration.

By default, no reflection policy for a route reflector is created.

Format

rr-filter { *extcomm-filter-number* | *extcomm-filter-name* }

undo rr-filter

Parameters

Parameter	Description	Value
extcomm-filter-number	specifies the number of the extended community filter supported by the route-reflector group. You can specify only one extended community filter each time.	It is an integer that ranges from 1 to 399.
extcomm-filter-name	specifies the name of the extended community filter supported by the route-reflector group. You can specify only one extended community filter each time.	The name is a string of 1 to 51 characters without any space. It is case-sensitive. When double quotation marks are used around the string, spaces are allowed in the string.

Views

BGP-VPNv4 address family view, BGP-VPNv6 address family view, BGP-MDT address family view, BGP-MVPN address family view

Default Level

2: Configuration level

Usage Guidelines

Full-mesh connections need to be established between IBGP peers in an AS to ensure the connectivity between the IBGP peers. When there are many IBGP peers, it is costly to establish a fully-meshed network. An RR or a confederation can be used to solve the problem. Only the IBGP route of which route-target extended community attribute meets the matching rules can be reflected. This allows load balancing among RRs.

Example

Create a route-reflector group, and enable the automatic filtering for VPNv4 route updates on the outbound interface. The group should be created on the basis of the permitted route target extended community attributes.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family vpnv4
[HUAWEI-bgp-af-vpnv4] rr-filter 10
```

10.4.53 service-id (VPN instance view)

Function

The **service-id** command sets a service ID for a VPN instance.

The **undo service-id** command deletes the service ID of a VPN instance.

By default, no service ID is set for a VPN instance.

Format

service-id *service-id*

undo service-id

Parameters

Parameter	Description	Value
service-id	Specifies the service ID of a VPN instance.	An integer ranging from 1 to 4294967295.

Views

VPN instance view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A service ID set in the view of a VPN instance identifies the service of the VPN instance, which facilitates later service query using the NMS.

A service ID is unique on a device. It distinguishes a VPN service from other VPN services on the network. A service ID used by a VPN instance cannot be allocated to other VPN instances.

Configuration Impact

If the **service-id** command is run repeatedly, the last configuration overrides the previous ones.

Example

Set a service ID for a VPN instance.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vrf1
[HUAWEI-vpn-instance-vrf1] service-id 123
```

10.4.54 source

Function

The **source** command configures the source address or source interface of the tunnel.

The **undo source** command deletes the configured source address or source interface.

The source address and source interface of a tunnel are not specified by default.

Format

source { *source-ip-address* | *interface-type interface-number* }

undo source

Parameters

Parameter	Description	Value
source-ip-address	Specifies the source address of a tunnel interface. If a tunnel interface works in IPv4-IPv6 mode, specify an IPv6 address as the source address of the tunnel interface.	The IPv4 address is in dotted decimal notation. The IPv6 address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
interface-type interface-number	Specifies the type and the number of the source interface of the tunnel. The following types of interfaces are often used: VLANIF and loopback.	-

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When configuring a GRE, MPLS TE, IPv4 over IPv6 tunnel or manual IPv6 over IPv4 tunnel, create a tunnel interface. After a tunnel interface is created, run the **source** command to specify the source IP address for the tunnel interface.

Prerequisites

A tunnel interface has been created using the **interface tunnel** command, and the encapsulation mode is set to GRE, MPLS TE, IPv4 over IPv6 or IPv6 over IPv4 of manual mode using the **tunnel-protocol** command.

Precautions

Two tunnel interfaces with the same encapsulation mode, source address, and destination address cannot be configured simultaneously.

You can configure a main interface working in Layer 3 mode as the source tunnel interface.

On the GRE, MPLS TE, IPv4 over IPv6 tunnel or manual IPv6 over IPv4 tunnel, the source address of the local tunnel interface is the destination address of the remote tunnel interface, and the destination address of the local tunnel interface is the source address of the remote tunnel interface.

Example

Set the tunnel type of Tunnel1 to IPv6 over IPv4 of manual mode and configure the source IP address of Tunnel1 as 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol ipv6-ipv4
[HUAWEI-Tunnel1] source 10.1.1.1
```

Configure Tunnel1 of GRE and use Loopback1 address as the interface address.

```
<HUAWEI> system-view
[HUAWEI] interface Loopback 1
[HUAWEI-LoopBack1] ip address 10.2.1.1 32
[HUAWEI-LoopBack1] quit
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol gre
[HUAWEI-Tunnel1] source loopback 1
```

10.4.55 supernet label-route advertise

Function

The **supernet label-route advertise disable** command disables a BGP device from advertising BGP supernet labeled routes.

The **undo supernet label-route advertise disable** or **supernet label-route advertise enable** command restores the default configuration.

By default, BGP supernet labeled routes can be preferentially selected and advertised.

Format

supernet label-route advertise disable

supernet label-route advertise enable

undo supernet label-route advertise disable

Parameters

None

Views

BGP view, BGP-IPv4 unicast address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A BGP supernet route has the same destination address and next hop address or has a more detailed destination address than the next hop address. Any route that meets one of the following conditions is a BGP supernet route.

- If you perform bitwise AND operations on the destination address mask with the destination address and next hop address, respectively, the calculated network addresses are the same, and the destination address mask is greater than or equal to the next hop address mask.
- If you perform bitwise AND operations on the destination address mask with the destination address and next hop address, respectively, the calculated network addresses are different. However, if you perform bitwise AND operations on the next hop address mask with the destination address and next hop address, respectively, the calculated network addresses are the same.

For example, the route destined for 10.6.6.6 in the following command output is a BGP supernet route.

```
<HUAWEI> display bgp routing-table
 BGP Local router ID is 10.1.1.2
 Status codes: * - valid, > - best, d - damped,
               h - history,  i - internal, s - suppressed, S - Stale
               Origin : i - IGP, e - EGP, ? - incomplete

 Total Number of Routes: 1
       Network            NextHop        MED        LocPrf    PrefVal Path/Ogn
   *>i  10.6.6.6/32        10.6.6.6       0          100       0      ?
```

Example

Disable a BGP device from advertising BGP supernet labeled routes.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] supernet label-route advertise disable
```

10.4.56 tunnel binding

Function

The **tunnel binding** command binds a specified tunnel to the destination IP address. Therefore, the tunnel can be used by a specified VPN.

The **undo tunnel binding** command cancels the binding.

By default, a tunnel is not bound to any IP address.

Format

tunnel binding destination *dest-ip-address* **te** { **tunnel** *interface-number* } &<1-6> [**ignore-destination-check**] [**down-switch**]

undo tunnel binding destination *dest-ip-address*

Parameters

Parameter	Description	Value
dest-ip-address	Specifies the destination address of the tunnel.	-
interface-number	Specifies the interface number of the bound tunnel interface.	-
ignore-destination-check	Specifies whether to ignore destination consistency check. If this parameter is enabled, a tunnel policy selects a TE tunnel for route recursion even if the destination address of that TE tunnel is different from the destination address specified in the tunnel policy.	-
down-switch	Indicates that the tunnel switchover is enabled. After this parameter is configured, an available tunnel, with the priority as LSP, CR-LSP, is adopted when the bound TE tunnel fails.	-

Views

Tunnel policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A tunnel policy determines the selection of proper tunnels for VPN services. There are two types of tunnel policies. Only one policy type can be configured in the tunnel policy view.

- Tunnel type prioritizing policy: Such a policy specifies the sequence in which different types of tunnels are selected. The **tunnel select-seq** command is used to configure a tunnel type prioritizing policy.
- Tunnel binding policy: Such a policy binds a tunnel to a VPN for service transmission. The **tunnel binding** command is used to configure a tunnel binding policy.

Only MPLS TE tunnels can be bound to VPNs. The **tunnel binding** command can specify the MPLS TE tunnels that are used for VPN binding, facilitating QoS deployment. If some VPN services have high requirements for QoS, run the **tunnel binding** command to use specific MPLS TE tunnels to transmit these VPN services.

Prerequisites

The **tunnel-policy** command is run to create a tunnel policy.

The **mpls te reserved-for-binding** command is run in the view of the tunnel interface to be bound to an MPLS TE tunnel.

Precautions

The **tunnel binding** command can be run repeatedly in the tunnel policy view so long as the value of *dest-ip-address* varies.

Apply the tunnel binding policy to the VPN instance so that the VPN instance can have its routes recursing to the bound MPLS TE tunnel.

Example

Bind the IP address of the remote PE, 10.2.2.9, to the local tunnel interface Tunnel1 in the tunnel policy view.

```
<HUAWEI> system-view
[HUAWEI] tunnel-policy tnlpolicyname
[HUAWEI-tunnel-policy-tnlpolicyname] tunnel binding destination 10.2.2.9 te tunnel 1
```

10.4.57 tunnel-selector (system view)

Function

The **tunnel-selector** command creates a tunnel selector and displays the tunnel selector view.

The **undo tunnel-selector** command cancels the setting.

By default, no tunnel selector is created.

Format

tunnel-selector *tunnel-selector-name* { **permit** | **deny** } **node** *node*

undo tunnel-selector *tunnel-selector-name* [**node** *node*]

Parameters

Parameter	Description	Value
tunnel-selector-name	Specifies the name of a tunnel selector.	The value is a string of 1 to 40 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
permit	Specifies the matching mode of the tunnel selector to **permit**. If a route matches all the **if-match** clauses of a node, the route matches the node and all the actions defined by the **apply** clause are performed on the route. If a route does not match one **if-match** clause of a node, the route continues to match the next node.	-
deny	Specifies the matching mode of the tunnel selector to **deny**. If a route matches all the **if-match** clauses of a node, the route is denied and does not match the next node.	-
node *node*	Specifies the index of the node of the tunnel selector. The route first matches the node with a smaller index value.	The value is an integer ranging from 0 to 65535.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **tunnel-selector** command is often used in BGP/MPLS IP VPN networking. A tunnel selector needs to be created in the following scenarios:

- The SPE in the HVPN networking needs to apply a tunnel policy to VPNv4 routes that are received from UPEs.

Follow-up Procedure

Configure the following clauses after creating a tunnel selector (each node of the tunnel selector consists of two parts):

- **if-match** clause: sets filtering conditions on a node. To filter routes by RD, run the **if-match rd-filter** command. To filter routes by next hop, run the **if-match ip next-hop** command.
- **apply** clause: applies a tunnel policy to the routes filtered by the **if-match** clause using the **apply tunnel-policy** command.

In addition, the system will have routes recursing to expected tunnels only after applying a tunnel selector. The **tunnel-selector** command can be run in the BGP view for the application of a tunnel selector.

Precautions

A change in the tunnel selector may cause VPN services to be interrupted because BGP-VPNv4 or BGP labeled routes may fail to recurse to tunnels.

Example

Create a tunnel selector named tps, and set the node number to 10 and the matching mode to **permit**.

```
<HUAWEI> system-view
[HUAWEI] tunnel-selector tps permit node 10
[HUAWEI-tunnel-selector]
```

10.4.58 tunnel-selector (BGP-VPNv4 address family view)

Function

The **tunnel-selector** command applies a tunnel selector to BGP-VPNv4 or BGP labeled routes.

The **undo tunnel-selector** command cancels the configuration.

By default, no tunnel selector is applied to BGP-VPNv4 or BGP labeled routes. BGP-VPNv4 or BGP labeled route recurse only to LSPs.

Format

tunnel-selector *tunnel-selector-name*

undo tunnel-selector

Parameters

Parameter	Description	Value
tunnel-selector-name	Specifies the name of a tunnel policy selector.	The value is a string of 1 to 40 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

BGP-VPNv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **tunnel-selector** command is often used in BGP/MPLS IP VPN networking. It can be used in the following scenarios to apply a tunnel selector to BGP-VPNv4 or BGP labeled routes:

- The SPE in the HVPN networking needs to apply a tunnel policy to VPNv4 routes that are received from UPEs.

Prerequisites

The **tunnel-selector** command is run to create a tunnel selector.

Precautions

Deleting the tunnel selector applied to BGP-VPNv4 or BGP labeled routes may cause VPN service interruption because the BGP-VPNv4 or BGP labeled routes may fail to recurse to tunnels.

Example

Apply a tunnel selector to BGP labeled routes.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family vpnv4
[HUAWEI-bgp-af-vpnv4] tunnel-selector tps
```

10.4.59 tunnel select-seq

Function

The **tunnel select-seq** command specifies the priority sequence of the tunnels taking part in load balancing.

The **undo tunnel select-seq load-balance-number** command restores the default setting.

By default, only LDP LSPs, BGP LSP or static LSPs are selected and no load balancing is performed.

Format

tunnel select-seq { **gre** | **lsp** | **cr-lsp** } * **load-balance-number** *load-balance-number*

undo tunnel select-seq

Parameters

Parameter	Description	Value
gre	Specifies a GRE tunnel. **NOTE** This parameter is not supported in this version.	-

Parameter	Description	Value
lsp	Specifies the LDP LSPs, BGP LSP or static LSPs. **NOTE** This parameter is not supported by the S5731S-S, S6730S-S, and S6735-S.	-
cr-lsp	Specifies the CR-LSP tunnel. **NOTE** This parameter is not supported by the S5731S-S, S6730S-S, and S6735-S.	-
load-balance-number	Specifies the number of tunnels taking part in load balancing.	The value is an integer that ranges from 1 to 6.

Views

Tunnel policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, a VPN instance uses LSPs for service transmission on the backbone network. To use other types of tunnels or configure load balancing for service transmission of the VPN instance, you need to apply a tunnel policy to the VPN instance.

Precautions

A tunnel policy determines the selection of proper tunnels for VPN services. There are two types of tunnel policies.

- Tunnel type prioritizing policy: Such a policy specifies the sequence in which different types of tunnels are selected. The **tunnel select-seq** command is used to configure a tunnel type prioritizing policy.
- Tunnel binding policy: Such a policy binds a tunnel to a VPN for service transmission. The **tunnel binding** command is used to configure a tunnel binding policy.

If the **tunnel select-seq** command is run, the VPN instance preferably selects the tunnel type with the highest priority according to the specified sequence. For example, after the **tunnel select-seq cr-lsp lsp load-balance-number 2** command is run in the tunnel policy view, the VPN instance will select CR-LSPs to transmit services on the backbone network.

- If two or more CR-LSPs are available on the network, the VPN instance randomly selects two of them for service transmission.
- If no CR-LSP or only one CR-LSP is available on the network, the VPN instance selects LSPs as substitutes with the existing CR-LSP for service transmission.
- If the number of tunnels used by the VPN instance is reduced to 1, the VPN instance uses the tunnel policy to re-select tunnels.

If **lsp** is specified in the command, three types of LSPs can serve as candidate tunnels: LDP LSP, BGP LSP, and static LSP. The priority sequence of these LSPs taking part in load balancing is LDP LSP > BGP LSP > static LSP. For example, if the **tunnel select-seq lsp cr-lsp load-balance-number 3** command is configured for the tunnel policy:

- If three or more LDP LSPs are available on the network, the VPN instance randomly selects three of them for service transmission.
- If less than three LDP LSPs are available on the network, the VPN instance selects BGP LSPs as substitutes to ensure that three LSPs work in load balancing mode to transmit services.
- If the total number of LDP and BGP LSPs available on the network is less than 3, the VPN instance selects static LSPs as substitutes to ensure that three LSPs work in load balancing mode to transmit services.

After the **tunnel select-seq** command is executed, apply the configured tunnel policy to the VPN instance so that the VPN instance can select tunnels based on the tunnel policy and have its services load-balanced across tunnels.

The load balancing mode configured using the **tunnel select-seq** command in a tunnel policy takes effect only for L3VPN.

Example

Configure a tunnel policy that only LDP LSPs, BGP LSP or static LSPs can be used and no load balancing is performed.

```
<HUAWEI> system-view
[HUAWEI] tunnel-policy l2
[HUAWEI-tunnel-policy-l2] tunnel select-seq lsp load-balance-number 1
```

10.4.60 tunnel-policy nonexistent-config-check

Function

The **tunnel-policy nonexistent-config-check** command configures whether a nonexistent tunnel policy can be specified in a command.

The **undo tunnel-policy nonexistent-config-check disable** command configures only an existing tunnel policy can be specified in a command.

By default, only an existing tunnel policy can be specified in a command.

Format

tunnel-policy nonexistent-config-check { **disable** | **enable** }

undo tunnel-policy nonexistent-config-check disable

Parameters

Parameter	Description	Value
disable	Indicates that a nonexistent tunnel policy can be specified in a command.	-
enable	Indicates that only an existing tunnel policy can be specified in a command.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

By default, if you specify a nonexistent tunnel policy in a command, the command does not take effect.

If you need the nonexistent tunnel policy can be specified in a command, run the **tunnel-policy nonexistent-config-check disable** command.

Example

# Indicates that a nonexistent tunnel policy can be specified in a command.

```
<HUAWEI> system-view
[HUAWEI] tunnel-policy nonexistent-config-check disable
```

10.4.61 tunnel-policy (system view)

Function

The **tunnel-policy** command creates a tunnel policy and displays the tunnel policy view.

The **undo tunnel-policy** command deletes the specified tunnel policy.

By default, no tunnel policy is created in the system.

Format

tunnel-policy *policy-name*

undo tunnel-policy *policy-name*

Parameters

Parameter	Description	Value
policy-name	Displays the name of a tunnel policy.	The value is a string of 1 to 39 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, a VPN instance selects LSPs without performing load balancing based on the default tunnel policy. If you want to make a change, run the **tunnel-policy** command to create a tunnel policy.

There are two types of tunnel policies:

- Tunnel type prioritizing policy: It specifies the sequence in which different types of tunnels are selected and the number of tunnels taking part in load balancing.
- Tunnel binding policy: It binds a tunnel to a destination address. In this manner, the VPN traffic bound for the destination address enters the bound tunnel only, and as a result, QoS is guaranteed for the VPN traffic.

Precautions

If you change the tunnel policy in a VPN instance, VPN services may be interrupted due to a possibility of recursion failures.

Run one of the following commands to perform further configuration on the created tunnel policy:

- To configure the tunnel policy as a tunnel type prioritizing policy, run the **tunnel select-seq** command.
- To configure the tunnel policy as a tunnel binding policy, run the **tunnel binding** command.

The system can select tunnels for a VPN instance based on a tunnel policy only after the tunnel policy is applied to the VPN instance. The mode in which a tunnel policy is applied to a VPN instance varies according to the VPN type.

Example

Create a tunnel policy named policy1 and enter the tunnel policy view.

```
<HUAWEI> system-view
[HUAWEI] tunnel-policy policy1
[HUAWEI-tunnel-policy-policy1]
```

10.4.62 tunnel-protocol

Function

The **tunnel-protocol** command configures the tunnel protocol on a tunnel interface.

The **undo tunnel-protocol** command restores the tunnel protocol to the default configuration.

By default, no tunnel protocol is used on a tunnel interface.

Format

tunnel-protocol { **gre** | **ipv6-ipv4** [**6to4** | **isatap**] | **ipv4-ipv6** | **mpls te** | **none** }

undo tunnel-protocol

Parameters

Parameter	Description	Value
gre	Indicate that the GRE tunnel protocol is configured on a tunnel interface. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the parameters.	-
ipv4-ipv6	Indicate that the IPv4 to IPv6 tunnel protocol is configured on a tunnel interface. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support the parameter.	-
ipv6-ipv4 [**6to4** | **isatap**]	Configure the tunnel protocol of the tunnel interface as ipv6-ipv4: ● **ipv6-ipv4**: use a manual IPv6 over IPv4 tunnel ● **ipv6-ipv4 6to4** : using 6to4 tunnel ● **ipv6-ipv4 isatap** : using isatap tunnel **NOTE** Only the S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support these parameter.	-

Parameter	Description	Value
mpls te	Indicate that the MPLS TE tunnel protocol is configured on a tunnel interface. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6720-EI, S6720S-EI, S6730-H, S6730-S, S6730S-S, and S6730S-H support the parameter.	-
none	Indicate that no tunnel protocol is configured on a tunnel interface.	-

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After creating a tunnel interface using the **interface tunnel** command, run the **tunnel-protocol** command to configure the tunnel encapsulation mode for the tunnel interface.

The following tunnel encapsulation modes are available:

- GRE: encapsulates packets of some network layer protocols such as IP or IPX to enable these encapsulated packets to be transmitted on networks running other protocols such as IP.
- IPv4-IPv6: creates tunnels on the IPv6 networks to connect IPv4 isolated sites so that IPv4 isolated sites can access other IPv4 networks through the IPv6 public network.
- IPv6-IPv4: creates tunnels on the IPv4 networks to connect IPv6 isolated sites so that IPv6 packets can be transmitted on IPv4 networks.
- MPLS TE: integrates the MPLS technology with traffic engineering. It can reserve resources by setting up LSP tunnels for a specified path in an attempt to avoid network congestion and balance network traffic.

Precautions

- The **none** mode indicates the initial configuration, that is, no tunnel encapsulation mode is configured. In practice, you must select another tunnel encapsulation mode.
- You must configure the tunnel encapsulation mode before setting the source IP address or other parameters for a tunnel interface. Changing the encapsulation mode of a tunnel interface deletes other parameters of the tunnel interface.

Example

Set the tunnel encapsulation mode of Tunnel2 to GRE.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 2
[HUAWEI-Tunnel2] tunnel-protocol gre
```

10.4.63 tnl-policy

Function

The **tnl-policy** command associates a tunnel policy with the current VPN instance address family.

The **undo tnl-policy** command dissociates the current VPN instance address family from a tunnel policy.

By default, no tunnel policy is associated with the VPN instance address family. By default, a tunnel is selected for a VPN in the sequence of the LSP, CR-LSP, and Local_IfNet, and no load balancing is performed.

Format

tnl-policy *policy-name*

undo tnl-policy

Parameters

Parameter	Description	Value
policy-name	Specifies the name of the tunnel policy to be associated with the VPN instance address family.	The value is a string of 1 to 39 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

VPN instance view, VPN instance IPv4 address family view, VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, a device only uses an LSP tunnel to forward data on the backbone network and cannot implement multi-path load balancing at the same time. To ensure transmission quality of services and specify a TE tunnel to transmit VPN services, or to improve transmission efficiency and implement load balancing, run the **tunnel-policy** command to configure a tunnel policy and run the **tnl-policy** command to reference the tunnel policy in the VPN address family view.

Prerequisites

1. The **ip vpn-instance** command has been executed to create a VPN instance and enter the VPN instance view.
2. The **ipv4-family** command has been executed to create a VPN instance and enter the VPN instance IPv4 address family view.
3. The **route distinguisher** command has been executed to set the RD of the VPN instance.

Precautions

If the tunnel policy associated with a VPN instance enabled with the address family cannot match an existing tunnel on the network, the routes in the VPN instance enabled with the address family will have routes recursing to tunnels based on the default tunnel policy. If the recursion fails, services will be interrupted.

If the address family of a VPN instance changes or the associated tunnel policy is deleted, VPN services will be interrupted for a short time even if tunnels matching the tunnel policy are available on the network. Therefore, use the **tnl-policy** command with caution.

Follow-up Procedure

If the associated tunnel policy does not exist, run the **tunnel-policy** command to create the tunnel policy.

Example

Associate a tunnel policy named **po1** with the VPN instance named *vpn2*.

```
<HUAWEI> system-view
[HUAWEI] tunnel-policy po1
[HUAWEI-tunnel-policy-po1] tunnel select-seq lsp load-balance-number 2
[HUAWEI-tunnel-policy-po1] quit
[HUAWEI] ip vpn-instance vpn2
[HUAWEI-vpn-instance-vpn2] ipv4-family
[HUAWEI-vpn-instance-vpn2-af-ipv4] route-distinguisher 100:1
[HUAWEI-vpn-instance-vpn2-af-ipv4] tnl-policy po1
```

10.4.64 transit-vpn

Function

The **transit-vpn** command ensures that the status of a VRF (VPN Routing and Forwarding table) obtained from MIB is always Up, no matter whether this VRF is bound to interfaces.

The **undo transit-vpn** command restores the default setting.

By default, the status of a VRF obtained from MIB is Up only if it is bound to at least one interface in the Up state.

NOTE

Only the following switch models support this command:

S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H

Format

transit-vpn

undo transit-vpn

Parameters

None.

Usage Guidelines

Usage Scenario

According to RFC, the status of a VRF obtained from MIB is Up only if it is bound to at least one interface in the Up state. In the HoVPN or H-VPN networking, however, a VRF does not need to be bound to any interface. If the VRF is not bound to an interface in this networking, the status of the VRF obtained from MIB is Down by default.

In this case, you can run the **transit-vpn** command to ensure that the status of a VRF obtained from MIB is always Up.

Prerequisites

The **route-distinguisher** command has been executed to set the RD of the VPN instance.

Example

Configure the status of the VRF vpna obtained from MIB to be always Up, no matter whether the VRF is bound to interfaces.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vpna
[HUAWEI-vpn-instance-vpna] ipv4-family
[HUAWEI-vpn-instance-vpna-af-ipv4] route-distinguisher 100:1
[HUAWEI-vpn-instance-vpna-af-ipv4] transit-vpn
```

10.4.65 undo vpn frr all

Function

Using the **undo vpn frr all** command, you can disable VPN FRR in all the VPN instances.

Format

undo vpn frr all

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The VPN FRR function may be configured in multiple VPN instances on a device. The **undo vpn frr** command takes a long time to cancel the VPN FRR function of all VPN instances one by one.

In the system view, run the **undo vpn frr all** command to simultaneously cancel the VPN FRR function of IPv4 and IPv6 address families in all VPN instances.

Precautions

To cancel the VPN FRR function of a VPN instance, run the **undo vpn frr** command.

Example

Disable VPN FRR of all the VPN instances in the system view.

```
<HUAWEI> system-view
[HUAWEI] undo vpn frr all
```

10.4.66 vpn-route cross multipath

Function

The **vpn-route cross multipath** command adds multiple VPNv4 or VPNv6 routes to a VPN instance with a different RD from these routes' RDs.

The **undo vpn-route cross multipath** command restores the default configuration.

By default, if the RDs of multiple VPNv4 or VPNv6 routes are different from the RD of a VPN instance, only the optimal route is added to the VPN instance.

Format

vpn-route cross multipath

undo vpn-route cross multipath

Parameters

None

Views

BGP-VPN instance IPv4 address family view or BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, if the RD of the VPN instance on the local PE is different from the RDs of the VPN instances on multiple remote PEs, and the RDs of the VPN instances on remote PEs are the same, the local PE adds only the optimal route to the VPN instance after receiving VPNv4 or VPNv6 routes with the same destination address from the remote PEs. As a result, load balancing or VPN FRR does not take effect. To resolve this problem, run the **vpn-route cross multipath** command on the local PE.

Configuration Impact

After you run the **vpn-route cross multipath** command, the local PE adds multiple VPNv4 or VPNv6 routes to a VPN instance with a different RD from these routes' RDs. The number of VPNv4 or VPNv6 routes that can be added to the VPN instance depends on whether load balancing or VPN FRR is configured.

- If no load balancing is configured, a maximum of two VPNv4 or VPNv6 routes can be added to the VPN instance.
- If you set the maximum number of equal-cost routes for load balancing to *n* using the **maximum load-balancing** command, *n* VPNv4 or VPNv6 routes can be added to the VPN instance.
- If you configure VPN FRR and set the maximum number of equal-cost routes for load balancing to *n* using the **maximum load-balancing** and **auto-frr** command, *n* + 1 VPNv4 or VPNv6 routes can be added to the VPN instance.

Example

Add multiple VPNv4 routes to a VPN instance with a different RD from these routes' RDs.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family vpn-instance vrf1
[HUAWEI-bgp-vrf1] vpn-route cross multipath
```

Add multiple VPNv6 routes to a VPN instance with a different RD from these routes' RDs.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv6-family vpn-instance vrf1
[HUAWEI-bgp6-vrf1] vpn-route cross multipath
```

10.4.67 vpn-target

Function

The **vpn-target** command configures the export or import VPN target extended community attribute for the VPN instance address family.

The **undo vpn-target** command deletes the setting.

By default, no export or import VPN target extended community list is configured for the VPN instance address family.

Format

vpn-target *vpn-target* &<1-8> [**both** | **export-extcommunity** | **import-extcommunity**]

undo vpn-target { **all** | *vpn-target* &<1-8> [**both** | **export-extcommunity** | **import-extcommunity**] }

NOTE

Only the following switch models support this command:

S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S

The S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, and S6720S-S only support the VPN instance view and VPN instance IPv4 address family view.

Parameters

Parameter	Description	Value
vpn-target	Specifies the VPN target extended community attribute to be added to the VPN target extended community list of the VPN instance address family. The forms of VPN targets are as follows: ● 2-byte AS number: 4-byte user-defined number, for example, 1:3. The AS number ranges from 0 to 65535. The user-defined number ranges from 0 to 4294967295. The AS number and the user-defined number cannot both be 0. That is, a VPN target cannot be 0:0. ● IPv4-address: 2-byte user-defined number, for example, 192.168.122.15:1. The IP address ranges from 0.0.0.0 to 255.255.255.255. The user-defined number ranges from 0 to 65535. ● Integral 4-byte AS number:2-byte user-defined number, for example, 65537:3. An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a VPN target cannot be 0:0. ● 4-byte AS number in dotted notation:2-byte user-defined number, for example, 0.0:3 or 0.1:0. A 4-byte AS number in dotted notation is in the format of *x.y*, where *x* and *y* are integers that range from 0 to 65535 and from 0 to 65535, respectively. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a VPN target cannot be 0.0:0.	-
both	Adds the VPN target extended community attribute to the export and import VPN target extended community lists of the VPN instance address family. If none of **both**, **export-extcommunity**, or **import-extcommunity** is specified, **both** is adopted by default.	-
export-extcommunity	Adds the VPN target extended community attribute to the export VPN target extended community lists of the VPN instance address family.	-
import-extcommunity	Adds the VPN target extended community attribute to the import VPN target extended community lists of the VPN instance address family.	-

Parameter	Description	Value
all	Delete all the VPN targets of the VPN instance IPv4 address family.	-

Views

VPN instance view, VPN instance IPv4 address family view, VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a VPN instance is configured on a PE, the **vpn-target** command must be used to configure a VPN target for the IPv4 or IPv6 address family of the VPN instance.

The VPN target controls route learning between VPN sites. A VPN target may be either an import VPN target or an export VPN target. An export VPN target is contained in a VPNv4 or IPv6 route to be advertised to a remote MP-BGP peer. After receiving a VPNv4 or IPv6 route, an MP-BGP peer compares the received export VPN target with the local import VPN target to determine whether the VPNv4 or IPv6 route can be added to the routing table of the local VPN instance enabled with the IPv4 or IPv6 address family.

Prerequisites

The **route-distinguisher** command has been executed to set the RD of the VPN instance.

Precautions

A VPN target configured using the **vpn-target** command will not overwrite any previously configured VPN target. If the number of configured VPN targets has reached the maximum limit, no VPN target can be added by using the **vpn-target** command.

After a VPN target is configured for the IPv4 or IPv6 address family of a VPN instance, only the routes that match the VPN target will be accepted by the IPv4 or IPv6 address family of the VPN instance.

If all the VPN targets of the IPv4 or IPv6 address family of a VPN instance are deleted using the **undo vpn-target** command, all routes learned by the IPv4 or IPv6 address family of the VPN instance from other VPN instances will be deleted.

Multiple VPN targets can be configured for the IPv4 or IPv6 address family of a VPN instance. One **vpn-target** command can configure a maximum of eight VPN targets at a time. If you want to configure more VPN targets in the VPN instance IPv4 or IPv6 address family view, run the **vpn-target** command multiple times. When VPN routes are advertised between VPN instances, if one of the VPN targets carried in the VPNv4 or IPv6 routes matches the import VPN target of the IPv4 or

IPv6 address family of a local VPN instance, the routes will be added to the routing table of the local VPN instance.

Example

Add 3:3 to the export VPN target extended community list and 4:4 to the import VPN target extended community list of the VPN instance named *vrf1*.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vrf1
[HUAWEI-vpn-instance-vrf1] ipv4-family
[HUAWEI-vpn-instance-vrf1-af-ipv4] route-distinguisher 100:1
[HUAWEI-vpn-instance-vrf1-af-ipv4] vpn-target 3:3 export-extcommunity
[HUAWEI-vpn-instance-vrf1-af-ipv4] vpn-target 4:4 import-extcommunity
```

10.4.68 vpn frr

Function

Using the **vpn frr** command, you can enable VPN FRR.

Using the **undo vpn frr** command, you can disable VPN FRR.

By default, VPN FRR is disabled.

Format

vpn frr route-policy *route-policy-name*

undo vpn frr

Parameters

Parameter	Description	Value
route-policy *route-policy-name*	Specifies the name of the route-policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

VPN instance view, VPN instance IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

VPN FRR is applied on a VPN where a CE is dual-homed to two PEs. VPN FRR uses a secondary tunnel to back up the primary tunnel and detects the connectivity of the primary tunnel in combination with rapid detection technologies such as BFD. When a fault occurs on the primary tunnel, a PE configured with VPN FRR can switch VPN traffic to the secondary tunnel before the VPN routes are converged. This improves reliability of data forwarding on the public network.

VPN FRR has two modes: VPN static FRR and VPN auto FRR. The **vpn frr** command configures manual VPN FRR and the **auto-frr** command configures VPN Auto FRR.

Compared with VPN Auto FRR, manual VPN FRR specifies backup next hop more precisely. If manual VPN FRR and VPN Auto FRR are configured simultaneously, manual VPN FRR takes preference over VPN Auto FRR. If manual VPN FRR fails, VPN Auto FRR takes effect.

Prerequisites

Manual VPN FRR function takes effect after the backup next hop is manually specified. It is recommended that you run the **route-policy** command to specify the backup next hop for VPN routes before configuring Manual VPN FRR function.

Follow-up Procedure

After configuring Manual VPN FRR function, run the **display ip routing-table vpn-instance** *vpn-instance-name ip-address* **verbose** command to check whether the route has a secondary tunnel and a backup label.

Precautions

NOTE

The **undo vpn frr** command cancels the VPN FRR function of only the specified VPN instance. In the system view, run the **undo vpn frr all** command to simultaneously cancel the VPN FRR function of IPv4 and IPv6 address families in all VPN instances.

Example

Specify the IP address of the backup next hop in the route-policy named **vpn_frr_rp**, and enable VPN FRR in the VPN instance view.

```
<HUAWEI> system-view
[HUAWEI] route-policy vpn_frr_rp permit node 10
[HUAWEI-route-policy] apply backup-nexthop 10.2.2.9
[HUAWEI-route-policy] quit
[HUAWEI] ip vpn-instance vpn1
[HUAWEI-vpn-instance-vpn1] ipv4-family
[HUAWEI-vpn-instance-vpn1-af-ipv4] route-distinguisher 100:1
[HUAWEI-vpn-instance-vpn1-af-ipv4] vpn frr route-policy vpn_frr_rp
[HUAWEI-vpn-instance-vpn1-af-ipv4] quit
```

10.5 VLL Configuration Commands

10.5.1 Command Support

Only the following switch models support VLL:

S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H

Command support and parameter support on your switches may differ from those described in this section. For details, see the specific commands.

10.5.2 bfd bind pw

Function

The **bfd bind pw** command configures a BFD session to detect a PW.

The **undo bfd** command deletes a specified BFD session.

By default, no BFD session is configured to detect a PW.

Format

bfd *cfg-name* **bind pw interface** *interface-type interface-number* [**secondary**]

undo bfd *cfg-name*

Parameters

Parameter	Description	Value
cfg-name	Specifies the name of the BFD session.	The value is a string of 1 to 15 case-insensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
interface *interface-type interface-number*	Specifies the type and number of the interface where the PW to be detected resides, namely, the AC interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
secondary	Indicates that the BFD session detects the secondary PW.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a transmission device exists on a direct link, BFD detects a link fault faster than a link detection mechanism on an interface. On networks demanding fast fault detection, run the **bfd bind pw** command to configure a BFD session to detect a PW.

Prerequisites

- A PW has been configured on an AC interface by running the **mpls l2vc** command.
- BFD has been enabled globally by running the **bfd** command.
- A single-segment or multi-segment PW has been configured.

Precautions

- When detecting a PW, BFD sessions must be bound to the source and destination ends of a PW.
- You need to create a BFD session to detect primary and secondary PWs separately.

NOTE

When running the **bfd bind pw** command to detect a multi-segment PW, ensure that the first-segment PW is a VLL PW configured on a non-SPE node.

When running the **bfd bind pw** command to detect a single-segment PW, ensure that the single-segment PW is configured on a non-SPE node.

Example

Create a BFD session to detect a PW.

```
<HUAWEI> system-view
[HUAWEI] bfd pe2 bind pw interface vlanif 10
```

10.5.3 ccc interface in-label out-label

Function

The **ccc interface in-label out-label** command creates a remote CCC connection between CEs connected to different PEs. This command must be configured on two PEs.

The **undo ccc** command deletes the CCC connection.

By default, no remote CCC connection is created.

Format

ccc *ccc-connection-name* **interface** *interface-type1 interface-number1* [**raw** | **tagged**] **in-label** *in-label-value* **out-label** *out-label-value* **nexthop** *nexthop-address* [**control-word** | **no-control-word**]

undo ccc *ccc-connection-name*

Parameters

Parameter	Description	Value
ccc-connection-name	Specifies the CCC connection name, which uniquely identifies a CCC connection on a PE.	The value is a string of 1 to 20 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
interface *interface-type1 interface-number1*	Specifies the type and number of the incoming interface of data traffic. In the preceding information: ● *interface-type1* specifies the interface type. ● *interface-number1* specifies the interface number.	-
raw	Sets the inbound interface to raw mode. When packets arrive at the inbound interface in raw mode, the system deletes the Provider tags (P-Tags) of packets.	By default, the tagged mode is used.
tagged	Sets the inbound interface to tagged mode. When packets arrive at the inbound interface in tagged mode, the system retains the Provider tags (P-Tags) of packets.	By default, the tagged mode is used.
in-label *in-label-value*	Specifies the inbound label.	The value is a decimal integer that ranges from 16 to 1023.
out-label *out-label-value*	Specifies the outbound label.	The value is a decimal integer that ranges from 0 to 1048575.
nexthop *nexthop-address*	Specifies the IP address of the next hop.	The value is in dotted decimal notation.
control-word | **no-control-word**	Enables or disable the control word (CW).	By default, the control word is disabled.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When two CEs connected to different PEs, use the **ccc interface in-label out-label** command to create a remote CCC connection between the CEs. This command must be executed on both PEs.

Precautions

An interface cannot serve as an L2VPN AC (Attachment Circuit) interface and L3VPN AC interface at the same time. After an interface is bound to an L2VPN, the Layer 3 features such as the IP address and routing protocol configured on this interface become invalid.

NOTE

The device supports only VLANIF interfaces as AC interfaces of CCC connections.

A PE uses connection names to identify different CCC connections. On different PEs, the same CCC connection can use different names. When a P is connected to a PE, the static LSP must be configured between the P and PE. Do not configure the name of a CCC connection as **type**. Otherwise, you cannot view information about the CCC connection using the **display vll ccc** *ccc-name* command. Note that the outgoing label of the previous device is the inner label of the next device.

By default, link type negotiation is enabled globally on the device. If a VLANIF interface is used as an AC-side interface for L2VPN, the configuration conflicts with link type negotiation. In this case, run the **lnp disable** command in the system view to disable link type negotiation.

Example

Create a remote CCC connection between CEs connected to different PE devices.

```
<HUAWEI> system-view
[HUAWEI] ccc ccc-connection interface vlanif 10 in-label 100 out-label 200 nexthop 10.1.1.2
```

10.5.4 ccc interface out-interface

Function

The **ccc interface out-interface** command creates a local CCC connection between two CEs connected to the same PE.

The **undo ccc** command deletes the CCC connection.

By default, no local CCC connection is created.

Format

ccc *ccc-connection-name* **interface** *interface-type1 interface-number1* [**raw** | **tagged**] **out-interface** *interface-type2 interface-number2* [**raw** | **tagged**]

undo ccc *ccc-connection-name*

Parameters

Parameter	Description	Value
ccc-connection-name	Specifies a CCC connection name, which uniquely identifies a CCC connection on a PE.	The value is a string of 1 to 20 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
interface *interface-type1 interface-number1*	Specifies the type and number of the interface connected to the first CE. ● *interface-type1* specifies the interface type. ● *interface-number1* specifies the interface number.	-
out-interface *interface-type2 interface-number2*	Specifies the type and number of the interface connected to the second CE. ● *interface-type2* specifies the interface type. ● *interface-number2* specifies the interface number.	-
raw	Sets the inbound interface to raw mode. When packets arrive at the inbound interface in raw mode, the system deletes the provider tags (P-tags) of packets.	By default, the tagged mode is used.
tagged	Sets the inbound interface to tagged mode. When packets arrive at the inbound interface in tagged mode, the system retains the provider tags (P-tags) of packets.	By default, the tagged mode is used.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When two CEs connect to the same PE, use the **ccc interface out-interface** command to create a local CCC connection between the CEs.

Precautions

An interface cannot serve as an L2VPN AC interface and L3VPN AC interface at the same time. After an interface is bound to an L2VPN, the Layer 3 features such as the IP address and routing protocol configured on this interface become invalid. After the interface is bound to a CCC connection, its sub-interfaces no longer transmit Layer 3 traffic.

NOTE

- The device supports only VLANIF interfaces as AC interfaces of CCC connections.

A CCC connection is bidirectional; therefore, only one connection is needed. Do not configure the name of a CCC connection as **type**; otherwise, you cannot view information about the CCC connection by running the **display vll ccc** command.

By default, link type negotiation is enabled globally on the device. If a VLANIF interface is used as an AC-side interface for L2VPN, the configuration conflicts with link type negotiation. In this case, run the **lnp disable** command in the system view to disable link type negotiation.

Example

Create a local CCC connection between two CEs connected to the same PE device.

```
<HUAWEI> system-view
[HUAWEI] mpls lsr-id 1.1.1.1
[HUAWEI] mpls
[HUAWEI-mpls] quit
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] quit
[HUAWEI] ccc ccc-connect-1 interface vlanif 10 out-interface vlanif 11
```

10.5.5 ce

Function

The **ce** command creates a CE and displays the MPLS-L2VPN-CE view.

The **undo ce** command deletes a CE.

By default, no CE is created in a L2VPN instances.

Format

ce *ce-name* [**id** *ce-id* [**range** *ce-range*] [**default-offset** *ce-offset*]]

undo ce *ce-name*

Parameters

Parameter	Description	Value
ce-name	Specifies the name of a CE.	The value is a string of 1 to 20 case-sensitive characters, spaces not supported.
id *ce-id*	Specifies the ID of the CE.	The value is a decimal integer that ranges from 0 to 249. A CE ID uniquely identifies a CE in a L2VPN instances. For convenience, you are advised to set the CE IDs in the sequence of natural number that starts from 1.
range *ce-range*	Specifies the number of CEs in an L2VPN instance.	The value is a decimal integer that ranges from 1 to 250 and the default is 10.
default-offset *ce-offset*	Indicates the default CE offset. The CE offset refers to the ID of the other local CE or the remote CE that establishes the connection with the local CE.	It can be either 0 or 1. The default is 0.

Views

MPLS-L2VPN instance view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a Kompella VLL networking, you can use the **ce** command to create a CE in a L2VPN instance and enter the MPLS-L2VPN-CE view.

Prerequisites

An RD has been configured for the L2VPN instance.

Precautions

ce-range can be increased but cannot be decreased. If multiple label blocks exist, the *ce-range* equals the total size of all label blocks. A device allocates labels to the ranges of Kompella L2VPN instances and VPLS VSIs from the same label block. Therefore, the ranges of Kompella L2VPN instances and VPLS VSIs cannot be larger than the size of the label block. Otherwise, the system displays a message indicating that the number of required labels exceeds the permitted maximum labels. As a result, the system fails to create a CE or fails to allocate a site ID to a VSI.

The constraints between **default-offset** and *ce-range* in this command and *ce-offset* in **connection** are as follows:

- If **default-offset** in this command is 0, *ce-offset* in the **connection** command must be less than *ce-range* in this command.
- If **default-offset** in this command is 1, *ce-offset* in the **connection** command must be not more than *ce-range* in this command and cannot be 0.

Example

Create a CE named ce1 inside the vpn1.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn vpn1 encapsulation ethernet
[HUAWEI-mpls-l2vpn-vpn1] route-distinguisher 100:1
[HUAWEI-mpls-l2vpn-vpn1] ce ce1 id 1 range 10
[HUAWEI-mpls-l2vpn-ce-vpn1-ce1]
```

10.5.6 connection

Function

The **connection** command creates a connection in Kompella mode between CEs.

The **undo connection ce-offset** command deletes a connection in Kompella mode between CEs.

By default, no connection in Kompella mode is created between CEs.

Format

connection [**ce-offset** *id*] **interface** *interface-type interface-number* [**tunnel-policy** *policy-name*] [**raw** | **tagged**] [**secondary**]

undo connection ce-offset *id*

Parameters

Parameter	Description	Value
ce-offset *id*	Specifies the ID of the peer CE connected to the L2VPN.	The value is a decimal integer that ranges from 0 to 249. *id* must be not more than *ce-range*. For the configuration about *ce-range*, see **ce**. For a remote connection, **ce-offset** and the ID of the remote CE must be the same; for a local connection between two CEs, **ce-offset** of a CE is the ID of the other CE.
interface *interface-type interface-number*	Specifies the type and number of the interface connected to the CE. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
tunnel-policy *policy-name*	Specifies the name of a tunnel policy applied to a VLL connection.	The value is a string of 1 to 39 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
raw	Sets the encapsulation mode to raw mode. In raw mode, the device deletes the Provider tag (P-Tag) in the packets. The P-Tag is inserted by an SP device to distinguish traffic from different users.	-
tagged	Sets the encapsulation mode to tagged mode. In tagged mode, the device retains the P-Tag in the packets.	-

Parameter	Description	Value
secondary	Specifies the secondary connection of the CE. If this parameter is not specified, the new connection becomes the primary connection. Specify this parameter only when a primary connection exists locally.	-

Views

MPLS-L2VPN-CE view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a Kompella VLL networking, you can use the **connection** command to create a connection.

Precautions

An interface cannot serve as an L2VPN AC interface and L3VPN AC interface at the same time. After an interface is bound to an L2VPN, the Layer 3 features such as the IP address and routing protocol configured on this interface become invalid.

NOTE

- When the sub-interface is bound to a VLL, the encapsulation protocol type of the main interface cannot be changed.
- If a sub-interface is bound to a VLL, the sub-interface can be deleted only after the sub-interface is unbound from the VLL.
- VLANIF interfaces, XGE interfaces, MultiGE interface, 25GE interface, 40GE interfaces, 100GE interfaces, GE interfaces, Eth-Trunk interfaces, XGE sub-interfaces, 25GE sub-interface, MultiGE sub-interfaces, 40GE sub-interfaces, 100GE sub-interfaces, GE sub-interfaces, or Eth-Trunk sub-interfaces can be used as AC interfaces connected to CEs.

  To use an XGE interface, a GE interface, a 25GE interface, a MultiGE interface, a 40GE interface, a 100GE interface, or an Eth-Trunk interface of the device as the AC interface of the PE, run the **undo portswitch** command to change a Layer 2 interface to a Layer 3 interface.
- The management interface cannot be configured as the AC interface connected to a CE.

When creating a connection in Kompella mode, you need to specify the peer CE ID and the local CE interface.

If you do not specify **ce-offset** *id*:

- For the first connection of the CE, by default, **ce-offset** *id* is the same as the **default-offset**. For the description about **default-offset**, see **ce**. If **ce-offset** equals the current CE ID, **ce-offset** increases by 1.

- For other connections, **ce-offset** *id* is the last CE ID plus 1. If the CE offset ID of the last connection plus 1 equals the current CE ID, the **ce-offset** *id* is the value obtained by CE offset of the last connection plus 2.

It is recommended that you number CE IDs from 1 in ascending order, and to configure connections in the order of CE IDs. To simplify configuration, you can use the default **ce-offset** directly in most connections.

After the command is configured, the default policy is adopted in the following situations:

- If you do not specify a policy name
- If the specified policy is not configured

In the default policy:

- Only LSP tunnels are selected.
- No load balancing is performed.

By default, link type negotiation is enabled globally on the device. If a VLANIF interface is used as an AC-side interface for L2VPN, the configuration conflicts with link type negotiation. In this case, run the **lnp disable** command in the system view to disable link type negotiation.

Example

Create a connection in Kompella mode.

```
<HUAWEI1> system-view
[HUAWEI1] mpls l2vpn vpn1 encapsulation vlan
[HUAWEI1-mpls-l2vpn-vpn1] route-distinguisher 100:1
[HUAWEI1-mpls-l2vpn-vpn1] vpn-target 1:1
[HUAWEI1-mpls-l2vpn-vpn1] ce ce1 id 1 range 10
[HUAWEI1-mpls-l2vpn-ce-vpn1-ce1] connection ce-offset 2 interface vlanif 10
<HUAWEI2> system-view
[HUAWEI2] mpls l2vpn vpn1 encapsulation vlan
[HUAWEI2-mpls-l2vpn-vpn1] route-distinguisher 100:1
[HUAWEI2-mpls-l2vpn-vpn1] vpn-target 1:1
[HUAWEI2-mpls-l2vpn-vpn1] ce ce2 id 2 range 10
[HUAWEI2-mpls-l2vpn-ce-vpn1-ce2] connection ce-offset 1 interface vlanif 20
```

10.5.7 display bgp l2vpn

Function

The **display bgp l2vpn** command displays information about the Kompella L2VPN label block stored in BGP.

Format

display bgp l2vpn { **all** | **group** [*group-name*] | **peer** [[*peer-ip-address*] **verbose**] | **route-distinguisher** *route-distinguisher* [**ce-id** *ce-id* [**label-offset** *label-offset*]] }

Parameters

Parameter	Description	Value
all	Displays all information about the local label block of Kompella L2VPN stored in BGP.	-
group *group-name*	Displays information about the label block of Kompella L2VPN stored in a specified BGP peer group.	The value is an existing BGP peer group.
peer-ip-address	Displays information about the Kompella L2VPN label block of the specified peer stored in BGP.	The value is in dotted decimal notation.
verbose	Displays detailed information about the Kompella L2VPN label block stored in BGP.	-
route-distinguisher *route-distinguisher*	Specifies the specific route identification value. The RD format can be any of the following: ● 2-byte AS number:4-byte user-defined number, for example, 101:3. An AS number ranges from 0 to 65535. A user-defined number ranges from 0 to 4294967295. The AS number and the user-defined number cannot be 0s at the same time. That is, an RD cannot be 0:0. ● Integral 4-byte AS number:2-byte user-defined number, for example, 65537:3. An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, an RD cannot be 0:0. ● 4-byte AS number in dotted notation:2-byte user-defined number, for example, 0.0:3 or 0.1:0. A 4-byte AS number in dotted notation is in the format of *x.y*, where *x* and *y* are integers that range from 0 to 65535 and from 0 to 65535, respectively. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, an RD cannot be 0.0:0. ● IPv4-address:2-byte user-defined number, for example, 192.168.122.15:1. An IP address ranges from 0.0.0.0 to 255.255.255.255. A user-defined number ranges from 0 to 65535.	-
ce-id *ce-id*	Specifies the number of CE of the L2VPN instance.	The value ranges from 0 to 65535.

Parameter	Description	Value
label-offset *label-offset*	Specifies the offset value of the label.	It is a decimal integer ranging from 0 to 65535.

Usage Guidelines

Usage Scenario

In a Kompella VLL networking, you can use the **display bgp l2vpn** command to check information about a label block, including the RD value, CE ID, label offset, start label in the label block, and BGP routing attributes of the label block.

Precautions

If **route-distinguisher**, **ce-id**, and **label-offset** all are specified, you can view the BGP extended community attribute, the value of each label in the label block, the status of the L2VPN connection status using this label as well as the BGP peers to which this label block is advertised.

Example

View the BGP L2VPN label block with the specified RD, CE ID, and label offset.

```
<HUAWEI> display bgp l2vpn route-distinguisher 1:1 ce-id 1 label-offset 0
 BGP Local router ID : 10.1.1.2, local AS number : 100
 Origin codes:i - IGP, e - EGP, ? - incomplete
 nexthop:6.6.6.6,  pref :100,     as-path :(null)
 label base: 35840, label range: 10, layer-2 mtu: 1500, encap type:Ethernet VLAN
 label          state
  35840           down
  35841           down
  35842           up
  35843           down
  35844           down
  35845           down
  35846           down
  35847           down
  35848           down
  35849           down
```

Table 10-47 Description of the **display bgp l2vpn** command output

Item	Description
BGP Local router ID	Local router ID of local BGP. Its format is the same as the IPv4 address.

Item	Description
Origin codes	The origin attributes of BGP route: ● i - IGP: Interior Gateway Protocol (IGP), It is of the highest priority. ● e - EGP: Exterior Gateway Protocol (EGP): It is of the second highest priority. ● ? - incomplete: It is of the lowest priority.
local AS number	Local autonomous system (AS) number.
nexthop	Next-hop address of MP-BGP.
pref	Local preference, which is one type of BGP routing attribute.
as-path	AS path attribute, which is one type of BGP routing attribute. It records the numbers of all ASs sequentially that a packet passes through from the local address to the destination address.
label base	Starting value of the label.
label range	Range of the labels.
layer-2 mtu	MTU value of the link layer.
encap type	Encapsulation mode of the link layer.
label	Allocated label.
state	Status of the allocated label.

10.5.8 display l2vpn ccc-interface vc-type

Function

The **display l2vpn ccc-interface vc-type** command displays information about the interface used by an L2VPN connection.

Format

display l2vpn ccc-interface vc-type { **all** | *vc-type* } [**down** | **up**]

Parameters

Parameter	Description	Value
all	Displays information about all interfaces of L2VPN connections.	-
vc-type	Specifies the type of the L2VPN connection.	The following types of the L2VPN connection are available: ● ccc: Cross Circuit Connection ● ldp-vc: L2VPN connection in the Martini mode ● static-vc: L2VPN connection in the SVC mode ● bgp-vc: L2VPN connection in the Kompella mode ● vpls-vc: VPLS connection
down	Displays information about interfaces of L2VPN connection in the Down state.	-
up	Displays information about interfaces of L2VPN connection in the Up state.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When locating L2VPN faults, you can use the **display l2vpn ccc-interface vc-type** command to view information about the AC interface of the current L2VPN connection, the total number of AC interfaces of various L2VPN connections, interface status, interface encapsulation type, and L2VPN connection types.

Example

Display information about all the interfaces of L2VPN.

```
<HUAWEI> display l2vpn ccc-interface vc-type all
Total ccc-interface of LDP VC: 1
up (1), down (0)
Interface               Encap Type             State    VC Type
Vlanif12                vlan                up       ldp-vc
```

Table 10-48 Description of the **display l2vpn ccc-interface vc-type** command output

Item	Description
Total ccc-interface of CCC : 2 up (2), down (0)	Total number of L2VPN connections is 2. Two connections is Up. No connection is Down.
Interface	Interface connected to the L2VPN connection on the switch.
Encap Type	Encapsulation type of the L2VPN connection. The encapsulation type can be VLAN encapsulation or Ethernet encapsulation.
State	Current status of the L2VPN connection. The status can be Up or Down.
VC Type	Type of the L2VPN connection: ● ccc: Cross Circuit Connection ● ldp-vc: L2VPN connection in the Martini mode ● static-vc: L2VPN connection in the SVC mode ● bgp-vc: L2VPN connection in the Kompella mode ● vpls-vc: VPLS connection

10.5.9 display mpls l2vc

Function

The **display mpls l2vc** command displays information about virtual circuits (VCs) in LDP mode.

Format

display mpls l2vc [*vc-id* | **interface** *interface-type interface-number* | **remote-info** [*vc-id* | **verbose**] | **state** { **down** | **up** }]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of the AC interface connected to the CE. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Parameter	Description	Value
remote-info	Displays information about the VC on the remote end.	-
vc-id	Displays static PW information with a specified VC ID.	The value is an integer that ranges from 1 to 4294967295.
verbose	Displays the detailed information about the VC on the remote end.	-
state { **down** | **up** }	Displays VC information based on the VC status. ● **down**: Displays information about the VC in Down state. ● **up**: Displays information about the VC in Up state.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display mpls l2vc** command displays information about the VCs in LDP signaling mode, including the Martini VC and PWE3 VC.

- If the interface is specified, information about VCs on the specified AC interface is displayed.
- If **remote-info** is specified but *vc-id* is not specified, information about all VCs set up by the remote and local peers is displayed.

Example

Display information about all the LDP VCs configured on the switch.

```
<HUAWEI> display mpls l2vc
 Total LDP VC : 1     1 up       0 down

 *client interface       : Vlanif1111 is up
  Administrator PW       : no

Domain Name            : --
```

Table 10-49 Description of the **display mpls l2vc** command output

Item	Description
Total LDP VC	Total number of established LDP VCs, including the number of LDP VCs in Up and Down state.
client interface	AC interface and its status.
Administrator PW	Whether the PW is an mPW. The PW can be an mPW only when the AC interface is a loopback interface. This field can be displayed as **yes** or **no**.
session state	Status of the LDP session established between both ends of the VC: ● up: The LDP session has been established. ● down: The LDP session is not established.

Item	Description
AC status	Status of the AC: ● up: An AC has been established. ● down: An AC is not established.
Ignore AC state	Whether the AC status change affects the status of services on the active or standby PWE3. ● enable: The impact of the AC status change on the status of services on the active or standby PWE3 is ignored. ● disable: The AC status change affects the status of services on the active or standby PWE3.
VC state	Status of the VC: ● up: A VC has been established. ● down: A VC is not established.
Label state	Label status: ● 0: The label can be used. ● 1: Wait for the SMB to confirm the label status. ● 2: The label is released. ● 3: SMB confirmation failed.
Token state	Token status: ● 0: The token can be used. ● 1: Wait for the SMB to confirm the token status. ● 2: The token is released. ● 3: SMB confirmation failed.
VC ID	ID of the VC, which uniquely identifies a VC. **NOTE** If the VC IDs on both ends are different, run the **mpls l2vc** command in the interface view to change the VC ID on one end to be the same as that on the other end.
VC type	Encapsulation type of the VC: ● VLAN ● Ethernet The PW can go Up only when the local and remote encapsulation types are the same.
destination	LSR ID of the VC peer device.
local VC label	Local VC label.
remote VC label	Remote VC label.

Item	Description
control word	Whether the control word is enabled: ● enable: The control word is enabled. ● disable: The control word is disabled.
forwarding entry	Whether forwarding entries exist.
local group ID	Local group ID.
remote group ID	Remote group ID.
manual fault	Whether a PW fault is simulated.
active state	Whether the PW is in active state. A PW in active state can forward packets.
link state	Integrative PW status: ● up ● down If any of the following status is Down, the PW link state is Down: ● Service PW status ● Status of the mPW associated with service PWs ● Status of the BFD session associated with service PWs ● PW state code ● PW status detected by VCCV ● OAM status
local VC MTU	MTU of the local VC.
remote VC MTU	MTU of the remote VC.
tunnel policy name	Name of the tunnel policy.
PW template name	Name of the PW template.
primary or secondary	Whether the VC is a primary VC or a secondary VC.
load balance type	Load balancing mode of Martini VLL: ● flow: indicates flow-based load balancing. ● packet: indicates packet-based load balancing.
Access-port	Whether the interface supports the access-port attribute: ● true: indicates that the interface supports the access-port attribute. ● false: indicates that the interface does not support the access-port attribute.

Item	Description
Switchover Flag	Whether a switchover has occurred.
create time	How long the VC has been created.
up time	How long the VC keeps the Up state. If the current PW status is Down, the value is 0.
last change time	How long the VC status remains unchanged.
VC last up time	Last time when the VC became Up.
VC total up time	Total duration of the VC in Up state.
CKey	Index of the public tunnel for VPN QoS.
NKey	Index of the public tunnel.
AdminPw interface	AC interface on which the mPW is bound to the PW. The AC interface must be a loopback interface. This field is displayed only when the PW is not an mPW: ● Name of the loopback interface. ● --: indicates that the PW is not bound to an mPW.
AdminPw link state	Status of the mPW bound to the PW. This field is displayed only when the PW is not an mPW. This field can be displayed as: ● Up ● Down ● --: indicates that the PW is not bound to an mPW.
Diffserv Mode	QoS DiffServ mode.
Service Class	QoS service class.
Color	QoS color.
DomainId	ID of a domain.
Domain Name	Name of a domain.

Display LDP VC information about the AC interface VLANIF 100.

```
<HUAWEI> display mpls l2vc interface vlanif 100
 *client interface       : Vlanif100  is up
  Administrator PW       : no

Table 10-50 Description of the **display mpls l2vc interface** command output

Item	Description
local AC OAM State	OAM status of the local AC. - up - down
local PSN OAM State	Status of the local device on the Packet Switch Network (PSN) side. - up - down

Item	Description
local forwarding state	Status of the local forwarding table. ● forwarding ● down
local status code	Status code of the local PW: ● 0x0: indicates that the local PW functions as the master PW and is in Up state. ● 0x20: indicates that the local PW functions as the backup PW and is in Up state. ● 0x1: indicates that the local PW functions as the master PW and is in Down state. ● 0x21: indicates that the local PW functions as the backup PW and is in Down state.
remote AC OAM state	OAM status of the remote AC. ● up ● down
remote PSN OAM state	Status of the remote device on the PSN side. ● up ● down
remote forwarding state	Status of the remote forwarding table. ● forwarding ● down
remote status code	Status code of the remote PW: ● 0x0: indicates that the remote PW functions as the master PW and is in Up state. ● 0x20: indicates that the remote PW functions as the backup PW and is in Up state. ● 0x1: indicates that the remote PW function as the master PW and is in Down state. ● 0x21: indicates that the remote PW function as the backup PW and is in Down state.
BFD for PW	Whether BFD for PW is enabled: ● available ● unavailable
VCCV State	Whether Virtual Circuit Connectivity Verification (VCCV) is enabled.

Item	Description
local VCCV	Type of VCCV supported on the local device. - By default, the VCCV type is **alert ttl lsp-ping bfd**, indicating that the control word function is disabled and LSP ping and BFD are supported for the alert channel. - If the control word function is enabled, the VCCV type is **cw alert ttl lsp-ping bfd**, indicating that LSP ping and BFD are supported for both the control word channel and the alert channel.
remote VCCV	Type of VCCV supported on the remote device. - By default, the VCCV type is **alert ttl lsp-ping bfd**, indicating that the control word function is disabled and LSP ping and BFD are supported for the alert channel. - If the control word function is enabled, the VCCV type is **cw alert ttl lsp-ping bfd**, indicating that LSP ping and BFD are supported for both the control word channel and the alert channel.
local control word	Whether the control word is enabled on the local device: - Disable - Enable
remote control word	Whether the control word is enabled on the remote device: - Disable - Enable
ignore standby state	Whether the status of the secondary PW is ignored.
VC Tunnel/token info: 1 tunnels/tokens	Information about the tunnel or token used by the VC. The value **1 tunnels/tokens** indicates that the PW uses one tunnel or token.
TNL type	Type of the tunnel used by the PW.
TNL ID	ID of the tunnel used by the PW.
Backup TNL Type	Type of the backup tunnel when PW over LDP FRR is used.

Item	Description
PW redundancy mode	PW redundancy mode. By default, the mode is FRR. - Independent: indicates that the PW is in negotiation mode. - frr: indicates that the PW is in FRR mode. - --: indicates that the PW is in master/slave mode.

Display the LDP VC information received from the remote peer.

```
<HUAWEI> display mpls l2vc remote-info
Total remote ldp vc : 1

TDM Encap Num      : --
TDM Bit Rate       : --
```

Table 10-51 Description of the **display mpls l2vc remote-info** command output

Item	Description
Total remote ldp vc	Total number of created remote LDP VCs.
Transport VC ID	VC ID, which uniquely identifies a VC.
Group ID	ID of the group to which the L2VPN belongs. The default value is 0.
Peer Addr and Peer Address	IP address of the remote peer.
Remote Encap	Encapsulation type of the remote VC. - vlan - ethernet

Item	Description
Remote VC Label	Remote VC label.
C Bit	Whether the control word is enabled: - 1: indicates that the control word is enabled. - 0: indicates that the control word is disabled.
MTU/CELLS	MTU of the L2VPN.
N Bit and Notification	Whether the Notification message is supported: - 1: indicates the message is supported. - 0: indicates the message is not supported.
S Bit and Status Code	Status code: - 0: indicates the forwarding state. - 1: indicates the non-forwarding state. - 32: indicates the backup state.
Match Local VC	Whether the local VC ID matches the remote VC ID: - MATCH - NOT-MATCH
Max ATM CELLS	Maximum number of ATM cells that can be transmitted. If ATM encapsulation is used, the value ranges from 1 to 28, and the default value is 28. If non-ATM encapsulation is used, double hyphens (--) are displayed.
TDM RTP Header	Whether the RTP-header option is enabled: - enable: The RTP header is added to TDM packets to be transparently transmitted. - disable: The RTP header is not added to TDM packets to be transparently transmitted. This is the default value. - --: Non-TDM encapsulation is used.
TDM Encap Num	Number of frames in a TDM packet. If TDM encapsulation is used, the value is 8, 16, 24, 32 or 40, and the default value is 32. If non-TDM encapsulation is used, double hyphens (--) are displayed.
TDM Bit Rate	Number of timeslots in a TDM packet. Number of timeslots in a TDM packet = Number of bytes in a TDM packet/Number of frames in a TDM packet

Display information about the VCs in Up state.

```
<HUAWEI> display mpls l2vc state up

10.5.10 display mpls l2vc brief

Function

The **display mpls l2vc brief** command displays brief information about LDP Layer 2 virtual circuits (L2VCs) on the device.

Format

display mpls l2vc brief

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display mpls l2vc brief** command is recommended when many L2VCs are configured on a device. The command output is more concise than that of the **display mpls l2vc** command.

Example

Display brief information about all LDP L2VCs on the device.

```
<HUAWEI> display mpls l2vc brief
 Total LDP VC : 1     1 up       0 down

 *Client Interface     : Vlanif1111
  Administrator PW     : no
  AC status            : up
  Ignore AC state      : disable
  VC state             : up
  Label state          : 0
  Token state          : 0
  VC ID                : 116119
  VC Type              : VLAN
  session state        : up
  Destination          : 10.6.6.6
  link state           : up
```

Table 10-52 Description of the **display mpls l2vc brief** command output

Item	Description
Total LDP VC	Total number of LDP VCs, including the number of LDP VCs in Up and Down state.

Item	Description
Client Interface	AC interface and its status.
Administrator PW	Whether the PW is an mPW. The PW can be an mPW only when the AC interface is a loopback interface.
AC status	Status of the AC: - up - down
Ignore AC state	Whether the AC status change affects the status of services on the active or standby PWE3. - enable: The impact of the AC status change on the status of services on the active or standby PWE3 is ignored. - disable: The AC status change affects the status of services on the active or standby PWE3.
VC state	Status of the VC: - up - down
Label state	Label status: - 0: The label can be used. - 1: Wait for the SMB to confirm the label status. - 2: The label is released. - 3: SMB confirming failed.
Token state	Token status: - 0: The label can be used. - 1: Wait for the SMB to confirm the label status. - 2: The label is released. - 3: SMB confirming failed.
VC ID	ID of the VC, which uniquely identifies a VC.
VC Type	Encapsulation type of the VC.
session state	Status of the session between peers: - up - down
Destination	Peer address.
link state	Status of the VC: - up - down

10.5.11 display mpls l2vpn

Function

The **display mpls l2vpn** command displays information about an L2VPN on a PE.

Format

display mpls l2vpn [*l2vpn-name* [**local-ce** | **remote-ce**]]

Parameters

Parameter	Description	Value
l2vpn-name	Specifies the VPN to be displayed.	The value is an existing VPN name.
local-ce	Displays information about all the local CEs of a specified L2VPN.	-
remote-ce	Displays information about remote CEs learned from other PEs of a specified L2VPN.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If you specify parameters, the **display mpls l2vpn** command displays information related to the parameters. If not, information about all the L2VPNs is displayed.

Example

Display information about all the VPNs configured on the PE.

```
<HUAWEI> display mpls l2vpn
VPN number: 1
vpn-name        encap-type   route-distinguisher     mtu   ce(L)  ce(R)
vpn1           ethernet     100:1                   1500   1      1
```

Table 10-53 Description of the display mpls l2vpn command output

Item	Description
vpn-name	Name of the created VPN instance.
encap-type	Encapsulation type of L2VPN.
route-distinguisher	RD of L2VPN.

Item	Description
mtu	MTU of L2VPN.
ce (L)	The number of local CE connections. "L" indicates "local".
ce (R)	Number of remote CE connections. "R" indicates "remote".

Display information about the L2VPN named vpn1.

```
<HUAWEI> display mpls l2vpn vpn1
VPN name: vpn1, encap type: vlan, local ce number(s): 1, remote ce number(s): 1
route distinguisher: 100:1, MTU: 128
import vpn target: 1:1
export vpn target: 1:1

remote vpn site(s) :
no.  remote-pe-id    route-distinguisher
1    3.3.3.9         100:1
```

Table 10-54 Description of the display mpls l2vpn vpn1 command output

Item	Description
VPN name	Name of the created VPN instance.
encap type	Encapsulation type of the L2VPN.
local ce number (s)	Number of local CE connections.
remote ce number (s)	Number of remote CE connections.
route distinguisher	RD of the local L2VPN.
MTU	MTU of the interface associated with the L2VPN.
import vpn target	Route attribute of the received VPN route.
export vpn target	Attributes configured for the target VPN route.
remote vpn site (s)	The following display is about the remote site.
no.	Remote peer number.
remote-pe-id	ID of remote PE peer. Usually, it is MPLS LSR-ID or the session address of the BGP peer.
route-distinguisher	RD of the remote L2VPN. For the related command, see **route-distinguisher (MPLS-L2VPN instance view)**.

Display information about the local CE on L2VPN named vpn1.

```
<HUAWEI> display mpls l2vpn vpn1 local-ce
ce-name            ce-id   range   conn-num  CEBase/LBBase/Offset/Range
ce1                1       10      1         0/21504/0/10
ce2                2       10      1         0/21514/0/10
```

Table 10-55 Description of the display mpls l2vpn vpn1 local-ce command output

Item	Description
ce-name	CE name.
ce-id	CE ID that uniquely identifies a CE.
range	Local CE range. Indicates how many CEs are connected to the local CEs.
conn-num	Number of local connections set for local CEs.
CEBase/LBBase/Offset/Range	Label block assigned by the CE with which the local port sets up a connection. 0/21504/0/10 indicates the offset base address of the label block/the initial value of the label block/initial CE offset/the number of remote labels.

Display information about the remote CE on the L2VPN named vpn1.

```
<HUAWEI> display mpls l2vpn vpn1 remote-ce
no.  ce-id peer-id         route-distinguisher      LB
1    2     3.3.3.9         100:1                    19456/0/10
```

Table 10-56 Description of the display mpls l2vpn vpn1 remote-ce command output

Item	Description
no.	Sequence number of the connection.
ce-id	ID of the remote CE.
peer-id	IP address of the remote peer.
route-distinguisher	RD of the remote peer.
LB	Remote Label block. 19456/0/10 indicates the initial value of the label block/remote initial CE offset/the number of remote labels.

10.5.12 display mpls l2vpn (route-target-list)

Function

The **display mpls l2vpn** command displays the VPN target list for Kompella VLL.

Format

display mpls l2vpn { **export-route-target-list** | **import-route-target-list** }

Parameters

Parameter	Description	Value
export-route-target-list	Displays the VPN target list for Kompella VLL in the outbound direction.	-
import-route-target-list	Displays the VPN target list for Kompella VLL in the inbound direction.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When an L2VPN connection in Kompella mode is Up but packet forwarding between CE devices fails, you can run this command to view the VPN target list of a specified VPN instance and check whether the VPN targets of the two PE devices match each other.

- The VPN target in the outbound direction of the local PE device must be the same as the VPN target in the inbound direction of the remote PE device.
- The VPN target in the inbound direction of the local PE device must be the same as the VPN target in the outbound direction of the remote PE device.

Example

Display the VPN target list for Kompella VLL in the inbound direction.

```
<HUAWEI> display mpls l2vpn import-route-target-list
import vpn target list:
 744:7  745:7  746:7  888:8
```

Display the VPN target list for Kompella VLL in the outbound direction.

```
<HUAWEI> display mpls l2vpn export-route-target-list
export vpn target list:
 755:7  888:8
```

Table 10-57 Description of the **display mpls l2vpn** command output

Item	Description
import vpn target list	VPN target list in the inbound direction.
export vpn target list	VPN target list in the outbound direction.

10.5.13 display mpls l2vpn connection

Function

The **display mpls l2vpn connection** command displays information about L2VPN connections of the Kompella mode.

Format

display mpls l2vpn connection *vpn-name* [**remote-ce** *ce-id* | **down** | **up** | **verbose**]

display mpls l2vpn connection [**summary** | **interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
vpn-name	Displays information about the specified L2VPN.	The value is an existing VPN name. If you do not specify a VPN name, information about all the L2VPNs is displayed.
remote-ce *ce-id*	Displays information about the remote connections of the specified CE.	The value is a decimal integer ranging from 0 to 249.
down	Displays the information of the connections that are Down. If you do not specify this parameter, the detailed information about connections in both Up and Down state is displayed.	-
up	Displays the information of the connections that are Up. If you do not specify this parameter, the detailed information about connections in both Up and Down state is displayed.	-

Parameter	Description	Value
verbose	Shows detailed information of connections. It is valid only when information about all the connections is displayed.	-
summary	Displays the summary information of connections.	-
interface *interface-type interface-number*	Displays information about the connections on the interface of the specified type and number. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-

Views

Default Level

1: Monitoring level

Usage Guidelines

After configuring an L2VPN connection of the Kompella mode, you can use the **display mpls l2vpn connection** *vpn-name* command to check the status of the connection.

The **display mpls l2vpn connection** command displays information about all the L2VPN connections of the Kompella mode on the local device.

Example

Display information about all the L2VPN Kompella connections.

```
<HUAWEI> display mpls l2vpn connection
1 total connections,
connections: 1 up, 0 down, 0 local, 1 remote, 0 unknown

VPN name: komcon1,
1 total connections,
connections: 1 up, 0 down, 0 local, 1 remote, 0 unknown

  CE name: 116-119, id: 2,
  Rid type status peer-id         route-distinguisher interface
  primary or not
--------------------------------------------------------------------------
  1    rmt  up      6.6.6.6         1:1                 Vlanif222
  primary
```

Table 10-58 Description of the display mpls l2vpn connection command output

Item	Description
1 total connections,connections: 1 up, 0 down, 0 local, 1 remote, 0 unknown	The first two lines indicate information about all the Kompella connections on the local device, including: ● Total number of connections ● Number of connections in the Up state ● Number of connections in the Down state ● Number of local connections ● Number of remote connections ● Number of unknown connections
VPN name	Name of the created VPN instance.
1 total connections,connections: 1 up, 0 down, 0 local, 1 remote, 0 unknown	Information about the VPN connections, including: ● Total number of connections ● Number of connections in the Up state ● Number of connections in the Down state ● Number of local connections ● Number of remote connections ● Number of unknown connections
CE name:	Name of the CE.
id:	CE ID of the CE connection, which uniquely identifies a CE in a VPN.
Rid	ID of the remote CE that establishes the connection with the local CE.
type	Type of the CE connection: ● rmt: indicates a remote connection. ● loc: indicates a local connection. ● ---: indicates the destination CE does not exist or the signaling connection setup fails when you set up a remote connection.
status	Status of the CE connection: ● Up: indicates the connection is set up successfully. ● Down: indicates the connection setup fails because the configuration is incorrect or the associated interface is Down.

Item	Description
peer-id	IP address of the peer that sets up the session with the local end.
route-distinguisher	RD of the VPN to which the CE belongs.
interface	Interface (an AC interface) connected to the CE.
primary or not	Whether the VC is a primary VC or a secondary VC.

Display the Kompella L2VPN remote connection on GE0/0/1

```
<HUAWEI> display mpls l2vpn connection interface gigabitethernet 0/0/1
conn-type: remote
    local vc state:         up
    remote vc state:          up
    local ce-id:            1
    local ce name:            ce1
    remote ce-id:             2
    intf (state,encap):        GigabitEthernet0/0/1(up,ethernet)
    peer id:               2.2.2.2
    route-distinguisher:       100:2
    local vc label:         31745
    remote vc label:          35842
    tunnel policy:           default
    CKey:                  2
    NKey:                   1
    primary or secondary:        primary
    forward entry exist or not: true
    forward entry active or not:true
    manual fault set or not:     not set
    AC OAM state:              up
    BFD for PW session index:   --
    BFD for PW state:           invalid
    BFD for LSP state:         true
    Local C bit is not set
    Remote C bit is not set
    tunnel type:             lsp
    tunnel id:              0x1000c
    Slave tunnel type:         lsp
    Slave tunnel id:          0x0
```

Table 10-59 Description of the remote connection in the display mpls l2vpn connection interface command output

Item	Description
conn-type	Type of the L2VPN connection: - local: indicates the local L2VPN connection. - remote: indicates the remote L2VPN connection. - unknown: indicates the unknown L2VPN connection. The reason that the unknown connection appears may be that the destination CE does not exist, or the signaling connection fails to be set up during the configuration of a remote connection.
local vc state	Status of the local VC: - Up: indicates that the connection is successfully set up. - Down: indicates the setup of the connection fails because the configuration is incorrect or the status of related interfaces is Down.
remote vc state	Status of the destination VC: - Up: indicates that the connection is successfully set up. - Down: indicates the setup of the connection fails because the configuration is incorrect or the status of related interfaces is Down.
local ce-id	ID of the local CE.
local ce name	Name of the local CE.
remote ce-id	ID of the destination CE that sets up the connection with the local CE.
intf (state,encap)	Status and encapsulation type of the local interface.
peer id	IP address of the peer setting up a session with the CE.
route-distinguisher	RD of the VPN to which the CE interface belongs.
local vc label	Label generated by the local system.
remote vc label	Remote label that is assigned to the local end by the remote LDP.

Item	Description
tunnel policy	Tunnel policy applied to the CE connection.
CKey	Index of the public tunnel (for VPN QoS).
NKey	Index of the public tunnel.
primary or secondary	Whether the VC is a primary VC or a secondary VC.
forward entry exist or not	Whether forwarding entries exist.
forward entry active or not	Whether forwarding entries are in the active state. (If so, user packets can be forwarded.)
manual fault set or not	Whether the PW fault is configured manually.
AC OAM state	OAM status of the local AC.
BFD for PW session index	Index of the BFD for PW.
BFD for PW state	Status of BFD for PW.
BFD for LSP state	Status of BFD for LSP.
Local C bit is not set	L2VPN disabled with the control word. If the control word is enabled, the information is not displayed.
Remote C bit is not set	The remote site disabled with the control word. If the control word is enabled, the information is not displayed.
tunnel type	Tunnel type. The tunnel transmits data of the CE in the public network.
tunnel id	ID of the tunnel. The tunnel transmits data of the CE in the public network.
Slave tunnel type	Type of the backup tunnel when PW over LDP FRR is applied.
Slave tunnel id	ID of the backup tunnel when PW over LDP FRR is applied.

Display the summary of the Kompella L2VPN connections.

```
<HUAWEI> display mpls l2vpn connection summary
1 total connections,
connections: 1 up,  0 down , 0 local, 1 remote, 0 unknown
No.   vpn-name    local-num remote-num unknown-num up-num total-num
1     vpn1              0         1          0         1      1
```

Table 10-60 Description of the display mpls l2vpn connection summary command output

Item	Description
total connections	Number of all L2VPN connections on the device.
connections:	Number of L2VPN connections of the following status: ● Up ● Down ● remote ● local ● unknown
No.	Sequence number of the connection.
vpn-name	VPN instance name. Various types of connections are displayed in the order of L2VPN instances.
local-num	Number of local connections of the L2VPN instance.
remote-num	Number of all remote connections of the L2VPN instance.
unknown-num	Number of all unknown connections of the L2VPN instance.
up-num	Total number of successful connections of the L2VPN instance.
total-num	Total number of connections of the L2VPN instance.

10.5.14 display mpls l2vpn forwarding-info

Function

The **display mpls l2vpn forwarding-info** command displays MPLS L2VPN forwarding information.

Format

display mpls l2vpn forwarding-info [*vc-label*] **interface** *interface-type interface-number*

Parameters

Parameter	Description	Value
vc-label	Specifies L2VPN VC label.	The value is a decimal integer that ranges from 16 to 1048575.
interface *interface-type interface-number*	Specifies the type and number of the interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display mpls l2vpn forwarding-info** command displays:

- Private network data carrying the specified label is forwarded from which tunnel.
- Whether the data supports the connectivity verification.
- Whether the data carries the control word.

Example

Display MPLS L2VPN forwarding information.

```
<HUAWEI> display mpls l2vpn forwarding-info interface vlanif 10
 The Main PW Forward Information :
VCLABEL TNLTYPE        ENTRYTYPE PWSTATE  BFDSTATE ADMIN CTLWORD CC CV TNLID
-------------------------------------------------------------------------------
35841   LSP            SEND      ACTIVE   UP       UP    FALSE   2  a  0x1
   1   Record(s) Found.

 The Second PW Forward Information :
VCLABEL TNLTYPE        ENTRYTYPE PWSTATE  BFDSTATE ADMIN CTLWORD CC CV TNLID
-------------------------------------------------------------------------------
   0   Record(s) Found.
```

Table 10-61 Description of the display mpls l2vpn forwarding-info interface command output

Item	Description
The Main PW Forward Information :	Forwarding information about the primary PW.
VCLABEL	Label of the VC bound to the interface.
TNLTYPE	Types of public network tunnels used by the VC such as LSP and CR-LSP.
ENTRYTYPE	Type of forwarding entries: ● SEND: forwarding entries of L2VPN except CCC ● CCC_SEND: forwarding entries of the CCC remote connection ● LOCAL: forwarding entries of the local connection ● INVALID: invalid forwarding entries
PWSTATE	PW state used for guiding packet forwarding: active or inactive. The primary PW and the secondary PW are mutually exclusive and both cannot be in the active state simultaneously.
BFDSTATE	BFD state used for guiding packet forwarding. If BFD is not configured, this flag bit is Up by default. If BFD is configured and the BFD session is Down (not Admin Down), this flag bit is Down and packets cannot be forwarded.
ADMIN	Whether the primary or secondary PW fault is configured manually: ● Up: indicates that the primary or secondary PW fault is not configured manually. ● Down: indicates that the primary or secondary PW fault is configured manually.
CTLWORD	Whether the control word is enabled on the local end: ● FALSE: indicates that the control word is disabled. ● TRUE: indicates that the control word is enabled.
CC	Connection channel of the VCCV: Control word Label alert.
CV	Connectivity verification.

Item	Description
TNLID	ID of the public tunnel used by the VC, which is a hexadecimal integer.
Record (s) Found	Number of VC forwarding entries on the local interface.
The Second PW Forward Information :	Forwarding information about the secondary PW.

Display MPLS L2VPN forwarding information with VC label as 35842.

```
<HUAWEI> display mpls l2vpn forwarding-info 35842 interface vlanif 10
 The Main PW Forward Information :
VCLABEL TNLTYPE        ENTRYTYPE PWSTATE  BFDSTATE ADMIN CTLWORD CC CV TNLID
--------------------------------------------------------------------------------
35842   LSP            SEND      ACTIVE   UP       UP    FALSE   0  0  0x1
   1   Record(s) Found.

 The Second PW Forward Information :
VCLABEL TNLTYPE        ENTRYTYPE PWSTATE  BFDSTATE ADMIN CTLWORD CC CV TNLID
--------------------------------------------------------------------------------
   0   Record(s) Found.
```

10.5.15 display mpls l2vpn label-space

Function

The **display mpls l2vpn label-space** command displays information about label space distribution and different types of labels in the label cache.

Format

display mpls l2vpn label-space

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After L2VPN is enabled, run the **display mpls l2vpn label-space** command and you can view information about label space distribution and different types of labels in the label cache.

Example

Display information about label space distribution when L2VPN is enabled and the cache contains labels.

```
<HUAWEI> display mpls l2vpn label-space
 there are 0 labels or label blocks in label-space.
 ------------------------------------------------------------
 label(s) released in SVC connection:             0
 label(s) released in LDP connection:             1
 label block(s) released in BGP connection:        0
 label(s) released in VPLS LDP connection:         0
 label block(s) released in VPLS BGP connection:   0
 ------------------------------------------------------------
```

Table 10-62 Description of the **display mpls l2vpn label-space** command output

Item	Description
Label	Indicates the value of the label in the label cache.
Label (s) released in SVC connection	Indicates the total number of labels in the label cache for the VLL SVC connections.
Label (s) released in LDP connection	Indicates the total number of labels in the label cache for the VLL LDP connections.
Label block (s) released in BGP connection	Indicates the total number of label blocks in the label cache for the VLL BGP connections.
Label (s) released in VPLS LDP connection	Indicates the total number of labels in the label cache for the VPLS LDP connections.
Label (s) released in VPLS BGP connection	Indicates the total number of labels in the label cache for the VPLS BGP connections.

10.5.16 display mpls l2vpn vpws

Function

The **display mpls l2vpn vpws** command displays information about the VPWS service.

Format

display mpls l2vpn vpws [**interface** *interface-type interface-number* [**verbose**]]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of an interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
verbose	Displays detailed VPWS service information.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

When configuring or commissioning VPWS, you can run the **display mpls l2vpn vpws** command to check whether VPWS service configurations are correct.

Note the following points when using the **display mpls l2vpn vpws** command:

- If **interface** *interface-type interface-number* is specified, only VPWS service information on a specified AC interface is displayed.
- If **verbose** is also specified, detailed information about the VPWS service on a specified AC interface is displayed.

Prerequisites

VPWS configurations are complete on the local end.

Example

Display VPWS service information.

```
<HUAWEI> display mpls l2vpn vpws

Pri : Primary          Sec : Secondary          Byp : Bypass
PWb : PW-bypass            ACb : AC-bypass

Access Circuit            Virtual Circuit            States Active   Role
GE0/0/2                  10.3.3.9:200                 Up     Active   Pri
                      10.2.2.9:201                Up     Inactive Sec
```

Table 10-63 Description of the display mpls l2vpn vpws command output

Item	Description
Access Circuit	Access circuit.

Item	Description
Virtual Circuit	Virtual circuit.
States	VC status, which can be: ● Up ● Down
Active	Activation status of a VC, which can be: ● Active ● Inactive
Role	Role of a PW, which can be: ● Pri: Primary PW ● Sec: Secondary PW ● PWb: PW-bypass ● ACb: AC-bypass ● Byp: Bypass

Display the detailed information about the VPWS service on a specified AC interface.

```
<HUAWEI> display mpls l2vpn vpws interface gigabitethernet 0/0/2 verbose

Access circuit     : GigabitEthernet0/0/2
Interface state    : Up
Protect mode       : FRR

Members:
Virtual Circuit              States Active   Role
10.3.3.9:200                  Up     Active   Primary

 VC last up time        : 2013/12/21 14:57:13
 VC total up time       : 0 days, 20 hours, 44 minutes, 40 seconds
```

Table 10-64 Description of the display mpls l2vpn vpws command output

Item	Description
Access Circuit	Access circuit.
Protect mode	Protection mode, which can be FRR, independent, or master.
Members	PW member.
Virtual Circuit	Virtual circuit.
States	VC status
Active	Activation status of a VC, which can be:
Role	Role of a PW, which can be: ● Pri: Primary PW ● Sec: Secondary PW ● PWb: PW-bypass ● ACb: AC-bypass ● Byp: Bypass
Primary	Information about the primary PW.
VC type	The type of a VC.
VC state	VC status.
Peer IP	IP address of a peer.
VC ID	ID of a VC. The value is an integer in decimal notation. The default value is 0.
Encapsulation type	Encapsulation type of a VC.
LDP session state	Status of an LDP session.
VC information (Local / Remote)	VC information (local/remote).
Label	VC label.
MTU	Maximum transmission unit of a VC interface.
Control word	Whether the control word is enabled.

Item	Description
Status code	Status code, which can be: - 0x0: indicates the forwarding state. - 0x1: indicates the non-forwarding state. - 0x06: indicates the ACOAM fault. - 0x18: indicates the public network fault. - 0x20: indicates the standby state.
Group ID	Group ID.
VCCV status	VCCV status.
VC last up time	Time when the VC last goes Up.
VC total up time	Total Up time of a VC.
Secondary	Information about the secondary PW.

10.5.17 display mpls label-stack vll interface

Function

The **display mpls label-stack vll interface** command displays information about label stacks in VLL networking.

Format

display mpls label-stack vll interface *interface-type interface-number*

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view information about label stacks in VLL networking, run the **display mpls label-stack vll interface** command.

Example

Display information about the label stack on VLANIF100 in VLL networking.

```
<HUAWEI> display mpls label-stack vll interface vlanif 100
Label-stack  : 1
Level        : 1
Type         : VLL primary
Label        : 1027
Level        : 2
Type         : LDP
Label        : --
OutInterface : Vlanif1024
```

Table 10-65 Description of the **display mpls label-stack vll interface** command output

Item	Description
Label-stack	Number of label stacks
Level	Number of labels
Type	Tunnel type
Label	Value of the outgoing label
OutInterface	Outbound interface

10.5.18 display mpls static-l2vc

Function

The **display mpls static-l2vc** command displays information about static VCs on the device.

Format

display mpls static-l2vc [*vc-id* | **interface** *interface-type interface-number* | **state** { **down** | **up** }]

Parameters

Parameter	Description	Value
vc-id	Displays information about a static VC with a specified VC ID.	The value is an integer that ranges from 1 to 4294967295.

Parameter	Description	Value
interface *interface-type interface-number*	Displays information about all static PWs on a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
state { **down** | **up** }	Displays VC information based on the VC status. ● **down**: Displays information about the VC in Down state. ● **up**: Displays information about the VC in Up state.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If you run the **display mpls static-l2vc** command with the interface name specified, information about static VCs on the interface connected to a CE is displayed. If no interface is specified, information about static VCs on all interfaces is displayed.

Example

Display information about static VCs on the device.

```
<HUAWEI> display mpls static-l2vc
 Total svc connections:  1,  1 up,  0 down

 *Client Interface     : Vlanif10 is up
  AC Status            : down
  VC State             : up
  VC ID                : 1
  VC Type              : VLAN
  Destination          : 2.2.2.2
  Transmit VC Label    : 400
  Receive VC Label     : 600
  Label Status         : 0
  Token Status         : 0
  Control Word         : Enable
  VCCV Capability      : cw alert ttl lsp-ping bfd
  active state         : active
  Link State           : down
  Tunnel Policy Name   : tun
  PW Template Name     : --
  Main or Secondary    : Main
```

```
load balance type    : flow
Access-port          : false
VC tunnel/token info : 1 tunnels/tokens
NO.0  TNL type       : lsp   , TNL ID : 0x800802
Backup TNL type      : lsp   , TNL ID : 0x0
Create time          : 0 days, 0 hours, 0 minutes, 34 seconds
UP time              : 0 days, 0 hours, 0 minutes, 31 seconds
Last change time     : 0 days, 0 hours, 0 minutes, 31 seconds
VC last up time      : 2011/07/04 20:29:18
VC total up time     : 0 days, 0 hours, 0 minutes, 33 seconds
CKey                 : 2
NKey                 : 1
BFD for PW           : unavailable
```

Table 10-66 Description of the **display mpls static-l2vc** command output

Item	Description
Total svc connections	Number of established SVCs, including the number of SVCs in Up and Down states.
Client Interface	AC interface and its status.
AC Status	Status of the AC: ● up ● down
VC State	Status of the VC: ● up ● down
VC ID	ID of the VC, which uniquely identifies a VC. If you run the **mpls static-l2vc** command without the VC ID specified, the value of this field is displayed as 0.
VC Type	Encapsulation type of the VC: ● VLAN ● Ethernet
Destination	LSR ID of the remote end on the VC.
Transmit VC Label	Local VC label.
Receive VC Label	Remote VC label.
Label Status	Whether the label can be used: ● 0: The label can be used. ● 1: Wait for the SMB to confirm the label status. ● 2: The label is released. ● 3: SMB confirmation failed.

Item	Description
Token Status	Whether the token can be used: - 0: The token can be used. - 1: Wait for the SMB to confirm the token status. - 2: The token is released. - 3: SMB confirmation failed.
Control Word	Whether the control word function is enabled: - enable - disable
VCCV Capability	Whether VCCV is enabled.
active state	Whether the PW is in active state. A PW in active state can forward packets. - active - inactive
Link State	Integrative PW status: - up - down If any of the following status is Down, the PW link state is Down: - Service PW status - OAM status
Tunnel Policy Name	Name of the tunnel policy.
PW Template Name	Name of the PW template.
Main or Secondary	Whether the VC is a primary VC or a secondary VC.
load balance type	Load balancing mode of Martini VLL: - flow: indicates flow-based load balancing. - packet: indicates packet-based load balancing.
Access-port	Whether the interface supports the access-port attribute: - true: indicates that the interface supports the access-port attribute. - false: indicates that the interface does not support the access-port attribute.
VC Tunnel/token info	Information about the VC tunnel or token used by the VC. The value **1 tunnels/tokens** indicates that the PW uses one tunnel or token.
NO.0 TNL Type	Type of the tunnel used by the PW

Item	Description
Backup TNL Type	Type of the backup tunnel when PW over LDP FRR is used.
Create time	How long the VC has been created.
UP time	How long the VC keeps the Up state.
Last change time	How long the VC status remains unchanged.
VC last up time	Last time when the VC became Up.
VC total up time	Total duration of the VC in Up state.
CKey	Index of the public tunnel for VPN QoS.
NKey	Index of the public tunnel.
BFD for PW	Whether BFD is configured. ● unavailable: indicates that BFD is not configured. ● available: indicates that BFD is configured. ● timeout: timeout period after which a BFD session fails to be established

Display information about static VCs on VLANIF 10.

```
<HUAWEI> display mpls static-l2vc interface vlanif 10
 *Client Interface     : Vlanif10 is up
  AC Status            : down
  VC State             : up
  VC ID                : 1
  VC Type              : VLAN
  Destination          : 2.2.2.2
  Transmit VC Label    : 400
  Receive VC Label     : 600
  Label Status         : 0
  Token Status         : 0
  Control Word         : Enable
  VCCV Capability      : cw alert ttl lsp-ping bfd
  active state         : active
  Link State           : down
  Tunnel Policy        : tun
  PW Template Name     : --
  Main or Secondary    : Main
  load balance type    : flow
  Access-port          : false
  VC tunnel/token info : 1 tunnels/tokens
  NO.0  TNL Type       : lsp   , TNL ID : 0x56
  Backup TNL Type      : lsp   , TNL ID : 0x0
  Create time          : 0 days, 0 hours, 0 minutes, 34 seconds
  UP time              : 0 days, 0 hours, 0 minutes, 31 seconds
  Last change time     : 0 days, 0 hours, 0 minutes, 31 seconds
  VC last up time      : 2011/07/04 20:29:18
  VC total up time     : 0 days, 0 hours, 0 minutes, 33 seconds
  CKey                 : 2

  Diffserv Mode        : uniform
  Service Class        : be
  Color                : --
  DomainId             : --
```

```
Domain Name          : --
BFD for PW          : unavailable
```

Table 10-67 Description of the **display mpls static-l2vc interface** command output

Item	Description
Client Interface	AC interface and its status.
AC Status	Status of the link between the PE and its directly connected CE.
VC State	Status of the VC.
VC ID	ID of the VC, which uniquely identifies a VC.
VC Type	Encapsulation type of the VC.
Destination	LSR ID of the remote end on the VC.
Transmit VC Label	VC label sent by the local device.
Receive VC Label	VC label received by the local device.
Control Word	Whether the control word function is enabled.
VCCV Capability	Whether VCCV is enabled.
Tunnel Policy	Name of the tunnel policy. The value -- indicates that no tunnel policy is configured.
PW Template Name	Name of the PW template. The value -- indicates that no PW template is configured.
Main or Secondary	Whether the VC is a primary VC or a secondary VC.
VC tunnel/token info	Information about the tunnel or token used by the VC. The value **1 tunnels/tokens** indicates that the PW uses one tunnel or token.
Create time	How long the VC has been created.
UP time	How long the VC keeps the Up state.
Last change time	How long the VC status remains unchanged.
VC last up time	Last time when the VC became Up.
VC total up time	Total duration of the VC in Up state.
CKey	Index of the public tunnel for VPN QoS.
NKey	Index of the public tunnel.
Diffserv Mode	QoS DiffServ mode for VLL services.
Service Class	QoS service class for VLL services.
Color	QoS color for VLL services.

Item	Description
DomainId	ID of a domain.
Domain Name	Name of a domain.
BFD for PW	Whether BFD is configured. - unavailable: indicates that BFD is not configured. - available: indicates that BFD is configured. - timeout: timeout period after which a BFD session fails to be established

Display information about SVCs in Up state between peers.

```
<HUAWEI> display mpls static-l2vc state up

VCCV Capability	Whether VCCV is enabled.
Tunnel Policy Name	Name of the tunnel policy.
PW Template Name	Name of the PW template.
Main or Secondary	Whether the VC is a primary VC or a secondary VC.
Create time	How long the VC has been created.
UP time	How long the VC keeps the Up state.
Last change time	How long the VC status remains unchanged.
VC last up time	Last time when the VC became Up.
VC total up time	Total duration of the VC in Up state.
CKey	Index of the public tunnel for VPN QoS.
NKey	Index of the public tunnel.
BFD for PW	Whether BFD is configured. ● unavailable: indicates that BFD is not configured. ● available: indicates that BFD is configured. ● timeout: timeout period after which a BFD session fails to be established

10.5.19 display mpls static-l2vc brief

Function

The **display mpls static-l2vc brief** command displays brief information about static VCs on the device.

Format

display mpls static-l2vc brief

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display mpls static-l2vc brief** command is recommended when a large number of static VCs are configured on the device.

Example

Display brief information about static VCs on the device.

```
<HUAWEI> display mpls static-l2vc brief
Total svc connections:  2,  1 up,  1 down

 *Client Interface            : Eth-Trunk2  is up
  AC Status                   : up
  VC State                    : up
  VC ID                       : 0
  VC Type                     : VLAN
  Destination                 : 10.1.1.1

 *Client Interface            : Eth-Trunk3  is down
  AC Status                   : down
  VC State                    : down
  VC ID                       : 100
  VC Type                     : Ethernet
  Destination                 : 10.1.1.2
```

Table 10-69 Description of the **display mpls static-l2vc brief** command output

Item	Description
Total SVC Connections	Number of established SVCs, including the number of SVCs in Up and Down states.
Client Interface	AC interface and its status.
AC Status	Status of the AC: ● up: An AC has been established. ● down: An AC is not established.
VC State	Status of the VC: ● up: A VC has been established. ● down: A VC is not established.

Item	Description
VC ID	ID of the static VC. If you run the **mpls static-l2vc** command without the VC ID specified, the value of this field is displayed as 0.
VC Type	Encapsulation type of the VC: ● VLAN ● Ethernet
Destination	IPv4 address of the peer. Generally, the value is the loopback address of the peer.

10.5.20 display traffic-statistics l2vpn interface

Function

The **display traffic-statistics l2vpn interface** command displays VLL traffic statistics on a specified interface.

Format

display traffic-statistics l2vpn interface *interface-type interface-number*

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays VLL traffic statistics on a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After enabling the function of collecting L2VPN traffic statistics by running the **mpls l2vpn traffic-statistics enable** command, you can run the **display traffic-statistics l2vpn interface** command to view traffic statistics on the created VLL. The VLL traffic sent and received through the interface are collected from the time when the VLL becomes Up to the time you run the **display traffic-statistics l2vpn interface** command.

Example

Display VLL traffic statistics on VLANIF10.

```
<HUAWEI> display traffic-statistics l2vpn interface vlanif 10
 Input: 1000 bytes, 10 packets
 Output: 2000 bytes, 20 packets
```

10.5.21 display vll ccc

Function

The **display vll ccc** command displays information about a CCC connection.

Format

display vll ccc [*ccc-name* | **type** { **local** | **remote** }]

Parameters

Parameter	Description	Value
ccc-name	Specifies the connection name.	The value is an existing connection name.
type	Specifies the CCC connection type.	-
local	Displays local CCC connections.	-
remote	Displays remote CCC connections.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After a CCC connection is configured, you can use the **display vll ccc** command to see whether the configuration is successful.

If you do not specify a connection name or type, information about all the existing CCC connections is displayed.

Example

Display a specified CCC connection.

```
<HUAWEI> display vll ccc CE1-CE2
name: CE1-CE2, type: remote, state: up
intf: Vlanif11 (up ethernet), in-label: 116 ,
out-label: 119 , nexthop: 10.1.1.1
no control word
VC last up time : 2009/10/08 13:38:01
VC total up time: 0 days, 0 hours, 11 minutes, 2 seconds
```

Display information about all the CCC connections.

```
<HUAWEI> display vll ccc
total  ccc vc : 1
local  ccc vc : 0,  0 up
remote ccc vc : 1,  1 up

name: CE1-CE2, type: remote, state: up,
intf: Vlanif11 (up), in-label: 116 , out-label: 119 , nexthop: 10.1.1.1
VC last up time : 2009/10/08 13:38:01
VC total up time: 0 days, 0 hours, 10 minutes, 50 seconds
```

Table 10-70 Description of the display vll ccc command output

Item	Description
total ccc vc	Total number of CCC local connections and remote connections at the local end.
local ccc vc	The number of CCC local connections at the local end.
remote ccc vc	The number of CCC remote connections at the local end.
name	Name of CCC connection in a character string.
type	Types of CCC connections. ● local: connection between two CEs that are connected to the same PE. ● remote: connection between CEs that are connected to two different PEs.

Item	Description
state	Status of a CCC connection: - down: indicates that the CCC connection fails because the configuration is incorrect or the associated interface is Down. - up: indicates that the CCC connection is set up successfully.
intf	Interface connected to the CCC connection. The S300, S500, S2700, S5700, and S6700 supports only VLANIF interfaces to be connected to CCC connections. By default, the Ethernet encapsulation type is adopted.
in-label	Incoming label of the CCC connection that is specified manually. It is consistent with the outgoing label of the peer end.
out-label	Outgoing label of the CCC connection which is specified manually. It is consistent with the incoming label of the peer end.
nexthop	Next-hop address of the CCC connection.
VC last up time	Indicates the last time the VC was Up.
VC total up time	Indicates the total duration the VC is Up.

Display information about all the local CCC connections.

```
<HUAWEI> display vll ccc type local
total local  ccc vc : 1,  1 up
name: c2, type: local, state: up,
intf1: Vlanif10 (up),  access-port: false

intf2: Vlanif11 (up),  access-port: false
VC last up time : 2009/03/23 11:16:07
VC total up time: 0 days, 0 hours, 14 minutes, 14 seconds
```

Table 10-71 Description of the display vll ccc type local command output

Item	Description
total local ccc vc	Total number of local CCC connections and the number of local CCC connections whose status is Up.
name	Name of the CCC connection in a character string.
type: local	Information about the local CCC connection. Local indicates the connection between two CEs that are connected to a PE.

Item	Description
state	Status of a CCC connection: - down: indicates that the CCC connection fails to be set up. The cause may be that the configuration is incorrect or the associated interface is Down. - up: indicates that the CCC connection is successfully set up.
intf1: Vlanif10 (up), intf2: Vlanif11 (up)	Interfaces of the local connection on two CEs. One is Vlanif10(the status is Up), and the other is Vlanif11(the status is Up).
access-port	Whether the interface supports the access-port attribute. - true: indicates that the interface supports the access-port attribute. - false: indicates that the interface does not support the access-port attribute.

Display information about all the remote CCC connections.

```
<HUAWEI> display vll ccc type remote
total remote ccc vc : 1,  1 up
name: CE1-CE2, type: remote, state: up,
intf: Vlanif11 (up), in-label: 116 , out-label: 119 , nexthop: 10.1.1.1
VC last up time : 2007/10/08 13:38:01
VC total up time: 0 days, 0 hours, 18 minutes, 10 seconds
```

Table 10-72 Description of the display vll ccc type remote command output

Item	Description
total remote ccc vc	Total number of remote CCC connections and the number of remote CCC connections whose status is Up.
name	Name of CCC connection in a character string.
type: remote	Type of the displayed CCC connection. The word **remote** indicates that the connection is of the remote type.
state	Status of a CCC connection: - down: indicates that the CCC connection fails to be set up. The cause may be that the configuration is incorrect or the associated interface is Down. - up: indicates that the CCC connection is successfully set up.

Item	Description
intf: Vlanif11 (up)	Access interface on the CE for setting up CCC connection at the local end. The interface is Vlanif11, and its status is Up.
in-label	Incoming label of the CCC connection. The label is manually specified, and is consistent with the outgoing label of the peer.
out-label	Outgoing label of the CCC connection. The label is manually specified, and is consistent with the incoming label of the peer.
nexthop	Next-hop address of the CCC connection.

10.5.22 interface-parameter-type vccv (interface view)

Function

The **interface-parameter-type vccv** command configures Mapping packets to carry the VCCV byte.

The **undo interface-parameter-type vccv** command deletes the VCCV byte (an interface parameter) in the Mapping packet.

By default, a Mapping packet carries the VCCV byte.

Format

interface-parameter-type vccv [**secondary**]

undo interface-parameter-type vccv [**secondary**]

Parameters

Parameter	Description	Value
secondary	Indicates that the configuration applies to the secondary VC. If this keyword is not specified, the command applies to the primary VC. The command can be configured only when a local VC exists.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

The command can be configured only when a local VC exists.

Example

When configuring the VLL in LDP mode on an interface, delete the VCCV byte in the Mapping packet.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] mpls l2vc 2.2.2.2 100
[HUAWEI-Vlanif10] undo interface-parameter-type vccv
```

10.5.23 ignore-mtu-match (MPLS-L2VPN instance view)

Function

The **ignore-mtu-match** command disables the MTU matching check of the L2VPN on both ends.

The **undo ignore-mtu-match** command enables the check.

By default, the PE checks whether MTUs of the L2VPN instances on both ends are consistent.

Format

ignore-mtu-match

undo ignore-mtu-match

Parameters

None

Views

MPLS-L2VPN instance view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a Kompella VLL networking, if a Huawei device connects to a non-Huawei device that does not support MTU matching check, run the **ignore-mtu-match** command to configure the Huawei device to ignore the check.

Prerequisites

vpn-target is not configured for the L2VPN instance.

Precautions

By default, a PE checks whether MTUs of the L2VPN instances at both ends are consistent. If not, the VC cannot be in the Up state.

Example

Ignore the check of MTU of the L2VPN instance named vpn1.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn vpn1
[HUAWEI-mpls-l2vpn-vpn1] ignore-mtu-match
```

10.5.24 l2vpn-family

Function

The **l2vpn-family** command displays the BGP-L2VPN address family view.

The **undo l2vpn-family** command deletes all configurations in the BGP-L2VPN address family view.

NOTE

You can run this command on the S5731S-S or S6730S-S to enter the BGP-L2VPN address family view but cannot configure VLL configuration commands in this view.

Only MPLS-capable devices support the VLL configuration commands in the BGP-L2VPN address family view. For the S5731-S and S6730-S, when the MPLS function license is not obtained, you can run this command to enter the BGP-L2VPN address family view but cannot configure VLL configuration commands in this view.

Format

l2vpn-family

undo l2vpn-family

Parameters

None

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

In Kompella VLL networking, you can run the **l2vpn-family** command to enter the BGP-L2VPN address family view.

Example

Display the BGP-L2VPN address family view.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] l2vpn-family
[HUAWEI-bgp-af-l2vpn]
```

10.5.25 manual-set pw-ac-fault

Function

The **manual-set pw-ac-fault** command simulates a fault on the primary or secondary PW.

The **undo manual-set pw-ac-fault** command cancels the fault that is simulated on a primary or secondary PW.

By default, no fault is simulated on a PW.

Format

manual-set pw-ac-fault [**secondary**]

undo manual-set pw-ac-fault [**secondary**]

Parameters

Parameter	Description	Value
secondary	Simulates a fault on the secondary PW. If this parameter is not specified, a fault is simulated on the primary PW.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a network where the primary and secondary PWs need to be configured, you can run the **manual-set pw-ac-fault** command to simulate a fault on the primary or secondary PW to check whether services can be switched between the primary and secondary PWs.

Prerequisites

A VC has been created.

Example

Simulate a fault on the PW.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] mpls l2vc 2.2.2.2 100
[HUAWEI-Vlanif10] manual-set pw-ac-fault
```

10.5.26 mpls l2vc

Function

The **mpls l2vc** command creates a Martini VLL.

The **undo mpls l2vc** command deletes the Martini VLL from an interface.

By default, no Martini L2VPN connection is created.

Format

mpls l2vc { *ip-address* | **pw-template** *pw-template-name* } * *vc-id* [**group-id** *group-id* | **tunnel-policy** *policy-name* | [**control-word** | **no-control-word**] | [**raw** | **tagged**] | **mtu** *mtu-value* | [**secondary** | **bypass**] | **ignore-standby-state**] *

undo mpls l2vc { *ip-address* | **pw-template** *pw-template-name* } * *vc-id* [**group-id** *group-id* | **tunnel-policy** *policy-name* | [**control-word** | **no-control-word**] | [**raw** | **tagged**] | **mtu** *mtu-value* | [**secondary** | **bypass**] | **ignore-standby-state**] *

undo mpls l2vc [**secondary** | **bypass**]

Parameters

Parameter	Description	Value
ip-address	Specifies the LSR ID of a peer device on the PW.	The value is in dotted decimal notation.
pw-template *pw-template-name*	Specifies the name of a PW template.	The value is a string of 1 to 19 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
vc-id	Specifies a L2VC ID.	The value is an integer that ranges from 1 to 4294967295.

Parameter	Description	Value
group-id *group-id*	Specifies a VC group ID. With the VC group ID specified, the system can execute the same operation on a group of VCs; therefore, fewer packets are exchanged between PEs. Only the VCs with the same attribute can be configured with the same VC group ID; otherwise, the PW may be torn down by mistake. This parameter is valid only on sub-interfaces.	The value is an integer that ranges from 1 to 4294967295.
tunnel-policy *policy-name*	Specifies the name of a tunnel policy.	The value is a string of 1 to 39 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
raw	Removes the provider-tag (P-Tag) from a packet. **NOTE** This parameter can be used only for Ethernet links. If neither **raw** nor **tagged** is specified, this command sets the **raw** mode on a main interface and the **tagged** mode on a sub-interface.	-
tagged	Retains the P-Tag in a packet. **NOTE** This parameter can be used only for Ethernet links. If neither **raw** nor **tagged** is specified, this command sets the **raw** mode on a main interface and the **tagged** mode on a sub-interface.	-

Parameter	Description	Value
control-word	Enables the control word function.	-
no-control-word	Disables the control word function.	-
mtu *mtu-value*	Specifies the MTU value. **NOTE** This parameter can be configured only on VLANIF interfaces. The MTU of another type of interface or its sub-interface can be configured in the PW template.	The value is an integer that ranges from 46 to 9600. The default value is 1500.
secondary	Indicates a secondary VC. If this parameter is not specified, a primary VC is created. You can configure a secondary VC only when the primary VC exists on the local device.	-
bypass	Indicates that the VC is a bypass VC. The encapsulation type of the bypass VC must be the same as that of the primary VC.	-
ignore-standby-state	Indicates that the PW ignores standby state information sent by the remote device.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a Martini VLL networking, you can run this command to create a VC connection for a Martini VLL.

According to different encapsulation modes on the AC interfaces, the system processes user packets in different ways, as shown in the following tables.

- Packet processing on the inbound interface in the VLL or PWE3 scenario.

AC Interface Type	Encapsulation Mode of raw	Encapsulation Mode of tagged
Dot1q termination sub-interface	Removes a tag.	No action is required.
Ethernet main interfaces	No action is required.	Adds a tag.
QinQ stacking sub-interface	No action is required.	Adds a tag.
QinQ termination sub-interface (in symmetrical mode)	Removes the outer tag.	No action is required.
QinQ termination sub-interface (in asymmetrical mode)	Removes two tags.	Removes the outer tag.
VLANIF interface (added to the VLAN in default mode)	No action is required.	Adds a tag (default VLAN ID of the interface).
VLANIF interface (added to the VLAN in non-default mode)	Removes the outer tag.	No action is required.

- Packet processing on the outbound interface in the VLL or PWE3 scenario.

AC Interface Type	Encapsulation Mode of raw	Encapsulation Mode of tagged
Dot1q termination sub-interface	Adds a tag.	No action is required.
Ethernet main interfaces	Adds a tag.	Replaces the tag with the tag that is encapsulated on the outbound interface.
QinQ stacking sub-interface	No action is required.	Removes a tag.
QinQ termination sub-interface (in symmetrical mode)	Adds the outer tag.	Replaces the outer tag with the tag that is encapsulated on the outbound interface.

AC Interface Type	Encapsulation Mode of raw	Encapsulation Mode of tagged
QinQ termination sub-interface (in asymmetrical mode)	Adds two tags.	Removes the outer tag and then adds two tags that are encapsulated on the outbound interface.
VLANIF interface (added to the VLAN in default mode)	No action is required.	Removes a tag.
VLANIF interface (added to the VLAN in non-default mode)	Adds the outer tag.	Replaces the tag with the tag that is encapsulated on the outbound interface.

Precautions

- An interface cannot function as an L2VPN AC interface and L3VPN AC interface at the same time. After an interface is bound to an L2VPN, Layer 3 features such as the IP address and routing protocol on this interface become invalid.
- You must create dynamic VCs on PEs at both ends of a PW to connect the PEs. The destination address of a VC is the LSR ID of the peer PE.
- You can set attributes for a PW template, including the remote peer, tunnel policy, control word, and VCCV. When configuring an LDP PW, you can directly apply the PW template without specifying attributes for the PW. After setting attributes for a PW template, you can update the PW template at any time. The modified PW template takes effect only after the **reset pw** command is run.
- If a PW attribute is specified in the **mpls l2vc** command, the corresponding PW attribute in the same PW template is invalid.
- If you do not specify a tunnel policy for a Martini connection, the default tunnel policy is used. By default, the LSP tunnel is preferentially selected and only one tunnel is used for load balancing. If a tunnel policy name is specified but the tunnel policy is not configured, the default tunnel policy is used.
- The MTU value is specified when you create Martini or PWE3 VLLs and is used for interconnection between the switch and other devices.
- You must configure the primary PW before configuring the secondary PW and delete the secondary PW before deleting the primary PW.
- When creating VCs dynamically, the latest configurations of some parameters override the previous ones. The parameters include **tunnel-policy** *tnl-policy-name*, **control-word**, and **no-control-word**.
- By default, link type negotiation is enabled globally on the device. If a VLANIF interface is used as an AC-side interface for L2VPN, the configuration conflicts with link type negotiation. In this case, run the **lnp disable** command in the system view to disable link type negotiation.
- When configuring BFD for static PW, the VC ID must be specified.

NOTE

- If a sub-interface is bound to a VLL, the sub-interface can be deleted only after the sub-interface is unbound from the VLL.
- If a sub-interface is bound to a VLL, you cannot change the encapsulation type of the main interface.

Example

Create a Martini connection on the VLANIF interface.

```
<HUAWEI> system-view
[HUAWEI] vlan batch 10
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] mpls l2vc 10.2.2.9 100
```

Create a Martini connection on the GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls l2vc 10.2.2.9 100
```

10.5.27 mpls l2vpn

Function

The **mpls l2vpn** command enables MPLS L2VPN and displays the MPLS L2VPN view.

The **undo mpls l2vpn** command disables MPLS L2VPN and deletes all the L2VPN configurations.

By default, the MPLS L2VPN function is disabled.

Format

mpls l2vpn

undo mpls l2vpn

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure MPLS L2VPN functions or perform configurations in the MPLS L2VPN view on the MPLS L2VPN network, run the **mpls l2vpn** command to enable MPLS L2VPN and enter the MPLS L2VPN view.

Prerequisites

Basic MPLS functions have been configured. For details, see the **mpls lsr-id** and **mpls** commands.

Precautions

When the command is configured, a P device does not need to be enabled with the MPLS L2VPN function.

After the **mpls l2vpn** command is executed:

- If MPLS L2VPN is disabled on the device, MPLS L2VPN is enabled and the MPLS L2VPN view is displayed.
- If MPLS L2VPN is enabled on the device, the MPLS L2VPN view is displayed.

NOTICE

After the **undo mpls l2vpn** command is run in the system view, L2VPN services may be interrupted, and all L2VPN configurations are cleared. If you want to restore the L2VPN configurations, re-run all the deleted commands.

Example

Enable MPLS L2VPN.

```
<HUAWEI> system-view
[HUAWEI] mpls lsr-id 10.1.1.1
[HUAWEI] mpls
[HUAWEI-mpls] quit
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn]
```

10.5.28 mpls l2vpn alarm verification disable

Function

The **mpls l2vpn alarm verification disable** command disables MPLS L2VPN alarm verification.

The **undo mpls l2vpn alarm verification disable** command enables MPLS L2VPN alarm verification.

By default, MPLS L2VPN alarm verification is enabled.

Format

mpls l2vpn alarm verification disable

undo mpls l2vpn alarm verification disable

Parameters

None

Views

MPLS-L2VPN view

Default Level

2: Configuration level

Usage Guidelines

If MPLS L2VPN alarm verification is enabled on a device, the device regularly sends service alarms to the fault management (FM) module until these alarms are cleared. The FM then compares received alarms with locally stored alarms. If a received alarm is different from any of the locally stored alarms, the FM module reports the alarm to the NMS. If a received alarm is the same as a locally stored alarm, the FM module does not report this alarm.

Sometimes, alarms cleared on the device may still be displayed on the NMS. To ensure alarm consistency between the device and NMS, the FM module ages out such alarms after three alarm verification intervals and then instructs the NMS to delete these alarms. This function effectively eliminates alarm residue to improve alarm reliability.

If a large number of services exist, MPLS L2VPN alarm verification may regularly drive the CPU usage to a high level, affecting service performance. In this case, you can run the **mpls l2vpn alarm verification disable** command to disable MPLS L2VPN alarm verification. After MPLS L2VPN alarm verification is disabled, the device sends service alarms to the FM module only once, and the FM module cannot age out cleared alarms.

Example

Disable MPLS L2VPN alarm verification.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] mpls l2vpn alarm verification disable
```

10.5.29 mpls l2vpn default martini

Function

The **mpls l2vpn default martini** command configures the dynamic VC signaling not to carry status information.

The **undo mpls l2vpn default martini** command restores the default configuration.

By default, the dynamic VC signaling carries status information.

Format

mpls l2vpn default martini

undo mpls l2vpn default martini

Parameters

None

Views

MPLS-L2VPN view

Default Level

2: Configuration level

Usage Guidelines

To configure the dynamic VC signaling not to carry status information in VLL scenarios, run the **mpls l2vpn default martini** command. In other scenarios, do not run this command.

NOTE

- If the dynamic VC signaling carries status information, the local end can send Notification messages to the peer end. For details about Notification messages, see Chapter "PWE3 Principles" in the "PWE3 Configuration".
- Before using the **mpls l2vpn default martini** command, you must delete the configurations of VCs (including PWE3 VCs and VPLS VCs) that support Notification messages.

Example

Configure the dynamic VC signaling not to carry status information.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] mpls l2vpn default martini
```

Restore the default dynamic VC signaling configuration.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] undo mpls l2vpn default martini
```

10.5.30 mpls l2vpn flow-label

Function

The **mpls l2vpn flow-label** command enables flow label-based load balancing for PWs on an interface.

The **undo mpls l2vpn flow-label** command disables flow label-based load balancing for PWs on an interface.

By default, flow label-based load balancing is disabled for PWs on an interface.

NOTE

Only the S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6730S-H, and S6730-H support this command.

Format

mpls l2vpn flow-label { **both** | **send** | **receive** } [**secondary**] [**static**]

undo mpls l2vpn flow-label { **both** | **send** | **receive** } [**secondary**] [**static**]

undo mpls l2vpn flow-label [**secondary**]

Parameters

Parameter	Description	Value
both	Enables flow label-based load balancing for outgoing traffic and incoming traffic.	-
send	Enables flow label-based load balancing for outgoing traffic.	-
receive	Enables flow label-based load balancing for incoming traffic.	-
secondary	Enables flow label-based load balancing for the secondary PW. If **secondary** is not configured, flow label-based load balancing is configured for the primary PW. Flow label-based load balancing can be configured for a secondary PW only if the secondary PW exists.	-
static	Statically configures flow label-based load balancing. For dynamic PWs, if **static** is not configured, the flow label-based load balancing capability of the local end is negotiated by the remote end. For static PWs, the flow label-based load balancing capability is statically configured, irrespective of whether **static** is configured.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When multiple links exist between provider (P) devices, configure flow label-based load balancing to improve L2VPN traffic forwarding efficiency. After flow label-based load balancing is enabled on a PE, the PE adds different labels for different

L2VPN data flows to distinguish the data flows. After a P device receives a data packet carrying a flow label, it performs the Hash calculation and selects a forwarding path based on the flow label in the data packet. This processing implements load balancing. You can run the **mpls l2vpn flow-label** command to enable flow label-based load balancing for L2VPN on an interface.

Prerequisites

Before you enable flow label-based load balancing for an interface, create a VC connection on this interface and enable Multiprotocol Label Switching (MPLS) L2VPN.

Precautions

Flow label-based load balancing can be enabled only when any of the following conditions is true:

- The **receive** parameter is configured on the local PE, and the **send** parameter is configured on the remote PE.
- The **send** parameter is configured on the local PE, and the **receive** parameter is configured on the remote PE.
- Both the **send** and **receive** parameters are configured on the local and remote PEs.

The **secondary** parameter indicates that flow label-based load balancing takes effect only for the secondary PW. If you specify **secondary** parameter, flow label-based load balancing takes effect only for the primary PW.

Example

Enable flow label-based load balancing for PWs on Vlanif 100.

```
<HUAWEI> system-view
[HUAWEI] interface Vlanif 100
[HUAWEI-Vlanif100] mpls l2vc 2.2.2.2 100
[HUAWEI-Vlanif100] mpls l2vpn flow-label both
```

10.5.31 mpls l2vpn ip-parse enable

Function

The **mpls l2vpn ip-parse enable** command enables the IP packet parsing function of the MPLS L2VPN module.

The **undo mpls l2vpn ip-parse enable** command disables the IP packet parsing function of the MPLS L2VPN module.

By default, the IP packet parsing function of the MPLS L2VPN module is enabled.

Format

mpls l2vpn ip-parse enable

undo mpls l2vpn ip-parse enable

NOTE

This command is supported only on the S6720-EI and S6720S-EI.

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a Layer 2 VPN scenario, if a traffic policy is configured in the inbound direction of an AC-side interface on a device, L2VPN traffic forwarded from a PE may incorrectly match the traffic policy. As a result, traffic fails to be forwarded. To ensure normal traffic forwarding, run the **undo mpls l2vpn ip-parse enable** command to disable the IP packet parsing function of the MPLS L2VPN module.

Precautions

If the enhanced load balancing mode is configured for an Eth-Trunk, it is recommended that the IP packet parsing function of the MPLS L2VPN module be enabled.

Example

Disable the IP packet parsing function of the MPLS L2VPN module.

```
<HUAWEI> system-view
[HUAWEI] undo mpls l2vpn ip-parse enable
```

10.5.32 mpls l2vpn l2vpn-name

Function

The **mpls l2vpn** *l2vpn-name* command creates a L2VPN instance in the Kompella mode.

The **undo mpls l2vpn** *l2vpn-name* command deletes the L2VPN instance.

By default, no Kompella L2VPN instance is created.

Format

mpls l2vpn *l2vpn-name* [**encapsulation** *encapsulation* [**control-word** | **no-control-word**]]

undo mpls l2vpn *l2vpn-name*

Parameters

Parameter	Description	Value
l2vpn-name	Specifies a L2VPN instance name.	The value must be an existing VPN instance name.
encapsulation *encapsulation*	Indicates the encapsulation type of the L2VPN instance. The encapsulation type can be **ethernet** or **vlan**.	-
control-word | **no-control-word**	Enables or disables the control word. By default, the control word is disabled.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a Kompella VLL networking, you can use this command to create a VPN.

Precautions

The specified encapsulation of an L2VPN must be the same as that of the CE interface.

Example

Create a VPN in Kompella mode.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn vpn1 encapsulation vlan
[HUAWEI-mpls-l2vpn-vpn1]
```

Enter the MPLS-L2VPN instance view.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn vpn1
[HUAWEI-mpls-l2vpn-vpn1]
```

10.5.33 mpls l2vpn pw bfd

Function

The **mpls l2vpn pw bfd** command enables dynamic BFD for PWs and adjusts BFD parameters on an AC interface.

The **undo mpls l2vpn pw bfd** command restores default BFD parameters of dynamic BFD for PWs on an AC interface.

By default, dynamic BFD for PWs is not configured on an AC interface.

Format

mpls l2vpn pw bfd [**detect-multiplier** *multiplier* | **min-rx-interval** *rx-interval* | **min-tx-interval** *tx-interval*] * [**remote-vcid** *vc-id*] [**secondary**]

undo mpls l2vpn pw bfd [**detect-multiplier** | **min-rx-interval** | **min-tx-interval**] * [**secondary**]

undo mpls l2vpn pw bfd [**detect-multiplier** *multiplier* | **min-rx-interval** *rx-interval* | **min-tx-interval** *tx-interval*] * [**remote-vcid** *vc-id*] [**secondary**]

Parameters

Parameter	Description	Value
detect-multiplier *multiplier*	Specifies the local detection multiplier.	The value is an integer that ranges from 3 to 50. The default value is 3.
min-rx-interval *rx-interval*	Specifies the minimum interval for receiving BFD packets.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-S, S5731-H and S5731S-H, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-S, S6730-H, and S6730S-H, the value ranges from 3 to 1000.

Parameter	Description	Value
min-tx-interval *tx-interval*	Specifies the minimum interval for sending BFD packets.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-S, S5731-H and S5731S-H, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-S, S6730-H, and S6730S-H, the value ranges from 3 to 1000.
remote-vcid *vc-id*	Specifies the VC ID of the peer device.	This parameter is mandatory when a multi-hop PW is detected. The value of this parameter is the VC ID of the remote end of the PW. The value is an integer that ranges from 1 to 4294967295.
secondary	Configures BFD and its parameters on the secondary PW. By default, BFD and its parameters are configured on the primary PW. **NOTE** The **secondary** parameter cannot be run on Loopback interface view.	-

Views

Interface view

2: Configuration level

Usage Guidelines

Usage Scenario

On a network where BFD is used to detect faults, run the **mpls l2vpn pw bfd** command to enable dynamic BFD for PWs and adjust BFD parameters on an AC interface.

Precautions

To reduce usage of system resources, when a BFD session is detected in Down state, the system changes the minimum interval for receiving BFD packets and the minimum interval for sending BFD packets to random values between 1000 ms and 3000 ms. When the BFD session becomes Up, the configured intervals are restored.

Example

Enable dynamic BFD for PWs on VLANIF 10 and set BFD parameters.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] mpls l2vc 2.2.2.2 100
[HUAWEI-Vlanif10] mpls l2vpn pw bfd min-rx-interval 100 min-tx-interval 100
```

10.5.34 mpls l2vpn reroute

Function

The **mpls l2vpn reroute** command configures the revertive switchover policy for the primary and secondary PWs in FRR or PW redundancy master/slave mode.

The **undo mpls l2vpn reroute** command restores the default revertive switchover policy.

By default, delayed revertive switchover is configured in FRR or PW redundancy master/slave mode.

Format

mpls l2vpn reroute { { **delay** *delay-time* | **immediately** } [**resume** *resume-time*] | **never** }

undo mpls l2vpn reroute

Parameters

Parameter	Description	Value
delay *delay-time*	Specifies the revertive switchover policy for the primary and secondary PWs as delayed revertive switchover, and sets the duration for delayed switchover.	The value is an integer that ranges from 10 to 1800, in seconds. The default value is 30.

Parameter	Description	Value
immediately	Specifies the revertive switchover policy for the primary and secondary PWs as immediate revertive switchover.	-
resume *resume-time*	Specifies a delay after which the local device notifies the peer PE on the secondary PW of the recovery. You can set this parameter only in VLL FRR mode.	The value is an integer that ranges from 0 to 600, in seconds. The default value is 10.
never	Specifies the revertive switchover policy for the primary and secondary PWs to none revertive switchover. After the primary PW recovers, traffic is not switched to it until the secondary PW is faulty.	-

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **mpls l2vpn reroute** command configures the revertive switchover policy for the primary and secondary PWs in FRR or PW redundancy master/slave mode.

Prerequisites

The primary and secondary PWs have been configured in FRR or PW redundancy master/slave mode. The revertive switchover policy cannot be configured for PW redundancy independent mode.

Precautions

In VLL FRR mode and in PW redundancy master/slave mode, the PW revertive switchover policy is classified into the following modes:

- Immediate revertive switchover: When the primary PW recovers from a fault, the local PE switches traffic back to the primary PW immediately and notifies the peer PE on the secondary PW of the fault. In FRR mode, the local PE notifies the peer PE on the secondary PW of the recovery after a delay of *resume-time*. In PW redundancy master/slave mode, the parameter *resume-time* is not supported.

  This revertive switchover applies to scenarios in which users hope traffic to be restored as soon as possible.

- Delayed revertive switchover: When the primary PW recovers from a fault, traffic is switched back to the primary PW after a period specified by *delay-time*. After traffic is switched back, the local device immediately notifies the peer device on the secondary PW of the fault. If *resume-time* is configured in FRR mode, the local device notifies the peer device on the secondary PW of the recovery after a delay of *resume-time*.

  On a large-scale network, packet loss caused by incomplete route convergence may occur during the switchback. To prevent this problem, configure traffic to be switched back after a delay.
- None revertive switchover: When the primary PW recovers from a fault, traffic is not switched back to the primary PW until the secondary PW becomes faulty.

  If you do not want traffic to be frequently switched between the primary and secondary PWs, you can use the non-revertive switchover.

In a CE asymmetrical networking, if the Ethernet OAM function is configured on a PE interface connected to a CE, and a revertive switchover policy is configured, the value of *resume-time* cannot be 0 seconds. The value must be equal to or greater than 1 second.

Example

Configure the device to switch traffic back to the primary PW 15 seconds after the primary PW recovers from a fault, notify the peer PE on the secondary PW of the fault when a switchover is performed, and notify the peer PE of the secondary PW of the recovery 20 seconds later.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls l2vc 10.1.1.9 100
[HUAWEI-Vlanif100] mpls l2vc 10.2.2.9 200 secondary
[HUAWEI-Vlanif100] mpls l2vpn reroute delay 15 resume 20
```

10.5.35 mpls l2vpn service-name

Function

The **mpls l2vpn service-name** command sets the name of an SVC or Martini VLL service or a PWE3 service.

The **undo mpls l2vpn service-name** command deletes the configured L2VPN service name.

By default, no L2VPN service name is configured in the system.

Format

mpls l2vpn service-name *service-name*

undo mpls l2vpn service-name

Parameters

Parameter	Description	Value
service-name	Specifies the name of an L2VPN service. This parameter uniquely identifies an L2VPN service on a PE.	The value is a string of 1 to 15 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, an SVC or Martini VLL service or a PWE3 service is uniquely identified by the combination of the VC ID and VC type, which are hard to remember and make maintenance complex. When a service name is used to uniquely identify an L2VPN service, the name can be defined based on requirements and the NMS operator can maintain the L2VPN service by clicking the name on the NMS graphical user interface (GUI). This simplifies operation and maintenance.

Prerequisites

An SVC or Martini VLL service or a PWE3 service has been configured on a service interface. A primary PW and a secondary PW can be configured for a Martini VLL or PWE3 service.

Precautions

On each PE, an L2VPN service name is unique. If an L2VPN service name has been used by a PW, it cannot be configured for another PW, or the system will display an error message.

If an L2VPN service already has a service name, this service name will be overwritten when a new name is configured for the L2VPN service. Therefore, when changing an L2VPN service name, you can directly configure a new service name without deleting the original one.

- Because the primary and secondary PWs are configured on the same interface, they are regarded as one PW, and a service name is configured for both of them.
- On each PE, an L2VPN service name is unique.

Example

Set an L2VPN service name to **pw1** on a service interface.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] mpls l2vc 10.1.1.1 1
[HUAWEI-Vlanif10] mpls l2vpn service-name pw1
```

10.5.36 mpls l2vpn vlan-stacking

Function

The **mpls l2vpn vlan-stacking** command configures the stacked VLAN ID for a main interface.

The **undo mpls l2vpn vlan-stacking** command deletes the stacked VLAN ID from a main interface.

By default, the system does not add a VLAN ID to a packet passing through the main interface.

Format

mpls l2vpn vlan-stacking stack-vlan *vlan-id*

undo mpls l2vpn vlan-stacking stack-vlan

Parameters

Parameter	Description	Value
stack-vlan *vlan-id*	Indicates the outer VLAN ID.	The value is an integer that ranges from 1 to 4094.

Views

GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the following conditions are met, run the **mpls l2vpn vlan-stacking stack-vlan** command to specify a VLAN for a main interface:

- The VLL or VSI using VLAN encapsulation is configured on the two PEs.
- The remote PE accepts packets with one more VLAN tag.
- The local PE is connected to a computer by using a GE interface, XGE interface, 25GE interface, MultiGE interface, 40GE interface, 100GE interface, or Eth-Trunk interface as the AC interface.

In this scenario, the computer sends and receives all packets. After a VLAN is specified for the main interface, the local PE performs the following operations:

- The local PE adds VLAN tags to the packets sent by the computer. The VLAN tags are encapsulated in the user packets, and are transparently transmitted to the remote PE.
- The local PE removes the outer VLAN tags from the packets sent by the remote PE, and forwards the packets to the computer.

Precautions

Before binding the main interface to the VLL or VSI, run the **mpls l2vpn vlan-stacking stack-vlan** command to specify a VLAN for the main interface.

To use an XGE interface, a GE interface, a 25GE interface, a MultiGE interface, a 40GE interface, a 100GE interface, or an Eth-Trunk interface of the device as the AC interface of the PE, run the **undo portswitch** command to change a Layer 2 interface to a Layer 3 interface.

Example

Configure MPLS VLL on the main interface and add VLAN tag 80 to incoming packets.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/13
[HUAWEI-GigabitEthernet0/0/13] undo portswitch
[HUAWEI-GigabitEthernet0/0/13] mpls l2vpn vlan-stacking stack-vlan 80
[HUAWEI-GigabitEthernet0/0/13] mpls l2vc 10.0.0.17 20 tagged
```

10.5.37 mpls l2vpn traffic-statistics enable

Function

The **mpls l2vpn traffic-statistics enable** command enables the system to collect VLL traffic statistics.

The **undo mpls l2vpn traffic-statistics enable** command disables the system from collecting VLL traffic statistics.

By default, the system is disabled from collecting VLL traffic statistics.

Format

mpls l2vpn traffic-statistics enable

undo mpls l2vpn traffic-statistics enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To collect traffic statistics in a VLL networking, use this command to the system to collect VLL traffic statistics.

Precautions

The system collects traffic statistics only for VLLs that are created after this command is executed.

You can view traffic statistics by running the **display traffic-statistics l2vpn interface** command.

Example

Enable the function that collects L2VPN traffic statistics.

```
<HUAWEI>system-view
[HUAWEI] mpls l2vpn traffic-statistics enable
Info: The modification can only take effect for newly created VC.
```

10.5.38 mpls l2vpn trigger if-down

Function

The **mpls l2vpn trigger if-down** command enables the notification of physical layer faults.

The **undo mpls l2vpn trigger if-down** command disables the notification of physical layer faults.

By default, the notification of physical layer faults is disabled.

Format

mpls l2vpn trigger if-down

undo mpls l2vpn trigger if-down

Parameters

None

Views

25GE interface view, 40GE interface view,100GE interface view, GE interface view, MultiGE interface view, or XGE interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a VLL FRR networking, an AC must detect failures of the corresponding PW to trigger link switching. This command enables the notification of physical layer faults so that ACs can detect failures of PWs.

Precautions

After the notification of physical layer faults is enabled:

- When a physical layer fault occurs on the PW side, the local AC interface is Down.
- When a physical layer fault occurs on the AC side, the local PE notifies the peer PE of the fault and the peer AC interface is Down.

After the fault is rectified, the Down AC interface automatically becomes Up.

Example

Enable the notification of physical layer faults.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls l2vc 1.1.1.1 1
[HUAWEI-GigabitEthernet0/0/1] mpls l2vpn trigger if-down
```

10.5.39 mpls static-l2vc

Function

The **mpls static-l2vc** command creates a static VC.

The **undo mpls static-l2vc** command deletes the static VCs.

By default, no static VC is created.

Format

mpls static-l2vc { { **destination** *ip-address* | **pw-template** *pw-template-name vc-id* } * | **destination** *ip-address vc-id* } **transmit-vpn-label** *transmit-label-value* **receive-vpn-label** *receive-label-value* [**tunnel-policy** *tnl-policy-name* | [**control-word** | **no-control-word**] | [**raw** | **tagged**]] *

undo mpls static-l2vc

undo mpls static-l2vc { { **destination** *ip-address* | **pw-template** *pw-template-name vc-id* } * | **destination** *ip-address vc-id* } **transmit-vpn-label** *transmit-label-value* **receive-vpn-label** *receive-label-value* [**tunnel-policy** *tnl-policy-name* | [**control-word** | **no-control-word**] | [**raw** | **tagged**]] *

Parameters

Parameter	Description	Value
destination *ip-address*	Specifies the LSR ID of a peer device on the PW.	The value is in dotted decimal notation.
pw-template *pw-template-name*	Specifies the name of a static PW template.	The value is a string of 1 to 19 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
vc-id	Specifies the VC ID.	The value is an integer that ranges from 1 to 4294967295.
transmit-vpn-label *transmit-label-value*	Specifies the value of a transmit label.	The value is an integer that ranges from 0 to 1048575.
receive-vpn-label *receive-label-value*	Specifies the value of a receive label.	The value is an integer that ranges from 16 to 1023.
tunnel-policy *tnl-policy-name*	Specifies the name of a tunnel policy.	The value is a string of 1 to 39 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
control-word | **no-control-word**	Enables or disables the control word function. By default, the control word function is disabled.	-
raw	Removes the provider-tag (P-Tag) from a packet.	-
tagged	Retains the P-Tag in a packet.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In an L2VPN networking, you can use this command to create a static VC between two PEs connected to CEs.

Precautions

- An interface cannot function as an L2VPN AC interface and L3VPN AC interface at the same time. After an interface is bound to an L2VPN, Layer 3 features such as the IP address and routing protocol on this interface become invalid.
- You can set attributes for a static PW template, including the remote peer, tunnel policy, control word, and VCCV. When configuring a static PW, you can directly use the static PW template without specifying attributes for the PW. After setting attributes for a static PW template, you can update the static PW template at any time. The modified static PW template takes effect only after the **reset pw** command is run.
- Static VCs must be created on PEs at both ends. The destination address of a VC is the LSR ID of the peer PE. The transmit label of the PE at one end is the receive label of the PE at the other end. If the labels do not match, traffic may fail to be forwarded even though the **static-l2vc** field is displayed as Up.
- If no tunnel policy is specified, the default tunnel policy is used. The default policy specifies that traffic is forwarded along the LSP and only one tunnel is used for load balancing. If a tunnel policy name is specified but the tunnel policy is not configured, the default tunnel policy is used.
- When configuring a static VC, note that the value of the transmit label ranges from 0 to 1048575. This ensures the communication between the device and different types of devices.
- When creating static VCs, the latest configurations of some parameters override the previous ones. The parameters include **tunnel-policy** *tnl-policy-name*, **control-word**, and **no-control-word**.
- By default, link type negotiation is enabled globally on the device. If a VLANIF interface is used as an AC-side interface for L2VPN, the configuration conflicts with link type negotiation. In this case, run the **lnp disable** command in the system view to disable link type negotiation.

NOTE

- If a sub-interface is bound to a VLL, the sub-interface can be deleted only after the sub-interface is unbound from the VLL.
- If a sub-interface is bound to a VLL, you cannot change the encapsulation type of the main interface.

Example

Configure a static VC. Set the LSR ID of the peer device to 1.1.1.1, transmit label to 100, and receive label to 100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] mpls static-l2vc destination 1.1.1.1 transmit-vpn-label 100 receive-vpn-label 100
```

Configure a static VC by applying a PW template and set values of the VC ID, transmit label, and receive label to 100 respectively.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] mpls static-l2vc pw-template pwt 100 transmit-vpn-label 100 receive-vpn-label 100
```

Delete a static VC.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] undo mpls static-l2vc
```

10.5.40 mtu (MPLS-L2VPN instance view)

Function

The **mtu** command sets the Maximum Transmission Unit (MTU) of a L2VPN instance.

The **undo mtu** command restores the default configuration.

By default, the MTU of a L2VPN instance is 1500 bytes.

Format

mtu *mtu-value*

undo mtu

Parameters

Parameter	Description	Value
mtu-value	Specifies the MTU of a L2VPN instance.	The value is a decimal integer that ranges from 46 to 16352 bytes.

Views

MPLS-L2VPN instance view

Default Level

2: Configuration level

Usage Guidelines

The VPN MTU must be unique on the whole network.

If MTUs, which belong to the same VPN, on two PEs are different, the PEs cannot exchange VC information and set up connections.

After **vpn-target** is configured for the MPLS L2VPN instance, the MTU of the MPLS L2VPN cannot be changed.

In Kompella interworking with other venders' devices that do not support the MTU matching check, to ensure the VC keeps the Up state, you can perform the following configuration on the S300, S500, S2700, S5700, and S6700:

- Configuring an MTU the same as that of other venders' devices
- Using the **ignore-mtu-match** command for the system to ignore the MTU matching check

Example

Set the MTU.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn vpn1
[HUAWEI-mpls-l2vpn-vpn1] mtu 1000
```

10.5.41 ping vc

Function

The **ping vc** command detects the status of a PW.

Format

ping vc *pw-type pw-id* [*peer-address*] [**-c** *echo-number* | **-m** *time-value* | **-s** *data-bytes* | **-t** *timeout-value* | **-exp** *exp-value* | **-r** *reply-mode* | **-v**] * **control-word** [**remote** *remote-ip-address peer-pw-id* | **draft6**] * [**ttl** *ttl-value*] [**pipe** | **uniform**]

ping vc *pw-type pw-id* [*peer-address*] [**-c** *echo-number* | **-m** *time-value* | **-s** *data-bytes* | **-t** *timeout-value* | **-exp** *exp-value* | **-r** *reply-mode* | **-v**] * **control-word** **remote** *remote-ip-address peer-pw-id* **sender** *sender-address* [**ttl** *ttl-value*] [**pipe** | **uniform**]

ping vc *pw-type pw-id* [*peer-address*] [**-c** *echo-number* | **-m** *time-value* | **-s** *data-bytes* | **-t** *timeout-value* | **-exp** *exp-value* | **-r** *reply-mode* | **-v**] * **label-alert** [**no-control-word**] [**remote** *remote-ip-address* | **draft6**] * [**pipe** | **uniform**]

ping vc *pw-type pw-id* [*peer-address*] [**-c** *echo-number* | **-m** *time-value* | **-s** *data-bytes* | **-t** *timeout-value* | **-exp** *exp-value* | **-r** *reply-mode* | **-v**] * **normal** [**no-control-word**] [**remote** *remote-ip-address peer-pw-id*] [**ttl** *ttl-value*] [**pipe** | **uniform**]

Parameters

Parameter	Description	Value
pw-type	Specifies the encapsulation type of a local PW.	Currently, PWs of the following types are supported: **ethernet**, **ip-interworking**, and **vlan**.

Parameter	Description	Value
pw-id	Specifies the ID of a local PW.	The value is an integer that ranges from 1 to 4294967295.
peer-address	Specifies the peer LSR ID of a local PW. In PWE3 and Martini VLL scenarios, if the VC IDs of the primary and secondary VCs are the same, this parameter must be specified to uniquely identify a PW.	The value is in dotted decimal notation.
-c *echo-number*	Specifies the number of Echo Request messages to be sent. If the network works unstably, you can set this parameter to a larger value to test network quality based on the packet loss ratio.	The value is an integer that ranges from 1 to 4294967295. The default value is 5.
-m *time-value*	Specifies the interval for sending Echo Request messages. Each time after the source sends an Echo Request message by using the **ping vc** command, it waits a period of time (2000 ms by default) before sending the next Echo Request message. You can set the interval for sending Echo Request messages through the parameter *time-value*. If the network works unstably, the value should be greater than or equal to 2000 ms.	The value is an integer that ranges from 1 to 10000, in milliseconds. The default value is 2000.
-s *data-bytes*	Specifies the number of bytes of the sent Echo Request messages.	The value is an integer that ranges from 65 to 8100, in bytes. The default value is 100.
-t *timeout-value*	Specifies the timeout period for sending Echo Request messages.	The value is an integer that ranges from 0 to 65535, in milliseconds. The default value is 2000.

Parameter	Description	Value
-exp *exp-value*	Specifies the EXP value of the sent Echo Request messages. **NOTE** If DSCP priority has been configured by running the **set priority** command, the *exp-value* parameter does not take effect.	The value is an integer that ranges from 0 to 7. The default value is 0.
-r *reply-mode*	Specifies the mode in which the peer returns MPLS Echo Reply messages. ● 1: No MPLS Echo Reply message is returned. ● 2: MPLS Echo Reply messages are encapsulated into IPv4/IPv6 UDP packets. ● 3: MPLS Echo Reply messages are encapsulated into IPv4/IPv6 UDP packets carrying the Router Alert option. ● 4: MPLS Echo Reply messages are returned through the control channel of the application plane.	The value is an integer that ranges from 1 to 4. The default value is 2.
-v	Displays the detailed information.	-
no-control-word	Disables the control word function.	-
control-word	Enables the control word function. The switching node along a multi-segment PW does not transmit ping packets. When the control word function is enabled, you can ping only the termination node of the PW. Before using the control word to ping the PW, you must enable the control word for a PW.	-
remote	Specifies information about the PW on the remote PE. Information specified by the remote PE is finally encapsulated into the ping packets. The PW can be searched on the remote PE based on the specified information. By default, information contained in the ping packets is the information about the PW on the local end, which applies to single-segment PWs.	-

Parameter	Description	Value
peer-pw-id	Specifies the ID of the PW on the peer.	The value is an integer that ranges from 1 to 4294967295. By default, the peer PW ID is the same as the local PW ID.
draft6	Specifies the command version. If this parameter is specified, the ping operation is performed based on "draft-ietf-mpls-lsp-ping-06". By default, the ping operation is performed based on RFC 4379.	-
pipe	Specifies the pipe mode. When a probe packet passes through the MPLS domain, the entire MPLS domain is considered as one hop and the IP TTL of the probe packet is reduced by one on the ingress and egress respectively.	-
uniform	Specifies the uniform mode. The IP TTL of the probe packet is reduced by one each time it passes through one hop in the MPLS domain.	-
remote-ip-address	Specifies the remote IP address. By default, the system searches for the IP address of the next hop based on the PW on the local PE. In the case of a multi-segment PW, if the ping operation is performed in control word mode, the IP address of the termination node must be specified. In MPLS router alert mode, the IP address of any switching node or the termination node can be specified. Then, the Echo Request message is sent to the peer and then sent back.	-
label-alert	Specifies the label alert mode. The switching node along a multi-segment PW sends ping packets forcibly. In MPLS router alert mode, you can ping any switching node along the PW.	-

Parameter	Description	Value
normal	Specifies the normal mode, that is, the TTL detection mode. In this mode, control word and router alert are not encapsulated in to MPLS Echo Request messages, and TTL values are used to detect PW connectivity.	-
ttl *ttl-value*	Specifies the TTL value.	The value is an integer that ranges from 1 to 255. The default value is 64.
sender *sender-address*	Specifies a source address. For end-to-end detection of a multi-segment PW, a source IP address needs to be specified for a public network device that communicates with the remote PE. Generally, the source IP address is the address of the adjacent SPE or UPE.	-

0: Visit level

Usage Guidelines

Usage Scenario

If a PW is Up, the **ping vc** command can be used to locate the fault on the PW. For example, a forwarding entry is abnormally lost or incorrect.

The **ping vc** command can be used to check a PW in the following scenarios:

VLL networking

Based on VLL types, the VLL PW ping can be classified into the following types:

- PWE3 VLL PW ping: In a PWE3 VLL networking, a PW ping is initiated to check the connectivity of a PW. A PWE3 VLL PW ping can be performed in control word mode, TTL mode, or label alert mode. In a ping test, a local PE sends an Echo Request message to the peer PE. After receiving the message, the peer PE abstracts and sends FEC information to the L2VPN module to determine whether the message has reached the egress. If so, the peer PE returns an Echo Reply message.
- Kompella VLL PW ping: A VLL PW ping is initiated to check the connectivity of a PW. Different from the PWE3 networking, the Kompella VLL does not need the PW template and supports the control word, TTL, and label alert modes.

VPLS networking

Based on the VPLS types, the VPLS PW ping can be classified into the following types:

- Martini VPLS PW ping: The Martini VPLS PW ping supports only the label alert mode. On a Hierarchical Virtual Private LAN Service (HVPLS) network, the Martini VPLS PW ping can only detect single-segment PWs. If an optional PW ID is configured and specified, the PW with the PW ID is detected. If the PW ID is not specified, the PW with a specified VSI ID is detected.
- Kompella VPLS PW ping: The Kompella VPLS PW ping supports only the label alert mode.

If a PW fault is detected by using the **ping vc** command, the **tracert vc** command can be used to locate the fault. Both the **ping vc** command and the **tracert vc** command can properly check the connectivity of PWs and locate faults.

Prerequisites

The MPLS module has been enabled on the device and works properly.

Precautions

control-word is recommended to detect the entire PW. Even though **label-alert** can be used to check the entire PW, the whole process is the same as the forwarding process only when **control-word** is used.

The execution of the **ping vc** command terminates when either of the following situations occurs:

- The ping packet reaches the egress.
- The TTL value of the ping packet reaches the upper threshold.

When a PE is single-homed to an SPE and two multi-segment PWs are deployed for PW redundancy, end-to-end detection cannot be performed for the secondary PW if services are transmitted over the primary PW. If services are transmitted over the secondary PW, the primary PW can only be detected segment by segment.

Example

Run the **ping vc** command in label alert mode on the device to check the connectivity of an Ethernet PW.

```
<HUAWEI> ping vc ethernet 100 -c 10 -m 10 -s 65 -t 100 -v label-alert remote 2.2.2.2
  Reply from 2.2.2.2: bytes=65 Sequence=1 time = 31 ms Return Code 3, Subcode 1
  Reply from 2.2.2.2: bytes=65 Sequence=2 time = 15 ms Return Code 3, Subcode 1
  Reply from 2.2.2.2: bytes=65 Sequence=3 time = 32 ms Return Code 3, Subcode 1
  Reply from 2.2.2.2: bytes=65 Sequence=4 time = 15 ms Return Code 3, Subcode 1
  Reply from 2.2.2.2: bytes=65 Sequence=5 time = 32 ms Return Code 3, Subcode 1
  Reply from 2.2.2.2: bytes=65 Sequence=6 time = 15 ms Return Code 3, Subcode 1
  Reply from 2.2.2.2: bytes=65 Sequence=7 time = 15 ms Return Code 3, Subcode 1
  Reply from 2.2.2.2: bytes=65 Sequence=8 time = 16 ms Return Code 3, Subcode 1
  Reply from 2.2.2.2: bytes=65 Sequence=9 time = 15 ms Return Code 3, Subcode 1
  Reply from 2.2.2.2: bytes=65 Sequence=10 time = 32 ms Return Code 3, Subcode 1

--- FEC: FEC 128 PSEUDOWIRE (NEW). Type = ethernet, ID = 100 ping statistics
  10 packet(s) transmitted
  10 packet(s) received
  0.00% packet loss
  round-trip min/avg/max = 15/21/32 ms
```

10.5.42 ping vc vpn-instance

Function

The **ping vc vpn-instance** command detects the status of a PW and locates the faulty node when a PW goes Down.

Format

ping vc vpn-instance *vpn-name local-ce-id remote-ce-id* [**-c** *echo-number* | **-m** *time-value* | **-s** *data-bytes* | **-t** *timeout-value* | **-exp** *exp-value* | **-r** *reply-mode* | **-v**] * { **label-alert** [**no-control-word**] | **control-word** }

Parameters

Parameter	Description	Value
vpn-instance *vpn-name*	Specifies the VPN name.	The value is an existing VPN instance name.
local-ce-id	Specifies the ID of the local CE.	The value is a decimal integer ranging from 0 to 249.
remote-ce-id	Specifies the ID of the local CE.	The value is a decimal integer ranging from 0 to 249.
-c *echo-number*	Specifies the number of the sent Echo Request packets.	The value is a decimal integer that ranges from 1 to 4294967295. The default value is 5.
-m *time-value*	Indicates the interval for sending Echo Request packets.	The value is a decimal integer that ranges from 1 to 10000, in milliseconds. By default, the value is 2000.
-s *data-bytes*	Specifies the number of bytes of an Echo Request packet.	The value is a decimal integer ranging from 65 to 8100. By default, the value is 100.
-t *timeout-value*	Specifies the timeout period for sending Echo Request packets.	The value is a decimal integer ranging from 0 to 65535. By default, the value is 2000.
-exp *exp-value*	Specifies the EXP value in an outer label in an Echo Request packet.	The value is an integer ranging from 0 to 7.

Parameter	Description	Value
-r *reply-mode*	Specifies the mode of sending Echo Reply packets. The meaning of each value is as follows: - 1: indicates no reply. - 2: indicates a reply with an IPv4 or IPv6 UDP datagram. - 3: indicates a reply with an IPv4 or IPv6 datagram carrying an MPLS router alert label. - 4: indicates a reply through the control channel of the application plane.	The value is a decimal integer ranging from 1 to 4. By default, the value is 2.
-v	Displays detailed information.	-
label-alert	Indicates that in the case of a multi-hop PW, ping packets are forcibly sent on the transit node. In Label Alert mode, you can ping all transit nodes of a PW.	-
no-control-word	Disables the control word mode.	-
control-word	Indicates that in the case of a multi-hop PW, ping packets are forwarded without being resolved. In the control word mode, you can ping only the egress of the PW. The ping in control word mode can be performed only after the control word of a PW is enabled.	-

Usage Guidelines

If the control-word is enabled for a PW, it is recommended that you specify the **control-word** parameter to detect the connectivity of the PW. This ensures that ping packets are transmitted in the same manner as data packets on the PW.

Example

Run the **ping vc vpn-instance** command in label-alert mode on the PE to detect the connectivity of the Kompella PW.

```
<HUAWEI> ping vc vpn-instance vpn1 1 2 -v label-alert
  Reply from 4.4.4.4: bytes=100 Sequence=1 time = 110 ms Return Code 3, Subcode 1
  Reply from 4.4.4.4: bytes=100 Sequence=2 time = 90 ms Return Code 3, Subcode 1
  Reply from 4.4.4.4: bytes=100 Sequence=3 time = 60 ms Return Code 3, Subcode 1
  Reply from 4.4.4.4: bytes=100 Sequence=4 time = 60 ms Return Code 3, Subcode 1
  Reply from 4.4.4.4: bytes=100 Sequence=5 time = 90 ms Return Code 3, Subcode 1

 --- FEC: L2 VPN ENDPOINT. Sender VEID = 1, Remote VEID = 2 ping statistics ---
  5 packet(s) transmitted
  5 packet(s) received
  0.00% packet loss
  round-trip min/avg/max = 60/82/110 ms
```

Table 10-73 Description of the ping vc vpn-instance command output

Item	Description
Reply from	IP address of the Echo Reply packet
bytes	Length of the Echo Reply packet
sequence	Sequence number of the Echo Reply packet
return code	Return code of the Echo Reply packet: ● 1: Malformed echo request received ● 2: One or more of the TLVs was not understood ● 3: Replying router is an egress for the FEC at stack-depth ● 4: Replying router has no mapping for the FEC at stack-depth ● 5: Downstream Mapping Mismatch ● 6: Upstream Interface Index Unknown ● 7: Reserved ● 8: Label switched at stack-depth ● 9: Label switched but no MPLS forwarding at stack-depth ● 10: Mapping for this FEC is not the given label at stack-depth ● 11: No label entry at stack-depth ● 12: Protocol not associated with interface at FEC stack-depth ● 13: Premature termination of ping due to label stack shrinking to a single label
Subcode	Subcode of the Echo Reply packet (indicating the depth of the label stack in the packet)
FEC	FEC TLV type (L2 VPN ENDPOINT indicates the Kompella PW that is negotiated by BGP)
Sender VEID	ID of the local CE
Remote VEID	ID of the remote CE

10.5.43 reset bgp l2vpn

Function

The **reset bgp l2vpn** command resets the TCP connection of the BGP L2VPN.

Format

reset bgp l2vpn { *as-number* | *peer-ip-address* | **all** | **internal** | **external** }

Parameters

Parameter	Description	Value
as-number	Indicates the number of the AS to which an L2VPN peer belongs.	-
peer-ip-address	Indicates the IP address of an L2VPN peer.	-
all	Resets all the L2VPN BGP connections.	-
internal	Resets the L2VPN BGP connection in the same AS.	-
external	Resets the L2VPN BGP connection across ASs.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

After the parameters configured in the BGP-L2VPN address family view are modified, you can run the **reset bgp l2vpn** command to reset the TCP connection of the BGP L2VPN. After that, BGP re-negotiates parameters, re-sends label information, and re-establishes the session.

If the BGP L2VPN application and other applications share the same TCP connection, the **reset bgp l2vpn** command resets BGP neighbor relationship of all applications on this TCP connection.

Example

Reset all the L2VPN BGP connections.

```
<HUAWEI> reset bgp l2vpn all
```

10.5.44 reset traffic-statistics l2vpn interface

Function

The **reset traffic-statistics l2vpn interface** command resets VLL traffic statistics on a specified interface.

Format

reset traffic-statistics l2vpn interface *interface-type interface-number*

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of a VLL AC interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

To collect new VLL traffic statistics in a VLL networking, run the **reset traffic-statistics l2vpn interface** command to reset the current VLL traffic statistics on the specified interface, and collect VLL traffic statistics again

Example

Reset VLL traffic statistics on VLANIF10.

```
<HUAWEI> reset traffic-statistics l2vpn interface vlanif 10
```

10.5.45 route-distinguisher (MPLS-L2VPN instance view)

Function

The **route-distinguisher** command configures an RD for an MPLS L2VPN instance.

By default, no RD is configured in the MPLS L2VPN instance view.

Format

route-distinguisher *route-distinguisher*

Parameters

Parameter	Description	Value
route-distinguisher	Specifies the value of an RD. The formats of an RD are as follows: - 16-bit AS number:32-bit user-defined number For example, 102:3. An AS number ranges from 0 to 65535. A user-defined number ranges from 0 to 4294967295. The AS number and the user-defined number cannot be 0s at the same time. That is, an RD cannot be 0:0. - 32-bit IP address:16-bit user-defined number For example, 192.168.122.15:1. An IP address ranges from 0.0.0.0 to 255.255.255.255. A user-defined number ranges from 0 to 65535. - Integral 4-byte AS number:2-byte user-defined number, for example, 65537:3. An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, an RD cannot be 0:0. - 4-byte AS number in dotted notation:2-byte user-defined number, for example, 0.0:3 or 0.1:0. A 4-byte AS number in dotted notation is in the format of *x.y*, where *x* and *y* are integers that both range from 0 to 65535. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, an RD cannot be 0.0:0.	-

Views

MPLS-L2VPN instance view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a Kompella VLL networking, an L2VPN instance takes effect only after an RD is configured.

Precautions

VPNs on the same PE have different RDs. The same VPN can have the same RD or different RDs on different PEs.

To change the RD of an L2VPN instance, delete the L2VPN instance and create a new L2VPN instance.

Kompella VLL and Kompella VPLS must use different RDs.

Example

Set the RD of an MPLS L2VPN instance to 300:1.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn vpn1 encapsulation vlan
[HUAWEI-mpls-l2vpn-vpn1] route-distinguisher 300:1
```

Set the RD of an MPLS L2VPN instance to 1.1.1.1:5.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn vpn2 encapsulation vlan
[HUAWEI-mpls-l2vpn-vpn2] route-distinguisher 1.1.1.1:5
```

Set the RD of an MPLS L2VPN instance to 16.30:50.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn vpn2 encapsulation vlan
[HUAWEI-mpls-l2vpn-vpn2] route-distinguisher 16.30:50
```

10.5.46 tracert vc

Function

The **tracert vc** command detects the status of a PW or locates a faulty node on a PW in Down state.

Format

tracert vc *pw-type pw-id* [*peer-address*] [**-exp** *exp-value* | **-f** *first-ttl* | **-m** *max-ttl* | **-r** *reply-mode* | **-t** *timeout-value*] * **control-word** [**draft6**] [**full-lsp-path**] [**pipe** | **uniform**]

tracert vc *pw-type pw-id* [*peer-address*] [**-exp** *exp-value* | **-f** *first-ttl* | **-m** *max-ttl* | **-r** *reply-mode* | **-t** *timeout-value*] * **control-word remote** *remote-ip-address* [**ptn-mode** | **full-lsp-path**] [**pipe** | **uniform**]

tracert vc *pw-type pw-id* [*peer-address*] [**-exp** *exp-value* | **-f** *first-ttl* | **-m** *max-ttl* | **-r** *reply-mode* | **-t** *timeout-value*] * **control-word remote** *remote-pw-id* **draft6** [**full-lsp-path**] [**pipe** | **uniform**]

tracert vc *pw-type pw-id* [*peer-address*] [**-exp** *exp-value* | **-f** *first-ttl* | **-m** *max-ttl* | **-r** *reply-mode* | **-t** *timeout-value*] * **label-alert** [**no-control-word**] [**remote** *remote-ip-address*] [**full-lsp-path**] [**draft6**] [**pipe** | **uniform**]

tracert vc *pw-type pw-id* [*peer-address*] [**-exp** *exp-value* | **-f** *first-ttl* | **-m** *max-ttl* | **-r** *reply-mode* | **-t** *timeout-value*] * **normal** [**no-control-word**] [**remote** *remote-ip-address*] [**full-lsp-path**] [**draft6**] [**pipe** | **uniform**]

Parameters

Parameter	Description	Value
pw-type	Specifies the PW type.	Currently, PWs of the following types are supported: **ethernet**, **vlan**, and **ip-interworking**.
pw-id	Specifies the local PW ID.	The value is an integer that ranges from 1 to 4294967295.
peer-address	Specifies a peer LSR ID for the local PW. In a PWE3 or Martini VLL scenario, if the primary and secondary VCs are configured with the same VC ID, this parameter must be specified to determine a unique PW to be monitored.	The value is in dotted decimal notation.
-exp *exp-value*	Specifies the EXP value in the outer label of an MPLS Echo Request packet. The default value is 0. **NOTE** If DSCP priority has been configured by running the **set priority** command, the *exp-value* parameter does not take effect.	The value is an integer that ranges from 0 to 7.
-f *first-ttl*	Specifies the initial Time-to-Live (TTL).	The value is an integer that ranges from 1 to 255, and must be smaller than the value of *max-ttl*. The default value is 1.
-m *max-ttl*	Specifies the maximum TTL.	The value is an integer that ranges from 1 to 255, and must be larger than the value of *first-ttl*. The default value is 30.

Parameter	Description	Value
-r *reply-mode*	Specifies the mode in which the peer returns MPLS Echo Reply packets. ● 1: No MPLS Echo Reply packet is returned. ● 2: The MPLS Echo Reply packet is encapsulated in IPv4/IPv6 UDP packets. ● 3: MPLS Echo Reply packets are encapsulated in IPv4/IPv6 /IPv6 UDP packets carrying the Router Alert option. ● 4: MPLS Echo Reply packets are returned through the control channel of the application plane.	The value is an integer that ranges from 1 to 4.
-t *timeout-value*	Specifies the timeout interval of an MPLS Echo Reply packet.	The value is an integer that ranges from 0 to 65535, in milliseconds. The default value is 5.
control-word	Indicates that the control word is encapsulated in the MPLS Echo Request packet.	-
label-alert	Indicates that the router alert label is encapsulated in the MPLS Echo Request packet.	-
no-control-word	Indicates that the control word is not encapsulated in the MPLS Echo Request packet.	-
normal	Indicates the normal mode where the router alert label and control word are not encapsulated in the MPLS Echo Request packet.	-
remote	Specifies information about the PW on the remote PE.	-

Parameter	Description	Value
remote-ip-address	Specifies the remote IP address. By default, the system searches for the IP address of the next hop based on the PW on the local PE. If **label-alert** is configured, you can specify the IP address of any switching node or the termination node.	-
remote-pw-id	Specifies the ID of the remote PW. By default, the ID of the local PW is used. If the tracert operation is performed in control word mode for a multi-segment PW, the IP address of the termination node must be specified.	-
ptn-mode	Specifies the PTN mode. In a multi-segment PW scenario, this parameter is indicated that trace VC packets are replied. You need to run the **lspv pw reply ptn-mode** command on both the SPE and TPE.	-
full-lsp-path	Displays the responses from all nodes along the LSP that the MPLS Echo Request packets pass through. If this parameter is not specified, only the responses from the PW nodes along the LSP are displayed.	-
pipe	Specifies the pipe mode. When a probe packet passes through the MPLS domain, the entire domain is regarded as one hop and the IP TTL of the probe packet is reduced by one on both the ingress and egress.	-
uniform	Specifies the uniform mode. The IP TTL of the probe packet is reduced by one each time it passes through one hop in the MPLS domain.	-

Parameter	Description	Value
draft6	Specifies the version of the **tracert vc** command. If this parameter is specified, the tracert operation is performed according to "draft-ietf-mpls-lsp-ping-06". By default, the tracert operation is performed according to RFC 4379. **NOTE** Tracert VC based on **draft6** is applied only to VLL over LDP scenarios.	-

Usage Guidelines

Usage Scenario

If a fault occurs on the PW, the **ping vc** command can be used to check the connectivity of the network, and the **tracert vc** command can be used to locate the fault and provide reference for fault diagnosis. If a PW is Up, the **ping vc** command can be used to locate the fault on the PW. For example, a forwarding entry is abnormally lost or incorrect. If a PW is down, the **tracert vc** command must be used to locate the faulty node on the PW.

The **tracert vc** command applies to the following networking scenarios:

- PWE3 VLL PW tracert

  In PWE3 VLL networking, PW tracert can help you obtain information about SPEs and Ps along the path that the message travels from the source to the destination, check the connectivity of the PW, and locate the fault of the PW.

  A PWE3 VLL PW tracert can be performed in control word mode, label alert mode, or TTL mode. The default mode is label alert. The TTL mode and control word mode are mutually exclusive.

  To detect faults on a VLL network with control word enabled, run the **tracert vc** *pw-type pw-id* **control-word** command.

  To encapsulate packets with the router alert label and detect faults on a VLL network, run the **tracert vc** *pw-type pw-id* **label-alert** command.

  If control word is not enabled and packets are not encapsulated with the router alert label, to detect faults on a VLL network, run the **tracert vc** *pw-type pw-id* command.

  The TTL value of the PW Tracert Request message is incremented by 1 each time. Each time the transit node (P) receives an Echo Request message after the TTL value of the message expires, it sends the Echo Request message to the LSPV module. Then the transit node returns an Echo Reply message carrying the next hop information.

Prerequisite

- The UDP module of each node works properly; otherwise, the tracert operation will fail.
- The MPLS module has been enabled on each node and works properly.
- The ICMP module of each node works properly; otherwise, " * * * " is displayed.

Procedure

The execution process of the **tracert vc** command is as follows:

1. The source sends an MPLS Echo Request packet with the TTL being 1. After the TTL times out, the first hop sends an MPLS Echo Reply packet to the source.
2. The source sends an MPLS Echo Request packet with the TTL being 2. After the TTL times out, the second hop sends an MPLS Echo Reply packet to the source.
3. The source sends an MPLS Echo Request packet with the TTL being 3. After the TTL times out, the third hop sends an MPLS Echo Reply packet to the source.
4. The preceding steps continue until the MPLS Echo Request packet reaches the destination.

When the device on each hop receives the MPLS Echo Request packet, it will respond with an MPLS Echo Reply packet, indicating that the tracert test ends. In the command output information of the source device, you can view the path that the packet passes through.

Configuration Impact

In control word mode, if a transit node receives an MPLS Echo Request packet whose TTL does not time out, it does not send the packet to the CPU. In this mode, the source obtains only a little PW information and cannot obtain information about the downstream devices of the transit node. This mode is recommended when the traffic volume is heavy.

In router alert mode, a transit node sends the received MPLS Echo Request packets to the CPU. In this mode, the source obtains a lot of PW information; therefore, device performance is affected when the traffic volume is heavy. This mode is recommended when the traffic volume is light.

Information specified by **remote** is encapsulated in MPLS Echo Request packets. The PW can be searched on the remote PE based on the specified information. By default, information contained in the MPLS Echo Request packets is about the PW on the local PE. This applies to single-segment PWs.

Precautions

- When the probe packet reaches the egress or the TTL reaches the upper threshold, the PW tracert is terminated.
- You can press **Ctrl + C** to terminate the execution of the **tracert vc** command.

When a PE is single-homed to an SPE and two multi-segment PWs are deployed for PW redundancy, end-to-end detection cannot be performed for the secondary PW if services are transmitted over the primary PW. If services are transmitted over the secondary PW, the primary PW can only be detected segment by segment.

Example

Trace a multi-segment PW. The encapsulation type, local PW ID, and remote PW ID of the PW is ethernet, 100, and 200.

```
<HUAWEI> tracert vc ethernet 100 control-word remote 200 draft6 full-lsp-path
 TTL   Replier           Time    Type      Downstream
 0                          Ingress   10.1.1.2/[1025 ]
 1     10.1.1.2          230 ms  Transit   10.2.1.2/[3 ]
 2     10.2.1.2          230 ms  Transit   10.3.1.2/[3 ]
 3     10.3.1.2          100 ms  Transit   10.4.1.2/[3 ]
 4     10.4.1.2          150 ms  Egress
```

Table 10-74 Description of the **tracert vc** command output

Item	Description
TTL	TTL value in an Echo Request packet. It represents the number of hops along the path through which an Echo Request packet passes.
Replier	IP address of the node sending MPLS Echo Reply packets.
Time	Time when the packet is processed.
Type	Node type. The value can be: ● Ingress: indicates an ingress node. ● Transit: indicates a transit node. ● Egress: indicates an egress node.
Downstream	IP address and label of the downstream node.

10.5.47 tracert vc vpn-instance

Function

The **tracert vc vpn-instance** command detects the hop-by-hop connectivity of the LSP between PEs in the Kompella networking.

Format

tracert vc -vpn-instance *vpn-name local-ce-id remote-ce-id* [**-exp** *exp-value* | **-f** *first-ttl* | **-m** *max-ttl* | **-r** *reply-mode* | **-t** *timeout-value*] * { **control-word** | **label-alert** [**no-control-word**] | **draft6** } [**full-lsp-path**]

Parameters

Parameter	Description	Value
-vpn-instance *vpn-name*	Specifies the VPN instance name.	The value is an existing VPN instance name.
local-ce-id	Specifies the ID of the local CE.	It is a decimal integer ranging from 0 to 249.
remote-ce-id	Specifies the ID of the remote CE.	It is a decimal integer ranging from 0 to 249.
-exp *exp-value*	specifies value of the EXP field in an outer label in an Echo Request packet.	It is a decimal integer ranging from 0 to 7.
-f *first-ttl*	Specifies the value of the first TTL.	It is a decimal integer ranging from 1 to 255 and must be smaller than *max-ttl*. By default, the value is 1.
-m *max-ttl*	Specifies the value of the maximum TTL.	It is a decimal integer ranging from 1 to 255 and must be greater than the value of *first-ttl*. By default, the value is 30.
-r *reply-mode*	Specifies the mode in which the peer responds to the Echo Reply packet. The meaning of each value is as follows: ● 1: indicates no reply. ● 2: indicates a reply with an IPv4 or IPv6 UDP datagram. ● 3: indicates a reply with an IPv4 or IPv6 datagram carrying an MPLS router alert label. ● 4: indicates a reply through the control channel of the application plane.	It is a decimal integer ranging from 1 to 4.
-t *timeout-value*	Specifies the timeout period for waiting for MPLS Echo Reply packets.	The value is a decimal integer ranging from 0 ms to 65535 ms. By default, the value is 5.

Parameter	Description	Value
control-word	Indicates the control word encapsulated in packets.	-
label-alert	Indicates the router alert label encapsulated in packets.	-
no-control-word	Disables the control word mode.	-
draft6	Indicates the version of the command. If the parameter is specified, the command is implemented according to draft-ietf-mpls-lsp-ping-06. By default, the command is implemented according to RFC 4379.	-
full-lsp-path	Displays information about responses of all nodes along the LSP that an Echo Request packet passes. If this parameter is not specified, only the response of each PW node along the LSP is displayed.	-

Usage Guidelines

Usage Scenario

In a Kompella networking, if any node on the backbone network fails, use this command to identify the faulty node.

The **tracert vc vpn-instance** command applies to the following networking scenarios:

- Kompella VLL PW tracert

  In Kompella VLL networking, you can start a VLL PW tracert to check PW connectivity.

  A VLL PW tracert can help you obtain information about PEs and Ps along the path that the message travels from the source to the destination, check the connectivity of the Layer 2 forwarding link, and locate faults of the PW.

  Different from the PWE3 VLL PW tracert, the Kompella VLL tracert does not need the PW template and can be performed in control word mode or label alert mode. The default mode is label alert. Like PWE3 VLL PW tracert, Kompella VLL tracert can be enabled using a command.

Precautions

If the control word is encapsulated in MPLS echo request packets on a multi-hop PW, the packets on the switch node are not sent to the CPU for processing until the TTL times out. In control word mode, the source obtains less PW information, but the performance of the node is seldom affected and the source is unaware of the downstream information about this transit node. When there are a large number of packets, the control word mode is recommended.

After the router alert is encapsulated, in the case of a multi-hop PW, on the transit node, the Echo Request packet is sent to the CPU. In Label Alert mode, the source obtains more PW information. However, when a large number of packets are transmitted, the performance of the node degrades severely. The Label Alert mode is recommended when a small number of packets are transmitted on the network.

Example

Perform the Tracert test on the VPN instance named vpn1 in label-alert mode.

```
<HUAWEI> tracert vc -vpn-instance vpn1 1 2 label-alert full-lsp-path
 TTL   Replier            Time    Type      Downstream
 0                          Ingress   20.1.1.1/[21505 1026 ]
 1     20.1.1.1          60 ms   Transit   30.1.1.1/[1026 ]
 2     30.1.1.1          50 ms   Transit   40.1.1.1/[3 ]
 3     4.4.4.4          70 ms   Egress
```

Table 10-75 Description of the **tracert vc vpn-instance** command output

Item	Description
TTL	TTL of MPLS Echo Request packets, indicating the number of hops along the tunnel that the packets pass.
Replier	Source IP address in an Echo Reply packet.
Time	How long a packet is processed
Type	Type of a node: ● Ingress ● Transit ● Egress
Downstream	Address and label of the downstream node

10.5.48 vpn-target (MPLS-L2VPN instance view)

Function

The **vpn-target** command specifies VPN targets for an L2VPN.

The **undo vpn-target** command deletes the VPN targets specified for an L2VPN.

By default, no VPN target is specified for an L2VPN.

Format

vpn-target *vpn-target* &<1-16> [**both** | **export-extcommunity** | **import-extcommunity**]

undo vpn-target { **all** | *vpn-target* &<1-16> [**both** | **export-extcommunity** | **import-extcommunity**] }

Parameters

Parameter	Description	Value
vpn-target	Adds a VPN target to the VPN. A VPN target can use any of the following formats: ● 16-bit AS number:32-bit user-defined number For example, 1:3. An AS number ranges from 0 to 65535. A user-defined number ranges from 0 to 4294967295. The AS number and the user-defined number cannot be 0s at the same time. That is, a VPN target cannot be 0:0. ● 32-bit IP address:16-bit user-defined number For example, 192.168.122.15:1. An IP address ranges from 0.0.0.0 to 255.255.255.255. A user-defined number ranges from 0 to 65535. ● Integral 4-byte AS number:2-byte user-defined number, for example, 65537:3. An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a VPN target cannot be 0:0. ● 4-byte AS number in dotted notation:2-byte user-defined number, for example, 0.0:3 or 0.1:0. A 4-byte AS number in dotted notation is in the format of *x.y*, where *x* and *y* are integers that range from 0 to 65535. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a VPN target cannot be 0.0:0.	-
import-extcommunity	Receives routing information carrying specified extended community attributes.	-
export-extcommunity	Specifies the extended community attributes carried in routing information to be sent.	-

Parameter	Description	Value
both	Specifies the extended community attributes of the received and the sent routing information.	-
all	Deletes all the VTs.	-

Views

MPLS-L2VPN instance view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a Kompella VLL networking, you can use this command to set the VPN target attribute for an L2VPN instance. The VPN target is used to set up a remote PW.

Precautions

If you do not specify any keywords, **both** is used by default.

Before configuring a VPN target, configure the Route Distinguisher (RD) for the L2VPN instance.

Example

Configure the VTs for an L2VPN named vpn1.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn vpn1 encapsulation vlan
[HUAWEI-mpls-l2vpn-vpn1] vpn-target 100:1
[HUAWEI-mpls-l2vpn-vpn1] vpn-target 1:1 2:2 export-extcommunity
[HUAWEI-mpls-l2vpn-vpn1] vpn-target 1.2.3.4:11 12:12 import-extcommunity
```

Delete the VT of vpn1.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn vpn1 encapsulation vlan
[HUAWEI-mpls-l2vpn-vpn1] undo vpn-target 12:12 import-extcommunity
```

Delete all the VTs of vpn1.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn vpn1 encapsulation vlan
[HUAWEI-mpls-l2vpn-vpn1] undo vpn-target all
```

10.6 PWE3 Configuration Commands

10.6.1 Command Support

Only the following switch models support PWE3:

S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H

10.6.2 bfd bind pw

Function

The **bfd bind pw** command configures a BFD session to detect a PW.

The **undo bfd** command deletes a specified BFD session.

By default, no BFD session is configured to detect a PW.

Format

bfd *cfg-name* **bind pw interface** *interface-type interface-number* [**secondary**]

undo bfd *cfg-name*

Parameters

Parameter	Description	Value
cfg-name	Specifies the name of the BFD session.	The value is a string of 1 to 15 case-insensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
interface *interface-type interface-number*	Specifies the type and number of the interface where the PW to be detected resides, namely, the AC interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
secondary	Indicates that the BFD session detects the secondary PW.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a transmission device exists on a direct link, BFD detects a link fault faster than a link detection mechanism on an interface. On networks demanding fast fault detection, run the **bfd bind pw** command to configure a BFD session to detect a PW.

Prerequisites

- A PW has been configured on an AC interface by running the **mpls l2vc** command.
- BFD has been enabled globally by running the **bfd** command.
- A single-segment or multi-segment PW has been configured.

Precautions

- When detecting a PW, BFD sessions must be bound to the source and destination ends of a PW.
- You need to create a BFD session to detect primary and secondary PWs separately.

NOTE

When running the **bfd bind pw** command to detect a multi-segment PW, ensure that the first-segment PW is a VLL PW configured on a non-SPE node.

When running the **bfd bind pw** command to detect a single-segment PW, ensure that the single-segment PW is configured on a non-SPE node.

Example

Create a BFD session to detect a PW.

```
<HUAWEI> system-view
[HUAWEI] bfd pe2 bind pw interface vlanif 10
```

10.6.3 bfd-detect

Function

The **bfd-detect** command enables dynamic BFD for PW in a PW template and adjusts the sending interval, receiving interval, and local detection multiplier of BFD detection packet.

The **undo bfd-detect** command restores the default configuration.

By default, dynamic BFD for PW is not enabled in a PW template.

Format

bfd-detect [**min-tx-interval** *tx-interval* | **min-rx-interval** *rx-interval* | **detect-multiplier** *multiplier*] *

undo bfd-detect

Parameters

Parameter	Description	Value
min-tx-interval *tx-interval*	Specifies the interval at which BFD packets are sent.	The value is an integer that ranges from 100 to 1000, in milliseconds. - After the **set service-mode enhanced** command is configured on the S5731-S, S5731-H and S5731S-H, the value ranges from 3 to 1000. - After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-S, S6730-H, and S6730S-H, the value ranges from 3 to 1000.
min-rx-interval *rx-interval*	Specifies the interval at which BFD packets are received.	The value is an integer that ranges from 100 to 1000, in milliseconds. - After the **set service-mode enhanced** command is configured on the S5731-S, S5731-H and S5731S-H, the value ranges from 3 to 1000. - After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-S, S6730-H, and S6730S-H, the value ranges from 3 to 1000.
detect-multiplier *multiplier*	Specifies the local detection multiplier value of a BFD session.	An integer ranging from 3 to 50. The value is 3 by default.

Views

PW template view

Default Level

2: Configuration level

Usage Guidelines

If the BFD session is found to be Down, the system automatically adjusts the receiving interval and sending interval of the local end to a random value ranging from 1000 ms to 3000 ms to reduce system resource utilization. When the BFD session restores the Up state, the user-defined interval is used again.

Example

Enable dynamic BFD detection, and set *min-tx-interval*, *min-rx-interval*, and *multiplier* to 100 ms, 100 ms, and 4 respectively in the PW template.

```
<HUAWEI> system-view
[HUAWEI] pw-template pwt
[HUAWEI-pw-template-pwt] bfd-detect min-rx-interval 100 min-tx-interval 100 detect-multiplier 4
```

10.6.4 bfd for pw enable

Function

The **bfd for pw enable** command enables the device to send BFD for PW packets to the protocol stack.

The **undo bfd for pw enable** command disables the device from sending BFD for PW packets to the protocol stack.

By default, the device does not send BFD for PW packets to the protocol stack, but discards or forwards the packets.

Format

bfd for pw enable

undo bfd for pw enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure a BFD session to detect a PW on a network requiring short link detection, run the **bfd for pw enable** command to enable the device to send BFD for PW packets to the protocol stack. If this command is not used, the device discards or forwards BFD for PW packets.

Precautions

The **bfd for pw enable** command must have been executed to configure a BFD session to detect a PW. If this command is not used, the **bfd for pw enable** command does not take effect.

Example

Enable the device to send BFD for PW packets to the protocol stack.

```
<HUAWEI> system-view
[HUAWEI] bfd for pw enable
```

10.6.5 control-word

Function

The **control-word** command enables the control word in a PW template.

The **undo control-word** command disables the control word in a PW template.

By default, the control word is disabled in a PW template.

Format

control-word

undo control-word

Parameters

None

Views

PW template view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In the case of load balancing, packets received by a device may be out of order. With the control word function, the device can reassemble the packets.

PW templates simplify the configuration of PWs with similar attributes. The control word attribute can be set using commands or a PW template. If the control word is configured using both commands and a PW template, only the control word configured using commands takes effect.

Prerequisites

- MPLS L2VPN has been enabled.
- A PW template has been created.

Configuration Impact

After a PW is established using a PW template where the control word function is enabled, the control word enabling status on both ends of the PW may be different after the PW template is restarted. As a result, system performance may be affected.

Follow-up Procedure

When configuring MPLS L2VPN on an interface, use a configured PW template.

Precautions

After the control word attribute is changed in a PW template:

- If the PW is in use, you do not need to reset the PW.
- If the PW template is being referenced by PWs, the configuration takes effect only after you run the **reset pw** command. Running the **reset pw** command may cause the disconnection and re-connection of related PWs. If multiple PWs use this template at the same time, the system operation is affected.

Example

Enable the control word in the PW template named **pwt**.

```
<HUAWEI> system-view
[HUAWEI] pw-template pwt
[HUAWEI-pw-template-pwt] control-word
```

Disable the control word in the PW template named **pwt**.

```
<HUAWEI> system-view
[HUAWEI] pw-template pwt
[HUAWEI-pw-template-pwt] undo control-word
```

10.6.6 display mpls l2vc

Function

The **display mpls l2vc** command displays information about virtual circuits (VCs) in LDP mode.

Format

display mpls l2vc [*vc-id* | **interface** *interface-type interface-number* | **remote-info** [*vc-id* | **verbose**] | **state** { **down** | **up** }]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of the AC interface connected to the CE. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
remote-info	Displays information about the VC on the remote end.	-
vc-id	Displays static PW information with a specified VC ID.	The value is an integer that ranges from 1 to 4294967295.
verbose	Displays the detailed information about the VC on the remote end.	-
state { **down** | **up** }	Displays VC information based on the VC status. - **down**: Displays information about the VC in Down state. - **up**: Displays information about the VC in Up state.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display mpls l2vc** command displays information about the VCs in LDP signaling mode, including the Martini VC and PWE3 VC.

- If the interface is specified, information about VCs on the specified AC interface is displayed.
- If **remote-info** is specified but *vc-id* is not specified, information about all VCs set up by the remote and local peers is displayed.

Example

Display information about all the LDP VCs configured on the switch.

```
<HUAWEI> display mpls l2vc
 Total LDP VC : 1     1 up       0 down
```

```
*client interface       : Vlanif1111 is up

Table 10-76 Description of the **display mpls l2vc** command output

Item	Description
Total LDP VC	Total number of established LDP VCs, including the number of LDP VCs in Up and Down state.
client interface	AC interface and its status.

Item	Description
Administrator PW	Whether the PW is an mPW. The PW can be an mPW only when the AC interface is a loopback interface. This field can be displayed as **yes** or **no**.
session state	Status of the LDP session established between both ends of the VC: ● up: The LDP session has been established. ● down: The LDP session is not established.
AC status	Status of the AC: ● up: An AC has been established. ● down: An AC is not established.
Ignore AC state	Whether the AC status change affects the status of services on the active or standby PWE3. ● enable: The impact of the AC status change on the status of services on the active or standby PWE3 is ignored. ● disable: The AC status change affects the status of services on the active or standby PWE3.
VC state	Status of the VC: ● up: A VC has been established. ● down: A VC is not established.
Label state	Label status: ● 0: The label can be used. ● 1: Wait for the SMB to confirm the label status. ● 2: The label is released. ● 3: SMB confirmation failed.
Token state	Token status: ● 0: The token can be used. ● 1: Wait for the SMB to confirm the token status. ● 2: The token is released. ● 3: SMB confirmation failed.
VC ID	ID of the VC, which uniquely identifies a VC. **NOTE** If the VC IDs on both ends are different, run the **mpls l2vc** command in the interface view to change the VC ID on one end to be the same as that on the other end.

Item	Description
VC type	Encapsulation type of the VC: ● VLAN ● Ethernet The PW can go Up only when the local and remote encapsulation types are the same.
destination	LSR ID of the VC peer device.
local VC label	Local VC label.
remote VC label	Remote VC label.
control word	Whether the control word is enabled: ● enable: The control word is enabled. ● disable: The control word is disabled.
forwarding entry	Whether forwarding entries exist.
local group ID	Local group ID.
remote group ID	Remote group ID.
manual fault	Whether a PW fault is simulated.
active state	Whether the PW is in active state. A PW in active state can forward packets.
link state	Integrative PW status: ● up ● down If any of the following status is Down, the PW link state is Down: ● Service PW status ● Status of the mPW associated with service PWs ● Status of the BFD session associated with service PWs ● PW state code ● PW status detected by VCCV ● OAM status
local VC MTU	MTU of the local VC.
remote VC MTU	MTU of the remote VC.
tunnel policy name	Name of the tunnel policy.
PW template name	Name of the PW template.
primary or secondary	Whether the VC is a primary VC or a secondary VC.

Item	Description
load balance type	Load balancing mode of Martini VLL: - flow: indicates flow-based load balancing. - packet: indicates packet-based load balancing.
Access-port	Whether the interface supports the access-port attribute: - true: indicates that the interface supports the access-port attribute. - false: indicates that the interface does not support the access-port attribute.
Switchover Flag	Whether a switchover has occurred.
create time	How long the VC has been created.
up time	How long the VC keeps the Up state. If the current PW status is Down, the value is 0.
last change time	How long the VC status remains unchanged.
VC last up time	Last time when the VC became Up.
VC total up time	Total duration of the VC in Up state.
CKey	Index of the public tunnel for VPN QoS.
NKey	Index of the public tunnel.
AdminPw interface	AC interface on which the mPW is bound to the PW. The AC interface must be a loopback interface. This field is displayed only when the PW is not an mPW: - Name of the loopback interface. - --: indicates that the PW is not bound to an mPW.
AdminPw link state	Status of the mPW bound to the PW. This field is displayed only when the PW is not an mPW. This field can be displayed as: - Up - Down - --: indicates that the PW is not bound to an mPW.
Diffserv Mode	QoS DiffServ mode.
Service Class	QoS service class.
Color	QoS color.
DomainId	ID of a domain.

Item	Description
Domain Name	Name of a domain.

Display LDP VC information about the AC interface VLANIF 100.

Table 10-77 Description of the **display mpls l2vc interface** command output

Item	Description
local AC OAM State	OAM status of the local AC. - up - down
local PSN OAM State	Status of the local device on the Packet Switch Network (PSN) side. - up - down
local forwarding state	Status of the local forwarding table. - forwarding - down
local status code	Status code of the local PW: - 0x0: indicates that the local PW functions as the master PW and is in Up state. - 0x20: indicates that the local PW functions as the backup PW and is in Up state. - 0x1: indicates that the local PW functions as the master PW and is in Down state. - 0x21: indicates that the local PW functions as the backup PW and is in Down state.
remote AC OAM state	OAM status of the remote AC. - up - down
remote PSN OAM state	Status of the remote device on the PSN side. - up - down
remote forwarding state	Status of the remote forwarding table. - forwarding - down
remote status code	Status code of the remote PW: - 0x0: indicates that the remote PW functions as the master PW and is in Up state. - 0x20: indicates that the remote PW functions as the backup PW and is in Up state. - 0x1: indicates that the remote PW function as the master PW and is in Down state. - 0x21: indicates that the remote PW function as the backup PW and is in Down state.

Item	Description
BFD for PW	Whether BFD for PW is enabled: - available - unavailable
VCCV State	Whether Virtual Circuit Connectivity Verification (VCCV) is enabled.
local VCCV	Type of VCCV supported on the local device. - By default, the VCCV type is **alert ttl lsp-ping bfd**, indicating that the control word function is disabled and LSP ping and BFD are supported for the alert channel. - If the control word function is enabled, the VCCV type is **cw alert ttl lsp-ping bfd**, indicating that LSP ping and BFD are supported for both the control word channel and the alert channel.
remote VCCV	Type of VCCV supported on the remote device. - By default, the VCCV type is **alert ttl lsp-ping bfd**, indicating that the control word function is disabled and LSP ping and BFD are supported for the alert channel. - If the control word function is enabled, the VCCV type is **cw alert ttl lsp-ping bfd**, indicating that LSP ping and BFD are supported for both the control word channel and the alert channel.
local control word	Whether the control word is enabled on the local device: - Disable - Enable
remote control word	Whether the control word is enabled on the remote device: - Disable - Enable
ignore standby state	Whether the status of the secondary PW is ignored.
VC Tunnel/token info: 1 tunnels/tokens	Information about the tunnel or token used by the VC. The value **1 tunnels/tokens** indicates that the PW uses one tunnel or token.
TNL type	Type of the tunnel used by the PW.
TNL ID	ID of the tunnel used by the PW.

Item	Description
Backup TNL Type	Type of the backup tunnel when PW over LDP FRR is used.
PW redundancy mode	PW redundancy mode. By default, the mode is FRR. ● Independent: indicates that the PW is in negotiation mode. ● frr: indicates that the PW is in FRR mode. ● --: indicates that the PW is in master/slave mode.

Display the LDP VC information received from the remote peer.

```
<HUAWEI> display mpls l2vc remote-info
Total remote ldp vc : 1

Transport  Group      Peer            Remote         Remote     C   MTU/  N   S
VC ID      ID         Addr            Encap          VC Label   Bit CELLS Bit Bit

101        0          10.3.3.9        ethernet       1024       0   1500  0   0
```

Display the detailed LDP VC information received from the remote peer.

```
<HUAWEI> display mpls l2vc remote-info verbose
Total remote LDP VC : 1

VC ID             : 1
VC Type           : vlan
VC Label          : 1025
Peer Address      : 10.5.5.5
Group ID          : 0
MTU               : 1500
Control Word      : 0
Notification      : 1
Status Code       : 0
Match Local VC    : MATCH
Max ATM CELLS     : --
TDM RTP Header    : --
TDM Encap Num     : --
TDM Bit Rate      : --
```

Table 10-78 Description of the **display mpls l2vc remote-info** command output

Item	Description
Total remote ldp vc	Total number of created remote LDP VCs.
Transport VC ID	VC ID, which uniquely identifies a VC.
Group ID	ID of the group to which the L2VPN belongs. The default value is 0.
Peer Addr and Peer Address	IP address of the remote peer.

Item	Description
Remote Encap	Encapsulation type of the remote VC. - vlan - ethernet
Remote VC Label	Remote VC label.
C Bit	Whether the control word is enabled: - 1: indicates that the control word is enabled. - 0: indicates that the control word is disabled.
MTU/CELLS	MTU of the L2VPN.
N Bit and Notification	Whether the Notification message is supported: - 1: indicates the message is supported. - 0: indicates the message is not supported.
S Bit and Status Code	Status code: - 0: indicates the forwarding state. - 1: indicates the non-forwarding state. - 32: indicates the backup state.
Match Local VC	Whether the local VC ID matches the remote VC ID: - MATCH - NOT-MATCH
Max ATM CELLS	Maximum number of ATM cells that can be transmitted. If ATM encapsulation is used, the value ranges from 1 to 28, and the default value is 28. If non-ATM encapsulation is used, double hyphens (--) are displayed.
TDM RTP Header	Whether the RTP-header option is enabled: - enable: The RTP header is added to TDM packets to be transparently transmitted. - disable: The RTP header is not added to TDM packets to be transparently transmitted. This is the default value. - --: Non-TDM encapsulation is used.
TDM Encap Num	Number of frames in a TDM packet. If TDM encapsulation is used, the value is 8, 16, 24, 32 or 40, and the default value is 32. If non-TDM encapsulation is used, double hyphens (--) are displayed.

Item	Description
TDM Bit Rate	Number of timeslots in a TDM packet. Number of timeslots in a TDM packet = Number of bytes in a TDM packet/Number of frames in a TDM packet

Display information about the VCs in Up state.

```
<HUAWEI> display mpls l2vc state up

10.6.7 display mpls l2vc brief

Function

The **display mpls l2vc brief** command displays brief information about LDP Layer 2 virtual circuits (L2VCs) on the device.

Format

display mpls l2vc brief

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display mpls l2vc brief** command is recommended when many L2VCs are configured on a device. The command output is more concise than that of the **display mpls l2vc** command.

Example

Display brief information about all LDP L2VCs on the device.

```
<HUAWEI> display mpls l2vc brief
 Total LDP VC : 1     1 up       0 down

 *Client Interface     : Vlanif1111
  Administrator PW     : no
  AC status            : up
  Ignore AC state      : disable
  VC state             : up
  Label state          : 0
  Token state          : 0
  VC ID                : 116119
  VC Type              : VLAN
  session state        : up
  Destination          : 10.6.6.6
  link state           : up
```

Table 10-79 Description of the **display mpls l2vc brief** command output

Item	Description
Total LDP VC	Total number of LDP VCs, including the number of LDP VCs in Up and Down state.
Client Interface	AC interface and its status.
Administrator PW	Whether the PW is an mPW. The PW can be an mPW only when the AC interface is a loopback interface.
AC status	Status of the AC: - up - down
Ignore AC state	Whether the AC status change affects the status of services on the active or standby PWE3. - enable: The impact of the AC status change on the status of services on the active or standby PWE3 is ignored. - disable: The AC status change affects the status of services on the active or standby PWE3.
VC state	Status of the VC: - up - down
Label state	Label status: - 0: The label can be used. - 1: Wait for the SMB to confirm the label status. - 2: The label is released. - 3: SMB confirming failed.
Token state	Token status: - 0: The label can be used. - 1: Wait for the SMB to confirm the label status. - 2: The label is released. - 3: SMB confirming failed.
VC ID	ID of the VC, which uniquely identifies a VC.
VC Type	Encapsulation type of the VC.
session state	Status of the session between peers: - up - down
Destination	Peer address.

Item	Description
link state	Status of the VC: ● up ● down

10.6.8 display mpls l2vc track admin-vc

Function

The **display mpls l2vc track admin-vc** command displays information about service PWs or switching PWs that are associated with an mPW.

Format

display mpls l2vc track admin-vc interface loopback *interface-number* [**upe**]

Parameters

Parameter	Description	Value
interface loopback *interface-number*	Specifies the loopback interface on which the mPW is configured.	-
upe	Displays information about switching PWs of the UPE type.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After service PWs or switching PWs are associated with an mPW, you can run the **display mpls l2vc track admin-vc** command to view information about these PWs, facilitating configuration and management.

Example

Display information about service PWs or switching PWs that are associated with the mPW configured on loopback 0.

```
<HUAWEI> display mpls l2vc track admin-vc interface loopback 0
Total VC         :  0    2 up      0 down

 Admin-PW state   :  up
 Peer IP          :  1.1.1.1
```

```
PW type          : UPE
Total VC         :  2     2 up      0 down

*Client Interface     : Vlanif10
 VC State             : up
 VC ID               : 1113
 VC Type              : Ethernet
 Link State           : up

*Client Interface     : Vlanif10
 VC State             : up
 VC ID               : 2223
 VC Type              : Ethernet
 Link State           : up
```

Table 10-80 Description of the display mpls l2vc track admin-vc command output

Item	Description
Total VC	Number of all the service PWs and switching PWs that are associated with the mPW.
Admin-PW state	Status of the mPW. ● down ● up
Peer IP	IP address of an mPW peer. The peers of the service or switching PWs must have the same IP address as that of the mPW.
PW type	PW type. Currently, only UPE is supported.
*Client Interface	AC interface of the service PW or switching PW.
VC State	VC status. ● down ● up
VC ID	VC ID. The VC ID uniquely identifies a VC together with the VC type.
VC Type	Encapsulation type of the VC. ● ethernet ● ip-interworking ● vlan
Link State	Forwarding status of the PW. ● down ● up

10.6.9 display mpls static-l2vc

Function

The **display mpls static-l2vc** command displays information about static VCs on the device.

Format

display mpls static-l2vc [*vc-id* | **interface** *interface-type interface-number* | **state** { **down** | **up** }]

Parameters

Parameter	Description	Value
vc-id	Displays information about a static VC with a specified VC ID.	The value is an integer that ranges from 1 to 4294967295.
interface *interface-type interface-number*	Displays information about all static PWs on a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
state { **down** | **up** }	Displays VC information based on the VC status. ● **down**: Displays information about the VC in Down state. ● **up**: Displays information about the VC in Up state.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If you run the **display mpls static-l2vc** command with the interface name specified, information about static VCs on the interface connected to a CE is displayed. If no interface is specified, information about static VCs on all interfaces is displayed.

Example

Display information about static VCs on the device.

```
<HUAWEI> display mpls static-l2vc
 Total svc connections:  1,  1 up,  0 down

 *Client Interface     : Vlanif10 is up
  AC Status            : down
  VC State             : up
  VC ID                : 1
  VC Type              : VLAN
  Destination          : 2.2.2.2
  Transmit VC Label    : 400
  Receive VC Label     : 600
  Label Status         : 0
  Token Status         : 0
  Control Word         : Enable
  VCCV Capability      : cw alert ttl lsp-ping bfd
  active state         : active
  Link State           : down
  Tunnel Policy Name   : tun
  PW Template Name     : --
  Main or Secondary    : Main
  load balance type    : flow
  Access-port          : false
  VC tunnel/token info : 1 tunnels/tokens
  NO.0  TNL type       : lsp   , TNL ID : 0x800802
  Backup TNL type      : lsp   , TNL ID : 0x0
  Create time          : 0 days, 0 hours, 0 minutes, 34 seconds
  UP time              : 0 days, 0 hours, 0 minutes, 31 seconds
  Last change time     : 0 days, 0 hours, 0 minutes, 31 seconds
  VC last up time      : 2011/07/04 20:29:18
  VC total up time     : 0 days, 0 hours, 0 minutes, 33 seconds
  CKey                 : 2
  NKey                 : 1
  BFD for PW           : unavailable
```

Table 10-81 Description of the **display mpls static-l2vc** command output

Item	Description
Total svc connections	Number of established SVCs, including the number of SVCs in Up and Down states.
Client Interface	AC interface and its status.
AC Status	Status of the AC: ● up ● down
VC State	Status of the VC: ● up ● down
VC ID	ID of the VC, which uniquely identifies a VC. If you run the **mpls static-l2vc** command without the VC ID specified, the value of this field is displayed as 0.

Item	Description
VC Type	Encapsulation type of the VC: ● VLAN ● Ethernet
Destination	LSR ID of the remote end on the VC.
Transmit VC Label	Local VC label.
Receive VC Label	Remote VC label.
Label Status	Whether the label can be used: ● 0: The label can be used. ● 1: Wait for the SMB to confirm the label status. ● 2: The label is released. ● 3: SMB confirmation failed.
Token Status	Whether the token can be used: ● 0: The token can be used. ● 1: Wait for the SMB to confirm the token status. ● 2: The token is released. ● 3: SMB confirmation failed.
Control Word	Whether the control word function is enabled: ● enable ● disable
VCCV Capability	Whether VCCV is enabled.
active state	Whether the PW is in active state. A PW in active state can forward packets. ● active ● inactive
Link State	Integrative PW status: ● up ● down If any of the following status is Down, the PW link state is Down: ● Service PW status ● OAM status
Tunnel Policy Name	Name of the tunnel policy.
PW Template Name	Name of the PW template.
Main or Secondary	Whether the VC is a primary VC or a secondary VC.

Item	Description
load balance type	Load balancing mode of Martini VLL: ● flow: indicates flow-based load balancing. ● packet: indicates packet-based load balancing.
Access-port	Whether the interface supports the access-port attribute: ● true: indicates that the interface supports the access-port attribute. ● false: indicates that the interface does not support the access-port attribute.
VC Tunnel/token info	Information about the VC tunnel or token used by the VC. The value **1 tunnels/tokens** indicates that the PW uses one tunnel or token.
NO.0 TNL Type	Type of the tunnel used by the PW
Backup TNL Type	Type of the backup tunnel when PW over LDP FRR is used.
Create time	How long the VC has been created.
UP time	How long the VC keeps the Up state.
Last change time	How long the VC status remains unchanged.
VC last up time	Last time when the VC became Up.
VC total up time	Total duration of the VC in Up state.
CKey	Index of the public tunnel for VPN QoS.
NKey	Index of the public tunnel.
BFD for PW	Whether BFD is configured. ● unavailable: indicates that BFD is not configured. ● available: indicates that BFD is configured. ● timeout: timeout period after which a BFD session fails to be established

Display information about static VCs on VLANIF 10.

```
<HUAWEI> display mpls static-l2vc interface vlanif 10
 *Client Interface     : Vlanif10 is up

Domain Name          : --
BFD for PW           : unavailable
```

Table 10-82 Description of the **display mpls static-l2vc interface** command output

Item	Description
Client Interface	AC interface and its status.
AC Status	Status of the link between the PE and its directly connected CE.
VC State	Status of the VC.
VC ID	ID of the VC, which uniquely identifies a VC.
VC Type	Encapsulation type of the VC.
Destination	LSR ID of the remote end on the VC.
Transmit VC Label	VC label sent by the local device.
Receive VC Label	VC label received by the local device.
Control Word	Whether the control word function is enabled.
VCCV Capability	Whether VCCV is enabled.
Tunnel Policy	Name of the tunnel policy. The value -- indicates that no tunnel policy is configured.
PW Template Name	Name of the PW template. The value -- indicates that no PW template is configured.
Main or Secondary	Whether the VC is a primary VC or a secondary VC.
VC tunnel/token info	Information about the tunnel or token used by the VC. The value **1 tunnels/tokens** indicates that the PW uses one tunnel or token.

Item	Description
Create time	How long the VC has been created.
UP time	How long the VC keeps the Up state.
Last change time	How long the VC status remains unchanged.
VC last up time	Last time when the VC became Up.
VC total up time	Total duration of the VC in Up state.
CKey	Index of the public tunnel for VPN QoS.
NKey	Index of the public tunnel.
Diffserv Mode	QoS DiffServ mode for VLL services.
Service Class	QoS service class for VLL services.
Color	QoS color for VLL services.
DomainId	ID of a domain.
Domain Name	Name of a domain.
BFD for PW	Whether BFD is configured. ● unavailable: indicates that BFD is not configured. ● available: indicates that BFD is configured. ● timeout: timeout period after which a BFD session fails to be established

Display information about SVCs in Up state between peers.

```
<HUAWEI> display mpls static-l2vc state up

Table 10-83 Description of the **display mpls static-l2vc state** command output

Item	Description
Total svc connections	Number of established SVCs, including the number of SVCs in Up and Down states.
Client Interface	AC interface and its status.
AC Status	Status of the AC.
VC State	Status of the VC.
VC ID	ID of the VC, which uniquely identifies a VC.
VC Type	Encapsulation type of the VC.
Destination	LSR ID of the remote end on the VC.
Transmit VC Label	Local VC label.
Receive VC Label	Remote VC label.
Control Word	Whether the control word function is enabled.
VCCV Capability	Whether VCCV is enabled.
Tunnel Policy Name	Name of the tunnel policy.
PW Template Name	Name of the PW template.
Main or Secondary	Whether the VC is a primary VC or a secondary VC.
Create time	How long the VC has been created.
UP time	How long the VC keeps the Up state.
Last change time	How long the VC status remains unchanged.
VC last up time	Last time when the VC became Up.
VC total up time	Total duration of the VC in Up state.
CKey	Index of the public tunnel for VPN QoS.
NKey	Index of the public tunnel.
BFD for PW	Whether BFD is configured. ● unavailable: indicates that BFD is not configured. ● available: indicates that BFD is configured. ● timeout: timeout period after which a BFD session fails to be established

10.6.10 display mpls static-l2vc brief

Function

The **display mpls static-l2vc brief** command displays brief information about static VCs on the device.

Format

display mpls static-l2vc brief

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display mpls static-l2vc brief** command is recommended when a large number of static VCs are configured on the device.

Example

Display brief information about static VCs on the device.

```
<HUAWEI> display mpls static-l2vc brief
Total svc connections:  2,  1 up,  1 down

 *Client Interface            : Eth-Trunk2  is up
  AC Status                   : up
  VC State                    : up
  VC ID                       : 0
  VC Type                     : VLAN
  Destination                 : 10.1.1.1

 *Client Interface            : Eth-Trunk3  is down
  AC Status                   : down
  VC State                    : down
  VC ID                       : 100
  VC Type                     : Ethernet
  Destination                 : 10.1.1.2
```

Table 10-84 Description of the **display mpls static-l2vc brief** command output

Item	Description
Total SVC Connections	Number of established SVCs, including the number of SVCs in Up and Down states.

Item	Description
Client Interface	AC interface and its status.
AC Status	Status of the AC: - up: An AC has been established. - down: An AC is not established.
VC State	Status of the VC: - up: A VC has been established. - down: A VC is not established.
VC ID	ID of the static VC. If you run the **mpls static-l2vc** command without the VC ID specified, the value of this field is displayed as 0.
VC Type	Encapsulation type of the VC: - VLAN - Ethernet
Destination	IPv4 address of the peer. Generally, the value is the loopback address of the peer.

10.6.11 display mpls switch-l2vc

Function

The **display mpls switch-l2vc** command displays information about PW switching, including static, dynamic, and mix PW switching.

Format

display mpls switch-l2vc [*ip-address vc-id* **encapsulation** *encapsulation-type* | **state** { **down** | **up** }]

Parameters

Parameter	Description	Value
ip-address	Specifies the LSR ID of the peer PE.	-
vc-id	Specifies the VC ID.	The value is an integer that ranges from 1 to 4294967295.

Parameter	Description	Value
encapsulation *encapsulation-type*	Specifies the PW encapsulation type.	Currently, the device supports the following types encapsulation types: **ethernet**, **vlan**, and **ip-interworking**.
state { **down** | **up** }	Displays VC information based on the VC status. ● **down**: Displays information about the VC in Down state. ● **up**: Displays information about the VC in Up state.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If parameters in the **display mpls switch-l2vc** command are not specified, information about all PW switching is displayed.

Example

Display information about the specified PW switching.

```
<HUAWEI> display mpls switch-l2vc 1.1.1.9 100 encapsulation ethernet
*Switch-l2vc type             : SVC<---->SVC
 Peer IP Address              : 3.3.3.9, 1.1.1.9
 VC ID                        : 100, 100
 VC Type                      : Ethernet
 VC State                     : up
 In/Out Label                 : 200/200, 100/100
 InLabel Status               : 0 , 0
 Control Word                 : Disable, Disable
 VCCV Capability              : alert ttl lsp-ping bfd, alert ttl lsp-ping bfd
 Switch-l2vc tunnel info      :
                                1 tunnels for peer 5.5.5.9
                                NO.0  TNL Type : lsp   , TNL ID : 0x11
                                1 tunnels for peer 1.1.1.9
                                NO.0  TNL Type : lsp   , TNL ID : 0xb
 CKey                         : 44, 1
 NKey                         : 43, 3
 Tunnel policy                : --,--
 Control-Word transparent     : YES
 Create time                  : 0 days, 0 hours, 7 minutes, 2 seconds
 UP time                      : 0 days, 0 hours, 7 minutes, 2 seconds
 Last change time             : 0 days, 0 hours, 7 minutes, 2 seconds
 VC last up time              : 2008/07/24 12:31:31
 VC total up time             : 0 days, 2 hours, 12 minutes, 51 seconds
```

Table 10-85 Description of the **display mpls switch-l2vc** command output (SVC-SVC)

Item	Description
Switch-l2vc Type	Switching type: - LDP-LDP - LDP-SVC - SVC-SVC When primary/secondary PWs and PW switching are configured, the value of this field must be LDP-LDP. - LDP: indicates a dynamic PW. - SVC: indicates a static PW.
Peer ip address	IP addresses of the peers at two ends of a switching PW, which are displayed in left and right columns respectively.
VC ID	ID of the VC, which uniquely identifies a VC. Here, the field indicates the two switched VC IDs.
VC Type	Encapsulation type of the VC.
VC State	Status of the VC: - Up: A VC has been established. - Down: A VC is not established.
In/Out Label	Incoming or outgoing label.
InLabel Status	Status of the inner label.
Control Word	Whether the control word function is enabled on both ends: - Disable - Enable
VCCV Capability	Type of VCCV supported on the local device. - By default, the VCCV type is **alert ttl lsp-ping bfd**, indicating that the control word function is disabled and LSP ping and BFD are supported for the alert channel. - If the control word function is enabled, the VCCV type is **cw alert ttl lsp-ping bfd**, indicating that LSP ping and BFD are supported for both the control word channel and the alert channel.

Item	Description
Switch-l2vc tunnel info: 1 tunnels for peer 3.3.3.9 NO.0 TNL Type : lsp , TNL ID : 0x11	Information about the tunnels on both ends: ● TNL Type: indicates the type of the tunnel. ● TTNL ID: indicates the tunnel ID.
CKey	Index of the public tunnel for VPN QoS.
NKey	Index of the public tunnel.
Tunnel policy	Name of the tunnel policy.
Control-Word transparent	Whether transparent transmission of the control word is enabled: ● yes ● no
Create Time	How long the VC has been created.
Up Time	How long the VC keeps the Up state.
Last Change Time	How long the VC status remains unchanged.
VC last up time :	Last time when the AC became Up.
VC total up time:	Total duration when the AC interface is Up.

Display information about the switched L2VCs in Up state between peers.

```
<HUAWEI> display mpls switch-l2vc state up
Total Switch VC : 1, 1 up, 0 down
*Switch-l2vc type             : LDP<---->LDP

 VC total up time             : 0 days, 2 hours, 12 minutes, 51 seconds
```

Table 10-86 Description of the **display mpls switch-l2vc** command output (LDP-LDP)

Item	Description
VC StatusCode	VC status code: - PSN: indicates the fault status at the public network side. - OAM: indicates the fault status at the AC side. - FW: indicates the forwarding status. -Local VC: indicates the local VC status. -Remote VC: indicates the remote VC status.
Session State	Status of the session: - Up: indicates that the session is successfully set up. - Down: indicates that the session is not set up. - None: indicates that no session exists.
Local/Remote Label	Incoming or outgoing label.
Local/Remote MTU	Local and remote MTU values of the PWs on two ends: - For LDP, both the local and remote MTU values are displayed. - For SVC, only the local MTU value is displayed.
Local/Remote Control Word	Whether the control word is enabled on both ends: - disable: indicates that the control word is disabled. - enable: indicates that the control word is enabled.
Local/Remote VCCV Capability	Whether VCCV is enabled on both ends: - CC: specifies the control channel type, which can be CW, alert, or TTL. - CV: specifies the connectivity verification mode, which can be LSP ping or BFD.
Control-Word transparent	Whether transparent transmission of the control word is enabled: - yes - no

Display information about all the switched L2VCs between peers.

10.6.12 display mpls switch-l2vc brief

Function

The **display mpls switch-l2vc brief** command displays brief information about all switching PWs, including static, dynamic, and mixed switching PWs.

Format

display mpls switch-l2vc brief

Parameters

None.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When many switching PWs are configured on the device, you can run this command to view brief information about the switching PWs. The command output of the **display mpls switch-l2vc brief** command is more concise than that of the **display mpls switch-l2vc** command.

Example

Display brief information about switching PWs.

```
<HUAWEI> display mpls switch-l2vc brief
Total Switch VC : 1,   1 up,   0 down
*Switch-l2vc Type           : LDP<---->LDP
 Peer IP Address            : 10.1.1.9, 10.2.2.9
 VC ID                      : 200, 100
 VC Type                    : VLAN
 VC State                   : up
 Session State              : up, up
```

Table 10-87 Description of the display mpls switch-l2vc brief command output

Item	Description
Total Switch VC	Number of established Martini VCs (using the LDP signaling), including the number of Martini VCs in Up and Down states.
Switch-l2vc Type	Switching type, which can be LDP-LDP, LDP-SVC, or SVC-SVC. If the primary and secondary switching VCs are configured, the switching types of these VCs can only be LDP-LDP. ● LDP: indicates a dynamic PW. ● SVC: indicates a static PW.
Peer IP Address	IP address of the peer.
VC ID	ID of the VC, which uniquely identifies a VC. Here, the field indicates the two switched VC IDs.
VC Type	Encapsulation type of the VC.
VC State	Status of the VC: ● up: A VC has been established. ● down: A VC is not established.
Session state	Status of the session between peers: ● up: indicates that the session is successfully set up. ● down: indicates that the session is not set up. ● none: indicates that no session exists.

10.6.13 display pw-template

Function

The **display pw-template** command displays information about PW templates.

Format

display pw-template [*pw-template-name*]

Parameters

Parameter	Description	Value
pw-template-name	Specifies the PW template name. If this parameter is not specified, information about all PW templates is displayed.	The value is an existing PW template name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If *pw-template-name* is not specified, information about all PW templates is displayed.

Example

Display information about all PW templates.

```
<HUAWEI> display pw-template
Total PW template number : 2
  PW Template Name : PWT
  PeerIP           : 2.2.2.2
  Tnl Policy Name  : --
  CtrlWord         : Enable
  MTU              : 1500
  Max Atm Cells    : 28
  ATM Pack Overtime: 1000
  Seq-Number       : Disable
  Transmit ATM Cells      : 28
  TDM Encapsulation Number: 32
  Jitter-Buffer           : 20
  Jitter-Buffer-Cep       : 1125
  Payload-Compression DBA : UNEQ
  Idle-Code               : ff
  Rtp-Header              : Disable
  VCCV Capability  : cw alert ttl lsp-ping bfd
  Total PW         : 6, Static PW : 1, LDP PW : 5

  PW Template Name : pwt
  PeerIP           : --
  Tnl Policy Name  : --
  CtrlWord         : Disable
  MTU              : 1500
  Max Atm Cells    : 28
  ATM Pack Overtime: 1000
  Seq-Number       : Disable
  Transmit ATM Cells      : 28
  TDM Encapsulation Number: 32
```

```
Jitter-Buffer          : 20
Jitter-Buffer-Cep      : 1125
Payload-Compression DBA : UNEQ
Idle-Code              : ff
Rtp-Header             : Disable
VCCV Capability  : alert ttl lsp-ping bfd
Total PW         : 0, Static PW : 0, LDP PW : 0
```

Table 10-88 Description of the **display pw-template** command output

Item	Description
Total PW template number	Total number of PW templates.
PW Template Name	PW template name.
PeerIP	Peer IP address.
Tnl Policy Name	Name of the public network tunnel policy applied to the PW.
CtrlWord	Whether the control word is enabled in the PW template. ● Disable ● Enable
MTU	Maximum transmission unit.
Max ATM cells	Maximum number of transmitted ATM cells.
ATM pack overtime	Delay in packaging ATM cells.
Seq-Number	Sequence number in the control word of the PW: ● If the sequence number function is enabled, the device checks the sequence number of each packet and discards any packet with an incorrect sequence number. ● If the sequence number function is disabled, the device does not check the sequence number when processing packets.
Transmit ATM Cells	Number of ATM cells sent by the local device.
TDM Encapsulation Number	Number of encapsulated TDM frames.
Jitter-Buffer	Maximum jitter buffer depth for TDM.
Jitter-Buffer-Cep	Maximum jitter buffer depth for TDM (with CEP encapsulation).
Payload-Compression DBA	Payload compression dynamic bandwidth allocation (DBA): ● UNEQ: Send DBA packets when unequipped circuit indications are detected. ● --: Payload compression DBA is not configured.

Item	Description
Idle-Code	Idle code that is filled when a jitter buffer underflow occurs.
Rtp-Header	Whether the RTP header is added to the transparently transmitted TDM frame.
VCCV Capability	VC connection verification mode. ● By default, the VCCV type is **alert ttl lsp-ping bfd**, indicating that the control word function is disabled and LSP ping and BFD are supported for the alert channel. ● If the control word function is enabled, the VCCV type is **cw alert ttl lsp-ping bfd**, indicating that LSP ping and BFD are supported for both the control word channel and the alert channel.
Total PW	Total number of PWs using this PW template, including static and dynamic PWs.

10.6.14 lspv pw reply ptn-mode

Function

The **lspv pw reply ptn-mode** command configures the SPE and TPE to reply trace VC packets in a multi-segment PW scenario.

The **undo lspv pw reply ptn-mode** command restores the default configuration.

By default, the **lspv pw reply ptn-mode** command is not configured.

Format

lspv pw reply ptn-mode

undo lspv pw reply ptn-mode

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

When the source end starts a tracert test in PTN mode to detect the connectivity of the multi-hop PW, the **lspv mpls-pw reply ptn-mode** command needs to be run on the SPE and TPE. If the PTN mode is not specified, the **lspv mpls-pw reply ptn-mode** command is not required.

Example

Run **lspv pw reply ptn-mode** command to enable the SPE and TPE to respond to tracert VC packets in PTN mode.

```
<HUAWEI> system-view
[HUAWEI] lspv pw reply ptn-mode
```

10.6.15 manual-set pw-ac-fault

Function

The **manual-set pw-ac-fault** command simulates a fault on the primary or secondary PW.

The **undo manual-set pw-ac-fault** command cancels the fault that is simulated on a primary or secondary PW.

By default, no fault is simulated on a PW.

Format

manual-set pw-ac-fault [**secondary**]

undo manual-set pw-ac-fault [**secondary**]

Parameters

Parameter	Description	Value
secondary	Simulates a fault on the secondary PW. If this parameter is not specified, a fault is simulated on the primary PW.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a network where the primary and secondary PWs need to be configured, you can run the **manual-set pw-ac-fault** command to simulate a fault on the primary or secondary PW to check whether services can be switched between the primary and secondary PWs.

Prerequisites

A VC has been created.

Example

Simulate a fault on the PW.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] mpls l2vc 2.2.2.2 100
[HUAWEI-Vlanif10] manual-set pw-ac-fault
```

10.6.16 mpls l2vc

Function

The **mpls l2vc** command creates a Martini VLL.

The **undo mpls l2vc** command deletes the Martini VLL from an interface.

By default, no Martini L2VPN connection is created.

Format

mpls l2vc { *ip-address* | **pw-template** *pw-template-name* } * *vc-id* [**group-id** *group-id* | **tunnel-policy** *policy-name* | [**control-word** | **no-control-word**] | [**raw** | **tagged**] | **mtu** *mtu-value* | [**secondary** | **bypass**] | **ignore-standby-state**] *

undo mpls l2vc { *ip-address* | **pw-template** *pw-template-name* } * *vc-id* [**group-id** *group-id* | **tunnel-policy** *policy-name* | [**control-word** | **no-control-word**] | [**raw** | **tagged**] | **mtu** *mtu-value* | [**secondary** | **bypass**] | **ignore-standby-state**] *

undo mpls l2vc [**secondary** | **bypass**]

Parameters

Parameter	Description	Value
ip-address	Specifies the LSR ID of a peer device on the PW.	The value is in dotted decimal notation.
pw-template *pw-template-name*	Specifies the name of a PW template.	The value is a string of 1 to 19 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
vc-id	Specifies a L2VC ID.	The value is an integer that ranges from 1 to 4294967295.
group-id *group-id*	Specifies a VC group ID. With the VC group ID specified, the system can execute the same operation on a group of VCs; therefore, fewer packets are exchanged between PEs. Only the VCs with the same attribute can be configured with the same VC group ID; otherwise, the PW may be torn down by mistake. This parameter is valid only on sub-interfaces.	The value is an integer that ranges from 1 to 4294967295.
tunnel-policy *policy-name*	Specifies the name of a tunnel policy.	The value is a string of 1 to 39 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
raw	Removes the provider-tag (P-Tag) from a packet. **NOTE** This parameter can be used only for Ethernet links. If neither **raw** nor **tagged** is specified, this command sets the **raw** mode on a main interface and the **tagged** mode on a sub-interface.	-

Parameter	Description	Value
tagged	Retains the P-Tag in a packet. **NOTE** This parameter can be used only for Ethernet links. If neither **raw** nor **tagged** is specified, this command sets the **raw** mode on a main interface and the **tagged** mode on a sub-interface.	-
control-word	Enables the control word function.	-
no-control-word	Disables the control word function.	-
mtu *mtu-value*	Specifies the MTU value. **NOTE** This parameter can be configured only on VLANIF interfaces. The MTU of another type of interface or its sub-interface can be configured in the PW template.	The value is an integer that ranges from 46 to 9600. The default value is 1500.
secondary	Indicates a secondary VC. If this parameter is not specified, a primary VC is created. You can configure a secondary VC only when the primary VC exists on the local device.	-
bypass	Indicates that the VC is a bypass VC. The encapsulation type of the bypass VC must be the same as that of the primary VC.	-
ignore-standby-state	Indicates that the PW ignores standby state information sent by the remote device.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a Martini VLL networking, you can run this command to create a VC connection for a Martini VLL.

According to different encapsulation modes on the AC interfaces, the system processes user packets in different ways, as shown in the following tables.

- Packet processing on the inbound interface in the VLL or PWE3 scenario.

AC Interface Type	Encapsulation Mode of raw	Encapsulation Mode of tagged
Dot1q termination sub-interface	Removes a tag.	No action is required.
Ethernet main interfaces	No action is required.	Adds a tag.
QinQ stacking sub-interface	No action is required.	Adds a tag.
QinQ termination sub-interface (in symmetrical mode)	Removes the outer tag.	No action is required.
QinQ termination sub-interface (in asymmetrical mode)	Removes two tags.	Removes the outer tag.
VLANIF interface (added to the VLAN in default mode)	No action is required.	Adds a tag (default VLAN ID of the interface).
VLANIF interface (added to the VLAN in non-default mode)	Removes the outer tag.	No action is required.

- Packet processing on the outbound interface in the VLL or PWE3 scenario.

AC Interface Type	Encapsulation Mode of raw	Encapsulation Mode of tagged
Dot1q termination sub-interface	Adds a tag.	No action is required.
Ethernet main interfaces	Adds a tag.	Replaces the tag with the tag that is encapsulated on the outbound interface.

AC Interface Type	Encapsulation Mode of raw	Encapsulation Mode of tagged
QinQ stacking sub-interface	No action is required.	Removes a tag.
QinQ termination sub-interface (in symmetrical mode)	Adds the outer tag.	Replaces the outer tag with the tag that is encapsulated on the outbound interface.
QinQ termination sub-interface (in asymmetrical mode)	Adds two tags.	Removes the outer tag and then adds two tags that are encapsulated on the outbound interface.
VLANIF interface (added to the VLAN in default mode)	No action is required.	Removes a tag.
VLANIF interface (added to the VLAN in non-default mode)	Adds the outer tag.	Replaces the tag with the tag that is encapsulated on the outbound interface.

Precautions

- An interface cannot function as an L2VPN AC interface and L3VPN AC interface at the same time. After an interface is bound to an L2VPN, Layer 3 features such as the IP address and routing protocol on this interface become invalid.
- You must create dynamic VCs on PEs at both ends of a PW to connect the PEs. The destination address of a VC is the LSR ID of the peer PE.
- You can set attributes for a PW template, including the remote peer, tunnel policy, control word, and VCCV. When configuring an LDP PW, you can directly apply the PW template without specifying attributes for the PW. After setting attributes for a PW template, you can update the PW template at any time. The modified PW template takes effect only after the **reset pw** command is run.
- If a PW attribute is specified in the **mpls l2vc** command, the corresponding PW attribute in the same PW template is invalid.
- If you do not specify a tunnel policy for a Martini connection, the default tunnel policy is used. By default, the LSP tunnel is preferentially selected and only one tunnel is used for load balancing. If a tunnel policy name is specified but the tunnel policy is not configured, the default tunnel policy is used.
- The MTU value is specified when you create Martini or PWE3 VLLs and is used for interconnection between the switch and other devices.
- You must configure the primary PW before configuring the secondary PW and delete the secondary PW before deleting the primary PW.

- When creating VCs dynamically, the latest configurations of some parameters override the previous ones. The parameters include **tunnel-policy** *tnl-policy-name*, **control-word**, and **no-control-word**.
- By default, link type negotiation is enabled globally on the device. If a VLANIF interface is used as an AC-side interface for L2VPN, the configuration conflicts with link type negotiation. In this case, run the **lnp disable** command in the system view to disable link type negotiation.
- When configuring BFD for static PW, the VC ID must be specified.

NOTE

- If a sub-interface is bound to a VLL, the sub-interface can be deleted only after the sub-interface is unbound from the VLL.
- If a sub-interface is bound to a VLL, you cannot change the encapsulation type of the main interface.

Example

Create a Martini connection on the VLANIF interface.

```
<HUAWEI> system-view
[HUAWEI] vlan batch 10
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] mpls l2vc 10.2.2.9 100
```

Create a Martini connection on the GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls l2vc 10.2.2.9 100
```

10.6.17 mpls l2vc admin

Function

The **mpls l2vc admin** command creates a management PW (mPW).

The **undo mpls l2vc admin** command deletes an mPW.

By default, no mPW is configured.

Format

mpls l2vc { *ip-address* | **pw-template** *pw-template-name* } * *vc-id* [**tunnel-policy** *policy-name* | **control-word** | **admin**] *

undo mpls l2vc [{ *ip-address* | **pw-template** *pw-template-name* } * *vc-id* [**tunnel-policy** *policy-name* | **control-word** | **admin**] *]

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address of the mPW peer, which is usually the LSR ID of the remote device.	The value is in dotted decimal notation.
pw-template *pw-template-name*	Specifies the name of a PW template.	The value is a string of 1 to 19 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
vc-id	Specifies a VC ID. The VC ID must be unique on the local device, and identifies a VC together with the VC type. After a VC ID is configured, it cannot be modified. To modify a VC ID, delete the VC and configure it again. The VC IDs of the primary VC, secondary VC, and bypass VC must be different.	The value is an integer that ranges from 1 to 4294967295.
tunnel-policy *policy-name*	Specifies the name of a tunnel policy. ● If the name of the tunnel policy is specified but the tunnel policy is not configured, the default tunnel policy is used. ● If the name of the tunnel policy is not specified, the default tunnel policy is used. The LSP tunnel is preferred and only one LSP is used for load balancing in the default tunnel policy. **NOTE** Before importing a tunnel policy, define the name and attribute of the tunnel policy in the system view first.	The value is a string of 1 to 39 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
control-word	Enables the control word function. After the control word function is enabled, the device processes the Sequence Number, Length, and Layer-2 PDU fields in the packets.	-
admin	Designates the created PW as an mPW.	-

Views

Loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BFD is often configured for PWs to quickly detect PW faults. If there are a large number of service PWs with the same source and destination, you can configure mPWs with the same source and destination as those of the service PWs and associate the service PWs with the mPWs. By tracking the status of the mPWs, BFD can quickly detect faults on service PWs associated with the mPWs. BFD does not need to be configured for service PWs. This method reduces the number of BFD sessions and saves system resources and public network link bandwidth.

You can run the **mpls l2vc admin** command to create an mPW.

Prerequisites

MPLS L2VPN has been enabled using the **mpls l2vpn** command.

If **pw-template** *pw-template-name* is specified, a PW template has been created using the **pw-template** command.

Follow-up Procedure

Run the **mpls l2vc track admin-vc** command to associate service PWs with the mPWs.

Precautions

Generally, an mPW is configured on the primary PW path but not the secondary PW path.

Example

Create an mPW on loopback 0 with the remote device LSR ID 1.1.1.1 and VC ID 1.

```
<HUAWEI> system-view
[HUAWEI] interface loopback 0
[HUAWEI-Loopback0] mpls l2vc 1.1.1.1 1 admin
```

10.6.18 mpls l2vc track admin-vc

Function

The **mpls l2vc track admin-vc** command associates service PWs with the mPWs.

The **undo mpls l2vc track admin-vc** command deletes the association between service PWs and mPWs.

By default, service PWs are not associated with the mPWs.

Format

mpls l2vc [**secondary** | **bypass**] **track admin-vc interface loopback** *interface-number*

undo mpls l2vc [**secondary** | **bypass**] **track admin-vc**

Parameters

Parameter	Description	Value
secondary	Associates the secondary service PW with the mPW.	-
bypass	Associates the bypass service PW with the mPW.	-
interface loopback *interface-number*	Specifies the loopback interface on which the mPW is configured.	The value is a decimal integer and must be the same as the number of the loopback interface on which the mPW is configured.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BFD is often configured for PWs to quickly detect PW faults. If there are a large number of service PWs with the same source and destination, you can configure mPWs with the same source and destination as those of the service PWs and associate these service PWs with the mPWs. By tracking the status of the mPWs, BFD can quickly detect faults on service PWs associated with the mPWs. BFD does not need to be configured for service PWs. This method reduces the number of BFD sessions and saves system resources and public network link bandwidth.

You can run the **mpls l2vc track admin-vc** command to associate service PWs with mPWs for service PW status monitoring.

Prerequisites

Service PWs and mPWs have been created using the **mpls l2vc** and **mpls l2vc admin** commands.

- An mPW and its associated service PW must have the same peers.
- A service PW can be associated with only one mPW.
- Multiple service PWs with the same source and destination can be associated with only one mPW.

Precautions

After service PWs are associated with an mPW, the mPW detects public network link faults in a unified manner.

- If the mPW status remains unchanged, traffic can be properly forwarded over service PWs.
- If the mPW detects a public link fault, the mPW changes its status from Up to Down and notifies all its associated service PWs.
  - If both primary and secondary service PWs exist, the mPW triggers a switchover between the primary and secondary service PWs.
  - If only one service PW exists, the service PW changes its status from Up to Down and stops forwarding data.
- After the fault is rectified, the mPW changes its status from Down to Up. If both primary and secondary service PWs exist, a switchover will be performed between them based on the configured revertive switching policy. If only one service PW exists, the service PW changes its status from Down to Up. The service PW then starts to forward traffic again.

The **mpls l2vc track admin-vc** command applies to only single-hop primary and secondary PWs and does not apply to multi-hop PWs.

Example

Associate the primary service PW with the mPW.

```
<HUAWEI> system-view
[HUAWEI] interface loopback 0
[HUAWEI-Loopback0] mpls l2vc 1.1.1.1 1 admin
[HUAWEI-Loopback0] quit
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] mpls l2vc 1.1.1.1 5
[HUAWEI-Vlanif10] mpls l2vc track admin-vc interface loopback 0
```

Associate the secondary service PW with the mPW.

```
<HUAWEI> system-view
[HUAWEI] interface loopback 1
[HUAWEI-Loopback1] mpls l2vc 2.2.2.2 2 admin
[HUAWEI-Loopback1] quit
[HUAWEI] interface vlanif 20
[HUAWEI-Vlanif20] mpls l2vc 1.1.1.1 10
[HUAWEI-Vlanif20] mpls l2vc 2.2.2.2 6 secondary
[HUAWEI-Vlanif20] mpls l2vc secondary track admin-vc interface loopback 1
```

Associate the bypass service PW with the mPW.

```
<HUAWEI> system-view
[HUAWEI] interface loopback 2
[HUAWEI-Loopback2] mpls l2vc 3.3.3.3 3 admin
[HUAWEI-Loopback2] quit
[HUAWEI] interface vlanif 30
[HUAWEI-Vlanif30] mpls l2vc 1.1.1.1 20 bypass
[HUAWEI-Vlanif30] mpls l2vc 3.3.3.3 7 bypass
[HUAWEI-Vlanif30] mpls l2vc bypass track admin-vc interface loopback 2
```

10.6.19 mpls l2vpn

Function

The **mpls l2vpn** command enables MPLS L2VPN and displays the MPLS L2VPN view.

The **undo mpls l2vpn** command disables MPLS L2VPN and deletes all the L2VPN configurations.

By default, the MPLS L2VPN function is disabled.

Format

mpls l2vpn

undo mpls l2vpn

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure MPLS L2VPN functions or perform configurations in the MPLS L2VPN view on the MPLS L2VPN network, run the **mpls l2vpn** command to enable MPLS L2VPN and enter the MPLS L2VPN view.

Prerequisites

Basic MPLS functions have been configured. For details, see the **mpls lsr-id** and **mpls** commands.

Precautions

When the command is configured, a P device does not need to be enabled with the MPLS L2VPN function.

After the **mpls l2vpn** command is executed:

- If MPLS L2VPN is disabled on the device, MPLS L2VPN is enabled and the MPLS L2VPN view is displayed.
- If MPLS L2VPN is enabled on the device, the MPLS L2VPN view is displayed.

NOTICE

After the **undo mpls l2vpn** command is run in the system view, L2VPN services may be interrupted, and all L2VPN configurations are cleared. If you want to restore the L2VPN configurations, re-run all the deleted commands.

Example

Enable MPLS L2VPN.

```
<HUAWEI> system-view
[HUAWEI] mpls lsr-id 10.1.1.1
[HUAWEI] mpls
[HUAWEI-mpls] quit
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn]
```

10.6.20 mpls l2vpn flow-label

Function

The **mpls l2vpn flow-label** command enables flow label-based load balancing for PWs on an interface.

The **undo mpls l2vpn flow-label** command disables flow label-based load balancing for PWs on an interface.

By default, flow label-based load balancing is disabled for PWs on an interface.

NOTE

Only the S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6730S-H, and S6730-H support this command.

Format

mpls l2vpn flow-label { **both** | **send** | **receive** } [**secondary**] [**static**]

undo mpls l2vpn flow-label { **both** | **send** | **receive** } [**secondary**] [**static**]

undo mpls l2vpn flow-label [**secondary**]

Parameters

Parameter	Description	Value
both	Enables flow label-based load balancing for outgoing traffic and incoming traffic.	-
send	Enables flow label-based load balancing for outgoing traffic.	-
receive	Enables flow label-based load balancing for incoming traffic.	-

Parameter	Description	Value
secondary	Enables flow label-based load balancing for the secondary PW. If **secondary** is not configured, flow label-based load balancing is configured for the primary PW. Flow label-based load balancing can be configured for a secondary PW only if the secondary PW exists.	-
static	Statically configures flow label-based load balancing. For dynamic PWs, if **static** is not configured, the flow label-based load balancing capability of the local end is negotiated by the remote end. For static PWs, the flow label-based load balancing capability is statically configured, irrespective of whether **static** is configured.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When multiple links exist between provider (P) devices, configure flow label-based load balancing to improve L2VPN traffic forwarding efficiency. After flow label-based load balancing is enabled on a PE, the PE adds different labels for different L2VPN data flows to distinguish the data flows. After a P device receives a data packet carrying a flow label, it performs the Hash calculation and selects a forwarding path based on the flow label in the data packet. This processing implements load balancing. You can run the **mpls l2vpn flow-label** command to enable flow label-based load balancing for L2VPN on an interface.

Prerequisites

Before you enable flow label-based load balancing for an interface, create a VC connection on this interface and enable Multiprotocol Label Switching (MPLS) L2VPN.

Precautions

Flow label-based load balancing can be enabled only when any of the following conditions is true:

- The **receive** parameter is configured on the local PE, and the **send** parameter is configured on the remote PE.
- The **send** parameter is configured on the local PE, and the **receive** parameter is configured on the remote PE.
- Both the **send** and **receive** parameters are configured on the local and remote PEs.

The **secondary** parameter indicates that flow label-based load balancing takes effect only for the secondary PW. If you specify **secondary** parameter, flow label-based load balancing takes effect only for the primary PW.

Example

Enable flow label-based load balancing for PWs on Vlanif 100.

```
<HUAWEI> system-view
[HUAWEI] interface Vlanif 100
[HUAWEI-Vlanif100] mpls l2vc 2.2.2.2 100
[HUAWEI-Vlanif100] mpls l2vpn flow-label both
```

10.6.21 mpls l2vpn ip-parse enable

Function

The **mpls l2vpn ip-parse enable** command enables the IP packet parsing function of the MPLS L2VPN module.

The **undo mpls l2vpn ip-parse enable** command disables the IP packet parsing function of the MPLS L2VPN module.

By default, the IP packet parsing function of the MPLS L2VPN module is enabled.

Format

mpls l2vpn ip-parse enable

undo mpls l2vpn ip-parse enable

NOTE

This command is supported only on the S6720-EI and S6720S-EI.

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a Layer 2 VPN scenario, if a traffic policy is configured in the inbound direction of an AC-side interface on a device, L2VPN traffic forwarded from a PE may incorrectly match the traffic policy. As a result, traffic fails to be forwarded. To ensure normal traffic forwarding, run the **undo mpls l2vpn ip-parse enable** command to disable the IP packet parsing function of the MPLS L2VPN module.

Precautions

If the enhanced load balancing mode is configured for an Eth-Trunk, it is recommended that the IP packet parsing function of the MPLS L2VPN module be enabled.

Example

Disable the IP packet parsing function of the MPLS L2VPN module.

```
<HUAWEI> system-view
[HUAWEI] undo mpls l2vpn ip-parse enable
```

10.6.22 mpls l2vpn no-request-message

Function

The **mpls l2vpn no-request-message** command disables the device from sending L2VPN label request messages to a specified peer.

The **undo mpls l2vpn no-request-message** command re-enables the device to send L2VPN label request messages to a specified peer.

By default, the system sends L2VPN label request messages to all its peers.

Format

mpls l2vpn no-request-message peer *ip-address*

undo mpls l2vpn no-request-message peer *ip-address*

Parameters

Parameter	Description	Value
peer *ip-address*	Specifies the LSR ID of a peer device on the PW.	The value is in dotted decimal notation.

Views

MPLS-L2VPN view

Default Level

2: Configuration level

Usage Guidelines

On a PW in PWE3/Martini mode between two PEs with a Huawei device functioning as one PE and a non-Huawei device functioning as the other, if the non-Huawei device does not have the capability of processing L2VPN label requests, the **mpls l2vpn no-request-message** command needs to be run on the Huawei device to allow communication between the two devices. This command cannot be used in other cases.

Example

Disable the device from sending L2VPN label request messages to a peer with the LSR ID being 10.2.2.9.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] mpls l2vpn no-request-message peer 10.2.2.9
```

10.6.23 mpls l2vpn pw bfd

Function

The **mpls l2vpn pw bfd** command enables dynamic BFD for PWs and adjusts BFD parameters on an AC interface.

The **undo mpls l2vpn pw bfd** command restores default BFD parameters of dynamic BFD for PWs on an AC interface.

By default, dynamic BFD for PWs is not configured on an AC interface.

Format

mpls l2vpn pw bfd [**detect-multiplier** *multiplier* | **min-rx-interval** *rx-interval* | **min-tx-interval** *tx-interval*] * [**remote-vcid** *vc-id*] [**secondary**]

undo mpls l2vpn pw bfd [**detect-multiplier** | **min-rx-interval** | **min-tx-interval**] * [**secondary**]

undo mpls l2vpn pw bfd [**detect-multiplier** *multiplier* | **min-rx-interval** *rx-interval* | **min-tx-interval** *tx-interval*] * [**remote-vcid** *vc-id*] [**secondary**]

Parameters

Parameter	Description	Value
detect-multiplier *multiplier*	Specifies the local detection multiplier.	The value is an integer that ranges from 3 to 50. The default value is 3.

Parameter	Description	Value
min-rx-interval *rx-interval*	Specifies the minimum interval for receiving BFD packets.	The value is an integer that ranges from 100 to 1000, in milliseconds. - After the **set service-mode enhanced** command is configured on the S5731-S, S5731-H and S5731S-H, the value ranges from 3 to 1000. - After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-S, S6730-H, and S6730S-H, the value ranges from 3 to 1000.
min-tx-interval *tx-interval*	Specifies the minimum interval for sending BFD packets.	The value is an integer that ranges from 100 to 1000, in milliseconds. - After the **set service-mode enhanced** command is configured on the S5731-S, S5731-H and S5731S-H, the value ranges from 3 to 1000. - After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-S, S6730-H, and S6730S-H, the value ranges from 3 to 1000.
remote-vcid *vc-id*	Specifies the VC ID of the peer device.	This parameter is mandatory when a multi-hop PW is detected. The value of this parameter is the VC ID of the remote end of the PW. The value is an integer that ranges from 1 to 4294967295.

Parameter	Description	Value
secondary	Configures BFD and its parameters on the secondary PW. By default, BFD and its parameters are configured on the primary PW. **NOTE** The **secondary** parameter cannot be run on Loopback interface view.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a network where BFD is used to detect faults, run the **mpls l2vpn pw bfd** command to enable dynamic BFD for PWs and adjust BFD parameters on an AC interface.

Precautions

To reduce usage of system resources, when a BFD session is detected in Down state, the system changes the minimum interval for receiving BFD packets and the minimum interval for sending BFD packets to random values between 1000 ms and 3000 ms. When the BFD session becomes Up, the configured intervals are restored.

Example

Enable dynamic BFD for PWs on VLANIF 10 and set BFD parameters.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] mpls l2vc 2.2.2.2 100
[HUAWEI-Vlanif10] mpls l2vpn pw bfd min-rx-interval 100 min-tx-interval 100
```

10.6.24 mpls l2vpn redundancy

Function

The **mpls l2vpn redundancy** command specifies the PW negotiation mode.

The **undo mpls l2vpn redundancy** command restores the default PW mode.

By default, a device determines the primary and secondary PWs locally by using FRR, without negotiating with other nodes.

Format

mpls l2vpn redundancy { **independent** | **master** }

undo mpls l2vpn redundancy { **independent** | **master** }

Parameters

Parameter	Description	Value
independent	Indicates PW redundancy in independent mode.	-
master	Indicates PW redundancy in master/slave mode.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After configuring the primary and secondary PWs on a PE, you can specify the PW redundancy mode. The following PW redundancy modes are supported:

- FRR mode:

  The FRR mode is the default PW redundancy mode and does not need to be configured.

  The FRR mode applies to VLL FRR and PWE3 FRR scenarios. The FRR mode must be used with PW OAM and AC OAM. End-to-end FRR can be performed only after OAM mapping is enabled on the PE.
- Master/slave mode:

  The master/slave mode is often used in scenarios where VLL accesses VPLS. After the **mpls l2vpn redundancy** command is configured on a PE, the PE determines the primary/secondary status of PWs based on its local configurations. The master/slave mode can use the bypass PW to isolate PW-side failures from AC-side failures.
- Independent mode:

  The independent mode is often used with E-Trunk, and VRRP. The independent mode can use the bypass PW to isolate PW-side failures, but cannot isolate AC-side failures.

Prerequisites

The primary and secondary PWs must have been configured on the PE.

Follow-up Procedure

The FRR mode and master/slave mode support revertive policies. You can run the **mpls l2vpn reroute** command to configure a revertive policy. By default, the revertive switching is performed after a delay.

The independent mode supports only immediate switchback.

Precautions

If the **mpls l2vpn redundancy** command is run more than once, the latest configuration overrides previous ones. The **undo mpls l2vpn redundancy** command restores the FRR mode. When using the **undo mpls l2vpn redundancy** command, ensure that the parameter in this command is the same as that in the corresponding **mpls l2vpn redundancy** command.

The FRR mode applies to VLL and PWE3. The master/slave mode and independent mode apply to PWE3.

- FRR mode: After the primary and secondary PW status is configured on a PE to which a CE is single-homed, the FRR PW redundancy mode is used by default. The local PE does not notify the remote PW of the primary/secondary PW status. As a result, the remote PE is unaware of the local primary/secondary status.
- Master/slave mode: After this mode is configured, the PE determines the primary/secondary status of PWs based on local configurations and sends the Forwarding (0x00) and Forwarding Standby (0x20) status signaling to the remote PE.
- Independent mode: After this mode is configured, the PE determines the primary/secondary status of the local PWs based on the status information sent by the remote PE and sends the Forwarding (0x00) status signaling to the remote PE.

Example

Determine the primary and secondary PWs on VLANIF100 by using the PW negotiation mode.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls l2vc 1.1.1.1 1
[HUAWEI-Vlanif100] mpls l2vc 2.2.2.2 2 secondary
[HUAWEI-Vlanif100] mpls l2vpn redundancy independent
```

10.6.25 mpls l2vpn reroute

Function

The **mpls l2vpn reroute** command configures the revertive switchover policy for the primary and secondary PWs in FRR or PW redundancy master/slave mode.

The **undo mpls l2vpn reroute** command restores the default revertive switchover policy.

By default, delayed revertive switchover is configured in FRR or PW redundancy master/slave mode.

Format

mpls l2vpn reroute { { **delay** *delay-time* | **immediately** } [**resume** *resume-time*] | **never** }

undo mpls l2vpn reroute

Parameters

Parameter	Description	Value
delay *delay-time*	Specifies the revertive switchover policy for the primary and secondary PWs as delayed revertive switchover, and sets the duration for delayed switchover.	The value is an integer that ranges from 10 to 1800, in seconds. The default value is 30.
immediately	Specifies the revertive switchover policy for the primary and secondary PWs as immediate revertive switchover.	-
resume *resume-time*	Specifies a delay after which the local device notifies the peer PE on the secondary PW of the recovery. You can set this parameter only in VLL FRR mode.	The value is an integer that ranges from 0 to 600, in seconds. The default value is 10.
never	Specifies the revertive switchover policy for the primary and secondary PWs to none revertive switchover. After the primary PW recovers, traffic is not switched to it until the secondary PW is faulty.	-

2: Configuration level

Usage Guidelines

Usage Scenario

The **mpls l2vpn reroute** command configures the revertive switchover policy for the primary and secondary PWs in FRR or PW redundancy master/slave mode.

Prerequisites

The primary and secondary PWs have been configured in FRR or PW redundancy master/slave mode. The revertive switchover policy cannot be configured for PW redundancy independent mode.

Precautions

In VLL FRR mode and in PW redundancy master/slave mode, the PW revertive switchover policy is classified into the following modes:

- Immediate revertive switchover: When the primary PW recovers from a fault, the local PE switches traffic back to the primary PW immediately and notifies the peer PE on the secondary PW of the fault. In FRR mode, the local PE notifies the peer PE on the secondary PW of the recovery after a delay of *resume-time*. In PW redundancy master/slave mode, the parameter *resume-time* is not supported.

  This revertive switchover applies to scenarios in which users hope traffic to be restored as soon as possible.
- Delayed revertive switchover: When the primary PW recovers from a fault, traffic is switched back to the primary PW after a period specified by *delay-time*. After traffic is switched back, the local device immediately notifies the peer device on the secondary PW of the fault. If *resume-time* is configured in FRR mode, the local device notifies the peer device on the secondary PW of the recovery after a delay of *resume-time*.

  On a large-scale network, packet loss caused by incomplete route convergence may occur during the switchback. To prevent this problem, configure traffic to be switched back after a delay.
- None revertive switchover: When the primary PW recovers from a fault, traffic is not switched back to the primary PW until the secondary PW becomes faulty.

  If you do not want traffic to be frequently switched between the primary and secondary PWs, you can use the non-revertive switchover.

In a CE asymmetrical networking, if the Ethernet OAM function is configured on a PE interface connected to a CE, and a revertive switchover policy is configured, the value of *resume-time* cannot be 0 seconds. The value must be equal to or greater than 1 second.

Example

Configure the device to switch traffic back to the primary PW 15 seconds after the primary PW recovers from a fault, notify the peer PE on the secondary PW of the fault when a switchover is performed, and notify the peer PE of the secondary PW of the recovery 20 seconds later.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls l2vc 10.1.1.9 100
[HUAWEI-Vlanif100] mpls l2vc 10.2.2.9 200 secondary
[HUAWEI-Vlanif100] mpls l2vpn reroute delay 15 resume 20
```

10.6.26 mpls l2vpn service-name

Function

The **mpls l2vpn service-name** command sets the name of an SVC or Martini VLL service or a PWE3 service.

The **undo mpls l2vpn service-name** command deletes the configured L2VPN service name.

By default, no L2VPN service name is configured in the system.

Format

mpls l2vpn service-name *service-name*

undo mpls l2vpn service-name

Parameters

Parameter	Description	Value
service-name	Specifies the name of an L2VPN service. This parameter uniquely identifies an L2VPN service on a PE.	The value is a string of 1 to 15 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, an SVC or Martini VLL service or a PWE3 service is uniquely identified by the combination of the VC ID and VC type, which are hard to remember and make maintenance complex. When a service name is used to uniquely identify an L2VPN service, the name can be defined based on requirements and the NMS operator can maintain the L2VPN service by clicking the name on the NMS graphical user interface (GUI). This simplifies operation and maintenance.

Prerequisites

An SVC or Martini VLL service or a PWE3 service has been configured on a service interface. A primary PW and a secondary PW can be configured for a Martini VLL or PWE3 service.

Precautions

On each PE, an L2VPN service name is unique. If an L2VPN service name has been used by a PW, it cannot be configured for another PW, or the system will display an error message.

If an L2VPN service already has a service name, this service name will be overwritten when a new name is configured for the L2VPN service. Therefore, when changing an L2VPN service name, you can directly configure a new service name without deleting the original one.

- Because the primary and secondary PWs are configured on the same interface, they are regarded as one PW, and a service name is configured for both of them.
- On each PE, an L2VPN service name is unique.

Example

Set an L2VPN service name to **pw1** on a service interface.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] mpls l2vc 10.1.1.1 1
[HUAWEI-Vlanif10] mpls l2vpn service-name pw1
```

10.6.27 mpls l2vpn stream-dual-receiving

Function

The **mpls l2vpn stream-dual-receiving** command configures an interface to receive packets from both the primary and secondary PWs.

The **undo mpls l2vpn stream-dual-receiving** command disables an interface from receiving packets from both the primary and secondary PWs.

By default, an interface cannot receive packets from the secondary PW.

Format

mpls l2vpn stream-dual-receiving

undo mpls l2vpn stream-dual-receiving

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a network configured with PW Redundancy, the **mpls l2vpn stream-dual-receiving** command must be run on a PE to which the CE is single homed, so that the PE can receive packets from both the primary and secondary PWs. This prevents packet loss during the PW switchover process.

If the command is not run, the PE receives packets only from the primary PW. This causes packet loss during a traffic switchover. After the primary PW recovers and a traffic switchover is triggered, the secondary PW on the PE becomes the primary PW and the PE notifies the peer of the status change. A delay in signaling transmission causes the peer PE to send packets along the secondary PW. After the PE receiving packets from the secondary PW, the PE discards the packets, resulting in packet loss.

Prerequisites

Primary and secondary PWs have been configured.

Precautions

The **mpls l2vpn stream-dual-receiving** command applies to only PWE3 L2VPN. If H-VPLS is configured, the command cannot be configured. If you configure this command, unidirectional broadcast traffic will be looped back.

Bypass PWs cannot be configured on a PE configured with the **mpls l2vpn stream-dual-receiving** command.

Kompella VLL FRR does not support the **mpls l2vpn stream-dual-receiving** command.

Example

Enable the device to receive packets from both the primary and secondary PWs on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls l2vc 1.1.1.1 1
[HUAWEI-Vlanif100] mpls l2vc 2.2.2.2 2 secondary
[HUAWEI-Vlanif100] mpls l2vpn stream-dual-receiving
```

10.6.28 mpls l2vpn switchover

Function

The **mpls l2vpn switchover** command switches traffic from the primary PW to the secondary PW.

The **undo mpls l2vpn switchover** command disables traffic switchover and switches traffic back to the primary PW.

By default, traffic switchover is not configured.

Format

mpls l2vpn switchover

undo mpls l2vpn switchover

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In master/slave PW redundancy mode, the traffic is transmitted over the primary PW in normal situations. If you want the traffic to be transmitted over the secondary PW due to reasons such as device upgrade or service re-deployment, you can use the **mpls l2vpn switchover** command to forcibly switch traffic from the primary PW to the secondary PW. After the device is upgraded or services are re-deployed, you can run the **undo mpls l2vpn switchover** command to forcibly switch traffic from the secondary PW to the primary PW.

- Before running the **mpls l2vpn switchover** command, ensure that the secondary PW is normal and can forward traffic.
- Before running the **undo mpls l2vpn switchover** command, ensure that the primary PW is normal and can forward traffic.

NOTE

If the secondary PW fails after traffic is forcibly switched to the secondary PW, the traffic will be switched back to the primary PW.

Prerequisites

The primary and secondary PWs have been established and are in the Up state.

Precautions

A PW switchover will be performed after you run the **mpls l2vpn switchover** or **undo mpls l2vpn switchover** command. If the PW to be switched to is Down or unavailable, the switchover fails.

Traffic cannot be switched from the primary PW to a bypass PW.

The two commands apply to only PWs working in master/slave mode. In a VLL FRR scenario, use the **manual-set pw-ac-fault** command to forcibly switch over PWs.

Example

Switch traffic from the primary PW to the secondary PW.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls l2vc 1.1.1.1 1
[HUAWEI-Vlanif100] mpls l2vc 2.2.2.2 2 secondary
```

```
[HUAWEI-Vlanif100] mpls l2vpn redundancy master
[HUAWEI-Vlanif100] mpls l2vpn switchover
```

10.6.29 mpls l2vpn vccv bfd-cv-negotiation fault-detection-only

Function

The **mpls l2vpn vccv bfd-cv-negotiation fault-detection-only** command sets the encapsulation type for BFD CV packets to be sent to remote peers.

The **undo mpls l2vpn vccv bfd-cv-negotiation fault-detection-only** command restores the default configuration.

By default, the device sends BFD CV packets with the encapsulation type 0x08 to all remote peers.

Format

mpls l2vpn vccv bfd-cv-negotiation fault-detection-only [**peer** *peer-address* { **enable** | **disable** }]

undo mpls l2vpn vccv bfd-cv-negotiation fault-detection-only [**peer** *peer-address*]

Parameters

Parameter	Description	Value
peer *peer-address*	Specifies the IP address of a remote peer.	The value is in dotted decimal notation.
enable	Sets the encapsulation type 0x04 for BFD CV packets to be sent to a specified remote peer.	-
disable	Set the encapsulation type 0x08 for BFD CV packets to be sent to a specified remote peer.	-

Views

MPLS L2VPN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Virtual Circuit Connectivity Verification (VCCV) is a mechanism to detect and diagnose end-to-end faults on PWs. VCCV provides a control channel between a PW's ingress and egress over which connectivity verification (CV) messages can be sent. A VCCV message includes a BFD control packet encapsulated as specified by the CV type. A BFD CV packet can be transmitted over a VCCV control channel after being encapsulated using BFD IP/UDP. As defined in RFC, BFD IP/UDP encapsulation for BFD CV packets are classified into two types:

- 0x04: used only for PW fault detection.
- 0x08: used for PW fault detection and AC/PW status signaling.

To control the encapsulation type of BFD CV packets to be sent to remote peers, run the **mpls l2vpn vccv bfd-cv-negotiation fault-detection-only** command.

- The **mpls l2vpn vccv bfd-cv-negotiation fault-detection-only** command sets the encapsulation type to 0x04 for BFD CV packets to be sent to all remote peers.
- The **undo mpls l2vpn vccv bfd-cv-negotiation fault-detection-only** command restores the default encapsulation type 0x08 for BFD CV packets to be sent to all remote peers.
- The **mpls l2vpn vccv bfd-cv-negotiation fault-detection-only peer** *peer-address* **enable** command sets the encapsulation type to 0x04 for BFD CV packets to be sent to a specified remote peer.
- The **mpls l2vpn vccv bfd-cv-negotiation fault-detection-only peer** *peer-address* **disable** command sets the encapsulation type to 0x08 for BFD CV packets to be sent to a specified remote peer.
- The **undo mpls l2vpn vccv bfd-cv-negotiation fault-detection-only peer** *peer-address* command restores the global encapsulation type for BFD CV packets to be sent to a specified remote peer.

Dynamic PWs support VCCV by default, and can use LDP signaling to advertise local attributes to remote peers. The default encapsulation type of BFD CV packets is 0x08. If a remote peer supports the encapsulation type 0x04 and BFD is used for communication, run the **mpls l2vpn vccv bfd-cv-negotiation fault-detection-only peer** *peer-address* **enable** command to change the encapsulation type of BFD CV packets to be sent to this peer to 0x04.

Precautions

After this command is run, PWs may be re-established, which causes a short service interruption.

Example

Set the encapsulation type 0x04 for BFD CV packets to be sent to remote peers.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] mpls l2vpn vccv bfd-cv-negotiation fault-detection-only
```

Set the encapsulation type 0x04 for BFD CV packets to be sent to a specified remote peer.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] mpls l2vpn vccv bfd-cv-negotiation fault-detection-only peer 10.10.10.1 enable
```

10.6.30 mpls static-l2vc

Function

The **mpls static-l2vc** command creates a static VC.

The **undo mpls static-l2vc** command deletes the static VCs.

By default, no static VC is created.

Format

mpls static-l2vc { { **destination** *ip-address* | **pw-template** *pw-template-name vc-id* } * | **destination** *ip-address vc-id* } **transmit-vpn-label** *transmit-label-value* **receive-vpn-label** *receive-label-value* [**tunnel-policy** *tnl-policy-name* | [**control-word** | **no-control-word**] | [**raw** | **tagged**]] *

undo mpls static-l2vc

undo mpls static-l2vc { { **destination** *ip-address* | **pw-template** *pw-template-name vc-id* } * | **destination** *ip-address vc-id* } **transmit-vpn-label** *transmit-label-value* **receive-vpn-label** *receive-label-value* [**tunnel-policy** *tnl-policy-name* | [**control-word** | **no-control-word**] | [**raw** | **tagged**]] *

Parameters

Parameter	Description	Value
destination *ip-address*	Specifies the LSR ID of a peer device on the PW.	The value is in dotted decimal notation.
pw-template *pw-template-name*	Specifies the name of a static PW template.	The value is a string of 1 to 19 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
vc-id	Specifies the VC ID.	The value is an integer that ranges from 1 to 4294967295.
transmit-vpn-label *transmit-label-value*	Specifies the value of a transmit label.	The value is an integer that ranges from 0 to 1048575.
receive-vpn-label *receive-label-value*	Specifies the value of a receive label.	The value is an integer that ranges from 16 to 1023.

Parameter	Description	Value
tunnel-policy *tnl-policy-name*	Specifies the name of a tunnel policy.	The value is a string of 1 to 39 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
control-word | **no-control-word**	Enables or disables the control word function. By default, the control word function is disabled.	-
raw	Removes the provider-tag (P-Tag) from a packet.	-
tagged	Retains the P-Tag in a packet.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In an L2VPN networking, you can use this command to create a static VC between two PEs connected to CEs.

Precautions

- An interface cannot function as an L2VPN AC interface and L3VPN AC interface at the same time. After an interface is bound to an L2VPN, Layer 3 features such as the IP address and routing protocol on this interface become invalid.
- You can set attributes for a static PW template, including the remote peer, tunnel policy, control word, and VCCV. When configuring a static PW, you can directly use the static PW template without specifying attributes for the PW. After setting attributes for a static PW template, you can update the static PW template at any time. The modified static PW template takes effect only after the **reset pw** command is run.
- Static VCs must be created on PEs at both ends. The destination address of a VC is the LSR ID of the peer PE. The transmit label of the PE at one end is the

receive label of the PE at the other end. If the labels do not match, traffic may fail to be forwarded even though the **static-l2vc** field is displayed as Up.

- If no tunnel policy is specified, the default tunnel policy is used. The default policy specifies that traffic is forwarded along the LSP and only one tunnel is used for load balancing. If a tunnel policy name is specified but the tunnel policy is not configured, the default tunnel policy is used.
- When configuring a static VC, note that the value of the transmit label ranges from 0 to 1048575. This ensures the communication between the device and different types of devices.
- When creating static VCs, the latest configurations of some parameters override the previous ones. The parameters include **tunnel-policy** *tnl-policy-name*, **control-word**, and **no-control-word**.
- By default, link type negotiation is enabled globally on the device. If a VLANIF interface is used as an AC-side interface for L2VPN, the configuration conflicts with link type negotiation. In this case, run the **lnp disable** command in the system view to disable link type negotiation.

NOTE

- If a sub-interface is bound to a VLL, the sub-interface can be deleted only after the sub-interface is unbound from the VLL.
- If a sub-interface is bound to a VLL, you cannot change the encapsulation type of the main interface.

Example

Configure a static VC. Set the LSR ID of the peer device to 1.1.1.1, transmit label to 100, and receive label to 100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] mpls static-l2vc destination 1.1.1.1 transmit-vpn-label 100 receive-vpn-label 100
```

Configure a static VC by applying a PW template and set values of the VC ID, transmit label, and receive label to 100 respectively.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] mpls static-l2vc pw-template pwt 100 transmit-vpn-label 100 receive-vpn-label 100
```

Delete a static VC.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] undo mpls static-l2vc
```

10.6.31 mpls switch-l2vc

Function

The **mpls switch-l2vc** command configures PW switching on the SPE to implement multi-segment PWs.

The **undo mpls switch-l2vc** command deletes PW switching.

The default policy is used for PW switching. In the default policy, LSP tunnels are used and the number of routes for load balancing is 1.

Format

Static PW

mpls switch-l2vc *ip-address vc-id* **trans** *trans-label* **recv** *received-label* [**tunnel-policy** *policy-name*] [**oam-packet pop flow-label**] **between** *ip-address vc-id* **trans** *trans-label* **recv** *received-label* [**tunnel-policy** *policy-name*] [**oam-packet pop flow-label**] **encapsulation** *encapsulation-type* [**control-word** [**cc** { **alert** | **cw** } * **cv lsp-ping**] | [**no-control-word**] [**cc alert cv lsp-ping**]] [**control-word-transparent**]

undo mpls switch-l2vc *ip-address vc-id* **trans** *trans-label* **recv** *received-label* [**tunnel-policy** *policy-name*] [**oam-packet pop flow-label**] **between** *ip-address vc-id* **trans** *trans-label* **recv** *received-label* [**tunnel-policy** *policy-name*] [**oam-packet pop flow-label**] **encapsulation** *encapsulation-type* [**control-word** [**cc** { **alert** | **cw** } * **cv lsp-ping**] | [**no-control-word**] [**cc alert cv lsp-ping**]] [**control-word-transparent**]

Dynamic PW

mpls switch-l2vc *ip-address vc-id* [**tunnel-policy** *policy-name*] [**oam-packet pop flow-label**] **between** *ip-address vc-id* [**tunnel-policy** *policy-name*] [**oam-packet pop flow-label**] **encapsulation** *encapsulation-type* [**control-word-transparent**]

undo mpls switch-l2vc *ip-address vc-id* [**tunnel-policy** *policy-name*] [**oam-packet pop flow-label**] **between** *ip-address vc-id* [**tunnel-policy** *policy-name*] [**oam-packet pop flow-label**] **encapsulation** *encapsulation-type* [**control-word-transparent**]

Mixed PW

mpls switch-l2vc *ip-address vc-id* [**tunnel-policy** *policy-name*] [**oam-packet pop flow-label**] **between** *ip-address vc-id* **trans** *trans-label* **recv** *received-label* [**tunnel-policy** *policy-name*] [**oam-packet pop flow-label**] **encapsulation** *encapsulation-type* [**mtu** *mtu-value*] [**control-word** [**cc** { **alert** | **cw** } * **cv lsp-ping**] | [**no-control-word**] [**cc alert cv lsp-ping**]] [**flow-label** { **both** | **send** | **receive** }] [**control-word-transparent**]

undo mpls switch-l2vc *ip-address vc-id* [**tunnel-policy** *policy-name*] [**oam-packet pop flow-label**] **between** *ip-address vc-id* **trans** *trans-label* **recv** *received-label* [**tunnel-policy** *policy-name*] [**oam-packet pop flow-label**] **encapsulation** *encapsulation-type* [**mtu** *mtu-value*] [**control-word** [**cc** { **alert** | **cw** } * **cv lsp-ping**] | [**no-control-word**] [**cc alert cv lsp-ping**]] [**flow-label** { **both** | **send** | **receive** }] [**control-word-transparent**]

undo mpls switch-l2vc { *ip-address vc-id* **encapsulation** *encapsulation-type* | **all** }

Parameters

Parameter	Description	Value
ip-address	Specifies the LSR ID of a peer device on the PW.	The value is in dotted decimal notation.

Parameter	Description	Value
vc-id	Specifies the L2VC ID.	The value is an integer that ranges from 1 to 4294967295.
trans *trans-label*	Specifies the static label for sending packets.	The value is an integer that ranges from 0 to 1048575.
recv *received-label*	Specifies the static label for receiving packets.	The value is an integer that ranges from 16 to 1023.
tunnel-policy *policy-name*	Specifies the name of a tunnel policy. If this parameter is not specified, the default tunnel policy is used, which preferentially selects the LSP tunnel and only one tunnel is used for load balancing.	The value is a string of 1 to 39 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
oam-packet pop flow-label	Specifies that flow labels of OAM packets are popped out. If OAM packets received from remote devices carry flow labels, the **oam-packet pop flow-label** parameter must be configured to pop out flow labels so that the SPEs can process the OAM packets. **NOTE** Only the S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6730S-H, and S6730-H support this parameter.	-
between	Specifies the switching PW that corresponds to the PW	-

Parameter	Description	Value
encapsulation *encapsulation-type*	Specifies the encapsulation type of a static PW.	The encapsulation types supported by PW switching are **ethernet**, **vlan**, and **ip-interworking**. **NOTE** Static and mixed PWs support only Ethernet and VLAN encapsulation types.
mtu *mtu-value*	Specifies the MTU for negotiating dynamic PW signaling. If the non-default MTU is set when you configure a dynamic PW, you need to set the MTU manually when configuring mixed PW switching; otherwise, the signaling negotiation at the dynamic PW side may fail.	The value is an integer that ranges from 46 to 9600.
control-word	Enables the control word function. By default, the control word function is disabled.	-
no-control-word	Disable the control word function.	-
cw	Indicates the mode in which the control word function is enabled.	-
alert	Indicates the label alert tunnel for VCCV ping.	-
cv	Indicates connectivity verification, which is enabled by default.	-
lsp-ping	Indicates connectivity verification in LSP ping mode for VCs, which is enabled by default.	-

Parameter	Description	Value
control-word-transparent	Enables transparent transmission of the control word. In the scenario where a PE is dual homed to SPEs and BFD for PW is enabled, transparent transmission of the control word must be enabled on the SPEs; otherwise, the BFD negotiation fails. By default, transparent transmission of the control word is disabled.	-
all	Deletes all PW switching.	-
flow-label both	Enables flow label-based load balancing for outgoing traffic and incoming traffic. **NOTE** Only the S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6730S-H, and S6730-H support this parameter.	-
flow-label send	Enables flow label-based load balancing for outgoing traffic. **NOTE** Only the S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6730S-H, and S6730-H support this parameter.	-
flow-label receive	Enables flow label-based load balancing for incoming traffic. **NOTE** Only the S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6730S-H, and S6730-H support this parameter.	-

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **mpls switch-l2vc** command configures PW switching on the SPE to implement multi-segment PWs.

PW switching can be classified into dynamic mode, static mode, and mixed mode. You can create PW switching of different types using different commands to meet site requirements:

- **Configuring static PW switching**: The two PW segments connected by an SPE are both static PWs. Static PW switching apples when static PWs are used on the entire network.
- **Configuring dynamic PW switching**: The two PW segments connected by an SPE are both dynamic PWs. Dynamic PW switching applies when dynamic PWs are used on the entire network.
- **Configuring mixed PW switching**: A mixed PW switching applies when an SPE connects a dynamic PW and a static PW.

Precautions

You need to configure the PW label for the static PW switching and for the static PW in the mixed PW switching.

The configuration of dynamic PW switching is simple. The remote label is sent from two neighboring ends (UPE or SPE) to the SPE through signaling. The CW and the VCCV are sent from two UPE nodes to the SPE through signaling.

When you configure mixed PW switching, the value of *ip-address vc-id* before **between** in the command is for the dynamic PW, and the value of *ip-address vc-id* after **between** in the command is for the static PW. The two values cannot be interchanged.

NOTE

- The VC IDs for PW switching can be different.
- The combination of the PW ID and PW type must be unique on each node. The PW IDs at two ends of PW switching can be the same.
- When creating PW switching, the latest configurations of some parameters override the previous ones. The parameters include **tunnel-policy** *policy-name*, **control-word-transparent**, **control-word**, **no-control-word**, **mtu** *mtu-value*, **oam-packet pop flow-label**, and **flow-label** { **both** | **send** | **receive** }.

Example

Configure dynamic PW switching.

```
<HUAWEI> system-view
[HUAWEI] mpls switch-l2vc 1.1.1.9 100 between 3.3.3.9 100 encapsulation vlan
```

Configure static PW switching.

```
<HUAWEI> system-view
[HUAWEI] mpls switch-l2vc 1.1.1.9 100 trans 100 recv 100 between 3.3.3.9 100 trans 200 recv 200
encapsulation vlan
```

Configure mixed PW switching.

```
<HUAWEI> system-view
[HUAWEI] mpls switch-l2vc 1.1.1.9 100 between 3.3.3.9 100 trans 200 recv 200 encapsulation vlan mtu
1500
```

Delete PW switching.

```
<HUAWEI> system-view
[HUAWEI] undo mpls switch-l2vc 1.1.1.9 100 encapsulation vlan
```

10.6.32 mtu (PW template view)

Function

The **mtu** command specifies the MTU in a PW template.

The **undo mtu** command restores the default setting.

By default, the MTU in a PW template is 1500.

Format

mtu *mtu-value*

undo mtu

Parameters

Parameter	Description	Value
mtu-value	Specifies the MTU in a PW template.	The value is an integer that ranges from 46 to 9600.

Views

PW template view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When creating a PW template, run the **mtu** command to specify the MTU for the PW template.

Precautions

When creating a Martini VLL or PWE3 VLL, if you set the MTU value by specifying **mtu** *mtu-value* in the **mpls l2vc** command. If you do not specify **mtu** *mtu-value*, the MTU in the PW template takes effect. If you do not specify **mtu** *mtu-value* in the **mpls l2vc** command and do not set the MTU in the PW template, the device uses the default MTU value 1500.

Example

Configure the MTU for the PW template **pw1**.

```
<HUAWEI> system-view
[HUAWEI] pw-template pw1
[HUAWEI-pw-template-pw1] mtu 1600
```

10.6.33 peer-address

Function

The **peer-address** command assigns a remote IP address to a PW template.

The **undo peer-address** command deletes the remote IP address assigned to a PW template.

By default, a PW template is not configured with a remote IP address.

Format

peer-address *ip-address*

undo peer-address

Parameters

Parameter	Description	Value
ip-address	Specifies the IPv4 address of the peer. Generally, *ip-address* is a loopback address of the peer and needs be the same as the destination address of the tunnel.	The value is in dotted decimal notation.

Views

PW template view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The peer IP address can be set either using a PW template or the **mpls l2vc** command. The PW template allows you to modify the peer IP address in real time. If you want to change the peer IP address using the **mpls l2vc** command, you must delete the existing peer IP address first.

After the peer IP address is changed:

- If the PW template is in use, you must run the **reset pw pw-template** command for the change to take effect. This, however, may disconnect and re-establish the PWs that apply the PW template.
- If the PW template is not in use, it does not need to restart.

Prerequisites

- MPLS L2VPN has been enabled in the system view.
- A PW template has been created in the system view.

Precautions

If the peer IP address has been configured using both a PW template and the **mpls l2vc** command, only the peer IP address configured using the **mpls l2vc** command takes effect.

Example

Assign a remote IP address to a PW template.

```
<HUAWEI> system-view
[HUAWEI] pw-template pwt
[HUAWEI-pw-template-pwt] peer-address 1.1.1.1
```

Modify a remote IP address in a PW template.

```
<HUAWEI> system-view
[HUAWEI] pw-template pwt
[HUAWEI-pw-template-pwt] undo peer-address
[HUAWEI-pw-template-pwt] peer-address 2.2.2.2
```

10.6.34 ping vc

Function

The **ping vc** command detects the status of a PW.

Format

ping vc *pw-type pw-id* [*peer-address*] [**-c** *echo-number* | **-m** *time-value* | **-s** *data-bytes* | **-t** *timeout-value* | **-exp** *exp-value* | **-r** *reply-mode* | **-v**] * **control-word** [**remote** *remote-ip-address peer-pw-id* | **draft6**] * [**ttl** *ttl-value*] [**pipe** | **uniform**]

ping vc *pw-type pw-id* [*peer-address*] [**-c** *echo-number* | **-m** *time-value* | **-s** *data-bytes* | **-t** *timeout-value* | **-exp** *exp-value* | **-r** *reply-mode* | **-v**] * **control-word remote** *remote-ip-address peer-pw-id* **sender** *sender-address* [**ttl** *ttl-value*] [**pipe** | **uniform**]

ping vc *pw-type pw-id* [*peer-address*] [**-c** *echo-number* | **-m** *time-value* | **-s** *data-bytes* | **-t** *timeout-value* | **-exp** *exp-value* | **-r** *reply-mode* | **-v**] * **label-alert** [**no-control-word**] [**remote** *remote-ip-address* | **draft6**] * [**pipe** | **uniform**]

ping vc *pw-type pw-id* [*peer-address*] [**-c** *echo-number* | **-m** *time-value* | **-s** *data-bytes* | **-t** *timeout-value* | **-exp** *exp-value* | **-r** *reply-mode* | **-v**] * **normal** [**no-**

control-word] [**remote** *remote-ip-address peer-pw-id*] [**ttl** *ttl-value*] [**pipe** | **uniform**]

Parameters

Parameter	Description	Value
pw-type	Specifies the encapsulation type of a local PW.	Currently, PWs of the following types are supported: **ethernet**, **ip-interworking**, and **vlan**.
pw-id	Specifies the ID of a local PW.	The value is an integer that ranges from 1 to 4294967295.
peer-address	Specifies the peer LSR ID of a local PW. In PWE3 and Martini VLL scenarios, if the VC IDs of the primary and secondary VCs are the same, this parameter must be specified to uniquely identify a PW.	The value is in dotted decimal notation.
-c *echo-number*	Specifies the number of Echo Request messages to be sent. If the network works unstably, you can set this parameter to a larger value to test network quality based on the packet loss ratio.	The value is an integer that ranges from 1 to 4294967295. The default value is 5.
-m *time-value*	Specifies the interval for sending Echo Request messages. Each time after the source sends an Echo Request message by using the **ping vc** command, it waits a period of time (2000 ms by default) before sending the next Echo Request message. You can set the interval for sending Echo Request messages through the parameter *time-value*. If the network works unstably, the value should be greater than or equal to 2000 ms.	The value is an integer that ranges from 1 to 10000, in milliseconds. The default value is 2000.
-s *data-bytes*	Specifies the number of bytes of the sent Echo Request messages.	The value is an integer that ranges from 65 to 8100, in bytes. The default value is 100.

Parameter	Description	Value
-t *timeout-value*	Specifies the timeout period for sending Echo Request messages.	The value is an integer that ranges from 0 to 65535, in milliseconds. The default value is 2000.
-exp *exp-value*	Specifies the EXP value of the sent Echo Request messages. **NOTE** If DSCP priority has been configured by running the **set priority** command, the *exp-value* parameter does not take effect.	The value is an integer that ranges from 0 to 7. The default value is 0.
-r *reply-mode*	Specifies the mode in which the peer returns MPLS Echo Reply messages. ● 1: No MPLS Echo Reply message is returned. ● 2: MPLS Echo Reply messages are encapsulated into IPv4/IPv6 UDP packets. ● 3: MPLS Echo Reply messages are encapsulated into IPv4/IPv6 UDP packets carrying the Router Alert option. ● 4: MPLS Echo Reply messages are returned through the control channel of the application plane.	The value is an integer that ranges from 1 to 4. The default value is 2.
-v	Displays the detailed information.	-
no-control-word	Disables the control word function.	-
control-word	Enables the control word function. The switching node along a multi-segment PW does not transmit ping packets. When the control word function is enabled, you can ping only the termination node of the PW. Before using the control word to ping the PW, you must enable the control word for a PW.	-

Parameter	Description	Value
remote	Specifies information about the PW on the remote PE. Information specified by the remote PE is finally encapsulated into the ping packets. The PW can be searched on the remote PE based on the specified information. By default, information contained in the ping packets is the information about the PW on the local end, which applies to single-segment PWs.	-
peer-pw-id	Specifies the ID of the PW on the peer.	The value is an integer that ranges from 1 to 4294967295. By default, the peer PW ID is the same as the local PW ID.
draft6	Specifies the command version. If this parameter is specified, the ping operation is performed based on "draft-ietf-mpls-lsp-ping-06". By default, the ping operation is performed based on RFC 4379.	-
pipe	Specifies the pipe mode. When a probe packet passes through the MPLS domain, the entire MPLS domain is considered as one hop and the IP TTL of the probe packet is reduced by one on the ingress and egress respectively.	-
uniform	Specifies the uniform mode. The IP TTL of the probe packet is reduced by one each time it passes through one hop in the MPLS domain.	-

Parameter	Description	Value
remote-ip-address	Specifies the remote IP address. By default, the system searches for the IP address of the next hop based on the PW on the local PE. In the case of a multi-segment PW, if the ping operation is performed in control word mode, the IP address of the termination node must be specified. In MPLS router alert mode, the IP address of any switching node or the termination node can be specified. Then, the Echo Request message is sent to the peer and then sent back.	-
label-alert	Specifies the label alert mode. The switching node along a multi-segment PW sends ping packets forcibly. In MPLS router alert mode, you can ping any switching node along the PW.	-
normal	Specifies the normal mode, that is, the TTL detection mode. In this mode, control word and router alert are not encapsulated in to MPLS Echo Request messages, and TTL values are used to detect PW connectivity.	-
ttl *ttl-value*	Specifies the TTL value.	The value is an integer that ranges from 1 to 255. The default value is 64.
sender *sender-address*	Specifies a source address. For end-to-end detection of a multi-segment PW, a source IP address needs to be specified for a public network device that communicates with the remote PE. Generally, the source IP address is the address of the adjacent SPE or UPE.	-

Usage Guidelines

Usage Scenario

If a PW is Up, the **ping vc** command can be used to locate the fault on the PW. For example, a forwarding entry is abnormally lost or incorrect.

The **ping vc** command can be used to check a PW in the following scenarios:

VLL networking

Based on VLL types, the VLL PW ping can be classified into the following types:

- PWE3 VLL PW ping: In a PWE3 VLL networking, a PW ping is initiated to check the connectivity of a PW. A PWE3 VLL PW ping can be performed in control word mode, TTL mode, or label alert mode. In a ping test, a local PE sends an Echo Request message to the peer PE. After receiving the message, the peer PE abstracts and sends FEC information to the L2VPN module to determine whether the message has reached the egress. If so, the peer PE returns an Echo Reply message.
- Kompella VLL PW ping: A VLL PW ping is initiated to check the connectivity of a PW. Different from the PWE3 networking, the Kompella VLL does not need the PW template and supports the control word, TTL, and label alert modes.

VPLS networking

Based on the VPLS types, the VPLS PW ping can be classified into the following types:

- Martini VPLS PW ping: The Martini VPLS PW ping supports only the label alert mode. On a Hierarchical Virtual Private LAN Service (HVPLS) network, the Martini VPLS PW ping can only detect single-segment PWs. If an optional PW ID is configured and specified, the PW with the PW ID is detected. If the PW ID is not specified, the PW with a specified VSI ID is detected.
- Kompella VPLS PW ping: The Kompella VPLS PW ping supports only the label alert mode.

If a PW fault is detected by using the **ping vc** command, the **tracert vc** command can be used to locate the fault. Both the **ping vc** command and the **tracert vc** command can properly check the connectivity of PWs and locate faults.

Prerequisites

The MPLS module has been enabled on the device and works properly.

Precautions

control-word is recommended to detect the entire PW. Even though **label-alert** can be used to check the entire PW, the whole process is the same as the forwarding process only when **control-word** is used.

The execution of the **ping vc** command terminates when either of the following situations occurs:

- The ping packet reaches the egress.
- The TTL value of the ping packet reaches the upper threshold.

When a PE is single-homed to an SPE and two multi-segment PWs are deployed for PW redundancy, end-to-end detection cannot be performed for the secondary

PW if services are transmitted over the primary PW. If services are transmitted over the secondary PW, the primary PW can only be detected segment by segment.

Example

Run the **ping vc** command in label alert mode on the device to check the connectivity of an Ethernet PW.

```
<HUAWEI> ping vc ethernet 100 -c 10 -m 10 -s 65 -t 100 -v label-alert remote 2.2.2.2
  Reply from 2.2.2.2: bytes=65 Sequence=1 time = 31 ms Return Code 3, Subcode 1
  Reply from 2.2.2.2: bytes=65 Sequence=2 time = 15 ms Return Code 3, Subcode 1
  Reply from 2.2.2.2: bytes=65 Sequence=3 time = 32 ms Return Code 3, Subcode 1
  Reply from 2.2.2.2: bytes=65 Sequence=4 time = 15 ms Return Code 3, Subcode 1
  Reply from 2.2.2.2: bytes=65 Sequence=5 time = 32 ms Return Code 3, Subcode 1
  Reply from 2.2.2.2: bytes=65 Sequence=6 time = 15 ms Return Code 3, Subcode 1
  Reply from 2.2.2.2: bytes=65 Sequence=7 time = 15 ms Return Code 3, Subcode 1
  Reply from 2.2.2.2: bytes=65 Sequence=8 time = 16 ms Return Code 3, Subcode 1
  Reply from 2.2.2.2: bytes=65 Sequence=9 time = 15 ms Return Code 3, Subcode 1
  Reply from 2.2.2.2: bytes=65 Sequence=10 time = 32 ms Return Code 3, Subcode 1

--- FEC: FEC 128 PSEUDOWIRE (NEW). Type = ethernet, ID = 100 ping statistics
  10 packet(s) transmitted
  10 packet(s) received
  0.00% packet loss
  round-trip min/avg/max = 15/21/32 ms
```

10.6.35 pw-template

Function

The **pw-template** command creates a PW template. In the PW template, you can set attributes for a PW, such as the peer, control word, and tunnel policy.

The **undo pw-template** command deletes a PW template.

By default, no PW template is created.

Format

pw-template *pw-template-name*

undo pw-template *pw-template-name*

Parameters

Parameter	Description	Value
pw-template-name	Specifies the PW template name.	The value is a string of 1 to 19 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Importing a PW template simplifies the configuration of PWs with similar attributes.

Prerequisites

L2VPN has been enabled by running the **mpls l2vpn** command.

Precautions

- If a PW template is applied to a PW, the PW template cannot be deleted.
- When a PW template is applied to a PW, the PW uses the PW attributes specified on the interface if the PW attributes specified on the interface are different from those specified in the template.
- When modifying attributes in a PW template, run the **reset pw** command to make the modification take effect. This will cause PW disconnection and reconnection.
- After a PW is bound to a link detection protocol, the remote IP address in the PW template cannot be changed. To change the remote IP address, unbind the PW from the link detection protocol.

Example

Create a PW template named **pwt1**.

```
<HUAWEI> system-view
[HUAWEI] pw-template pwt1
[HUAWEI-pw-template-pwt1]
```

10.6.36 reset pw

Function

The **reset pw** command re-creates a PW or a PW template.

Format

reset pw { [**peer-address** *peer-address*] *pw-id pw-type* | **pw-template** *pw-template-name* }

Parameters

Parameter	Description	Value
peer-address *peer-address*	Specifies the IPv4 address of the target PE.	The value is in dotted decimal notation.

Parameter	Description	Value
pw-id	Specifies the ID of a VC connected to L2VPN.	The value is an integer that ranges from 1 to 4294967295.
pw-type	Specifies the encapsulation type of a PW.	Currently, PWs of the following types are supported: **ethernet**, **vlan**, and **ip-interworking**.
pw-template	Re-creates all PWs in the PW template.	-
pw-template-name	Specifies the PW template name.	The value is an existing PW template name.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

After changing the parameters in a PW template, you need to run the **reset pw pw-template** command to make the modification take effect. The configuration on the PW template applies to all PWs using this PW template. You can configure the attributes of a PW by using a PW template or commands. The attributes configured by using commands take precedence over those configured by using the template. If you configure PW attributes by using commands, the corresponding attributes in the PW template do not take effect. Therefore, if you run the **reset pw pw-template** and **reset pw** *pw-id* commands, the PW attributes remain unchanged. To change a PW attribute, configure the attribute in the PW template but do not configure attribute by using a command.

Example

Re-create a PW by specifying the VC ID and VC type.

```
<HUAWEI> reset pw 100 vlan
```

Re-create all PWs that use the PW template named **pwt1**.

```
<HUAWEI> reset pw pw-template pwt1
```

10.6.37 tnl-policy (PW template view)

Function

The **tnl-policy** command configures a tunnel policy for a PW template.

The **undo tnl-policy** command deletes the tunnel policy configured for a PW template.

By default, no tunnel policy is configured for a PW template.

Format

tnl-policy *policy-name*

undo tnl-policy

Parameters

Parameter	Description	Value
policy-name	Specifies the tunnel policy name of a PW.	The value is a string of 1 to 39 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

PW template view

Default Level

2: Configuration level

Usage Guidelines

The **tnl-policy** command specifies a PWE3 tunnel policy based on which a PW selects a tunnel to be associated with.

If no policy is configured, an LSP tunnel is selected and load balancing is not performed.

Example

Configure a tunnel policy named **policy1** for a PW template named **pwt**.

```
<HUAWEI> system-view
[HUAWEI] pw-template pwt
[HUAWEI-pw-template-pwt] tnl-policy policy1
```

10.6.38 tracert vc

Function

The **tracert vc** command detects the status of a PW or locates a faulty node on a PW in Down state.

Format

tracert vc *pw-type pw-id* [*peer-address*] [**-exp** *exp-value* | **-f** *first-ttl* | **-m** *max-ttl* | **-r** *reply-mode* | **-t** *timeout-value*] * **control-word** [**draft6**] [**full-lsp-path**] [**pipe** | **uniform**]

tracert vc *pw-type pw-id* [*peer-address*] [**-exp** *exp-value* | **-f** *first-ttl* | **-m** *max-ttl* | **-r** *reply-mode* | **-t** *timeout-value*] * **control-word remote** *remote-ip-address* [**ptn-mode** | **full-lsp-path**] [**pipe** | **uniform**]

tracert vc *pw-type pw-id* [*peer-address*] [**-exp** *exp-value* | **-f** *first-ttl* | **-m** *max-ttl* | **-r** *reply-mode* | **-t** *timeout-value*] * **control-word remote** *remote-pw-id* **draft6** [**full-lsp-path**] [**pipe** | **uniform**]

tracert vc *pw-type pw-id* [*peer-address*] [**-exp** *exp-value* | **-f** *first-ttl* | **-m** *max-ttl* | **-r** *reply-mode* | **-t** *timeout-value*] * **label-alert** [**no-control-word**] [**remote** *remote-ip-address*] [**full-lsp-path**] [**draft6**] [**pipe** | **uniform**]

tracert vc *pw-type pw-id* [*peer-address*] [**-exp** *exp-value* | **-f** *first-ttl* | **-m** *max-ttl* | **-r** *reply-mode* | **-t** *timeout-value*] * **normal** [**no-control-word**] [**remote** *remote-ip-address*] [**full-lsp-path**] [**draft6**] [**pipe** | **uniform**]

Parameters

Parameter	Description	Value
pw-type	Specifies the PW type.	Currently, PWs of the following types are supported: **ethernet**, **vlan**, and **ip-interworking**.
pw-id	Specifies the local PW ID.	The value is an integer that ranges from 1 to 4294967295.
peer-address	Specifies a peer LSR ID for the local PW. In a PWE3 or Martini VLL scenario, if the primary and secondary VCs are configured with the same VC ID, this parameter must be specified to determine a unique PW to be monitored.	The value is in dotted decimal notation.
-exp *exp-value*	Specifies the EXP value in the outer label of an MPLS Echo Request packet. The default value is 0. **NOTE** If DSCP priority has been configured by running the **set priority** command, the *exp-value* parameter does not take effect.	The value is an integer that ranges from 0 to 7.

Parameter	Description	Value
-f *first-ttl*	Specifies the initial Time-to-Live (TTL).	The value is an integer that ranges from 1 to 255, and must be smaller than the value of *max-ttl*. The default value is 1.
-m *max-ttl*	Specifies the maximum TTL.	The value is an integer that ranges from 1 to 255, and must be larger than the value of *first-ttl*. The default value is 30.
-r *reply-mode*	Specifies the mode in which the peer returns MPLS Echo Reply packets. ● 1: No MPLS Echo Reply packet is returned. ● 2: The MPLS Echo Reply packet is encapsulated in IPv4/IPv6 UDP packets. ● 3: MPLS Echo Reply packets are encapsulated in IPv4/IPv6 /IPv6 UDP packets carrying the Router Alert option. ● 4: MPLS Echo Reply packets are returned through the control channel of the application plane.	The value is an integer that ranges from 1 to 4.
-t *timeout-value*	Specifies the timeout interval of an MPLS Echo Reply packet.	The value is an integer that ranges from 0 to 65535, in milliseconds. The default value is 5.
control-word	Indicates that the control word is encapsulated in the MPLS Echo Request packet.	-
label-alert	Indicates that the router alert label is encapsulated in the MPLS Echo Request packet.	-

Parameter	Description	Value
no-control-word	Indicates that the control word is not encapsulated in the MPLS Echo Request packet.	-
normal	Indicates the normal mode where the router alert label and control word are not encapsulated in the MPLS Echo Request packet.	-
remote	Specifies information about the PW on the remote PE.	-
remote-ip-address	Specifies the remote IP address. By default, the system searches for the IP address of the next hop based on the PW on the local PE. If **label-alert** is configured, you can specify the IP address of any switching node or the termination node.	-
remote-pw-id	Specifies the ID of the remote PW. By default, the ID of the local PW is used. If the tracert operation is performed in control word mode for a multi-segment PW, the IP address of the termination node must be specified.	-
ptn-mode	Specifies the PTN mode. In a multi-segment PW scenario, this parameter is indicated that trace VC packets are replied. You need to run the **lspv pw reply ptn-mode** command on both the SPE and TPE.	-
full-lsp-path	Displays the responses from all nodes along the LSP that the MPLS Echo Request packets pass through. If this parameter is not specified, only the responses from the PW nodes along the LSP are displayed.	-
pipe	Specifies the pipe mode. When a probe packet passes through the MPLS domain, the entire domain is regarded as one hop and the IP TTL of the probe packet is reduced by one on both the ingress and egress.	-

Parameter	Description	Value
uniform	Specifies the uniform mode. The IP TTL of the probe packet is reduced by one each time it passes through one hop in the MPLS domain.	-
draft6	Specifies the version of the **tracert vc** command. If this parameter is specified, the tracert operation is performed according to "draft-ietf-mpls-lsp-ping-06". By default, the tracert operation is performed according to RFC 4379. **NOTE** Tracert VC based on **draft6** is applied only to VLL over LDP scenarios.	-

Usage Guidelines

Usage Scenario

If a fault occurs on the PW, the **ping vc** command can be used to check the connectivity of the network, and the **tracert vc** command can be used to locate the fault and provide reference for fault diagnosis. If a PW is Up, the **ping vc** command can be used to locate the fault on the PW. For example, a forwarding entry is abnormally lost or incorrect. If a PW is down, the **tracert vc** command must be used to locate the faulty node on the PW.

The **tracert vc** command applies to the following networking scenarios:

- PWE3 VLL PW tracert

  In PWE3 VLL networking, PW tracert can help you obtain information about SPEs and Ps along the path that the message travels from the source to the destination, check the connectivity of the PW, and locate the fault of the PW.

  A PWE3 VLL PW tracert can be performed in control word mode, label alert mode, or TTL mode. The default mode is label alert. The TTL mode and control word mode are mutually exclusive.

  To detect faults on a VLL network with control word enabled, run the **tracert vc** *pw-type pw-id* **control-word** command.

  To encapsulate packets with the router alert label and detect faults on a VLL network, run the **tracert vc** *pw-type pw-id* **label-alert** command.

  If control word is not enabled and packets are not encapsulated with the router alert label, to detect faults on a VLL network, run the **tracert vc** *pw-type pw-id* command.

The TTL value of the PW Tracert Request message is incremented by 1 each time. Each time the transit node (P) receives an Echo Request message after the TTL value of the message expires, it sends the Echo Request message to the LSPV module. Then the transit node returns an Echo Reply message carrying the next hop information.

Prerequisite

- The UDP module of each node works properly; otherwise, the tracert operation will fail.
- The MPLS module has been enabled on each node and works properly.
- The ICMP module of each node works properly; otherwise, " * * * " is displayed.

Procedure

The execution process of the **tracert vc** command is as follows:

1. The source sends an MPLS Echo Request packet with the TTL being 1. After the TTL times out, the first hop sends an MPLS Echo Reply packet to the source.
2. The source sends an MPLS Echo Request packet with the TTL being 2. After the TTL times out, the second hop sends an MPLS Echo Reply packet to the source.
3. The source sends an MPLS Echo Request packet with the TTL being 3. After the TTL times out, the third hop sends an MPLS Echo Reply packet to the source.
4. The preceding steps continue until the MPLS Echo Request packet reaches the destination.

When the device on each hop receives the MPLS Echo Request packet, it will respond with an MPLS Echo Reply packet, indicating that the tracert test ends. In the command output information of the source device, you can view the path that the packet passes through.

Configuration Impact

In control word mode, if a transit node receives an MPLS Echo Request packet whose TTL does not time out, it does not send the packet to the CPU. In this mode, the source obtains only a little PW information and cannot obtain information about the downstream devices of the transit node. This mode is recommended when the traffic volume is heavy.

In router alert mode, a transit node sends the received MPLS Echo Request packets to the CPU. In this mode, the source obtains a lot of PW information; therefore, device performance is affected when the traffic volume is heavy. This mode is recommended when the traffic volume is light.

Information specified by **remote** is encapsulated in MPLS Echo Request packets. The PW can be searched on the remote PE based on the specified information. By default, information contained in the MPLS Echo Request packets is about the PW on the local PE. This applies to single-segment PWs.

Precautions

- When the probe packet reaches the egress or the TTL reaches the upper threshold, the PW tracert is terminated.

- You can press **Ctrl + C** to terminate the execution of the **tracert vc** command.

When a PE is single-homed to an SPE and two multi-segment PWs are deployed for PW redundancy, end-to-end detection cannot be performed for the secondary PW if services are transmitted over the primary PW. If services are transmitted over the secondary PW, the primary PW can only be detected segment by segment.

Example

Trace a multi-segment PW. The encapsulation type, local PW ID, and remote PW ID of the PW is ethernet, 100, and 200.

```
<HUAWEI> tracert vc ethernet 100 control-word remote 200 draft6 full-lsp-path
 TTL   Replier            Time    Type      Downstream
 0                            Ingress   10.1.1.2/[1025 ]
 1     10.1.1.2          230 ms  Transit   10.2.1.2/[3 ]
 2     10.2.1.2          230 ms  Transit   10.3.1.2/[3 ]
 3     10.3.1.2          100 ms  Transit   10.4.1.2/[3 ]
 4     10.4.1.2          150 ms  Egress
```

Table 10-89 Description of the **tracert vc** command output

Item	Description
TTL	TTL value in an Echo Request packet. It represents the number of hops along the path through which an Echo Request packet passes.
Replier	IP address of the node sending MPLS Echo Reply packets.
Time	Time when the packet is processed.
Type	Node type. The value can be: - Ingress: indicates an ingress node. - Transit: indicates a transit node. - Egress: indicates an egress node.
Downstream	IP address and label of the downstream node.

10.7 VPLS Configuration Commands

10.7.1 Command Support

Only the following switch models support VPLS:

S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H

10.7.2 broadcast-suppression cir cbs (VSI view)

Function

The **broadcast-suppression cir cbs** command enables the broadcast traffic suppression function in a VSI.

The **undo broadcast-suppression** command disables the broadcast traffic suppression function in the VSI.

By default, the broadcast traffic suppression function is disabled in a VSI.

Format

broadcast-suppression cir *cir-value* **cbs** *cbs-value*

undo broadcast-suppression

Parameters

Parameter	Description	Value
cir *cir-value*	Specifies the Committed Information Rate (CIR), that is, the allowed rate at which traffic can pass through.	The value is an integer that ranges from 0 to 10000000, in kbit/s.
cbs *cbs-value*	Specifies the Committed Burst Size (CBS), that is, the traffic that can pass instantly, or the depth of the first token bucket.	The value is an integer that ranges from 10000 to 4294967295, in bytes.

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a VPLS network, broadcast packets, multicast packets, and unknown unicast packets are transmitted in broadcast mode and copied to neighboring ACs and PWs. If a large number of broadcast packets are sent to the access device on the network, the device has to make a lot of copies of these broadcast packets, which wastes bandwidth and resources, and degrades the performance of the system. You can run the **broadcast-suppression cir cbs** command to suppress the broadcast traffic in the VSI. The rate of broadcast traffic on the VPLS network is limited.

Prerequisites

A VSI has been created using the **vsi** *vsi-name* [**auto** | **static**] command.

Precautions

The **broadcast-suppression cir cbs** command can be configured in a maximum of 100 VSIs.

Example

Set the CIR to 100 kbit/s and the CBS to 18800 bytes for the broadcast traffic that can pass in **VSI1**.

```
<HUAWEI> system-view
[HUAWEI] vsi VSI1
[HUAWEI-vsi-VSI1] broadcast-suppression cir 100 cbs 18800
```

10.7.3 bfd bind pw vsi

Function

The **bfd bind pw vsi** command configures a BFD session on a non-SPE node to detect a PW.

The **undo bfd** command deletes the specified BFD session.

By default, no BFD session is configured to detect the PW.

Format

bfd *cfg-name* **bind pw vsi** *vsi-name* **peer** *peer-address* [**vc-id** *vc-id*] [**remote-peer** *remote-peer-address* **pw-ttl** { **auto-calculate** | *ttl-number* }]

undo bfd *cfg-name*

Parameters

Parameter	Description	Value
cfg-name	Specifies the name of a BFD session.	The value is a string of 1 to 15 case-insensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
vsi *vsi-name*	Specifies the name of a VSI.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
peer *peer-address*	Specifies the destination IP address of the VPLS PW, which is usually the LSR ID.	The value is in dotted decimal notation.
vc-id *vc-id*	Specifies the ID of a Layer 2 VC.	The value is an integer ranging from 1 to 4294967295.
remote-peer *remote-peer-address*	Specifies the IP address used as the destination address of the PW to be detected by a BFD session, which is usually the LSR ID.	The value is in dotted decimal notation. It cannot be in the format of 127.X.X.X.
pw-ttl	Indicates the BFD session detects the PW in TTL mode.	-
auto-calculate	Indicates that the number of hops along a PW is counted automatically.	-
ttl-number	Specifies the number of hops along the PW to be detected.	The value is an integer ranging from 1 to 255.

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BFD sessions can rapidly detect links on the network. You can run the **bfd bind pw vsi** command to detect a single-hop VPLS PW or a multi-hop PW formed by connecting a VPLS PW to a VLL PW. The **bfd bind pw vsi** command detects the VPLS PW in unicast mode and specifies the VPLS PW to be detected through the parameter **peer** *peer-address*.

- If the configured BFD session is used to detect an end-to-end single-hop VPLS PW, the value of **peer** *peer-address* and the value of **remote-peer** *remote-peer-address* are identical. In this case, you can run the **bfd** *cfg-name* **bindpw vsi** *vsi-name* **peer** *peer-address* command only. The TTL value is 255.
- If the BFD session is used to detect a multi-hop PW formed by connecting a VPLS PW to a VLL PW, you need to specify the destination IP address of the VPLS PW through **peer** *peer-address* and the destination IP address of the multi-hop PW through **remote-peer** *remote-peer-address*.
  - If **auto-calculate** is specified, the system automatically counts the number of hops along the PW to be detected based on **remote-peer** *remote-peer-address*.
  - If **ttl** *ttl-number* is specified, the number of hops along the PW to be detected is manually set.

NOTE

When running the **bfd bind pw vsi** command to detect a multi-hop PW, ensure that the first-hop PW is the VPLS PW, which must be configured on a non-SPE node.

When running the **bfd bind pw vsi** command to detect a single-hop VPLS PW, ensure that the single-hop VPLS PW is configured on a non-SPE node.

If VPLS forwards data through TE tunnels, PW detection using a BFD session is not supported.

Prerequisites

The PW to be detected must exist. The BFD session must be established between the source and destination of the PW.

Before running the **bfd bind pw vsi** command, ensure that the following configuration operations have been performed:

- The BFD function has been enabled globally through the **bfd** command.
- A single-hop VPLS PW or multi-hop PW formed by connecting a VPLS PW to a VLL PW has been created.

Precautions

This command is used to configure a BFD session to detect a VPLS PW only in TTL mode.

Example

Configure a BFD session on a non-SPE node to detect the VPLS PW in TTL mode.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] bfd vplspw bind pw vsi vsi1 peer 2.2.2.2 vc-id 123 remote-peer 3.3.3.3 pw-ttl auto-calculate
```

10.7.4 bfd for vsi-pw enable

Function

The **bfd for vsi-pw enable** command enables the device to send BFD for VSI-PW packets to the protocol stack.

The **undo bfd for vsi-pw enable** command disables the device from sending BFD for VSI-PW packets to the protocol stack.

By default, the device does not send BFD for VSI-PW packets to the protocol stack, but discards or forwards the packets.

Format

bfd for vsi-pw enable

undo bfd for vsi-pw enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When performing BFD for VSI PW, the device needs to send BFD for VSI-PW packets to the protocol stack. Therefore, the **bfd for vsi-pw enable** command must be run.

Precautions

If you run the **undo bfd for vsi-pw enable** command to disable the device from sending BFD for VSI-PW packets to the protocol stack, the BFD for VSI-PW packets are discarded or forwarded. The **bfd for vsi-pw enable** command and other BFD commands can be run in any sequence.

After the **bfd for vsi-pw enable** command is run in the system view, the BFD for VSI-PW packets are sent to the protocol stack. If this command is not run, the BFD for VSI PW packets are discarded or forwarded, and the BFD for VSI PW function does not take effect.

Example

Enable the device to send BFD for VSI-PW packets to the protocol stack.

```
<HUAWEI> system-view
[HUAWEI] bfd for vsi-pw enable
```

Disable the device from sending BFD for VSI-PW packets to the protocol stack.

```
<HUAWEI> system-view
[HUAWEI] undo bfd for vsi-pw enable
```

10.7.5 bgp-ad

Function

The **bgp-ad** command displays the BGP-AD view.

Format

bgp-ad

Parameters

None

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

To establish the BGP-AD VSI, you need to run the **bgp-ad** command in the VSI view to display the BGP-AD view. In the BGP-AD view, you can configure parameters such as VPLS-ID and VPN-Target.

Example

Enter the BGP-AD view.

```
<HUAWEI> system-view
[HUAWEI] vsi v100
[HUAWEI-vsi-v100] bgp-ad
[HUAWEI-vsi-v100-bgpad]
```

10.7.6 description (VSI view)

Function

The **description** command configures the description of a Virtual Switch Instance (VSI).

The **undo description** command deletes the description of a VSI.

By default, no description of the VSI is configured.

Format

description *description*

undo description

Parameters

Parameter	Description	Value
description	Specifies the description of a VSI.	The value is a string of 1 to 64 case-sensitive characters with spaces.

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

The **description** command can be used to identify different VSIs or describe the functions of VSIs.

Example

Configure the description of the current VSI.

```
<HUAWEI> system-view
[HUAWEI] vsi v100
[HUAWEI-vsi-v100] description vsi for company1
```

10.7.7 display bgp l2vpn-ad routing-table

Function

The **display bgp l2vpn-ad routing-table** command displays BGP L2VPN-AD routes.

Format

display bgp l2vpn-ad [**route-distinguisher** *route-distinguisher*] **routing-table** [**vpls-ad**] [*ipv4-address* | **statistics**]

display bgp l2vpn-ad routing-table peer *ipv4-address* **advertised-routes** [**vpls-ad**] [*ipv4-address* | **statistics**]

display bgp l2vpn-ad routing-table peer *ipv4-address* **received-routes** [**active**] [**statistics**]

display bgp l2vpn-ad routing-table vpws route-distinguisher *route-distinguisher* [**ce-id** *ce-id* [**label-offset** *label-offset*]]

display bgp l2vpn-ad routing-table { **vpws** | **vpls** | **all** } [**statistics**]

display bgp l2vpn-ad routing-table peer *ipv4-address* **advertised-routes vpls-ad** *ipv4-address*

display bgp l2vpn-ad routing-table peer *ipv4-address* **received-routes vpls-ad** [**active**] [**statistics**]

display bgp l2vpn-ad routing-table vpls route-distinguisher *route-distinguisher* [**site-id** *site-id* [**label-offset** *label-offset*]]

display bgp l2vpn-ad routing-table peer *ipv4-address* **received-routes** { **vpws** | **vpls** | **all** } [**statistics**]

display bgp l2vpn-ad routing-table peer *ipv4-address* **advertised-routes vpws** [**statistics** | **route-distinguisher** *route-distinguisher* **ce-id** *ce-id* **label-offset** *label-offset*]

display bgp l2vpn-ad routing-table peer *ipv4-address* **advertised-routes vpls** [**statistics** | **route-distinguisher** *route-distinguisher* **site-id** *site-id* **label-offset** *label-offset*]

display bgp l2vpn-ad routing-table peer *ipv4-address* **advertised-routes all** [**statistics**]

display bgp l2vpn-ad routing-table peer *ipv4-address* **received-routes vpls-ad** *network*

display bgp l2vpn-ad routing-table peer *ipv4-address* **received-routes vpws route-distinguisher** *route-distinguisher* **ce-id** *ce-id* **label-offset** *label-offset*

display bgp l2vpn-ad routing-table peer *ipv4-address* **received-routes vpls route-distinguisher** *route-distinguisher* **site-id** *site-id* **label-offset** *label-offset*

Parameters

Parameter	Description	Value
route-distinguisher *route-distinguisher*	Displays BGP L2VPN-AD routing information of the specified RD.	-
ipv4-address	Specifies the IPv4 network address.	-
statistics	Display the statistics of the BGP L2VPN-AD routes.	-
peer	Displays the routing information for the specified BGP peer.	-
advertised-routes	Displays the routes advertised to the specified peer.	-
received-routes	Displays the routes received from the specified peer.	-
active	Displays the active routes received from the specified peer.	-

Parameter	Description	Value
network	Specifies the IPv4 network address.	-
vpls-ad	Displays VPLS-AD route information.	-
vpws	Displays VPWS route information.	-
vpls	Displays VPLS route information.	-
all	Displays information about all types of routes.	-
ce-id *ce-id*	Specifies the CE ID.	The value is a decimal integer ranging from 0 to 65535.
site-id *site-id*	Specifies the site ID of a VSI.	The value is a decimal integer ranging from 0 to 65535.
label-offset *label-offset*	Specifies the offset of a label.	The value is a decimal integer ranging from 0 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can specify different parameters to view the specific routing information.

Example

Display all the BGP L2VPN-AD routing information.

```
<HUAWEI> display bgp l2vpn-ad routing-table

 Local AS number : 100
```

```
 BGP Local router ID is 10.1.150.122
 Status codes: * - valid, > - best, d - damped,
               h - history,  i - internal, s - suppressed, S - Stale
               Origin : i - IGP, e - EGP, ? - incomplete

 Total number of routes from all PE: 2
 Route Distinguisher: 1:1

      Network            NextHop        MED        LocPrf    PrefVal Path/Ogn

 *>   1.1.1.9/32         0.0.0.0                              0      ?
 *>i  3.3.3.9/32         3.3.3.9                    100        0      ?
```

Display the detailed routing information of a specified route.

```
<HUAWEI> display bgp l2vpn-ad routing-table 3.3.3.9

 BGP local router ID : 10.1.150.122
 Local AS number : 100

 Total routes of Route Distinguisher(1:1): 1
 BGP routing table entry information of 3.3.3.9/32:
 From: 3.3.3.9 (192.2.2.2)

Table 10-90 Description of the display bgp l2vpn-ad routing-table command output

Item	Description
Network	Network address in the BGP routing table
NextHop	Next Hop address through which the packet has to be sent
MED	Multi-Exit discriminator
LocPrf	Local preference
PrefVal	Value preferred by the protocol
Path/Ogn	AS-Path number and the attributes of Origin
BGP Local router ID	ID of the local BGP device. The ID is in the same format as an IPv4 address.
Local AS number	Local AS number.
Total routes of Route Distinguisher	Total number of L2VPN-AD routes with a specified RD.
BGP routing table entry information of x.x.x.x/x	The following information is about a specified BGP routing entry.
From	IP address of the route originator.
Route Duration	Route duration.
Relay IP Nexthop	Recursive next-hop IP address.
Relay IP Out-Interface	Recursive outbound interface.
Original nexthop	Original next hop.
Qos information	QoS information. - 0x20000000: indicates that the **apply behavior** command has been run. - 0x40000001–0x40000FFF: indicates that the **apply qos-local-id** *qos-local-id* command has been run and the *qos-local-id* varies from 1 to 4095. - 0x80000001–0x80000007: indicates that the **apply ip-precedence** *precedence* command has been run and the *precedence* varies from 1 to 7. - 0x0: indicates that the preceding QoS configurations are not performed.
Ext-Community	Extended community attribute of BGP.

Item	Description
AS-path	AS_Path attribute. **Nil** indicates that the attribute value is null.
origin	Origin attribute of the BGP route. ● IGP: The routes imported into the BGP routing table by using the **network** command. ● EGP: The routes are obtained by EGP. ● Incomplete: The origin of the routes cannot be determined, for example, the routes imported into the BGP routing table by using the **import-route** command.
localpref	Local preference of the BGP route.
pref-val	Preferred value.
valid	Valid BGP route.
internal	Internal BGP route.
best	The BGP route is the optimal route.
select	The BGP route is a preferred route.
pre 255	The preference of the BGP route is 255.
IGP cost 1	Indicates the IGP cost is 1.
Not advertised to any peer yet	The BGP route has not been advertised to any peer.

Display detailed information about the specified invalid VPLS-AD routes.

```
<HUAWEI> display bgp l2vpn-ad routing-table 1.1.1.1
 BGP local router ID : 10.1.1.2
 Local AS number : 100

 Total routes of Route Distinguisher(1:1): 1
 BGP routing table entry information of 1.1.1.1/32:
 From: 1.1.1.1 (10.1.1.1)
 Route Duration: 00h00m30s
 Relay IP Nexthop: 10.1.1.1
 Relay IP Out-Interface: GigabitEthernet0/0/0
 Original nexthop: 1.1.1.1
 Qos information : 0x0
 Ext-Community:RT <100 : 1>, Layer2 Info <1 : 1>

 AS-path Nil, origin incomplete, localpref 100, pref-val 0, internal, select, pre 255, invalid for route-policy
not pass
 Not advertised to any peer yet
```

Table 10-91 Description of the display bgp l2vpn-ad routing-table command output

Item	Description
BGP local router ID	ID of the local BGP router. The format is the same as the IPv4 address.
Local AS number	Local AS number.
Total routes of Route Distinguisher(1:1)	The total number of routes with the RD of 1:1.
BGP routing table entry information of 1.1.1.1/32	The following information is about 1.1.1.1/32 routing entries.
From	IP address of the router that sends the route. 10.1.1.1 is the IP address of the source interface of the peer with which the BGP connection is established, and 1.1.1.1 is the Router ID of the peer.
Route Duration	Duration of routes.
Relay IP Nexthop	Recursive next hop.
Relay IP Out-Interface	Recursive outbound interface.
Original nexthop	Original next hop.
Qos information	QoS information. ● 0x20000000: indicates that the **apply behavior** command has been run. ● 0x40000001–0x40000FFF: indicates that the **apply qos-local-id** *qos-local-id* command has been run and the *qos-local-id* varies from 1 to 4095. ● 0x80000001–0x80000007: indicates that the **apply ip-precedence** *precedence* command has been run and the *precedence* varies from 1 to 7. ● 0x0: indicates that the preceding QoS configurations are not performed.
Ext-Community	Extended community attribute.
AS-path Nil	AS_Path attribute, with Nil indicating that the attribute value is null.

Item	Description
origin incomplete	Well-known mandatory property. This property defines the origin of a path and records how a route turns to a BGP route. The property has the following three values: ● IGP: The priority of this value is the highest. The origin property of the routes that are added to the BGP routing table by using the **network (BGP)** command is IGP. ● EGP: The priority of this value is second to that of IGP. The origin property of the routes imported from EGP is EGP. ● Incomplete: The priority of this value is the lowest. The value indicates the origin of a route is unknown. The origin property of the routes that are added to the BGP routing table by using the **import-route (BGP)** command is Incomplete.
localpref	Local priority.
pref-val	Value preferred by the protocol.
internal	The BGP route is an internal route.
select	The BGP route is a preferred route.
pre 255	The priority of the BGP route is 255.
invalid for route-policy not pass	Reason why a route is invalid: ● invalid for route-policy not pass: The route does not match the route-policy. ● invalid for supernet route: The route is a supernet route. ● invalid for IP unreachable: The route fails to recurse to another route. ● invalid for supernet route not advertise: No supernet routes are advertised. ● invalid for supernet label route not advertise: No supernet labeled routes are advertised. ● invalid for next-hop unreachable: The next-hop IP address is unreachable. ● invalid for tunnel unreachable: The route fails to recurse to a tunnel.

Item	Description
Not advertised to any peer yet	The BGP route has not been advertised to any peer yet.

10.7.8 display bgp vpls

Function

The **display bgp vpls** command displays information about VPLS in the BGP routing table.

Format

display bgp vpls { **all** | **route-distinguisher** *route-distinguisher* [**site-id** *site-id* [**label-offset** *label-offset*]] }

Parameters

Parameter	Description	Value
all	Displays all VPLS information in the BGP VPLS address family.	-

Parameter	Description	Value
route-distinguisher *route-distinguisher*	Displays the VSI information about the specified Route Distinguisher (RD). The formats of an RD are as follows: - 16-bit AS number:32-bit user-defined number: for example, 101:3. An AS number ranges from 0 to 65535, and a user-defined number ranges from 0 to 4294967295. The AS number and user-defined number cannot be both 0. That is, a VPLS ID cannot be 0:0. - Integral 4-byte AS number:2-byte user-defined number, for example, 65537:3. An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a VPLS ID cannot be 0:0. - 4-byte AS number in dotted notation:2-byte user-defined number, for example, 0.0:3 or 0.1:0. A 4-byte AS number in dotted notation is in the format of *x.y*, where *x* and *y* are integers that range from 1 to 65535 and from 0 to 65535, respectively. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a VPLS ID cannot be 0.0:0. - 32-bit IP address:16-bit user-defined number: for example, 192.168.122.15:1. An IPv4 address ranges from 0.0.0.0 to 255.255.255.255, and a user-defined number ranges from 0 to 65535.	-
site-id *site-id*	Displays the VSI of the specified site ID.	The value is an integer that ranges from 0 to 65534.
label-offset *label-offset*	Displays the VSI information about the specified label offset.	The value is an integer that ranges from 0 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can specify the parameter values of the command to view required VPLS.

When the output information is excessive, you can run the **display bgp vpls peer** command to view information about the BGP peer in the VPLS, and run the **display bgp vpls group** command to view information about the BGP peer group in the VPLS.

Example

Display the VPLS with the VSI of the BGP RD as 1.1.1.2:1.

```
<HUAWEI> display bgp vpls route-distinguisher 1.1.1.2:1
BGP Local Router ID : 10.1.1.1, Local AS Number : 100
Status codes : * - active, > - best

-------------------------------------------------------------------------------
Route Distinguisher: 1.1.1.2:1
   SiteID Offset NextHop         Range LabBase TunnelID   FromPeer        MHPref
-------------------------------------------------------------------------------
>  1      0      0.0.0.0         3     35840   0x0        0.0.0.0         0
```

Table 10-92 Description of the display bgp vpls route-distinguisher command output

Item	Description
BGP Local Router ID	ID of the BGP local router. To set the value, run the **router-id** command.
Local AS Number	Local AS number. To set the value, run the **bgp** command.
Status codes	Route status. - *: active route - >: best route
Route Distinguisher	RD of the VPN instance. To set the value, run the **route-distinguisher** command.
SiteID	Site ID of the remote VSI. To set the value, run the **site** command.
Offset	Offset of the site ID. The value is 0 or 1 and the default value is 0. To set the value, run the **site** command.
Nexthop	IP address of the next hop.

Item	Description
Range	Range of the number of sites in the VSI. The value is a decimal integer. To set the value, run the **site** command.
LabBase	Start number of the allocated labels.
Tunnel ID	Tunnel ID, which is automatically allocated by the system and is in hexadecimal notation.
FromPeer	IP address of the BGP peer.
MHPref	Multi-homing preference. To set the value, run the **multi-homing-preference** command.

10.7.9 display l2vpn ccc-interface vc-type

Function

The **display l2vpn ccc-interface vc-type** command displays information about the interface used by an L2VPN connection.

Format

display l2vpn ccc-interface vc-type { **all** | *vc-type* } [**down** | **up**]

Parameters

Parameter	Description	Value
all	Displays information about all interfaces of L2VPN connections.	-
vc-type	Specifies the type of the L2VPN connection.	The following types of the L2VPN connection are available: • ccc: Cross Circuit Connection • ldp-vc: L2VPN connection in the Martini mode • static-vc: L2VPN connection in the SVC mode • bgp-vc: L2VPN connection in the Kompella mode • vpls-vc: VPLS connection

Parameter	Description	Value
down	Displays information about interfaces of L2VPN connection in the Down state.	-
up	Displays information about interfaces of L2VPN connection in the Up state.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When locating L2VPN faults, you can use the **display l2vpn ccc-interface vc-type** command to view information about the AC interface of the current L2VPN connection, the total number of AC interfaces of various L2VPN connections, interface status, interface encapsulation type, and L2VPN connection types.

Example

Display information about all the interfaces of L2VPN.

```
<HUAWEI> display l2vpn ccc-interface vc-type all
Total ccc-interface of LDP VC: 1
up (1), down (0)
Interface                 Encap Type               State      VC Type
Vlanif12                  vlan                  up         ldp-vc
```

Table 10-93 Description of the **display l2vpn ccc-interface vc-type** command output

Item	Description
Total ccc-interface of CCC : 2 up (2), down (0)	Total number of L2VPN connections is 2. Two connections is Up. No connection is Down.
Interface	Interface connected to the L2VPN connection on the switch.
Encap Type	Encapsulation type of the L2VPN connection. The encapsulation type can be VLAN encapsulation or Ethernet encapsulation.
State	Current status of the L2VPN connection. The status can be Up or Down.

Item	Description
VC Type	Type of the L2VPN connection: ● ccc: Cross Circuit Connection ● ldp-vc: L2VPN connection in the Martini mode ● static-vc: L2VPN connection in the SVC mode ● bgp-vc: L2VPN connection in the Kompella mode ● vpls-vc: VPLS connection

10.7.10 display l2vpn vsi-list tunnel-policy

Function

The **display l2vpn vsi-list tunnel-policy** command displays the correlation between tunnel policies and VSIs.

Format

display l2vpn vsi-list tunnel-policy *policy-name*

Parameters

Parameter	Description	Value
policy-name	Specifies the name of a PW tunnel policy.	The value is an existing tunnel policy.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Using the **display l2vpn vsi-list tunnel-policy** *policy-name* command, you can view the names of VSIs that create a PW using the specified tunnel policy.

Example

Display the name of the tunnel policy used by the VSI.

```
<HUAWEI> display l2vpn vsi-list tunnel-policy p1
Using Tunnel-Policy p1 VSI Instance statistics:
------------------------------------------------------------------------
  vsi v1
```

```
vsi v2
vsi v3
```

Table 10-94 Description of the display l2vpn vsi-list tunnel-policy command output

Item	Description
Using Tunnel-Policy p1 VSI Instance statistics	Names of all the PW VSIs established by the specified tunnel policy.
vsi	VSI name.

10.7.11 display loop-detect

Function

The **display loop-detect** command displays blocking information about L2VPN loop detection.

Format

display loop-detect

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After L2VPN loop detection is enabled on an interface by running the **loop-detect enable** command, you can run the **display loop-detect** command to check blocking information about L2VPN loop detection. The information helps determine whether loops occur on an L2VPN network, facilitating fault location.

Example

Display blocking information about L2VPN loop detection on interfaces.

```
<HUAWEI> display loop-detect
-----------------------------------------------------------------
Interface                 RecoverTime  Action     Status
-----------------------------------------------------------------
GigabitEthernet0/0/1.1       20         block      NORMAL
GigabitEthernet0/0/2.1       20         block      NORMAL
-----------------------------------------------------------------
```

Table 10-95 Description of the **display loop-detect** command output

Item	Description
Interface	Interface with L2VPN loop detection enabled. To enable L2VPN loop detection on an interface, run the **loop-detect enable** command.
RecoverTime	Period for restoring an interface to normal state. To specify this period, run the **loop-detect recovery-time** command.
Action	Action after an L2VPN loop is detected: ● BLOCK: Block this interface.
Status	Status of an interface with L2VPN loop detection enabled: ● NORMAL: No loop is detected. ● BLOCK: A loop is detected, and the interface is blocked.

10.7.12 display mpls l2vpn resource

Function

The **display mpls l2vpn resource** command displays MPLS L2VPN specifications and usage information.

Format

display mpls l2vpn resource

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To check MPLS L2VPN specifications and usage information in routine maintenance, run the **display mpls l2vpn resource** command.

Example

Display MPLS L2VPN specifications and usage information.

```
<HUAWEI> display mpls l2vpn resource

Public Capacity Statistics
 Statistics Item                 Supported Number      Used Number

```

Table 10-96 Description of the **display mpls l2vpn resource** command output

Item	Description
Public Capacity Statistics	MPLS L2VPN capacity statistics
Statistics Item	Statistics item
Supported Number	Maximum number allowed
Used Number	Number already used
L2VPN AC Number	Number of L2VPN AC interfaces, including the maximum number allowed and number already used
L2VPN VC Number	Number of L2VPN VCs, including the maximum number allowed and number already used
VPWS Capacity Statistics	VPWS capacity statistics
L2VPN Local CCC Number	Number of VLLs in local CCC mode, including the maximum number allowed and number already used
L2VPN Remote CCC Number	Number of VLLs in remote CCC mode, including the maximum number allowed and number already used
L2VPN SVC Number	Number of VLLs in SVC mode, including the maximum number allowed and number already used
L2VPN LDP VC Number	Number of LDP VLLs, including the maximum number allowed and number already used

Item	Description
L2VPN BGP VC Number	Number of BGP VLLs, including the maximum number allowed and number already used
L2VPN Switch VC Number	Number of Switch VC, including the maximum number allowed and number already used
VPLS Capacity Statistics	VPLS capacity statistics
L2VPN VSI Number	Number of VSIs, including the maximum number allowed and number already used
L2VPN BGP VSI Number	Number of BGP VSIs, including the maximum number allowed and number used
L2VPN VSI VC Number	Number of VSI VCs, including the maximum number allowed and number already used
L2VPN VSI PWG Number	Number of protection groups for a VSI, including the maximum number allowed and number already used

10.7.13 display mpls label-stack vpls vsi

Function

The **display mpls label-stack vpls vsi** command displays information about label stacks in a VPLS scenario.

Format

display mpls label-stack vpls vsi *vsi-name* **peer** *peer-ip-address* **vc-id** *vc-id*

Parameters

Parameter	Description	Value
vsi-name	Specifies the name of a VSI.	The value is an existing VSI.
peer *peer-ip-address*	Specifies the IP address of a peer.	The value is in dotted decimal notation.
vc-id *vc-id*	Specifies the VPLS PW ID.	The value is an integer ranging from 1 to 4294967295.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view PW traffic forwarding information in a Martini VPLS scenario, run the **display mpls label-stack vpls vsi** command.

Example

Display stack label information in a Martini VPLS scenario with the peer IP address **1.1.1.9** and PW ID **11**.

```
<HUAWEI> display mpls label-stack vpls vsi a1 peer 1.1.1.9 vc-id 11
Label-stack  : 1
Level        : 1
Type         : VPLS
Label        : 1028
Level        : 2
Type         : LDP
Label        : --
OutInterface : Vlanif1024
```

Table 10-97 Description of the **display mpls label-stack vpls vsi** command output

Item	Description
Label-stack	Number of label stacks
Level	Number of label layers
Type	Tunnel type
Label	Outgoing label value
OutInterface	Outbound interface name

10.7.14 display oam-mac list

Function

The **display oam-mac list** command displays the MAC address list for the diagnostic test on the MAC address learning capacity.

Format

display oam-mac list

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display oam-mac list** command displays MAC address lists of all the **mac populate** or **mac purge** operations that are available on the device.

NOTE

Before performing diagnostic test of the MAC address learning capacity, you need to apply for a MAC address specialized for the diagnostic test. In this case, the diagnostic test does not impact on the normal forwarding.

At present, only the following MAC addresses are used in the diagnostic test.

- 0018-82a4-3fb1
- 0018-82a4-3fb2
- 0018-82a4-3fb3
- 0018-82a4-3fb4
- 0018-82a4-3fb5
- 0018-82a4-3fb6
- 0018-82a4-3fb7
- 0018-82a4-3fb8
- 0018-82a4-3fb9
- 0018-82a4-3fba

Example

Display the MAC address list for the diagnostic test of the MAC address learning capacity.

```
<HUAWEI> display oam-mac list
No.  Mac Address
 1  0018-82a4-3fb1
 2  0018-82a4-3fb2
 3  0018-82a4-3fb3
 4  0018-82a4-3fb4
 5  0018-82a4-3fb5
 6  0018-82a4-3fb6
 7  0018-82a4-3fb7
 8  0018-82a4-3fb8
 9  0018-82a4-3fb9
10  0018-82a4-3fba
```

10.7.15 display oam-mac statistics

Function

The **display oam-mac statistics** command displays the statistics about the number of MAC diagnostic packets.

Format

display oam-mac statistics { **populate** | **purge** | **purge-register** | **all** }

Parameters

Parameter	Description	Value
populate	Displays the statistics about the number of populate packets.	-
purge	Displays the statistics about the number of purge packets.	-
purge-register	Displays the statistics about the number of purge register packets.	-
all	Displays the statistics about the number of MAC diagnostic packets of all types.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Using the **display oam-mac statistics** command, you can view the number of MAC diagnostic packets that is counted since the **reset oam-mac statistics** command was run.

Example

Display the statistics about the number of populate packets that are received by the device.

```
<HUAWEI> display oam-mac statistics populate
Received populate packet: 3
```

Display the statistics about the number of all MAC diagnostic packets that are received by the device.

```
<HUAWEI> display oam-mac statistics all
 Received populate packet: 3
 Received purge packet: 1
 Received purge register packet: 2
```

Table 10-98 Description of the display oam-mac statistics all command output

Item	Description
Received populate packet	Number of received populate packets.
Received purge packet	Number of received purge packets.
Received purge register packet	Number of received purge register packets.

10.7.16 display traffic-statistics vsi

Function

The **display traffic-statistics vsi** command displays the statistics about the public traffic on all VPLS PWs in a specified VSI.

Format

display traffic-statistics vsi *vsi-name*

Parameters

Parameter	Description	Value
vsi-name	Specifies the name of a specified VSI.	The value is an existing VSI.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After the VPLS network is configured, you can run the **display traffic-statistics vsi** command to view the statistics about the traffic on all VPLS PWs in a specified VSI.

Precautions

- Currently, this command only displays the statistics about the traffic on the Martini VPLS PWs in the VSI.
- Within five minutes, if a PW goes Down, traffic before the PW is Down cannot be used to compute the traffic rate in the five minutes.

Example

Display the statistics about the traffic on all VPLS PWs in a specified VSI.

```
<HUAWEI> display traffic-statistics vsi newvsi
vsi-name: newvsi
Peer-address: 10.22.33.20
Negotiation-vc-id: 2
Statistics last cleared: never
Last 300 seconds input rate : 0 bytes/sec, 0 packets/sec
Last 300 seconds output rate: 0 bytes/sec, 0 packets/sec
Input: 0 bytes, 0 packets
Output: 0 bytes, 0 packets
```

Table 10-99 Description of the display traffic-statistics vsi command output

Item	Description
vsi-name	VSI name.
Peer-address	IP address of the remote peer.
Negotiation-vc-id	VC ID of the PW.
Statistics last cleared	Last time when statistics are cleared.
Last 300 seconds input rate	Rate of incoming traffic in the last 300 seconds.
Last 300 seconds output rate	Rate of outgoing traffic in the last 300 seconds.
Input	Number of packets received by the PW from the AC.
Output	Number of packets sent from the PW to the AC.

10.7.17 display traffic-statistics vsi peer

Function

The **display traffic-statistics vsi peer** command displays the statistics about the public traffic on a VPLS PW in a specified VSI.

Format

display traffic-statistics vsi *vsi-name* **peer** *peer-address*

Parameters

Parameter	Description	Value
vsi-name	Specifies the name of a specified VSI.	The value is an existing VSI.
peer-address	Specifies the peer IP address of the PW.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After the VPLS network is configured, you can run the **display traffic-statistics vsi peer** command to view the statistics about the traffic on the PW.

Precautions

- Currently, this command only displays the statistics about the traffic on the Martini VPLS PWs in the VSI.
- Within five minutes, if a PW goes Down, traffic before the PW is Down cannot be used to compute the traffic rate in the five minutes.

Example

Display the statistics about the outgoing traffic on the specified VPLS PW.

```
<HUAWEI> display traffic-statistics vsi newvsi peer 10.22.33.20
vsi-name: newvsi
Peer-address: 10.22.33.20
Negotiation-vc-id: 2
Statistics last cleared: never
Last 300 seconds input rate : 0 bytes/sec, 0 packets/sec
Last 300 seconds output rate: 0 bytes/sec, 0 packets/sec
Input: 0 bytes, 0 packets
Output: 0 bytes, 0 packets
```

Table 10-100 Description of the display traffic-statistics vsi peer command output

Item	Description
vsi-name	VSI name.
Peer-address	IP address of the remote peer.
Negotiation-vc-id	VC ID of the PW.
Statistics last cleared	Last time when statistics are cleared.
Last 300 seconds input rate	Rate of incoming traffic in the last 300 seconds.
Last 300 seconds output rate	Rate of outgoing traffic in the last 300 seconds.
Input	Number of packets received by the PW from the AC.
Output	Number of packets sent from the PW to the AC.

10.7.18 display traffic-statistics vsi peer ldp129

Function

The **display traffic-statistics vsi peer ldp129** command displays the statistics about the public traffic on a BGP-AD VPLS PW in a specified VSI.

Format

display traffic-statistics vsi *vsi-name* **peer** *peer-address* **ldp129**

Parameters

Parameter	Description	Value
vsi-name	Specifies the name of a VSI. The specified VSI must be a VSI of the BGP-AD VPLS.	The value is an existing VSI.
peer-address	Specifies the peer IP address of the PW.	-
ldp129	Specifies the statistics about the public traffic in the BGP-AD VPLS that uses LDP 129 signaling.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After the BGP-AD VPLS configuration is complete, you can run the **display traffic-statistics vsi peer ldp129** command to view the statistics about the traffic on the PW.

Prerequisites

The following operations have been performed before this command is used:

1. The BGP-AD VPLS has been configured.
2. The traffic statistics function has been enabled using the **traffic-statistics enable (VSI-BGPAD view)** command or the **traffic-statistics peer enable (VSI-BGPAD)** command in the VSI-BGPAD view.

Precautions

- The **display traffic-statistics vsi peer ldp129** command only displays the statistics about the traffic on the PW in the BGP-AD VPLS.

- Within five minutes, if a PW goes Down, traffic before the PW is Down cannot be used to compute the traffic rate in the five minutes.

Example

Display the statistics about the public traffic on the specified PW in the BGP-AD VPLS.

```
<HUAWEI> display traffic-statistics vsi vplsad1 peer 10.22.33.20 ldp129
vsi-name: vplsad1
Peer-address: 10.22.33.20
Statistics last cleared: never
Last 300 seconds input rate : 0 bytes/sec, 0 packets/sec
Last 300 seconds output rate: 0 bytes/sec, 0 packets/sec
Input: 0 bytes, 0 packets
Output: 0 bytes, 0 packets
```

Table 10-101 Description of the display traffic-statistics vsi peer ldp129 command output

Item	Description
vsi-name	VSI name.
Peer-address	IP address of the peer device.
Statistics last cleared	Last time when statistics are cleared.
Last 300 seconds input rate	Rate of incoming traffic in the last 300 seconds.
Last 300 seconds output rate	Rate of outgoing traffic in the last 300 seconds.
Input	Number of packets received by the PW from the AC.
Output	Number of packets sent from the PW to the AC.

10.7.19 display traffic-statistics vsi peer negotiation-vc-id

Function

The **display traffic-statistics vsi peer negotiation-vc-id** command displays the statistics about the public traffic on the Martini VPLS PW in a specified VSI.

Format

display traffic-statistics vsi *vsi-name* **peer** *peer-address* **negotiation-vc-id** *vc-id*

Parameters

Parameter	Description	Value
vsi-name	Specifies the name of a specified VSI.	The value is an existing VSI.
peer-address	Specifies the peer IP address of the PW.	-
vc-id	Specifies the VC ID of the PW.	The value is an integer that ranges from 1 to 4294967295.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After the Martini VPLS network is configured, you can run the **display traffic-statistics vsi peer negotiation-vc-id** command to view the statistics about the traffic on the PW.

Prerequisites

The following operations have been performed before this command is used:

1. The Martini VPLS has been configured.
2. The traffic statistics function has been enabled using the **traffic-statistics enable (VSI-LDP view)** command or the **traffic-statistics peer enable** command in the VSI-LDP view.

Precautions

- Currently, this command only displays the statistics about the traffic on the Martini VPLS PWs in the VSI.
- Within five minutes, if a PW goes Down, traffic before the PW is Down cannot be used to compute the traffic rate in the five minutes.

Example

Display the statistics about the traffic on the specified Martini VPLS PW.

```
<HUAWEI> display traffic-statistics vsi newvsi peer 10.22.33.20 negotiation-vc-id 2
vsi-name: newvsi
Peer-address: 10.22.33.20
Negotiation-vc-id: 2
Statistics last cleared: never
Last 300 seconds input rate : 0 bytes/sec, 0 packets/sec
Last 300 seconds output rate: 0 bytes/sec, 0 packets/sec
```

```
Input: 0 bytes, 0 packets
Output: 0 bytes, 0 packets
```

Table 10-102 Description of the display traffic-statistics vsi peer negotiation-vc-id command output

Item	Description
vsi-name	VSI name.
Peer-address	IP address of the remote peer.
Negotiation-vc-id	VC ID of the PW.
Statistics last cleared	Last time when statistics are cleared.
Last 300 seconds input rate	Rate of incoming traffic in the last 300 seconds.
Last 300 seconds output rate	Rate of outgoing traffic in the last 300 seconds.
Input	Number of packets received by the PW from the AC.
Output	Number of packets sent from the PW to the AC.

10.7.20 display traffic-statistics vsi peer remote-site

Function

The **display traffic-statistics vsi peer remote-site** command displays the statistics about the public traffic on the Kompella VPLS PW in a specified VSI.

Format

display traffic-statistics vsi *vsi-name* **peer** *peer-address* **remote-site** *site-id*

Parameters

Parameter	Description	Value
vsi-name	Specifies the name of a specified VSI.	The value is an existing VSI.
peer-address	Specifies the peer IP address of the PW.	-
site-id	Specifies the remote site ID.	The value is an integer that ranges from 0 to 65534.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After the Kompella VPLS network is configured, you can run the **display traffic-statistics vsi peer remote-site** command to view the statistics about the traffic on the PW.

Prerequisites

The following operations have been performed before this command is used:

1. The Kompella VPLS has been configured.
2. The traffic statistics function has been enabled using the **traffic-statistics peer remote-site enable (Kompella)** command in the VSI-BGP view.

Precautions

- The Kompella VPLS PW is uniquely identified by the user-defined VSI name, the next-hop IP address, and the remote site value.
- Within five minutes, if a PW goes Down, traffic before the PW is Down cannot be used to compute the traffic rate in the five minutes.

Example

Display the statistics about the traffic on the specified Kompella VPLS PW.

```
<HUAWEI> display traffic-statistics vsi newvsi peer 10.22.33.20 remote-site 2
vsi-name: newvsi
Peer-address: 10.22.33.20
Negotiation-vc-id: 2
Statistics last cleared: never
Last 300 seconds input rate : 0 bytes/sec, 0 packets/sec
Last 300 seconds output rate: 0 bytes/sec, 0 packets/sec
Input: 0 bytes, 0 packets
Output: 0 bytes, 0 packets
```

Table 10-103 Description of the display traffic-statistics vsi peer remote-site command output

Item	Description
vsi-name	VSI name.
Peer-address	IP address of the remote peer.
Remote-site-id	Remote Site ID.
Statistics last cleared	Last time when statistics are cleared.
Last 300 seconds input rate	Rate of incoming traffic in the last 300 seconds.
Last 300 seconds output rate	Rate of outgoing traffic in the last 300 seconds.

Item	Description
Input	Number of packets received by the PW from the AC.
Output	Number of packets sent from the PW to the AC.

10.7.21 display vpls connection

Function

The **display vpls connection** command displays the VPLS connection.

Format

display vpls connection [**ldp** | **bgp** | **bgp-ad** | **vsi** *vsi-name*] [**down** | **up**] [**verbose**]

Parameters

Parameter	Description	Value
ldp	Displays information about LDP signaling connections.	-
bgp	Displays information about BGP signaling connections.	-
bgp-ad	Displays information about BGP AD signaling connections.	-
vsi *vsi-name*	Displays information about connections of the specified VSI.	The value is an existing VSI.
down	Displays information about connections in Down state.	-
up	Displays information about connections in Up state.	-
verbose	Displays detailed information about connections.	-

Usage Guidelines

Usage Scenario

After VPLS services are configured, you can run the **display vpls connection** command with different keywords or parameters to view information about specific VPLS connections.

Prerequisites

One of the following operations has been performed before the **display vpls connection** command is used:

- Configuring Kompella VPLS
- Configuring Martini VPLS
- Configuring BGP AD VPLS

Precautions

If no keyword or parameter is specified, information about all VPLS connections in Up state is displayed.

Example

Display information about the connections of all VSIs.

```
<HUAWEI> display vpls connection

2 total connections,
connections: 2 up, 0 down, 1 ldp, 1 bgp, 0 bgpad

VSI Name: a2                          Signaling: ldp
VsiID      EncapType              PeerAddr         InLabel   OutLabel  VCState
2          vlan                  3.3.3.9          1026      1025      up
VSI Name: bgp1                          Signaling: bgp
SiteID     RD                    PeerAddr         InLabel   OutLabel  VCState
2          168.1.1.2:1            3.3.3.9          35842     35841     up
```

Table 10-104 Description of the display vpls connection command output

Item	Description
VSI Name	Name of the VSI. To set the value, run the **vsi** command.
Signaling	Signaling mode: ldp, bgp, bgpad or ldp bgpad. To set the value, run the **pwsignal** or **bgp-ad** command.
VsiID	VSI ID. To set the value, run the **vsi-id** command.

Item	Description
EncapType	VPLS encapsulation type of the VSI, namely, the encapsulation type of the packets transmitted over the VC. To set the value, run the **encapsulation** command.
PeerAddr	IP addresses of the peer.
InLabel	VC label distributed locally.
OutLabel	Local outgoing label, namely, the VC label distributed by the peer.
VCState	Status of the VC.
SiteID	Site ID of the remote VSI. To set the value, run the **site** command.
RD	RD used for identifying a VSI on the PE in the VPLS using BGP signaling. To set the value, run the **route-distinguisher** command.

Display the detailed information about all VSI connections.

```
<HUAWEI> display vpls connection verbose
VSI Name: a2                              Signaling: ldp
  **Remote Vsi ID   : 2
    VC State        : up
    Encapsulation   : vlan
    Group ID        : 0
    MTU             : 1500
    Peer Ip Address : 3.3.3.9
    PW Type         : label
    Local VC Label  : 1026
    Remote VC Label : 1025
    Tunnel Policy   : --
    Tunnel ID       : 0x1
VSI Name: bgp1                             Signaling: bgp
  **Remote Site ID     : 2
    VC State           : up
    RD                 : 168.1.1.2:1
    Encapsulation      : vlan
    MTU                : 1500
    Peer Ip Address    : 3.3.3.9
    PW Type            : label
    Local VC Label     : 35842
    Remote VC Label    : 35841
    Tunnel Policy      : --
    Tunnel ID          : 0x1
    Remote Label Block : 35840/5/0
    Export vpn target  : 100:1
```

Table 10-105 Description of the display vpls connection verbose command output

Item	Description
VSI Name	Name of the VSI. To set the value, run the **vsi** command.
Signaling	Signaling mode: ldp, bgp, bgpad or ldp bgpad.
Remote Vsi ID	Remote VSI ID that is consistent with the local VSI ID.
VC State	Status of the VC, which can be Up or Down.
Encapsulation	VPLS encapsulation type of the VSI, namely, the encapsulation type of the packets transmitted over the VC. The encapsulation type is VLAN or Ethernet. To set the value, run the **encapsulation** command.
Group ID	Group identifier.
MTU	Maximum transmission unit. To set the value, run the **mtu** command.
Peer Ip Address	IP addresses of the peer.
PW Type	Type of the PW.
Local VC Label	Local VC label.
Remote VC Label	Remote VC label.
Tunnel Policy	Tunnel policy that is used by the L2VPN.
Tunnel ID	Tunnel ID.
Remote Label Block	Remote label block.
Export vpn target	Outbound extended community attribute to the target VPN.

Display the detailed information about connections of a VSI named **bgp1**

```
<HUAWEI> display vpls connection vsi bgp1 verbose
VSI Name: bgp1                            Signaling: bgp
  **Remote Site ID     : 2
    VC State           : up
    RD                 : 168.1.1.2:1
    Encapsulation      : vlan
    MTU                : 1500
    Peer Ip Address    : 3.3.3.9
    PW Type            : label
    Local VC Label     : 35842
    Remote VC Label    : 35841
    Tunnel Policy      : --
    Tunnel ID          : 0x1
    Remote Label Block : 35840/5/0
    Export vpn target  : 100:1
```

Table 10-106 Description of the display vpls connection vsi vsi-name verbose command output

Item	Description
VSI Name	Name of the VSI.
Signaling	Signaling mode: ldp, bgp, bgpad or ldp bgpad.
Remote Site ID	the Site ID of remote peer.
VC State	Status of the VC.
RD	Local router distinguisher.
Encapsulation	VPLS encapsulation type of the VSI, namely, the encapsulation type of the packets transmitted over the VC.
MTU	Maximum transmission unit.
Peer Ip Address	IP addresses of the peer.
PW Type	Type of the PW.
Local VC Label	VC label distributed locally.
Remote VC Label	VC label distributed by the peer.
Tunnel Policy	Tunnel policy.
Tunnel ID	Tunnel ID.
Remote Label Block	Remote label block.
Export vpn target	Outbound extended community attribute to the target VPN.

Display information about BGP AD VPLS connections with peers.

```
<HUAWEI> display vpls connection bgp-ad

1 total bgpad connections ,
connections: 1 up, 0 down

VSI Name: vplsad1                     Signaling: bgpad
VPLS ID             EncapType      PeerAddr        InLabel   OutLabel  VCState
168.1.1.1:1         vlan           3.3.3.9         1027      1026      up
```

Table 10-107 Description of the display vpls connection bgp-ad command output

Item	Description
VSI Name	Name of the VSI.

Item	Description
Signaling	VPLS signaling mode: - ldp - bgp - bgpad - ldp bgpad
VPLS ID	Identifier of a BGP AD VPLS domain.
EncapType	VPLS encapsulation type of the VSI, namely, the encapsulation type of the packets transmitted over the VC: - VLAN - Ethernet
PeerAddr	IP addresses of the peer.
InLabel	VC label distributed locally.
OutLabel	Local outgoing label, namely, the VC label distributed by the peer.
VCState	Status of the VC. - up - down

Display detailed information about BGP AD connections of the VSIs that are in Up state.

```
<HUAWEI> display vpls connection bgp-ad up verbose
VSI Name: vplsad1                         Signaling: bgpad
  **VPLS ID          : 168.1.1.1:1
    VC State         : up
    Encapsulation    : vlan
    Group ID         : 0
    MTU              : 1500
    Peer Ip Address : 3.3.3.9
    PW Type          : label
    Local VC Label  : 1027
    Remote VC Label : 1026
    Tunnel Policy   : --
```

Table 10-108 Description of the display vpls connection bgp-ad up verbose command output

Item	Description
VSI Name	Name of the VSI.

Item	Description
Signaling	VPLS signaling mode: - ldp - bgp - bgpad - ldp bgpad
VPLS ID	Identifier of a BGP AD VPLS domain.
Encapsulation	VPLS encapsulation type of the VSI, namely, the encapsulation type of the packets transmitted over the VC: - VLAN - Ethernet
Group ID	Group identifier
MTU	Maximum transmission unit.
Peer Ip Address	IP addresses of the peer.
Local VC Label	VC label distributed locally.
Remote VC Label	Local outgoing label, namely, the VC label distributed by the peer.
Tunnel Policy	Name of a tunnel policy used by the VPLS.

10.7.22 display vpls forwarding-info

Function

The **display vpls forwarding-info** command displays forwarding information of all VSIs.

Format

display vpls forwarding-info [**vsi** *vsi-name* [**peer** *peer-address* [**negotiation-vc-id** *vc-id* | **remote-site** *site-id*]] | **state** { **up** | **down** }] [**verbose**]

Parameters

Parameter	Description	Value
vsi *vsi-name*	Displays forwarding information of a specified VSI.	The value is an existing VSI.

Parameter	Description	Value
peer *peer-address*	Specifies the peer IP address of the PW.	The value is in dotted decimal notation.
negotiation-vc-id *vc-id*	Specifies the VC ID of the PW.	The value is an integer that ranges from 1 to 4294967295.
remote-site *site-id*	Specifies the remote site ID.	The value is an integer that ranges from 0 to 65534.
state	Displays the forwarding information about VSIs based on the PW status.	-
up	Displays the forwarding information about the VSIs whose PWs are in Up state.	-
down	Displays the forwarding information about the VSIs whose PWs are in Down state.	-
verbose	Displays detailed forwarding information of the VSI.	-

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After the VPLS is configured, you can run the **display vpls forwarding-info** command to view the forwarding information of all VSIs.

Prerequisites

One of the following operations has been performed before the **display vpls forwarding-info** command is used:

- Configuring Kompella VPLS
- Configuring Martini VPLS
- Configuring BGP AD VPLS

Precautions

- The **display vpls forwarding-info vsi** *vsi-name* command is used to display forwarding information of a specified VSI (in Martini mode or Kompella mode).
- The **display vpls forwarding-info vsi** *vsi-name* **peer** *peer-address* [**negotiation-vc-id** *vc-id*] command is used to display forwarding information of a specified PW in the Martini VSI.
- The **display vpls forwarding-info vsi** *vsi-name* **peer** *peer-address* **remote-site** *site-id* command is used to display forwarding information about a specified PW in the Kompella VSI.

Example

Display brief forwarding information of all PWs in all VSIs.

```
<HUAWEI> display vpls forwarding-info
Total Number   : 2,        2  up,  0  down

Vsi-Name                       PeerIP          VcOrSiteId  PwState
a2                           3.3.3.9         2           UP
vplsad1                        3.3.3.9         0           UP
```

Display brief information about the VSI PWs in Up state.

```
<HUAWEI> display vpls forwarding-info state up
Total Number   : 2,        2  up,  0  down

Vsi-Name                       PeerIP          VcOrSiteId  PwState
a2                           3.3.3.9         2           UP
vplsad1                        3.3.3.9         0           UP
```

Table 10-109 Description of the display vpls forwarding-info command output

Item	Description
Total Number	The number of VSI.
Vsi-Name	Name of the VSI.
PeerIP	Peer IP address of the PW in the VSI.
VcOrSiteId	● VSI ID for the Martini VSI. ● Site ID for the Kompella VSI.
PwState	PW status: ● Up ● Down

Display detailed forwarding information of all PWs in all VSIs.

```
<HUAWEI> display vpls forwarding-info verbose
Total Number   : 2,        2  up,  0  down

**Vsi-Name      : a2
  Vsi Index     : 0                          PwState      : UP
  Peer IP       : 3.3.3.9                    VcOrSiteId   : 2
  InVcLabel     : 1026                         OutVcLabel   : 1025
  BroadTunnelID : 0x1                            OutInterface : Vlanif1025
```

```
  MainPwToken   : 0x1                         SlavePwToken : 0x0

  InVcLabel     : 1036                      OutVcLabel   : 1031
  BroadTunnelID : 0x1                         OutInterface : Vlanif1025
  MainPwToken   : 0x1                         SlavePwToken : 0x0
  NKey          : 0x9                    CKey          : 0x1b
```

Table 10-110 Description of the display vpls forwarding-info verbose command output

Item	Description
Total Number	The number of VSI.
Vsi-Name	Name of the VSI.
Vsi Index	VSI index.
PwState	PW status: ● Up ● Down
Peer IP	Peer IP address of the PW in the VSI.
VcOrSiteId	● VSI ID for the Martini VSI. ● Site ID for the Kompella VSI.
InVcLabel	Incoming label of the VC.
OutVcLabel	Outgoing label of the VC.
BroadTunnelID	ID of the tunnel used for broadcast.
OutInterface	Outbound interface.
MainPwToken	Token of the master PW.
SlavePwToken	Token of the slave PW.

Item	Description
NKey	Network key. Each NKey corresponds to one peer + tunnel policy.
CKey	User key. Each CKey corresponds to a PW.

10.7.23 display vpls multicast-ping statistics

Function

The **display vpls multicast-ping statistics** command displays the statistics on the number of sent and received MFIB Ping packets.

Format

display vpls multicast-ping statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Using the **display vpls multicast-ping statistics** command, you can view the statistics on the number of MFIB Ping packets that are received and sent by the device since the last time the **reset vpls multicast-ping statistics** command was run.

Example

Display the statistics on the number of MFIB Ping packets.

```
<HUAWEI> display vpls multicast-ping statistics
Total sent: 5 packet(s)
Total received: 5 packet(s)
Vpls Mfib-ping echo request sent: 5 packet(s), received: 0 packet(s)
Vpls Mfib-ping echo reply sent: 0 packet(s), received: 5 packet(s)
```

Table 10-111 Description of the display vpls multicast-ping statistics command output

Item	Description
Total sent	Total number of sent packets.
Total received	Total number of received packets.
Vpls Mfib-ping echo request	Number of sent and received VPLS MFIB Ping Echo Request packets.
Vpls Mfib-ping echo reply	Number of sent and received VPLS MFIB Ping Echo Reply packets.

10.7.24 display vpls multicast-trace statistics

Function

The **display vpls multicast-trace statistics** command displays the statistics on the number of sent and received MFIB Trace packets.

Format

display vpls multicast-trace statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display vpls multicast-trace statistics** command to view the number of sent and received MFIB Trace packets since the last time the **reset vpls multicast-trace statistics** command is executed.

Example

Display the statistics on the number of MFIB Trace packets.

```
<HUAWEI> display vpls multicast-trace statistics
Total sent: 2 packet(s)
Total received: 2 packet(s)
Vpls Mfib-trace echo request sent: 2 packet(s), received: 0 packet(s)
Vpls Mfib-trace echo reply sent: 0 packet(s), received: 2 packet(s)
```

Table 10-112 Description of the display vpls multicast-trace statistics command output

Item	Description
Total sent	Total number of sent packets.
Total received	Total number of received packets.
Vpls Mfib-trace echo request	Number of sent and received VPLS MFIB Trace Echo Request packets.
Vpls Mfib-trace echo reply	Number of sent and received VPLS MFIB Trace Echo Reply packets.

10.7.25 display vpls-ping statistics

Function

The **display vpls-ping statistics** command displays the statistics on the number of sent and received VPLS MAC Ping packets.

Format

display vpls-ping statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Using the **display vpls-ping statistics** command, you can view the statistics on the number of sent and received VPLS MAC Ping packets on the device.

Example

Display the statistics on the number of VPLS MAC Ping packets.

```
<HUAWEI> display vpls-ping statistics
Vpls-ping statistics:
Total sent: 104797 packet (s)
Total received: 104792 packet (s)
vpls-ping request sent: 13 packet (s), received: 104784 packet (s)
vpls-ping reply sent: 104784 packet (s), received: 8 packet (s)
```

Table 10-113 Description of the display vpls-ping statistics command output

Item	Description
Total sent	Total number of sent VPLS MAC Ping packets.
Total received	Total number of received VPLS MAC Ping packets.
vpls-ping request sent	Number of sent VPLS Ping Request packets.
vpls-ping reply sent	Number of sent VPLS Ping Reply packets.

10.7.26 display vpls-trace statistics

Function

The **display vpls-trace statistics** command displays the statistics on the number of sent and received VPLS MAC Trace packets.

Format

display vpls-trace statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Using the **display vpls-trace statistics** command, you can view the statistics on the number of sent and received VPLS MAC Trace packets on the device.

Example

Display the statistics on the number of VPLS MAC Trace packets.

```
<HUAWEI> display vpls-trace statistics
Vpls-trace statistics:
Total sent : 4 packet (s)
Total received : 4 packet (s)
vpls-trace request sent: 4 packet (s), received: 0 packet (s)
vpls-trace reply sent: 0 packet (s), received: 4 packet (s)
```

Table 10-114 Description of the display vpls-trace statistics command output

Item	Description
Total sent	Total number of sent VPLS MAC Trace packets.
Total received	Total number of received VPLS MAC Trace packets.
vpls-trace request sent	Number of sent VPLS MAC Trace Request packets.
vpls-trace reply sent	Number of sent VPLS MAC Trace Reply packets.

10.7.27 display vsi

Function

The **display vsi** command displays information about a VSI.

Format

display vsi [**name** *vsi-name*] [**verbose**]

display vsi [**name** *vsi-name*] **peer-info** [**statistics**]

display vsi name *vsi-name* **peer-info** *peer-ip* [**verbose**]

Parameters

Parameter	Description	Value
name *vsi-name*	Displays the name of a specified VSI.	The value is an existing VSI.
verbose	Displays detailed information about the VSI.	-
peer-info	Displays detailed information or statistics about the PW status of peers.	-
statistics	Displays statistics about the PW status of peers.	-
peer-ip	Displays detailed information about the PW status of the peer with a specified IP address.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When you run the **display vsi** command:

- The **display vsi** command displays information about VSIs. By default, information of all VSIs is displayed.
- The **display vsi peer-info** command displays detailed information about the PW status of peers of all VSIs.
- The **display vsi name** *vsi-name* **peer-info** command displays detailed information about the PW status of peers to a specified VSI.
- The **display vsi name** *vsi-name* **peer-info** *peer-ip* command displays detailed information about the PW status of a specific peer to a specified VSI.
- The **display vsi peer-info statistics** command displays statistics about the PW status of peers of all VSIs.
- The **display vsi name** *vsi-name* **peer-info statistics** command displays statistics about the PW status of a specific peer to a specified VSI.

Example

Display information about the VSI named **a2**.

```
<HUAWEI> display vsi name a2
Vsi                   Mem    PW   Mac       Encap     Mtu   Vsi
Name                  Disc   Type Learn     Type      Value State
--------------------------------------------------------------------------
a2                    static ldp  unqualify vlan      1500  up
```

Display information about the hybrid VSI named **vsi1**.

```
<HUAWEI> display vsi name vsi1
Vsi                   Mem    PW    Mac       Encap     Mtu   Vsi
Name                  Disc   Type  Learn     Type      Value State
--------------------------------------------------------------------------
vsi1                  --     mixed unqualify vlan      1500  up
```

Table 10-115 Description of the **display vsi** command output

Item	Description
Vsi Name	Name of the VSI. To set the value, run the **vsi** command.
Mem Disc	Member discovery mode: ● static ● auto ● --

Item	Description
PW Type	PW type: - ldp - bgp - bgpad - mixed
Mac Learn	Mode of learning the MAC address.
Encap Type	Encapsulation type. - vlan - ethernet If the encapsulation types on both ends are different, run the **encapsulation** { **ethernet** | **vlan** } command in the VSI view to change the encapsulation type on one end to be the same as that on the other end.
Mtu Value	Maximum transmission unit. If the MTU values on both ends are different, run the **mtu** *mtu-value* command in the VSI view to change the MTU values on one end to be the same as that on the other end.
Vsi State	Status of the VSI: - up - down - *down

Display detailed information about all VSIs.

```

Table 10-116 Description of the **display vsi verbose** command output

Item	Description
VSI Name	Name of the VSI.
Administrator VSI	Whether the VSI is an administrator VSI: ● yes ● no
Isolate Spoken	Whether the forwarding isolation function is enabled: ● enable ● disable
VSI Index	Index of the VSI.
PW Signaling	Type of the PW signaling, which can be ldp, bgp, bgpad or ldp bgpad. To set the value, run the **pwsignal** or **bgp-ad** command.
Member Discovery Style	Member discovery mode, which can be auto or static.
PW MAC Learn Style	Mode of MAC address learning of the PW.

Item	Description
Encapsulation Type	VPLS encapsulation type of the VSI: - VLAN - Ethernet If the PW encapsulation types on both ends are different, run the **encapsulation** { **ethernet** | **vlan** } command in the VSI view to change the encapsulation type on one end to be the same as that on the other end.
MTU	Maximum transmission unit. If the MTU values on both ends are different, run the **mtu** *mtu-value* command in the VSI view to change the MTU values on one end to be the same as that on the other end.
Diffserv Mode	VSI QoS mode.
Mpls Exp	EXP priority in MPLS packets.
DomainId	ID of a domain.
Domain Name	Domain name.
Ignore AcState	Whether the **vpls ignore-ac-state** command is used to prevent the status of a VSI from being affected by the status of the Attachment Circuit (AC).
P2P VSI	A P2P VSI identifier, which can be: - enable: indicates that the VSI is a P2P VSI. - disable: indicates that the VSI is not a P2P VSI.
Create Time	Time when the VSI is created.
VSI State	Status of the VSI: - up - down - administratively down
BGP RD	Route distinguisher. The BGP RD is an identifier on the local device for identifying a VSI on the PE in BGP VPLS. This item is displayed only when the VPLS type is Kompella.
SiteID/Range/Offset	Site ID, site range (the number of sites), and initial site ID offset of the VSI on the local device. This item is displayed only when the VPLS type is Kompella.
Import vpn target	Inbound extended community attribute from the target VPN. This item is displayed only when the VPLS type is Kompella.

Item	Description
Export vpn target	Outbound extended community attribute to the target VPN. This item is displayed only when the VPLS type is Kompella.
Remote Label Block	Initial value, label range, and initial site ID offset of the remote label block. This item is displayed only when the VPLS type is Kompella.
Local Label Block	Initial value, label range, and initial site ID offset of the local label block. This item is displayed only when the VPLS type is Kompella.
VSI ID	VSI ID that is displayed only when the Martini VPLS is configured. If the VSI IDs or negotiation IDs on both ends are different, run the **vsi-id** *vsi-id* or **peer (VSI-LDP view)** command in the VSI-LDP view to change the VSI ID or negotiation ID on one end to be the same as that on the other end.
Peer Router ID	ID of the peer device. This item is displayed only when the VPLS type is Martini.
Negotiation-vc-id	VC ID for negotiation.
primary or secondary	Whether the PW is a primary PW or a secondary PW.
ignore-standby-state	Whether the PW ignores the secondary state sent from the peer device. yes: Ignore the secondary state sent from the peer device. no: Do not ignore the secondary state sent from the peer device.
VC Label	Label value of the VC. This item is displayed only when the VPLS type is Martini.
Peer Type	PW type of the peer, which can be Dynamic or Static. This item is displayed only when the VPLS type is Martini.
Session	Status of the session between the local end and its peer. The status can be Up or Down. This item is displayed only when the VPLS type is Martini.
Tunnel ID	Tunnel ID that is displayed only when the Martini VPLS is configured.
Broadcast Tunnel ID	Tunnel ID (for broadcast).
Broad BackupTunnel ID	ID of the selected backup broadcast tunnel.
CKey	Index of the public tunnel for VPN QoS.
NKey	Index of the public tunnel.

Item	Description
Stp Enable	Whether STP for PW is enabled: - 0: disabled - 1: enable
PwIndex	PW index.
Control Word	Whether the control word is enabled for the local end on the PW: - enable: The control word is enabled. - disable: The control word is disabled.
BFD for PW	Whether BFD is configured: - unavailable: not configured - available: configured - timeout: timeout period after which a BFD session fails to be established
Interface Name	Name of the interface bound to the VSI.
Access Port	Whether the interface supports the access-port attribute: - true: indicates that the interface supports the access-port attribute. - false: indicates that the interface does not support the access-port attribute.
State	Status of the AC bound to the VSI. - up - down
Last Up Time	Last time when the AC interface goes Up.
Total Up Time	Total time when the AC interface is Up.
PW Information	Information about the PW.
Peer Ip Address	IP addresses of the peer.
PW State	Status of the PW. - up - down - backup
Local VC Label	VC label distributed locally.
Remote VC Label	VC label distributed by the peer.

Item	Description
Remote Control Word	Whether the control word is enabled for the remote end on the PW: ● enable: The control word is enabled. ● disable: The control word is disabled.
PW Type	Type of the PW.
Local VCCV	Type of VCCV supported on the local device.
Remote VCCV	Type of VCCV supported on the remote device.
Tunnel ID	Tunnel ID.
Main PW Token	Token of the master PW.
Slave PW Token	Token of the slave PW.
Tnl Type	Type of a tunnel. ● LSP ● CR-LSP ● GRE ● Other
OutInterface	Outbound interface.
Backup OutInterface	Outbound interface of the selected backup broadcast tunnel.
PW Last Up Time	Last time when the PW goes Up.
PW Total Up Time	Total time when the PW is Up.

Table 10-117 Description of the **display vsi name bgp1 verbose** command output

Item	Description
VSI Name	Name of the VSI.
Administrator VSI	Whether the VSI is an administrator VSI: ● yes: It is an administrator VSI. ● no: It is not an administrator VSI.
Isolate Spoken	Whether the forwarding isolation function is enabled: ● enable ● disable
VSI Index	Index of the VSI.
PW Signaling	Type of the PW signaling, which can be ldp, bgp, bgpad or ldp bgpad.
Member Discovery Style	Member discovery mode, which can be auto or static.
PW MAC Learn Style	Mode of MAC address learning of the PW.

Item	Description
Encapsulation Type	VPLS encapsulation type of the VSI, namely, the encapsulation type of the packets transmitted over the VC: ● VLAN ● Ethernet If the PW encapsulation types on both ends are different, run the **encapsulation** { **ethernet** | **vlan** } command in the VSI view to change the encapsulation type on one end to be the same as that on the other end.
MTU	Maximum transmission unit. If the MTU values on both ends are different, run the **mtu** *mtu-value* command in the VSI view to change the MTU values on one end to be the same as that on the other end.
Diffserv Mode	VSI QoS mode.
Mpls Exp	EXP priority in MPLS packets.
DomainId	ID of a domain.
Domain Name	Domain name.
Ignore AcState	Whether the **vpls ignore-ac-state** command is used to prevent the status of a VSI from being affected by the status of the AC.
Create Time	Time when the VSI is created.
VSI State	Status of the VSI: ● up ● down ● administratively down
BGP RD	Route distinguisher. The BGP RD is an identifier on the local device for identifying a VSI on the PE in BGP VPLS. This item is displayed only when the VPLS type is Kompella.
SiteID/Range/Offset	Site ID, site range (the number of sites), and initial site ID offset of the VSI on the local device. This item is displayed only when the VPLS type is Kompella.
Import vpn target	Inbound extended community attribute from the target VPN.
Export vpn target	Outbound extended community attribute to the target VPN.

Item	Description
Local Label Block	Initial value, label range, and initial site ID offset of the local label block.

Display information about the BGP AD VSI named **vplsad1**.

```

Table 10-118 Description of the **display vsi name vplsad1 verbose** command output

Item	Description
PW Signaling	Type of the PW signaling, which can be ldp, bgp, bgpad or ldp bgpad.
Member Discovery Style	Member discovery mode: ● auto: indicates automatic member discovery. When creating a VSI on a Kompella VPLS network, configure **auto** in the **vsi** command. ● static: indicates static member discovery. When creating a VSI on a Martini VPLS network, configure **static** in the **vsi** command. ● --: When creating a VSI on a BGP AD VPLS network, do not configure the member discovery mode in the **vsi** command.
VPLS ID	Identifier for identifying a BGP AD VSI on various PEs.
RD	Route Distinguisher, which is the same as the VPLS ID in the BGP AD VSI.
SAII	Source Attachment Individual Identifier, which is a local IP address used during negotiation on the creation of a PW in the BGP AD VSI.
TAII	Target Attachment Individual Identifier, which is a remote IP address used during negotiation on the creation of a PW in the BGP AD VSI.

Display detailed information of PW status of peers to all VSIs.

```
<HUAWEI> display vsi peer-info

VSI Name: a2                                   Signaling: ldp
-------------------------------------------------------------------
Peer              Transport  Local      Remote      VC
Addr              VC ID/TAII  VC Label   VC Label    State
-------------------------------------------------------------------
10.3.3.9            2         1026       1025        up
```

Display detailed information of PW status of a specific peer to a specified VSI.

```
<HUAWEI> display vsi name a2 peer-info 10.3.3.9

VSI Name: a2                              Signaling: ldp
-----------------------------------------------------------------
Peer              Transport  Local      Remote      VC
Addr              VC ID/TAII  VC Label   VC Label    State
-----------------------------------------------------------------
10.3.3.9            2          1026       1025        up
```

Table 10-119 Description of the **display vsi peer-info** command output

Item	Description
Vsi Name	Name of the VSI.
Signaling	Signaling mode, which can be ldp, bgp, bgpad or ldp bgpad.
Peer Addr	IP addresses of the peer.
Transport VC ID/TAII	● VC ID for an LDP PW ● TAII for a BGP-AD PW
Local VC Label	VC label distributed locally.
Remote VC Label	VC label distributed by the peer.
VC State	Status of the PW. ● up ● down

Display statistics about PW status of peers to all VSIs.

```
<HUAWEI> display vsi peer-info statistics
Total Local Peers: 1          1 Up         0 Down
-------------------------------------------------------
Vsi Name                     Up Peers      Down Peers
-------------------------------------------------------
a2                          1             0
```

Display statistics about PW status of peers to a specified VSI.

```
<HUAWEI> display vsi name a2 peer-info statistics
Vsi Name                     Up Peers      Down Peers
-------------------------------------------------------
a2                          1             0
```

Table 10-120 Description of the **display vsi peer-info statistics** command output

Item	Description
Total Local Peers	Total number of remote peers to the local end, that is, total number of PWs.
Up	Total number of PWs in Up state.
Down	Total number of PWs in Down state.

Item	Description
Vsi Name	Name of the VSI.
Up Peers	Total number of PWs in Up state in a specified VSI.
Down Peers	Total number of PWs in Down state in a specified VSI.

10.7.28 display vsi bgp-ad

Function

The **display vsi bgp-ad** command displays the VPN targets of the local and remote devices in a BGP AD VPLS domain.

Format

display vsi bgp-ad { **export-vt** | **import-vt** | **remote-export-vt** }

Parameters

Parameter	Description	Value
export-vt	Displays local export VPN targets, namely, the export VPN targets of all local BGP AD VSIs.	-
import-vt	Displays local import VPN targets, namely, the import VPN targets of all local BGP AD VSIs.	-
remote-export-vt	Displays remote export VPN targets, namely, VPN targets received from BGP AD peers.	-

1: Monitoring level

Usage Guidelines

Usage Scenario

When you configure or debug BGP AD VPLS, you can run the **display vsi bgp-ad** command to check the correctness of VPN targets that are locally configured or sent from peers.

Prerequisites

BGP AD VPLS member information has been configured on the local or remote end.

Precautions

When you run the **display vsi bgp-ad** command:

- To view import VPN targets that are configured locally, specify **import-vt** in the command.
- To view export VPN targets that are configured locally, specify **export-vt** in the command.
- To view export VPN targets that are sent from peers, specify **remote-export-vt** in the command.

Example

Display local import VPN targets in a BGP AD VPLS domain.

```
<HUAWEI> display vsi bgp-ad import-vt
import vpn target list:
  100:1                 192.168.12.4:100       312:250
  192.168.120.220:53364  100:100               5.5.5.5:13
  312:250
```

Display local export VPN targets in a BGP AD VPLS domain.

```
<HUAWEI> display vsi bgp-ad export-vt
export vpn target list:
  100:1                 192.168.12.4:100       312:250
  192.168.120.220:53364  100:100               5.5.5.5:13
  312:250
```

Display remote export VPN targets in a BGP AD VPLS domain.

```
<HUAWEI> display vsi bgp-ad remote-export-vt
remote export vpn target list:
  100:1                 192.168.12.4:100       312:250
  192.168.120.220:53364  100:100               5.5.5.5:13
  312:250
```

Table 10-121 Description of the display vsi command output

Item	Description
import vpn target list	List of import VPN targets configured locally.
export vpn target list	List of export VPN targets configured locally.
remote export vpn target list	List of export VPN targets sent from remote BGP AD PEs.

10.7.29 display vsi bgp-ad remote

Function

The **display vsi bgp-ad remote** command displays information about a specified remote peer of a PE in a BGP AD VPLS domain.

Format

display vsi bgp-ad remote vpls-id *vpls-id*

Parameters

Parameter	Description	Value
vpls-id *vpls-id*	Specifies the VPLS ID of a remote peer.	A VPLS ID is in one of the following formats: • 16-bit AS number: a 32-bit user-defined number, for example, 1:3. The AS number ranges from 0 to 65535. The user-defined number ranges from 0 to 4294967295. The AS number and the user-defined number cannot both be 0. That is, a VPN target cannot be 0:0. • 32-bit IP address: a 16-bit user-defined number, for example, 192.168.122.15:1. The IP address ranges from 0.0.0.0 to 255.255.255.255. The user-defined number ranges from 0 to 65535. • Integral 4-byte AS number:2-byte user-defined number, for example, 65537:3. An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a VPN target cannot be 0:0. • 4-byte AS number in dotted notation:2-byte user-defined number, for example, 0.0:3 or 0.1:0. A 4-byte AS number in dotted notation is in the format of *x.y*, where *x* and *y* are integers that range from 0 to 65535. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a VPN target cannot be 0.0:0.

Usage Guidelines

When you configure or debug BGP AD VPLS, the **display vsi bgp-ad remote** command can be used to display information about a remote peer in a BGP AD VSI such as the VPLS ID, VSI ID, and ERT configured on that peer.

Example

Display information about a BGP AD peer with the VPLS ID of 10.1.1.1:1.

```
<HUAWEI> display vsi bgp-ad remote vpls-id 10.1.1.1:1
BGP AD Network Layer Reachability Information
----------------------------------------------
 *Peer            :3.3.3.9
  VPLS ID          :10.1.1.1:1
  VSI ID          :3.3.3.9
  VSI index        :2
  Export vpn target:100:1
----------------------------------------------
```

Table 10-122 Description of the display vsi bgp-ad remote command output

Item	Description
Peer	Peer IP address.
VPLS ID	VPLS ID configured on the remote peer. To set the value, run the **vpls-id** command.
VSI ID	VSI ID configured on the remote peer. To set the value, run the **vsi-id** command.
VSI index	Local VSI index matching BGP AD network layer reachability information sent by the remote peer.
Export vpn target	List of export VPN targets sent from the remote peer.

10.7.30 display vsi mac-withdraw loop-detect

Function

The **display vsi mac-withdraw loop-detect** command displays information about MAC withdraw loop detection.

Format

display vsi [**name** *vsi-name*] **mac-withdraw loop-detect**

Parameters

Parameter	Description	Value
name *vsi-name*	Specifies the name of a VSI.	The value is an existing VSI.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After you enable MAC withdraw loop detection, run the **display vsi mac-withdraw loop-detect** command to view information about MAC withdraw loop detection. If you specify **name** *vsi-name*, the command output shows information about MAC withdraw loop detection in a specified VSI. If you do not specify **name** *vsi-name*, the command output shows information about MAC withdraw loop detection in all VSIs.

Example

Display information about MAC withdraw loop detection in all VSIs.

```
<HUAWEI> display vsi mac-withdraw loop-detect
Total number of vsi detect loop is 2.
Support max hop 255.

Vsi name        : VSI1
Last loop type  : detect loop
Send peer       : 10.5.5.5
Receive peer    : 10.2.2.2
Last loop time  : 2012/10/26 11:35:59

Vsi name        : VSI2
Last loop type  : exceed max hop
Send peer       : 10.5.5.5
Receive peer    : 10.3.3.3
Last loop time  : 2012/10/26 11:35:59
```

Display information about MAC withdraw loop detection in VSI1.

```
<HUAWEI> display vsi name VSI1 mac-withdraw loop-detect
Vsi name        : VSI1
Last loop type  : detect loop
Send peer       : 10.5.5.5
Receive peer    : 10.2.2.2
Last loop time  : 2012/10/26 11:35:59
```

Table 10-123 Description of the **display vsi mac-withdraw loop-detect** command output

Item	Description
Total number of vsi detect loop	Number of MAC Withdraw message loops.
Support max hop 255	Indicates that the maximum number of hops supported by MAC Withdraw loop detection is 255.
Vsi name	Name of the VSI in which a MAC Withdraw message loop occurred.

Item	Description
Last loop type	Type of the MAC Withdraw message loop. The values are as follows: ● **detect loop**: The PE detects that a MAC Withdraw message loop occurs. ● **exceed max hop**: The number of hops for forwarding MAC Withdraw messages exceeds the maximum number of hops.
Send peer	Peer to which MAC Withdraw messages are sent.
Receive peer	Peer from which MAC Withdraw messages are received.
Last loop time	Time when the MAC Withdraw message loop occurs.

10.7.31 display vsi protect-group

Function

The **display vsi protect-group** command displays information about the PW protection group of a specified VSI.

Format

display vsi name *vsi-name* **protect-group** [*group-name* [**verbose** | **history**]]

Parameters

Parameter	Description	Value
name *vsi-name*	Specifies the VSI name.	The value is an existing VSI name.
group-name	Specifies the name of a PW protection group.	The value is an existing PW protection group.
verbose	Displays detailed information.	-
history	Displays historical switchover information about PWs in a PW protection group.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After a PW protection group is configured, you can run the **display vsi protect-group** command to view summary or detailed information about the PW protection group of a specified VSI and check whether PW configurations have taken effect. When maintaining a PW protection group, you can track the running status of the group by viewing historical switchover information about PWs in the group.

Prerequisites

A PW protection group has been created and the primary and secondary PWs have jointed the group.

Example

Display summary information about the PW protection group of VSI vsi1.

```
<HUAWEI> display vsi name vsi1 protect-group

Vsi name: vsi1
Protect group num: 1

Protect-group: vsi1
-------------------------------------------------------------------------------
PeerIp:VcId              Pref   Active
-------------------------------------------------------------------------------
3.3.3.3:10               2      Active
3.3.3.9:10               4      Inactive
```

Table 10-124 Description of the **display vsi protect-group** command output

Item	Description
Vsi name	VSI name.
Protect group num	Number of a PW protection group.
Protect-group	Name of a PW protection group.
PeerIp:VcId	Peer IP address of a PW:VC ID. This pair uniquely identifies a PW.
Pref	PW priority specified by running the **peer preference** command in the protect-group view.

Item	Description
Active	Forwarding status of a PW: ● Active: The PW can send service packets. ● Inactive: The PW cannot send service packets, but can send OAM packets if the PW is Up.

Display detailed information about the PW protection group group1 of VSI vsi1.

```
<HUAWEI> display vsi name vsi1 protect-group group1 verbose

Vsi name           : vsi1
Protect group      : group1
Protect mode       : PW redundancy master
Reroute policy     : delay 30s
Last change time   : 2012/11/27 11:11:55
Last change action : 3.3.3.9:10 to 3.3.3.3:10
Last change reason : config changed
Holdoff remain time: --
Reroute remain time: --

Members            :
 PeerIp:VcId                Pri/Sec   Active

 3.3.3.3:10                 Primary   Active
 3.3.3.9:10                 Secondary Inactive
```

Table 10-125 Description of the **display vsi protect-group** command output

Item	Description
Protect mode	PW redundancy mode of a PW protection group: PW redundancy master: The PW redundancy mode is master/slave.
Reroute policy	Revertive switching policy of a PW protection group. The default revertive switching delay is 30s. In master/ slave mode, you can modify the revertive switching policy by running the **reroute** command in the protect-group view.
Last change time	Last PW switching time.
Last change action	Last PW switching action. A PW is uniquely identified by peerIP:VcID.

Item	Description
Last change reason	Reason for last PW switching: ● manual force switch: The PW switching is triggered by the **protect-switch force** command. ● manual clear switch: The PW switching is triggered by the **protect-switch clear** command. ● config changed: The PW switching is triggered by configuration changes such as PW addition, PW deletion, or PW priority changes. ● fault detected: The PW switching is triggered by failures detected by BFD or VCCV. ● PW down: The PW switching occurs because the active PW goes Down. ● PW up: The PW switching occurs because the active PW goes Up again.
Holdoff remain time	Remaining time before a switching is performed. **NOTE** If the value is **--**, no switching delay is configured.
Reroute remain time	Remaining time before a revertive switching is performed. **NOTE** If the value is **--**, no revertive switching delay is configured.
Members	Displays members in a PW protection group.
Pri/Sec	Primary/secondary status of a PW: ● Primary: The PW is a primary PW. ● Secondary: The PW is a secondary PW.

Display historical switchover information about PWs in PW protection group group1 of VSI vsi1.

```
<HUAWEI> display vsi name vsi1 protect-group group1 history

Vsi name      : vsi1
Protect group : group1

Date/Time     : 2012/11/27 11:05:40
Action        : 3.3.3.9:10 to 3.3.3.3:10
Reason        : manual clear switch

Date/Time     : 2012/11/27 11:06:29
Action        : 3.3.3.3:10 to 3.3.3.9:10
Reason        : manual force switch

Date/Time     : 2012/11/27 11:06:48
Action        : 3.3.3.9:10 to 3.3.3.3:10
Reason        : PW down

Date/Time     : 2012/11/27 11:11:31
Action        : 3.3.3.3:10 to 3.3.3.9:10
Reason        : PW up
```

```
Date/Time     : 2012/11/27 11:11:55
Action        : 3.3.3.9:10 to 3.3.3.3:10
Reason        : config changed
```

Table 10-126 Description of the **display vsi protect-group history** command output

Item	Description
Date/Time	PW switching time. For example, 2011-08-09 16:31:32 indicates that PW switching occurred on 16:31:32 of August 9, 2011.
Action	PW switching action. A PW is uniquely identified by peerIP:VcID.
Reason	Reason for PW switching: ● manual force switch: The PW switching is triggered by the **protect-switch force** command. ● manual clear switch: The PW switching is triggered by the **protect-switch clear** command. ● config changed: The PW switching is triggered by configuration changes such as PW addition, PW deletion, or PW priority changes. ● fault detected: The PW switching is triggered by failures detected by BFD or VCCV. ● PW down: The PW switching occurs because the active PW goes Down. ● PW up: The PW switching occurs because the active PW goes Up again.

10.7.32 display vsi pw out-interface

Function

The **display vsi pw out-interface** command displays information about the outgoing interface of a VSI PW.

Format

display vsi pw out-interface [**vsi** *vsi-name*]

Parameters

Parameter	Description	Value
vsi *vsi-name*	Specifies the name of a VSI.	The value is an existing VSI.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run the **display vsi pw out-interface** command to view information about the actual outgoing interface of the PW.

Precautions

This command applies to the Martini VPLS PW and BGP-AD VPLS PW.

Example

Display information about the outgoing interface of the VSI PW.

```
<HUAWEI> display vsi pw out-interface
Total: 2
--------------------------------------------------------------------------------
Vsi Name                        peer           vcid       interface
--------------------------------------------------------------------------------
a2                          3.3.3.9         2         Vlanif1025

vplsad1                       3.3.3.9         --         Vlanif1025
```

Table 10-127 Description of the display vsi pw out-interface command output

Item	Description
Vsi Name	VSI name.
peer	VSI peer.
vcid	VC ID.
interface	Outgoing interface of a VSI PW.

10.7.33 display vsi remote

Function

The **display vsi remote** command displays information about a remote VSI.

Format

display vsi remote ldp [**router-id** *ip-address*] [**pw-id** *pw-id*]

display vsi remote bgp [**nexthop** *nexthop-address* [**export-vpn-target** *vpn-target*] | **route-distinguisher** *route-distinguisher*]

display vsi remote ldp129 [**vpls-id** *vpls-id* [**router-id** *ip-address*]]

display vsi remote fec129 [**vpls-id** *vpls-id* [**router-id** *ip-address*]] [**verbose**]

display vsi remote ldp verbose

Parameters

Parameter	Description	Value
ldp	Displays information about remote VSIs using LDP signaling.	-
bgp	Displays information about remote VSIs using BGP signaling.	-
ldp129	Displays information about remote VSIs using LDP 129 signaling.	-
fec129	Displays information about remote VSIs using FEC 129 signaling.	-
vpls-id *vpls-id*	Specifies the ID of a VPLS domain to which multiple VSIs on PEs belong.	The *vpls-id* value has four formats. For details, see **Table 10-128**.
router-id *ip-address*	Displays the information about the remote VSIs of the specified peer. *ip-address* specifies an IPv4 address of the peer.	The value is in dotted decimal notation. If you set the **router id** parameter to 255.255.255.255, the remote VSIs of all peers are displayed.
pw-id *pw-id*	Displays the information about the remote VSIs of the specified PW. *pw-id* specifies the ID of a VC, which uniquely identifies a VC.	The value is an integer that ranges from 1 to 4294967295.
nexthop *nexthop-address*	Displays the label block sent by the remote end according to the next hop address of the label block.	The value is in dotted decimal notation.

Parameter	Description	Value
export-vpn-target *vpn-target*	Displays the label block sent by the remote end according to the next hop address of the label block and the route attributes in the outgoing direction.	The value is a string that ranges from 3 to 21.
route-distinguisher *route-distinguisher*	Displays the label block sent by the remote end according to the RD.	RD is short for route distinguisher. The *route-distinguisher* value has four formats. For details, see **Table 10-128**.
verbose	Display detailed information about the remote VSIs.	-

Table 10-128 Values of *vpls-id* and *route-distinguisher*

vpls-id and *route-distinguisher* Value Format	Value	Example
16-bit AS number:32-bit user-defined number	An AS number ranges from 0 to 65535, and a user-defined number ranges from 0 to 4294967295. The AS number and user-defined number cannot be both 0. That is, a VPLS ID or RD cannot be 0:0.	101:3
Integral 4-byte AS number:2-byte user-defined number	An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a VPLS ID or RD cannot be 0:0.	65537:3
4-byte AS number in dotted notation:2-byte user-defined number. A 4-byte AS number in dotted notation is in the format of *x.y*	The *x* and *y* are integers that range from 1 to 65535 and from 0 to 65535, respectively. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a VPLS ID or RD cannot be 0.0:0.	0.0:3 or 0.1:0
32-bit IP address:16-bit user-defined number	An IPv4 address ranges from 0.0.0.0 to 255.255.255.255, and a user-defined number ranges from 0 to 65535.	192.168.122.15:1

Usage Guidelines

To view information about remote VSIs, configure one of the following parameters in the **display vsi remote** command:

- Run the **display vsi remote ldp** command on a Martini VPLS network.
- Run the **display vsi remote bgp** command on a Kompella VPLS network.
- Run the **display vsi remote ldp129** or **display vsi remote fec129** command on a BGP AD VPLS network.

Example

Display information about the remote VSIs using LDP signaling.

```
<HUAWEI> display vsi remote ldp
Vsi       Peer          VC      Group   Encap      MTU    Vsi    State
ID        RouterID        Label   ID      Type       Value  Index  Code
2         10.3.3.9       1025     0       vlan       1500   0      FORWARD
```

Table 10-129 Description of the display vsi remote ldp command output

Item	Description
Vsi ID	ID of the VSI.
Peer RouterID	Peer IP address.
VC Label	VC label.
Group ID	Group ID.
Encap Type	PW encapsulation type: ● vlan ● ethernet
MTU Value	MTU value.
Vsi Index	Index of the VSI.

Item	Description
State Code	Remote state code: - FORWARD: indicates that forwarding is supported. - NO FORWARD: indicates that forwarding is not supported. - STANDBY: indicates the secondary PW. - AC FAULT: indicates that the peer AC interface is faulty. - PSN FAULT: indicates that a fault occurs on the public network between the local end and peer end. - -: indicates that the interworking mode negotiated between two devices is Martini.

Display information about the remote VSIs using BGP signaling.

```
<HUAWEI> display vsi remote bgp
   Total Number       : 1
 **BGP RD             : 10.1.1.2:1
   Ref Number         : 1
   NextHop            : 10.3.3.9
   EncapType          : vlan
   MTU                : 1500
   Export vpn target  : 100:1
   SiteID             : 2
   Remote Label Block : 100001/5/0
```

Table 10-130 Description of the display vsi remote bgp command output

Item	Description
Total Number	Number of the remote VSIs using BGP signaling.
BGP RD	RD of the local VSI.
Ref Number	Serial number of the remote VSI.
NextHop	Next hop address.
EncapType	Encapsulation type: - vlan - ethernet
MTU	Maximum transmission unit.
Export vpn target	RT in the outgoing direction.
SiteID	Site ID of the remote VSI.
Remote Label Block	Remote label block.

Display information about the remote VSIs using LDP 129 signaling.

```
<HUAWEI> display vsi remote fec129
Codes: C(Control word), A(Alert), T(TTL), P(LSP-Ping), B(BFD)
      S(Support), N(No support)
--------------------------------------------------------------------------------
VPLS        Peer      VC        Source    Encap          MTU   VSI   VCCV
ID          RouterID  Label     AII       Type           Value Index |C|A|T|P|B|
--------------------------------------------------------------------------------
10.1.1.1:1  10.3.3.9  1026      10.3.3.9  vlan           1500  2     |N|S|N|S|N|
```

Table 10-131 Description of the display vsi remotefec129 command output

Item	Description
VPLS ID	VPLS ID of the VSI.
VCCV	Supported VCCV detection types.

Display detailed information about remote VSIs using LDP signaling.

```
<HUAWEI> display vsi remote ldp verbose
Total remote VSI : 1

VSI ID            : 2
VSI Index         : 0
VC Type           : vlan
VC Label          : 1025
Peer Address      : 10.3.3.9
Group ID          : 0
MTU               : 1500
Status Code       : FORWARD
Match Local VC    : MATCH
Control Word      : disable
```

Table 10-132 Description of the display vsi remote ldp verbose command output

Item	Description
Total remote VSI	Total number of remote VSIs.
VSI ID	ID of a remote VSI.
VSI Index	Index of a remote VSI.
VC Type	Remote VC encapsulation type.
VC Label	Remote VC label.
Peer Address	Remote peer address.
Group ID	Remote group ID. The default value is 0.
MTU	MTU of a remote VC.

Item	Description
Status Code	Status of a remote VC: ● FORWARD: The remote VC is in the forwarding state. ● STANDBY: The remote VC is in the standby state. ● AC FAULT: The remote AC interface is faulty. ● PSN FAULT: The remote VC is faulty. ● NO FORWARD: The remote VC cannot forward packets owing to other reasons.
Match Local VC	Whether a VC matching the remote VC ID exists on the local end: ● MATCH: A VC matching the remote VC ID exists on the local end. ● NOT-MATCH: No VC matching the remote VC ID exists on the local end.
Control Word	Whether the control word is enabled: ● enable: The control word is enabled. ● disable: The control word is disabled.

10.7.34 display vsi services

Function

The **display vsi services** command displays information about the AC interface associated with the VSI.

Format

display vsi services { **all** | *vsi-name* | **interface** *interface-type interface-number* | **vlan** *vlan-id* }

Parameters

Parameter	Description	Value
all	Displays the information about AC interfaces associated with all VSIs.	-
vsi-name	Displays the information about AC interfaces associated with the specified VSI.	The value is an existing VSI.

Parameter	Description	Value
interface *interface-type* *interface-number*	Specifies the type and number of the AC interface associated with the VSI. ● *interface-type* specifies the type of the interface. ● *interface-number* specifies the number of the interface.	-
vlan *vlan-id*	Displays information about the specified VLAN AC interface associated with the VSI.	The value is an integer that ranges from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display vsi services** command displays status of the AC interface associated with the VSI, and can be used for fault diagnosis.

Example

Display information about the AC interfaces associated with all VSIs.

```
<HUAWEI> display vsi services all
Total: 2
Code: AS(Admin Status), PS(Physical Status)
------------------------------------------------------------------------------
Interface                      Vsi Name                      AS    PS
------------------------------------------------------------------------------
GigabitEthernet0/0/1               1                            up    up
Vlanif1024                      a2                         up    up
------------------------------------------------------------------------------
```

Display information about the AC interface associated with the VSI named **a2**.

```
<HUAWEI> display vsi services a2
Total: 1
Code: AS(Admin Status), PS(Physical Status)
------------------------------------------------------------------------------
Interface                      Vsi Name                      AS    PS
------------------------------------------------------------------------------
Vlanif1024                      a2                         up    up
------------------------------------------------------------------------------
```

Display information about the GE0/0/1 interface associated with the VSI.

```
<HUAWEI> display vsi services interface gigabitethernet0/0/1
Total: 1
Code: AS(Admin Status), PS(Physical Status)
------------------------------------------------------------------------------
Interface                      Vsi Name                      AS    PS
------------------------------------------------------------------------------
```

```
GigabitEthernet0/0/1              1                          down  up
-------------------------------------------------------------------------------
```

Display information about the AC interface in VLAN 1024 associated with the VSI.

```
<HUAWEI> display vsi services vlan 1024
Total: 1
Code: AS(Admin Status), PS(Physical Status)
-------------------------------------------------------------------------------
Interface                       Vsi Name                   AS    PS
-------------------------------------------------------------------------------
Vlanif1024                       a2                        up    up
-------------------------------------------------------------------------------
```

Table 10-133 Description of the display vsi services command output

Item	Description
Interface	Name of the interface.
Vsi Name	Name of the VSI that is bound to the interface.
AS	Status of the VSI that is bound to the interface: ● up: indicates that the VSI is in Up state. ● down: indicates that the VSI is in Down state. ● *down: indicates that the VSI status is AdminDown.
PS	Physical status of the interface: ● up: indicates that the physical status of the interface is Up. ● down: indicates that the physical status of the interface is Down.

10.7.35 display vsi statistics

Function

The **display vsi statistics** command displays VSI statistics, including the PW and AC status.

Format

display vsi name *vsi-name* **statistics**

Parameters

Parameter	Description	Value
name *vsi-name*	Specifies the name of a VSI.	The value is an existing VSI.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To check the statistics of a specified VSI, including its PW and AC status, run the **display vsi statistics** command.

Example

Display the statistics of a VSI named **vsi1**.

```
<HUAWEI> display vsi name vsi1 statistics

 VSI Name               : vsi1
 VSI State              : up
 PW                     : 1 up, 0 down, 1 backup
 BFD for PW             : 0 up, 0 down
 AC                     : 1 up, 0 down, 0 AC OAM down
 Ignore AcState         : disable
```

Table 10-134 Description of the **display vsi statistics** command output

Item	Description
VSI Name	VSI name
VSI State	VSI status
PW	Number of PWs in each state
BFD for PW	Number of PWs (tracked by BFD) in each state
AC	Number of ACs in each state
Ignore AcState	Whether the function to ignore AC status is enabled

10.7.36 encapsulation (VSI view)

Function

The **encapsulation** command configures the encapsulation type of the interface in the VSI view.

The **undo encapsulation** command restores the encapsulation type of the interface to the default setting.

By default, the encapsulation type is VLAN.

Format

encapsulation { **ethernet** | **vlan** }

undo encapsulation ethernet

Parameters

Parameter	Description	Value
ethernet	Indicates that the encapsulation type is Ethernet.	-
vlan	Indicates the VLAN encapsulation format that meets the 802.1Q standard.	-

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When you configure the VPLS function, run the **encapsulation** command to configure the encapsulation type of the interface.

Prerequisites

The following operations must have been performed before this command is used:

- The **pwsignal bgp** command and the **route-distinguisher** *route-distinguisher* command have been executed for Kompella VPLS.
- The **pwsignal ldp** command and the **vsi-id** *vsi-id* command have been executed for Martini VPLS.
- The **bgp-ad** command and the **vpls-id** *vpls-id* command have been executed for BGP AD VPLS.

Example

Configure the encapsulation type of the current VSI as Ethernet.

```
<HUAWEI> system-view
[HUAWEI] vsi a2 static
[HUAWEI-vsi-a2] pwsignal ldp
[HUAWEI-vsi-a2-ldp] vsi-id 101
[HUAWEI-vsi-a2-ldp] quit
[HUAWEI-vsi-a2] encapsulation ethernet
```

10.7.37 encapsulation rfc4761-compatible

Function

The **encapsulation rfc4761-compatible** command enables a device to comply with RFC 4761 to encapsulate Kompella VPLS packets.

The **undo encapsulation rfc4761-compatible** command restores the default encapsulation type of Kompella VPLS packets.

By default, Kompella VPLS packets use the Huawei proprietary encapsulation type. Huawei defines 4 for VLAN encapsulation and 5 for Ethernet encapsulation for Kompella VPLS.

Format

encapsulation rfc4761-compatible

undo encapsulation rfc4761-compatible

Parameters

None

Views

VSI-BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

RFC 4761 defines that the encapsulation type of Kompella VPLS packets is 19. Huawei defines 4 for VLAN encapsulation and 5 for Ethernet encapsulation for Kompella VPLS. Therefore, the encapsulation type of Kompella VPLS packets needs to be modified when Huawei devices communicate with non-Huawei devices.

When the device sends Kompella VPLS packets, run the **encapsulation rfc4761-compatible** command to enable the device to modify the encapsulation type of Kompella VPLS packets from Type 4 or 5 to Type 19. When the device receives Kompella VPLS packets, the device modifies the encapsulation type of Kompella VPLS packets from Type 19 to Type 4 or 5 automatically without running any command.

NOTE

When the device works as a PE, the encapsulation type is determined by the CE access mode. If the CE accesses the PE in VLAN mode, the PE encapsulates packets sent by the CE in Type 4. If the CE accesses the PE in Ethernet mode, the PE encapsulates packets sent by the CE in Type 5. VLAN and Ethernet modes are described as follows:

- VLAN: Ethernet frames transmitted between the CE and PE are attached with a VLAN tag. The tag is a service delimiter required by an ISP to differentiate clients. It is also called P-tag.
- Ethernet: Ethernet frames transmitted between the CE and PE do not have a service delimiter. If the header of Ethernet frames carries a VLAN tag, this tag is the inner VLAN tag of user packets, and is of no use to the PE. It is also called U-tag.

Precautions

The **encapsulation rfc4761-compatible** command is only used for Huawei and non-Huawei devices to communicate with each other.

Example

Enable the device to comply with RFC 4761 to encapsulate Kompella VPLS packets.

```
<HUAWEI> system-view
[HUAWEI] vsi bgp1
[HUAWEI-vsi-bgp1] pwsignal bgp
[HUAWEI-vsi-bgp1-bgp] encapsulation rfc4761-compatible
```

10.7.38 flow-label (VSI-LDP view)

Function

The **flow-label** command enables flow label-based load balancing for a VSI.

The **undo flow-label** command disables flow label-based load balancing of a VSI.

By default, flow label-based load balancing for a VSI is disabled.

NOTE

Only the S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6730S-H, and S6730-H support this command.

Format

flow-label { **both** | **send** | **receive** } [**static**]

undo flow-label [{ **both** | **send** | **receive** } [**static**]]

Parameters

Parameter	Description	Value
both	Enables flow label-based load balancing for outgoing traffic and incoming traffic.	-

Parameter	Description	Value
send	Enables flow label-based load balancing for outgoing traffic.	-
receive	Enables flow label-based load balancing for incoming traffic.	-
static	Statically configures flow label-based load balancing. For dynamic PWs, if **static** is not configured, the flow label-based load balancing capability of the local end is negotiated by the remote end. For static PWs, the flow label-based load balancing capability is statically configured, irrespective of whether **static** is configured.	-

Views

VSI-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When multiple links exist between P devices on a PW, to improve L2VPN traffic forwarding efficiency and ease the forwarding burden on P devices, run the **flow-label** command to configure flow label-based load balancing. After flow label-based load balancing is enabled on a PE, the PE adds different flow labels for different L2VPN data flows to distinguish the data flows. After a P device receives a data packet carrying a flow label, it selects a forwarding path based on the flow label in the data packet. This processing implements load balancing.

To enable flow label-based load balancing for all PWs in a VSI, run the **flow-label** command in the VSI-LDP view.

Prerequisites

MPLS L2VPN has been enabled.

Precautions

Flow label-based load balancing can be enabled only when any of the following conditions is true:

- The **receive** parameter is configured on the local PE, and the **send** parameter is configured on the remote PE.
- The **send** parameter is configured on the local PE, and the **receive** parameter is configured on the remote PE.
- Both the **send** and **receive** parameters are configured on the local and remote PEs.

If the static flow label-based load balancing configuration does not match on both ends, the device discards packets carrying a flow label, causing packet loss.

Example

Enable flow label-based load balancing for Martini VPLS.

```
<HUAWEI> system-view
[HUAWEI] vsi 1 static
[HUAWEI-vsi-1] pwsignal ldp
[HUAWEI-vsi-1-ldp] flow-label both
```

10.7.39 flow-label (VSI-LDP-PW view)

Function

The **flow-label** command enables flow label-based load balancing for an L2VPN PW.

The **undo flow-label** command disables flow label-based load balancing of an L2VPN PW.

The **flow-label disable** command disables flow label-based load balancing of an L2VPN PW.

The **undo flow-label disable** command restores flow label-based load balancing of an L2VPN PW.

By default, if flow label-based load balancing is enabled for a VSI, the PWs in this VSI also have flow label-based load balancing enabled; if flow label-based load balancing is disabled for a VSI, the PWs in this VSI also have flow label-based load balancing disabled.

NOTE

Only the S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6730S-H, and S6730-H support this command.

Format

flow-label { **both** | **send** | **receive** } [**static**]

undo flow-label [{ **both** | **send** | **receive** } [**static**]]

flow-label disable

undo flow-label disable

Parameters

Parameter	Description	Value
both	Enables flow label-based load balancing for outgoing traffic and incoming traffic.	-
send	Enables flow label-based load balancing for outgoing traffic.	-
receive	Enables flow label-based load balancing for incoming traffic.	-

Parameter	Description	Value
static	Statically configures flow label-based load balancing. For dynamic PWs, if **static** is not configured, the flow label-based load balancing capability of the local end is negotiated by the remote end. For static PWs, the flow label-based load balancing capability is statically configured, irrespective of whether **static** is configured.	-

Views

VSI-LDP-PW view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an L2VPN carrying service traffic, when multiple links exist between Ps, flow label-based load balancing can be configured to improve traffic forwarding efficiency and reduce the forwarding pressure on the Ps. After flow label-based load balancing is enabled on a PE, the PE adds different flow labels for different L2VPN data flows to distinguish the data flows. After a P device receives a data packet carrying a flow label, it selects a forwarding path based on the flow label in the data packet. This processing implements load balancing.

To enable flow label-based load balancing for VLL PWs or PWE3 PWs, run the **flow-label** command in the PW template view, and specify the configured PW template when creating VLL PWs or PWE3 PWs.

- If flow label-based load balancing is configured for both a VSI and a PW in this VSI, the configuration of the PW takes precedence.
- If the **undo flow-label** command is run in the VSI-LDP-PW view, only the flow label-based load balancing capability that has been configured using the **flow-label** command in the VSI-LDP-PW view is disabled.
- If the **flow-label** command has been run for a VSI but not for a PW, you can run the **flow-label disable** command in the VSI-LDP-PW view to disable flow label-based load balancing of the PW. If the PW needs the flow label-based load balancing capability again, you can run the **undo flow-label disable** command to restore flow label-based load balancing.

Prerequisites

MPLS L2VPN has been enabled.

Precautions

Flow label-based load balancing can be enabled only when any of the following conditions is true:

- The **receive** parameter is configured on the local PE, and the **send** parameter is configured on the remote PE.

- The **send** parameter is configured on the local PE, and the **receive** parameter is configured on the remote PE.
- Both the **send** and **receive** parameters are configured on the local and remote PEs.

If the static flow label-based load balancing configuration does not match on both ends, the device discards packets carrying a flow label, causing packet loss.

Example

Enable flow label-based load balancing for a PW.

```
<HUAWEI> system-view
[HUAWEI] vsi 1 static
[HUAWEI-vsi-1] pwsignal ldp
[HUAWEI-vsi-1-ldp] pw p1
[HUAWEI-vsi-1-ldp-pw-p1] flow-label both
```

Disable flow label-based load balancing for the PW **pw1**.

```
<HUAWEI> system-view
[HUAWEI] vsi 1 static
[HUAWEI-vsi-1] pwsignal ldp
[HUAWEI-vsi-1-ldp] flow-label send
[HUAWEI-vsi-1-ldp] peer 1.1.1.1
[HUAWEI-vsi-1-ldp] peer 1.1.1.1 pw pw1
[HUAWEI-vsi-1-ldp-pw-pw1] flow-label disable
```

10.7.40 holdoff (protect-group view)

Function

The **holdoff** command configures a switching delay for a PW protection group with the master/slave PW redundancy mode.

The **undo holdoff** command deletes the switching delay for a PW protection group with the master/slave PW redundancy mode.

By default, no switching delay is configured for a PW protection group with the master/slave PW redundancy mode. In this situation, if a fault occurs on the primary PW, traffic immediately switches from the primary PW to the secondary PW.

Format

holdoff *holdoff-time*

undo holdoff

Parameters

Parameter	Description	Value
holdoff-time	Specifies the switching delay.	The value is an integer ranging from 1 to 180, in seconds.

Views

protect-group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, if a working path fails, traffic immediately switches to the protection path. If the working path flaps or an error occurs in the detection mechanism, traffic frequently switches between the working and protection paths. If you want to avoid this problem in a PW protection group with the master/slave PW redundancy mode, run the **holdoff** command to configure a switching delay. If the working path recovers before the specified switching delay expires, traffic does not switch to the protection path. If the working path remains faulty after the specified switching delay expires, traffic switches to the protection path.

Prerequisites

The PW redundancy mode of the PW protection group is master/slave.

Precautions

If the **holdoff** command is run multiple times, the latest configuration overrides the previous ones.

After you configure a switching delay, traffic forwarded during the delay period will be interrupted if the primary PW fails to recover before the delay period expires.

A PW protection group with the independent PW redundancy mode does not support delayed switching.

NOTE

On a VPLS network that uses BFD for fault detection, traffic immediately switches from the primary PW to the secondary PW after BFD detects a fault on the primary PW, no matter whether delayed switching is configured. It is recommended that you determine whether to use BFD or delayed switching based on your actual network requirements.

Example

Configure a switching delay of 60s for a PW protection group.

```
<HUAWEI> system-view
[HUAWEI] vsi vsi1
[HUAWEI-vsi-vsi1] pwsignal ldp
[HUAWEI-vsi-vsi1-ldp] protect-group group1
[HUAWEI-vsi-vsi1-ldp-protect-group-group1] protect-mode pw-redundancy master
[HUAWEI-vsi-vsi1-ldp-protect-group-group1] holdoff 60
```

10.7.41 hub-mode enable

Function

The **hub-mode enable** command sets the VSI attribute of an AC interface to hub.

The **undo hub-mode enable** command sets the VSI attribute of an AC interface to spoke.

By default, the VSI attribute of an AC interface is hub.

NOTE

Only the S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6730S-H and S6730-H support this command.

Format

hub-mode enable

undo hub-mode enable

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **isolate spoken** command is run in the VSI view, forwarding isolation is enabled on AC interfaces in a VSI, and all AC interfaces in this VSI have their VSI attribute set to spoke. If one AC interface wants to communicate with other AC interfaces in the same VSI, run the **hub-mode enable** command on this AC interface to set its VSI attribute to hub.

Prerequisites

Interfaces have been bound to a VSI instance by running the **l2 binding** command.

Example

Set the VSI attribute of VLANIF100 to hub.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] quit
```

```
[HUAWEI] vsi v100 static
[HUAWEI-vsi-v100] pwsignal ldp

```

10.7.42 ignore-ac-state

Function

The **ignore-ac-state** command enables a VSI to retain in Up state regardless of the Attachment Circuit (AC) state.

The **undo ignore-ac-state** command restores the default setting.

By default, the VSI state changes with the AC state.

Format

ignore-ac-state

undo ignore-ac-state

Parameters

None

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

To verify whether a VSI can work normally on the new network before a VPLS network migration, run the **ignore-ac-state** command in the VSI view on the new device. This command enables the VSI to retain in Up state on the new device before the AC-side device is connected to the new device. When the AC interface is Down and the PW is Up, the VSI is Up. When the AC interface is Up and the PW is Down, the VSI is still Up.

Example

Enable a VSI to retain in Up state regardless of the AC state.

```
<HUAWEI> system-view
[HUAWEI] vsi vsi1
[HUAWEI-vsi-vsi1] pwsignal ldp
[HUAWEI-vsi-vsi1-ldp] vsi-id 2
[HUAWEI-vsi-vsi1-ldp] quit
[HUAWEI-vsi-vsi1] ignore-ac-state
```

10.7.43 ignore-mtu-match (VSI view)

Function

The **ignore-mtu-match** command enables the device to ignore the MTU matching check and re-encapsulate the sent VPLS packets.

The **undo ignore-mtu-match** command disables the device from ignoring the MTU matching check and re-encapsulating the sent VPLS packets.

By default, the device does not ignore the MTU matching check or re-encapsulate sent VPLS packets.

Format

ignore-mtu-match

undo ignore-mtu-match

Parameters

None

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In the communication in Kompella mode with devices of other vendors, you can use the **ignore-mtu-match** command to ignore the MTU check for VSIs if the devices of other vendors do not support the check. By default, the PE device checks whether MTUs of the VSIs on both ends are matched. If the MTUs of the VSIs on two ends are different, the VC cannot go Up.

As defined by the latest RFC, the encapsulation type of PW in the Kompella VPLS is 19. Huawei devices support only the Ethernet encapsulation and VLAN encapsulation. In the communication in Kompella mode with devices of other vendors, you can use the **ignore-mtu-match** command if the devices of other vendors require to receive a VPLS packet with the encapsulation type as 19. After the **ignore-mtu-match command** is run, the sent VPLS packet adopts encapsulation type 19.

Prerequisites

The following operations have been performed before this command is used:

1. BGP has been configured as the PW signaling protocol using the **pwsignal bgp** command.
2. The RD of the VSI has been configured using the **route-distinguisher** *route-distinguisher* command.

Precautions

- This command is valid only for the VPLS in Kompella mode and does not take effect in the VPLS in Martini mode. In the Martini VPLS, the MTU values of the VSIs on two ends must be the same.
- Huawei devices can interwork with devices of other vendors only when the **ignore-mtu-match** command is used together with the **vpls bgp encapsulation** command.

Example

Disable the MTU matching check of a VSI named **bgp1** and use encapsulation type 19 for the sent VPLS packet so that a Huawei device is connected to devices of other vendors.

```
<HUAWEI> system-view
[HUAWEI] vsi bgp1 auto
[HUAWEI-vsi-bgp1] pwsignal bgp
[HUAWEI-vsi-bgp1-bgp] route-distinguisher 100:1
[HUAWEI-vsi-bgp1-bgp] quit
[HUAWEI-vsi-bgp1] ignore-mtu-match
```

10.7.44 ignore-stp-loopcheck

Function

The **ignore-stp-loopcheck** command disables STP loop detection function of PW, that is, the PW that cannot be blocked by STP.

The **undo ignore-stp-loopcheck** command restores the default configuration.

By default, STP loop detection is enabled for the PW.

Format

ignore-stp-loopcheck

undo ignore-stp-loopcheck

Parameters

None

Views

VSI-LDP-PW view

Default Level

2: Configuration level

Usage Guidelines

After STP loop detection is enabled, a PW may be blocked when an STP loop is detected. If you do not want a PW to be blocked upon an STP loop, you can run this command to disable STP loop detection.

Example

Disable STP loop detection function of the PW named pw1.

```
<HUAWEI> system-view
[HUAWEI] vsi aa static
[HUAWEI-vsi-aa] pwsignal ldp
[HUAWEI-vsi-aa-ldp] vsi-id 1
[HUAWEI-vsi-aa-ldp] peer 1.1.1.1
[HUAWEI-vsi-aa-ldp] peer 1.1.1.1 pw pw1
[HUAWEI-vsi-aa-ldp-pw-pw1] ignore-stp-loopcheck
```

10.7.45 ingress-lsp protect-mode

Function

The **ingress-lsp protect-mode** command configures the protection mode for BGP ingress LSPs.

The **undo ingress-lsp protect-mode** command restores the default setting.

By default, no protection mode is configured for BGP ingress LSPs.

Format

ingress-lsp protect-mode bgp-frr

undo ingress-lsp protect-mode

Parameters

Parameter	Description	Value
bgp-frr	Configures the protection mode for BGP ingress LSPs to BGP Auto FRR.	-

Views

BGP view, BGP-IPv4 unicast address family view

Default Level

2: Configuration level

Usage Guidelines

To protect the links between the PE and its dual-homed ASBRs and the ASBRs themselves in the same AS, you can configure the protection mode of BGP Auto FRR.

Before configuring the protection mode of BGP Auto FRR, enable the BGP Auto FRR function.

It is recommended that the selection of labeled BGP IPv4 routes be based on the **bestroute nexthop-resolved tunnel** command.

Example

Configure the protection mode of BGP Auto FRR for BGP ingress LSPs.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] ingress-lsp protect-mode bgp-frr
```

10.7.46 interface-parameter-type vccv (VSI-LDP-PW view)

Function

The **interface-parameter-type vccv** command restores the default setting.

The **undo interface-parameter-type vccv** command deletes the VCCV byte right after the interface parameter in the Mapping packet.

By default, a mapping packet carries the VCCV byte.

Format

interface-parameter-type vccv

undo interface-parameter-type vccv

Parameters

None

Views

VSI-LDP-PW view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the switch communicates with the devices of VRP V300R001 and all branching versions, and the LDP VPLS is configured, run the **undo interface-parameter-type vccv** command.

Prerequisites

The following operations have been performed before this command is used:

1. LDP has been configured as the PW signaling protocol using the **pwsignal ldp** command.
2. The VSI ID has been configured using the **vsi-id** *vsi-id* command.
3. The peer of the VSI has been configured using the **peer** *peer-address* command.
4. The PW has been configured using the **peer** *peer-address* [**negotiation-vc-id** *vc-id*] **pw** *pw-name* command.

Example

When configuring the VPLS in LDP mode, delete the VCCV byte from the Mapping packet.

```
<HUAWEI1> system-view
[HUAWEI] vsi vsi1 static
[HUAWEI-vsi-vsi1] pwsignal ldp
[HUAWEI-vsi-vsi1-ldp] vsi-id 100
[HUAWEI-vsi-vsi1-ldp] peer 2.2.2.2
[HUAWEI-vsi-vsi1-ldp] peer 2.2.2.2 pw pw1
[HUAWEI-vsi-vsi1-ldp-pw-pw1] undo interface-parameter-type vccv
```

10.7.47 interface-status-change mac-withdraw enable

Function

The **interface-status-change mac-withdraw enable** command enables the PEs to send LDP MAC Withdraw messages to all peers when the status of the AC interface bound to the VSI changes.

The **undo interface-status-change mac-withdraw enable** command disables the PEs from sending LDP MAC Withdraw messages to all peers when the status of the AC interface bound to the VSI changes.

By default, a PE does not send LDP MAC Withdraw messages when the status of the AC interface bound to the VSI changes.

Format

interface-status-change mac-withdraw enable

undo interface-status-change mac-withdraw enable

Parameters

None

Views

VSI-LDP view, VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On enterprise networks, you can configure this command on the PE to enable the PE to update the MAC address entry when the AC link is in Down state. In this way, the PE connected to the SPE sends LDP MAC Withdraw messages to all peers when the status of the SPE-side interface changes.

Precautions

If the local end sends MAC-Withdraw messages, the remote VSI clears local MAC addresses and learns new MAC addresses.

After you run the **interface-status-change mac-withdraw enable** command, the PE sends LDP MAC-Withdraw messages to all peers if the status of the interface bound to the VSI changes:

- From Down to Up.
- From Up to Down.

The **interface-status-change mac-withdraw enable** takes effect only when the **mac-withdraw enable** is configured.

Example

Enable the PE to send LDP MAC Withdraw messages to all peers when the status of the AC interface bound to the VSI changes.

```
<HUAWEI> system-view
[HUAWEI] vsi v1 static
[HUAWEI-vsi-v1] pwsignal ldp
[HUAWEI-vsi-v1-ldp] interface-status-change mac-withdraw enable
```

10.7.48 isolate spoken

Function

The **isolate spoken** command enables forwarding isolation between AC interfaces in a VSI.

The **undo isolate spoken** command disables forwarding isolation between AC interfaces in a VSI.

By default, forwarding isolation between AC interfaces in a VSI is disabled.

NOTE

Only the S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6730S-H and S6730-H support this command.

Format

isolate spoken

undo isolate spoken

Parameters

None

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If multiple users are bound to the same VSI, you can use the **isolate spoken** command to enable forwarding isolation between AC interfaces. After this command is run, the VSI attribute of all AC interfaces in the VSI is spoke, preventing the users from communicating with each other.

Prerequisites

- For Martini VPLS, the **pwsignal ldp** and **vsi-id** *vsi-id* commands have been run.
- For Kompella VPLS, the **pwsignal bgp** and **route-distinguisher** *route-distinguisher* commands have been run.
- For BGP AD VPLS, the **bgp-ad** and **vpls-id** *vpls-id* commands have been run.

Example

Enable forwarding isolation between AC interfaces in a VSI in Martini VPLS.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] quit
[HUAWEI] vsi v100 static
[HUAWEI-vsi-v100] pwsignal ldp
[HUAWEI-vsi-v100-ldp] vsi-id 100
[HUAWEI-vsi-v100-ldp] quit
[HUAWEI-vsi-v100] isolate spoken
```

Enable forwarding isolation between AC interfaces in a VSI in Kompella VPLS.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] quit
```

```
[HUAWEI] vsi v101 auto
[HUAWEI-vsi-v101] pwsignal bgp
[HUAWEI-vsi-v101-bgp] route-distinguisher 100:1
[HUAWEI-vsi-v101-bgp] quit
[HUAWEI-vsi-v101] isolate spoken
```

Enable forwarding isolation between AC interfaces in a VSI in BGP AD VPLS.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] quit
[HUAWEI] vsi v102
[HUAWEI-vsi-v102] bgp-ad
[HUAWEI-vsi-v102-bgpad] vpls-id 100:2
[HUAWEI-vsi-v102-bgpad] quit
[HUAWEI-vsi-v102] isolate spoken
```

10.7.49 l2 binding

Function

The **l2 binding** command binds an interface to a VSI.

The **undo l2 binding** command unbinds an interface to a VSI.

By default, the interface is not bound to any VSI.

Format

l2 binding vsi *vsi-name*

undo l2 binding vsi *vsi-name*

Parameters

Parameter	Description	Value
vsi *vsi-name*	Specifies the name of the VSI to be bound with an interface.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In the VPLS, run the **l2 binding** command on the PE to bind the interface that is connected to the CE to the corresponding VSI.

Precautions

When an interface is bound to a VSI, the MTU can be configured in the interface view but does not take effect. The MTU configured in the VSI is used for PW MTU negotiation.

In the VPLS application, different CEs are transparently connected to each other in the same network segment of a LAN through VSIs, and the IP addresses of the CEs must be different.

NOTE

- If an interface is used as a VPLS AC-side interface and a multicast inbound interface at the same time, multicast data cannot be forwarded normally on this interface. (S5731-H, S5731-S, S5731S-S, S5731S-H, S5732-H, S6730S-H, S6730-S, S6730S-S, and S6730-H do not have this restriction.)
- If a sub-interface is bound to a VSI, you can delete the sub-interface only after unbinding it from the VSI.
- To use a 40GE, 100GE, XGE, 25GE, MultiGE, GE, or Eth-Trunk interface of the switch as an AC-side interface, run the **undo portswitch** command to change the interface to a Layer 3 interface before running the **l2 binding** command.
- Before running the **l2 binding** command on a sub-interface, add the main interface to a VLAN.
- The **l2 binding** command and the **ip address** command cannot be configured on the CE-side interface of the PE at the same time.
- If a main interface is bound to a VSI instance, the sub-interfaces of the main interface cannot be bound to the VSI instance. Similarly, if the sub-interface of a main interface is bound to a VSI instance, the main interface cannot be bound to the VSI instance.

Example

Bind a VLANIF interface to the VSI.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] l2 binding vsi company2
```

Bind a GigabitEthernet interface to a VSI.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] l2 binding vsi company2
```

10.7.50 l2vpn-ad-family

Function

The **l2vpn-ad-family** command displays the BGP L2VPN-AD address family view.

The **undo l2vpn-ad-family** command deletes all configurations in the BGP L2VPN-AD address family view.

Format

l2vpn-ad-family

undo l2vpn-ad-family

Parameters

None

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The BGP AD VPLS shares a TCP connection with the common BGP. Most BGP AD VPLS configurations are the same as the common BGP configurations. To exchange information about BGP AD VPLS members, enable peers to exchange information about VPLS members in the BGP L2VPN-AD address family view. Run the **l2vpn-ad-family** command to enter the BGP L2VPN-AD address family view.

Prerequisites

Generally, BGP peers need to be configured in the BGP view to implement the configuration of basic BGP functions.

Example

Enter the BGP L2VPN-AD address family view.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] l2vpn-ad-family
[HUAWEI-bgp-af-l2vpn-ad]
```

10.7.51 loop-detect enable

Function

The **loop-detect enable** command enables L2VPN loop detection on an interface.

The **undo loop-detect enable** command disables L2VPN loop detection on the interface.

By default, L2VPN loop detection is disabled on the interface.

Format

loop-detect enable

undo loop-detect enable

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Redundant links are used on an Ethernet switching network to provide link backup and enhance network reliability. The use of redundant links, however, may produce loops, causing broadcast storms and unstable MAC address entries. This degrades communication quality or even interrupts communication. On a traditional Layer 2 network, the Spanning Tree Protocol (STP) is usually used to prevent loops.

VPLS is an L2VPN technology providing LAN-like services over the MPLS network. It allows sites in diverse locations to connect the MPLS network and communicate with each other, which frees Ethernet LAN deployment from restrictions imposed by physical locations. As a Layer 2 Ethernet technology, VPLS has the following disadvantages:

- If the customer network leases multiple lines, loops may occur due to incorrect customer configuration or in other unexpected cases, leading to broadcast storms.
- If the customer network traverses a third-party network, loops may occur due to incorrect third-party network configuration or in other unexpected cases, leading to broadcast storms.

STP needs to be deployed on CEs, having high dependency on the customer network. The complex and changing features of the customer network increase the maintenance difficulty of the carrier.

To prevent loops on an L2VPN network, you can run the **loop-detect enable** command on an AC interface of a PE to configure L2VPN loop detection on the AC interface. After this function is enabled, when detecting a loop on the L2VPN network, the PE will automatically block an interface on the loop, report an alarm, and eliminate the loop.

Prerequisites

The interface has been bound to a VSI instance using the **l2 binding** command on the interface.

NOTE

- The interface must be an AC interface bound to a specified VSI. For details about the binding between an AC interface and a VSI, see **Binding VSIs to AC Interfaces**.

Example

Enable L2VPN loop detection on GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
```

```
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] l2 binding vsi company2
[HUAWEI-GigabitEthernet0/0/1] loop-detect enable
```

10.7.52 loop-detect detection pe-vid ce-vid

Function

The **loop-detect detection pe-vid ce-vid** command specifies a VLAN range to which a QinQ termination sub-interface sends L2VPN loop detection packets.

The **undo loop-detect detection pe-vid ce-vid** command deletes the VLAN range to which the QinQ termination sub-interface sends L2VPN loop detection packets.

By default, the QinQ termination sub-interface does not send L2VPN loop detection packets.

Format

loop-detect detection pe-vid *pe-vid* **ce-vid** *low-vid* [**to** *high-vid*]

undo loop-detect detection pe-vid *pe-vid* **ce-vid** *low-vid* [**to** *high-vid*]

Parameters

Parameter	Description	Value
pe-vid *pe-vid*	Specifies the outer VLAN ID in L2VPN loop detection packets sent by the QinQ termination sub-interface.	The value is an integer in the range of 2 to 4094.
ce-vid *low-vid*	Specifies the start inner VLAN ID in L2VPN loop detection packets sent by the QinQ termination sub-interface.	The value is an integer in the range of 1 to 4094.
high-vid	Specifies the end inner VLAN ID in L2VPN loop detection packets sent by the QinQ termination sub-interface.	The value is an integer in the range of 1 to 4094. The value of *high-vid* must be greater than that of *low-vid*.

Views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you run the **loop-detect enable** command to enable L2VPN loop detection on an interface, the QinQ termination sub-interface does not send L2VPN loop detection packets by default. You need to run the **loop-detect detection pe-vid ce-vid** command to configure the VLAN range to which the QinQ termination sub-interface sends L2VPN loop detection packets. After the VLAN range is configured, the device sends L2VPN loop detection packets to the specified VLANs. If a loop is detected in a VLAN, the sub-interface will stop sending L2VPN loop detection packets to all these VLANs.

Prerequisites

L2VPN loop detection has been enabled on the interface using the **loop-detect enable** command.

Example

Configure the QinQ termination sub-interface GigabitEthernet0/0/1.1 to send L2VPN loop detection packets to VLANs 2 to 10.

```
<HUAWEI> system-view
[HUAWEI] vcmp role silent
[HUAWEI] interface gigabitethernet
[HUAWEI-GigabitEthernet0/0/1] port link-type hybrid
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] interface gigabitethernet 0/0/1.1
[HUAWEI-GigabitEthernet0/0/1.1] qinq termination pe-vid 300 ce-vid 2 to 20
[HUAWEI-GigabitEthernet0/0/1.1] l2 binding vsi company2
[HUAWEI-GigabitEthernet0/0/1.1] loop-detect enable
[HUAWEI-GigabitEthernet0/0/1.1] loop-detect detection pe-vid 300 ce-vid 2 to 10
```

10.7.53 loop-detect detection vid

Function

The **loop-detect detection vid** command specifies a VLAN range to which a Dot1q termination sub-interface sends L2VPN loop detection packets.

The **undo loop-detect detection vid** command deletes the VLAN range to which the Dot1q termination sub-interface sends L2VPN loop detection packets.

By default, the Dot1q termination sub-interface does not send L2VPN loop detection packets.

Format

loop-detect detection vid *low-vid* [**to** *high-vid*]

undo loop-detect detection vid *low-vid* [**to** *high-vid*]

Parameters

Parameter	Description	Value
low-vid	Specifies the start VLAN ID in L2VPN loop detection packets sent by the Dot1q termination sub-interface.	The value is an integer in the range of 2 to 4094.
high-vid	Specifies the end VLAN ID in L2VPN loop detection packets sent by the Dot1q termination sub-interface.	The value is an integer in the range of 2 to 4094. The value of *high-vid* must be greater than that of *low-vid*.

Views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After L2VPN loop detection is enabled on an interface using the **loop-detect enable** command, the Dot1q termination sub-interface does not send L2VPN loop detection packets by default. You need to run the **loop-detect detection vid** command to configure the VLAN range to which the Dot1q termination sub-interface sends L2VPN loop detection packets. After the VLAN range is configured, the device sends L2VPN loop detection packets to the specified VLANs. If a loop is detected in a VLAN, the sub-interface will stop sending L2VPN loop detection packets to all these VLANs.

Prerequisites

L2VPN loop detection has been enabled on the interface using the **loop-detect enable** command.

Example

Configure the Dot1q termination sub-interface GigabitEthernet0/0/1.1 to send L2VPN loop detection packets to VLANs 3 to 10.

```
<HUAWEI> system-view
[HUAWEI] vcmp role silent
[HUAWEI] interface gigabitethernet
[HUAWEI-GigabitEthernet0/0/1] port link-type hybrid
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] interface gigabitethernet 0/0/1.1
[HUAWEI-GigabitEthernet0/0/1.1] dot1q termination vid 2 to 10
[HUAWEI-GigabitEthernet0/0/1.1] l2 binding vsi company2
```

```
[HUAWEI-GigabitEthernet0/0/1.1] loop-detect enable
[HUAWEI-GigabitEthernet0/0/1.1] loop-detect detection vid 3 to 10
```

10.7.54 loop-detect recovery-time

Function

The **loop-detect recovery-time** command specifies a period for restoring an interface to normal state.

The **undo loop-detect recovery-time** command restores the default period for restoring an interface to normal state.

By default, an AC interface restores a blocked interface every 15 seconds.

Format

loop-detect recovery-time *recovery-time*

undo loop-detect recovery-time

Parameters

Parameter	Description	Value
recovery-time *recovery-time*	Specifies a period for an AC interface to restore a blocked interface.	The value is an integer in the range of 15 to 255, in seconds. By default, the value is 15 seconds.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After an AC interface enabled with L2VPN loop detection detects a loop, a period can be specified for the AC interface to restore a blocked interface. That is, if a blocked interface does not receive any L2VPN loop detection packet within the period specified by *recovery-time*, it will be restored to normal state.

If a device is on multiple loops, interfaces on the device may alternate between blocked and normal states during the initial detection stage. To prevent interface status flapping, you are advised to set *recovery-time* to a larger value.

Prerequisites

L2VPN loop detection has been enabled on the interface using the **loop-detect enable** command.

Example

Configure the Dot1q termination sub-interface GigabitEthernet0/0/1.1 to restore a blocked interface every 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] vcmp role silent
[HUAWEI] interface gigabitethernet
[HUAWEI-GigabitEthernet0/0/1] port link-type hybrid
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] interface gigabitethernet 0/0/1.1
[HUAWEI-GigabitEthernet0/0/1.1] dot1q termination vid 1 to 10
[HUAWEI-GigabitEthernet0/0/1.1] l2 binding vsi company2
[HUAWEI-GigabitEthernet0/0/1.1] loop-detect enable
[HUAWEI-GigabitEthernet0/0/1.1] loop-detect recovery-time 20
```

10.7.55 local-mac remove all-but-mine

Function

The **local-mac remove all-but-mine** command enables a local provider edge (PE) device to delete user MAC address entries, except those entries associated with the PW that sends MAC Withdraw messages with the TLV type of 0x404.

The **undo local-mac remove all-but-mine** command restores the default configuration.

A PE removes all MAC addresses by default after receiving MAC Withdraw messages with the TLV type of 0x404.

Format

local-mac remove all-but-mine

undo local-mac remove all-but-mine

Parameters

None

Views

VSI view

Default Level

2: Configuration level

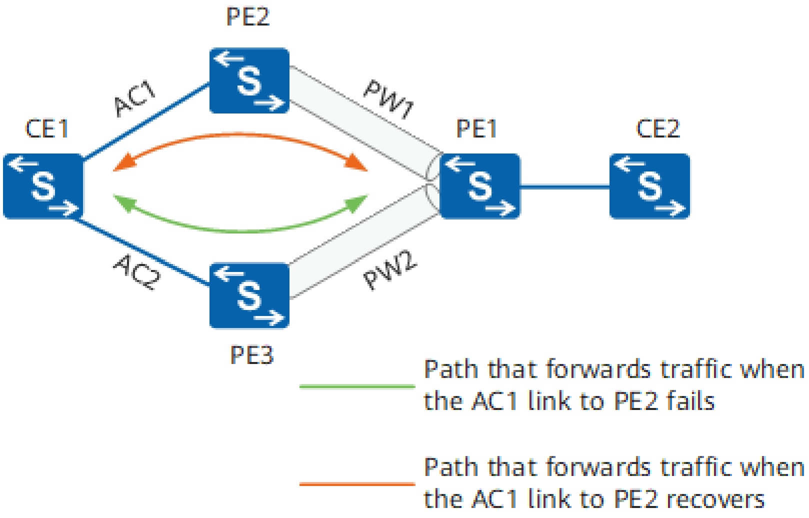
Usage Guidelines

Usage Scenario

A customer edge (CE) device is dual-homed to two PEs over pseudo wires (PWs) on a virtual private LAN service (VPLS) network. If a PE finds that an AC fault is removed, the PE sends MAC Withdraw messages with the TLV type of 0x404 to instruct a remote PE to update MAC address entries and perform a traffic switchover. For example, CE1 is connected to CE2 over primary PW1 and secondary PW2 on the network shown in **Figure 10-1**. After a fault in AC1 or PE2 is removed, PE2 sends to PE1 MAC Withdraw messages with the TLV type of 0x404 over PW1. After PE1 receives the messages, PE1 removes MAC addresses but retains those associated with PW1. The procedure complies with RFC. User traffic can then switch from PW2 to PW1.

To allow communication between a Huawei device and a non-Huawei device in compliance with RFC, run the **local-mac remove all-but-mine** command. This command is run only on PE1 shown in **Figure 10-1**.

Figure 10-1 CE dual-homing to a VPLS network



Precautions

This command takes effect on a PE that receives MAC Withdraw messages only with the TLV type of 0x404.

Example

Enable a PE to remove all MAC address entries but retain MAC address entries associated with a PW over which the PE receives MAC Withdraw messages with the TLV type of 0x404.

```
<HUAWEI> system-view
[HUAWEI] vsi vsi1
[HUAWEI-vsi-vsi1] local-mac remove all-but-mine
```

10.7.56 mac-address static vlanif

Function

The **mac-address static vlanif** command configures a static MAC address entry. The outgoing interface of this entry is added to the specified VLAN corresponding to the VLANIF interface. The VLANIF interface is bound to a VSI.

The **undo mac-address static vlanif** command deletes a static MAC address entry.

By default, the system does not configure any static MAC address entry.

Format

mac-address static *mac-address interface-type interface-number* **vlanif** *interface-number* **vsi** *vsi-name*

undo mac-address static *mac-address interface-type interface-number* **vlanif** *interface-number* **vsi** *vsi-name*

Parameters

Parameter	Description	Value
static	Indicates the static entry that is not aged. When a frame of a specific MAC address is received, the frame is forwarded through the outgoing interface directly. After being configured and saved, the entries are still stored in the table even if the system is reset.	-
mac-address	Specifies the unicast MAC address in the format of H-H-H.	An H is a hexadecimal number of 1 to 4 bits, such as 00e0 and fc01. If you enter less than four digits, 0s are padded before the input digits. For example, if e0 is entered, 00e0 is displayed. The MAC address cannot be a broadcast MAC address (FFFF-FFFF-FFFF) or a multicast MAC address (the eighth bit is 1).
interface-type interface-number	Specifies the type and number of an interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
vlanif *interface-number*	Specifies the number of the VLANIF interface bound to a VSI.	-

Parameter	Description	Value
vsi *vsi-name*	Specifies the name of a specified VSI.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The VPLS provides reachability through MAC address learning. Each PE maintains a MAC address table.

The device learns source MAC addresses and then creates the MAC address table. However, the device cannot identify whether the packets are from authorized users or hackers, which brings security threats. If a hacker sets the source MAC address of attack packets to the MAC address of an authorized user and connects to another interface of the device, the device learns an incorrect MAC address entry. The packets that should be forwarded to the authorized user are forwarded to the hacker.

To improve interface security, the network administrator can manually create MAC address entries to bind MAC addresses of authorized users to specified interfaces using the **mac-address static vlanif** command. This prevents hackers from intercepting data of authorized users.

Prerequisites

The network administrator is familiar with the MAC addresses of the devices on the network that need to use static MAC address entries for communications; otherwise, the configuration will interrupt authorized users' communications.

In the **mac-address static vlanif** command, the interface must be a Layer 2 interface that has been added to the VLAN corresponding to the VLANIF interface. The VLANIF interface must be bound to the VSI configured in the command.

Precautions

After being created, the static MAC address entries will not be aged. When receiving a frame of a specific MAC address, the device forwards the frame through the outgoing interface directly. After being configured and saved, the MAC address entries are still stored in the table even if the system is reset.

A physical interface that is associated with a VSI can be bound to several VLANs. The VSI that is bound to a VLANIF interface can be associated with several physical interfaces. Therefore, you need to specify a physical interface and a VLANIF interface when configuring static MAC address entries for VSIs bound to the VLANIF interface.

Manually created MAC address entries take precedence over automatically created MAC address entries. Static MAC address entries and blackhole MAC address entries take precedence over dynamic MAC address entries.

If the user service changes, specify a new VSI bound to the interface. In this way, data of the user is not forwarded through the previously configured static MAC address entries. You need to configure new MAC address entries on the device or enable the device to learn dynamic MAC address entries to forward the data.

Example

Bind VLANIF10 to the VSI named **abc**, and add a MAC address entry with the MAC address being 00e0-fc12-3456 to the VSI. When a frame that belongs to VLAN 10 and has the destination MAC address 00e0-fc12-3456 is received, it is forwarded through the outgoing interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] vsi abc static
[HUAWEI-vsi-abc] pwsignal ldp
[HUAWEI-vsi-abc-ldp] vsi-id 1
[HUAWEI-vsi-abc-ldp] quit
[HUAWEI-vsi-abc] quit
[HUAWEI] vlan 10
[HUAWEI-vlan10] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type access
[HUAWEI-GigabitEthernet0/0/1] port default vlan 10
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] l2 binding vsi abc
[HUAWEI-Vlanif10] quit
[HUAWEI] mac-address static 00e0-fc12-3456 gigabitethernet 0/0/1 vlanif 10 vsi abc
```

10.7.57 mac-address static vsi

Function

The **mac-address static vsi** command configures a static MAC address entry. The outgoing interface in this entry is bound to a specified VSI.

The **undo mac-address static vsi** command deletes a static MAC address entry.

By default, the system does not configure any static MAC address entry.

Format

mac-address static *mac-address interface-type interface-number* **vsi** *vsi-name*

undo mac-address static *mac-address interface-type interface-number* **vsi** *vsi-name*

undo mac-address static vsi *vsi-name*

Parameters

Parameter	Description	Value
static	Indicates the static entry that is not aged. When a frame of a specific MAC address is received, the frame is forwarded through the outgoing interface directly. After being configured and saved, the entries are still stored in the table even if the system is reset.	-
mac-address	Specifies the unicast MAC address in the format of H-H-H.	An H is a hexadecimal number of 1 to 4 bits, such as 00e0 and fc01. If you enter less than four digits, 0s are padded before the input digits. For example, if e0 is entered, 00e0 is displayed. The MAC address cannot be a broadcast MAC address (FFFF-FFFF-FFFF) or a multicast MAC address (the eighth bit is 1).
interface-type interface-number	Specifies the type and number of an interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	The interface can be a GE interface, a GE sub-interface, an XGE interface, an XGE sub-interface, a 25GE interface, a 25GE sub-interface, a 40GE interface, a 40GE sub-interface, a 100GE interface, a 100GE sub-interface, an Eth-Trunk interface, or an Eth-Trunk sub-interface. The interface in this command is a Layer 3 interface bound to a VSI.
vsi *vsi-name*	Specifies the name of a specified VSI.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Usage Guidelines

Usage Scenario

The VPLS provides reachability through MAC address learning. Each PE maintains a MAC address table.

The device learns source MAC addresses and then creates the MAC address table. However, the device cannot identify whether the packets are from authorized users or hackers, which brings security threats. If a hacker sets the source MAC address of attack packets to the MAC address of an authorized user and connects to another interface of the device, the device learns an incorrect MAC address entry. The packets that should be forwarded to the authorized user are forwarded to the hacker.

To improve interface security, the network administrator can manually create MAC address entries to bind MAC addresses of authorized users to specified interfaces using the **mac-address static vlanif** command. This prevents hackers from intercepting data of authorized users.

Prerequisites

The network administrator is familiar with the MAC addresses of the devices on the network that need to use static MAC address entries for communications; otherwise, the configuration will interrupt authorized users' communications.

In the **mac-address static vsi** command, the interface must be a Layer 3 interface bound to a VSI.

Precautions

After being created, the static MAC address entries will not be aged. When receiving a frame of a specific MAC address, the device forwards the frame through the outgoing interface directly. After being configured and saved, the MAC address entries are still stored in the table even if the system is reset.

Manually created MAC address entries take precedence over automatically created MAC address entries. Static MAC address entries and blackhole MAC address entries take precedence over dynamic MAC address entries.

If the user service changes, specify a new VSI bound to the interface. In this way, data of the user is not forwarded through the previously configured static MAC address entries. You need to configure new MAC address entries on the device or enable the device to learn dynamic MAC address entries to forward the data.

Example

Add a static MAC address entry to the VSI named **abc**. When the destination MAC address of a received frame is 00e0-fc33-4455, the frame is forwarded in the VSI named **abc**.

```
<HUAWEI> system-view
[HUAWEI] vsi abc static
[HUAWEI-vsi-abc] pwsignal ldp
[HUAWEI-vsi-abc-ldp] vsi-id 1
[HUAWEI-vsi-abc-ldp] quit
[HUAWEI-vsi-abc] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
```

```
[HUAWEI-GigabitEthernet0/0/1] l2 binding vsi abc
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] mac-address static 00e0-fc33-4455 gigabitethernet 0/0/1 vsi abc
```

10.7.58 mac-diagnose enable

Function

The **mac-diagnose enable** command enables diagnostic test on the MAC address learning capacity.

The **mac-diagnose disable** command disables diagnostic test on the MAC address learning capacity.

The **undo mac-diagnose enable** command disables diagnostic test on the MAC address learning capacity.

By default, diagnostic test on the MAC address learning capacity is enabled.

Format

mac-diagnose enable

mac-diagnose disable

undo mac-diagnose enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To rectify a Layer 2 communication fault on the device, run the **mac-diagnose enable** command to enable diagnostic test on the MAC address learning capacity.

Precautions

Using the **mac-diagnose enable** command, you can enable diagnostic test on the MAC address learning capacity. The **mac-populate** and **mac-purge** operations can be performed only when diagnostic test on the MAC address learning capacity is enabled. Otherwise, the **mac-populate** and **mac-purge** operations cannot be performed. In addition, information and statistics on populated OAM MAC address are cleared.

Example

Enable diagnostic test on the MAC address learning capacity.

```
<HUAWEI> system-view
[HUAWEI] mac-diagnose enable
```

Disable diagnostic test on the MAC address learning capacity.

```
<HUAWEI> system-view
[HUAWEI] mac-diagnose disable
```

10.7.59 mac-learning

Function

The **mac-learning enable** command enables MAC address learning for a VSI.

The **mac-learning disable** command disables MAC address learning of a VSI.

The **undo mac-learning disable** command enables MAC address learning for a VSI.

By default, MAC address learning is enabled for a VSI.

Format

mac-learning { **enable** | **disable** }

undo mac-learning disable

Parameters

Parameter	Description	Value
enable	Enables a VSI to learn MAC addresses.	-
disable	Disables a VSI to learn MAC addresses.	-

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To disable MAC address learning in a VSI on a VPLS network, run the **mac-learning disable** command. The VPLS network then functions similarly to a VPWS network. For example, if there are only two PEs with each connecting to one CE, disabling MAC address learning in a VSI on a PE reduces the PE's pressure.

Configuration Impact

After the **mac-learning disable** command is run for a VSI, the VSI can no longer automatically learn MAC addresses, causing packets to be broadcast on the network. Therefore, exercise caution when running this command.

Example

Disable MAC address learning of the current VSI.

```
<HUAWEI> system-view
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] mac-learning disable
```

10.7.60 mac-limit (VSI view)

Function

The **mac-limit** command configures the MAC address limit rules on a VSI.

The **undo mac-limit** command restores the default setting.

By default, none of the MAC address limit rule is configured on a VSI.

NOTE

Only the S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6730S-H and S6730-H support this command.

Format

mac-limit { **action** { **discard** | **forward** } | **alarm** { **disable** | **enable** } | **maximum** *max-number* } *

undo mac-limit

Parameters

Parameter	Description	Value
action	Indicates the action performed on packets when the number of MAC entries reaches the limit. By default, the system discards the packets.	-
discard	Indicates that after the number of MAC entries reaches the limit, the system discards the packet whose destination MAC address does not map to any entry in the MAC address table.	-
forward	Indicates that after the number of MAC entries reaches the limit, the system broadcasts a packet whose destination MAC address does not map to any entry in the MAC address table, but does not learn the destination MAC address of the packet.	-

Parameter	Description	Value
alarm	Indicates whether an alarm is generated when the number of MAC address entries reaches the limit.	-
disable	Indicates that no alarm is generated when the number of MAC address entries reaches the limit.	-
enable	Indicates that an alarm is generated in syslog mode when the number of MAC address entries reaches the limit. By default, an alarm is sent to the NM station.	-
maximum *max-number*	Specifies the maximum number of MAC address entries that the current VSI can learn. **NOTE** Set **maximum** *max-number* before you set **action** or **alarm**.	The value is an integer that ranges from 0 to 4096.

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To prevent attacks, you can run the **mac-limit** command to limit the maximum number of MAC addresses that the current VSI can learn.

Precautions

If the VSI has learned some MAC addresses, run the **undo mac-address dynamic** command to clear the learned MAC addresses. Otherwise, the **mac-limit** command cannot limit the MAC address learning accurately.

When the **mac-limit** command is executed for the first time, you can configure **action** and **alarm** only after **maximum** *max-number* is configured. If the **mac-limit** command is not executed for the first time, there is no special requirement on the configuration sequence.

Example

Set the maximum number of MAC addresses that can be learned to 100 on the VSI PW.

```
<HUAWEI> system-view
[HUAWEI] vsi 1
[HUAWEI-vsi-1] mac-limit maximum 100
```

10.7.61 mac-populate

Function

The **mac-populate** command populates an OAM MAC address to initiate a diagnostic test on the MAC address learning capacity.

Format

mac-populate vsi *vsi-name* **mac** *mac-address* [**packet-num** *num* | **flood**] *

Parameters

Parameter	Description	Value
vsi *vsi-name*	Specifies the name of the VSI on which the operation is performed.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
mac *mac-address*	Specifies the MAC address for the diagnostic test, expressed in the format of H-H-H.	The value is in H-H-H format. The values are as follows: • 0018-82a4-3fb1 • 0018-82a4-3fb2 • 0018-82a4-3fb3 • 0018-82a4-3fb4 • 0018-82a4-3fb5 • 0018-82a4-3fb6 • 0018-82a4-3fb7 • 0018-82a4-3fb8 • 0018-82a4-3fb9 • 0018-82a4-3fba
packet-num *num*	Specifies the number of packets to be sent.	The value is a decimal integer that ranges from 1 to 5. The default value is 3.
flood	Indicates that the OAM MAC address is flooded throughout the VSI.	-

Views

All views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To rectify a Layer 2 communication fault on the device, you can run the **mac-populate** command to populate an OAM MAC address into the device to initiate a diagnostic test.

Prerequisites

The diagnostic test on the MAC address learning capacity has been enabled using the **mac-diagnose enable** command.

Precautions

The **mac-populate** command does not support BGP AD VPLS.

Using the **mac-populate** command, you can populate an OAM MAC address into the device.

- If the **mac-populate** command does not contain **flood**, an OAM MAC address is only populated into the local device.
- If the **mac-populate** command contains **flood**, an OAM MAC is flooded throughout the VSI and then populated into the peer and local devices.

NOTE

The OAM MAC address populated into the local and peer devices can control the forwarding. Under the guidance of the OAM MAC address, the peer device forwards the received packets corresponding to the OAM MAC address to the local device.

The default aging time of OAM MAC addresses is 150 seconds.

Example

Populate an OAM MAC address into the VSI named **vsi1**, flood the OAM MAC address over the domain, and set the number of packets to be sent to 3.

```
<HUAWEI> mac-populate vsi vsi1 mac 0018-82a4-3fb1 flood packet-num 3
```

10.7.62 mac-purge

Function

The **mac-purge** command purges an OAM MAC address from the forwarding table.

Format

mac-purge vsi *vsi-name* **mac** *mac-address* [**packet-num** *num* | **register** | **flood**] *

Parameters

Parameter	Description	Value
vsi *vsi-name*	Specifies the name of the VSI on which the operation is performed.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
mac *mac-address*	Specifies the MAC address for the diagnostic test, expressed in the format of H-H-H.	The value is in H-H-H format. The values are as follows: ● 0018-82a4-3fb1 ● 0018-82a4-3fb2 ● 0018-82a4-3fb3 ● 0018-82a4-3fb4 ● 0018-82a4-3fb5 ● 0018-82a4-3fb6 ● 0018-82a4-3fb7 ● 0018-82a4-3fb8 ● 0018-82a4-3fb9 ● 0018-82a4-3fba
packet-num *num*	Specifies the number of packets to be sent.	The value is a decimal integer that ranges from 1 to 5. The default value is 3.
register	Specifies the MAC address reserved for the OAM test. **NOTE** If the preceding command contains **register**, an OAM MAC address is populated into the local device or the peer device to make the device discard received packets corresponding to the OAM MAC address.	-
flood	Indicates that the OAM MAC address is flooded throughout the VSI.	-

Views

All views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To rectify a Layer 2 communication fault on the device, you can run the **mac-purge** command to clear OAM MAC addresses populated into the device.

Prerequisites

The diagnostic test on the MAC address learning capacity has been enabled using the **mac-diagnose enable** command.

Precautions

- If *vsi-name* in the **mac-purge** command for purging an OAM MAC address is not identical with *vsi-name* in the **mac-purge** command that is previously used in populating the OAM MAC address, the OAM MAC address cannot be cleared.
- A maximum of 100 OAM MAC addresses of **populate** and **register+populate** types can be populated into a device.
- The **mac-purge** command does not support BGP AD VPLS.

Using the **mac-purge** command, you can purge the populated OAM MAC address that is specialized for the test or register an OAM MAC address to a device to make the device discard the received packets corresponding to the OAM MAC address.

Test objects vary according to parameters.

- If the **mac-purge** command contains **flood**, an OAM MAC address is flooded throughout the VSI and then purged from all devices in the VSI and the local device into which the OAM MAC address has been populated. If the preceding command does not contain **flood**, the OAM MAC address is purged only from the local device.
- If the **mac-purge** command contains **register**, an OAM MAC address is registered on the device to make the device discard the packet corresponding to the OAM MAC address after receiving them.

Example

Purge the OAM MAC address from the VSI named **vsi1**, flood the OAM MAC address over the domain, and set the number of packets to be sent to 3.

```
<HUAWEI> mac-purge vsi vsi1 mac 0018-82a4-3fb1 flood packet-num 3
```

10.7.63 mac-withdraw enable

Function

The **mac-withdraw enable** command enables a VSI to delete the local MAC address and inform all the remote peers of the deletion.

The **undo mac-withdraw enable** command disables a VSI to delete the local MAC address and inform all the remote peers of the deletion.

By default, the MAC-withdraw function is disabled.

Format

mac-withdraw enable

undo mac-withdraw enable

Parameters

None

Views

VSI-LDP view, VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On enterprise networks, if the remote end specifies the local end as the UPE, the remote AC interface does not inform the local end to cancel the label after the AC interface is faulty. In this case, the local end is unaware of an AC fault or a UPE fault. The VSI remains Up and does not delete the corresponding MAC address entries in time. As a result, the remote end cannot receive data streams sent by the local end. After the **mac-withdraw enable** command is executed, the VSI deletes the local MAC address and informs all the remote peers of the deletion when an AC fault or a UPE fault occurs and the VSI remains Up. This solves the preceding problem.

Precautions

When an AC fault or a UPE fault occurs and the VSI remains Up, the UPE device needs to switch the VPLS traffic to another LSP if the UPE device accesses the SPE device in dual-homed mode. The SPE device then only needs to inform the other SPEs corresponding to the VSI to delete the MAC entries learnt from this VSI. After traffic switchover, the SPEs re-learn MAC entries from each other.

This command must be configured on SPEs.

The **mac-withdraw enable** command must be used together with the **interface-status-change mac-withdraw enable** command.

Example

Configure a VSI named v100 to delete the local MAC addresses and inform all the remote peers of the deletion when an AC fault or a UPE fault occurs and the VSI remains Up.

```
<HUAWEI> system-view
[HUAWEI] vsi v100 static
[HUAWEI-vsi-v100] pwsignal ldp
[HUAWEI-vsi-v100-ldp] mac-withdraw enable
```

10.7.64 mac-withdraw propagate enable

Function

The **mac-withdraw propagate enable** command enables a PE to forward a received MAC Withdraw message to peers.

The **undo mac-withdraw propagate enable** command disables a PE from forwarding a received MAC Withdraw message to peers.

By default, a PE does not forward a received MAC Withdraw message.

Format

mac-withdraw propagate enable

undo mac-withdraw propagate enable

Parameters

None

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an LDP or BGP AD VPLS network, after a local PE receives a MAC Withdraw message, the local PE needs to forward the MAC Withdraw message to its peers. Otherwise, its peers cannot detect network topology changes or learn new MAC addresses in a timely manner. As a result, traffic loss caused by invalid MAC addresses will occur. The **mac-withdraw propagate enable** command enables a PE to forward a received MAC Withdraw message to peers.

Precautions

After you run the **mac-withdraw propagate enable** command on a PE, the PE forwards a received MAC Withdraw message to its peers according to the split horizon principle:

- The MAC Withdraw message received from a UPE will be forwarded to NPEs and other UPEs.
- The MAC Withdraw message received from an NPE will be forwarded to UPEs, but will not be forwarded to other NPEs.

Example

Configure vsi100 on a PE to forward a received MAC Withdraw message to peers.

```
<HUAWEI> system-view
[HUAWEI] vsi vsi100
[HUAWEI-vsi-vsi100] mac-withdraw propagate enable
```

10.7.65 mpls l2vpn default vlan

Function

The **mpls l2vpn default vlan** command configures the default VLAN for a main interface.

The **undo mpls l2vpn default vlan** command deletes the default VLAN of a main interface.

Format

mpls l2vpn default vlan *vlan-id*

undo mpls l2vpn default vlan

Parameters

Parameter	Description	Value
vlan-id	Specifies the default VLAN ID of a main interface.	The value is an integer that ranges from 1 to 4094.

Views

GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the following conditions are met, you can run the **mpls l2vpn default vlan** command to specify the default VLAN on a main interface:

- The VSI using VLAN encapsulation is configured on the two PEs.
- The remote PE accepts only the tagged packets.

- The local PE is connected to a computer by using a GE interface, XGE interface, 25GE interface, MultiGE interface, 40GE interface, 100GE interface, or Eth-Trunk interface as the AC interface.

  In this scenario, the computer sends and receives only untagged packets. After the default VLAN is specified on the main interface, the local PE performs the following operations:
  - The local PE adds VLAN tags to the packets sent by the computer. The VLAN tags are encapsulated in the user packets, and are transparently transmitted to the remote PE.
  - The local PE removes the VLAN tags from the packets sent by the remote PE, and forwards the packets to the computer.

Precautions

Before binding the main interface to the VSI, you need to run the **mpls l2vpn default vlan** command to specify the default VLAN of the main interface.

If the remote PE can replace the VLAN tags in the packets with the VLAN tag of the AC-side outgoing interface when terminating the PW, the default VLAN on the main interface of the local PE can be set to any VLAN ID. Otherwise, the default VLAN of the main interface must be the same as the VLAN of the AC-side outgoing interface on the remote PE.

To use an XGE interface, a GE interface, a 25GE interface, a MultiGE interface, a 40GE interface, a 100GE interface, or an Eth-Trunk interface of the device as the AC interface of the PE, run the **undo portswitch** command to change a Layer 2 interface to a Layer 3 interface.

Example

Configure the default VLAN of primary interface.

```
[HUAWEI] interface gigabitethernet 0/0/2
[HUAWEI-GigabitEthernet0/0/2] undo portswitch
[HUAWEI-GigabitEthernet0/0/2] mpls l2vpn default vlan 100
```

10.7.66 mpls l2vpn ip-parse enable

Function

The **mpls l2vpn ip-parse enable** command enables the IP packet parsing function of the MPLS L2VPN module.

The **undo mpls l2vpn ip-parse enable** command disables the IP packet parsing function of the MPLS L2VPN module.

By default, the IP packet parsing function of the MPLS L2VPN module is enabled.

Format

mpls l2vpn ip-parse enable

undo mpls l2vpn ip-parse enable

NOTE

This command is supported only on the S6720-EI and S6720S-EI.

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a Layer 2 VPN scenario, if a traffic policy is configured in the inbound direction of an AC-side interface on a device, L2VPN traffic forwarded from a PE may incorrectly match the traffic policy. As a result, traffic fails to be forwarded. To ensure normal traffic forwarding, run the **undo mpls l2vpn ip-parse enable** command to disable the IP packet parsing function of the MPLS L2VPN module.

Precautions

If the enhanced load balancing mode is configured for an Eth-Trunk, it is recommended that the IP packet parsing function of the MPLS L2VPN module be enabled.

Example

Disable the IP packet parsing function of the MPLS L2VPN module.

```
<HUAWEI> system-view
[HUAWEI] undo mpls l2vpn ip-parse enable
```

10.7.67 mpls l2vpn mac-withdraw disable

Function

The **mpls l2vpn mac-withdraw disable** command disables the VLL from sending MAC Withdraw messages on a VPLS network with primary and secondary VLLs.

The **undo mpls l2vpn mac-withdraw disable** command restores the default setting.

By default, the VLL is enabled to send MAC Withdraw messages on a VPLS network with primary and secondary VLLs.

Format

mpls l2vpn mac-withdraw disable

undo mpls l2vpn mac-withdraw disable

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a VPLS scenario with primary and secondary VLLs, the primary and secondary VLLs send MAC Withdraw messages to the VPLS-enabled RSG each time a primary/secondary PW switchover is performed. After receiving the MAC Withdraw messages, the VPLS-enabled RSG clears all learned MAC addresses. Then packets will be transmitted in broadcast mode. To prevent packets from being broadcast, run the **mpls l2vpn mac-withdraw disable** command to disable the VLL in Ethernet or VLAN encapsulation mode from sending MAC-Withdraws messages during a primary/secondary PW switchover.

Precautions

This command takes effect only in a VPLS scenario with primary and secondary VLLs. In other scenarios, do not run the **mpls l2vpn mac-withdraw disable** command; otherwise, services will be interrupted.

Example

Disable the VLL in Ethernet or VLAN encapsulation mode from sending MAC Withdraw messages during a primary/secondary PW switchover.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] mpls l2vc 2.2.2.2 100
[HUAWEI-Vlanif10] mpls l2vc 4.4.4.4 200 secondary
[HUAWEI-Vlanif10] mpls l2vpn mac-withdraw disable
```

10.7.68 mpls l2vpn vlan-stacking

Function

The **mpls l2vpn vlan-stacking** command configures the stacked VLAN ID for a main interface.

The **undo mpls l2vpn vlan-stacking** command deletes the stacked VLAN ID from a main interface.

By default, the system does not add a VLAN ID to a packet passing through the main interface.

Format

mpls l2vpn vlan-stacking stack-vlan *vlan-id*

undo mpls l2vpn vlan-stacking stack-vlan

Parameters

Parameter	Description	Value
stack-vlan *vlan-id*	Indicates the outer VLAN ID.	The value is an integer that ranges from 1 to 4094.

Views

GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the following conditions are met, run the **mpls l2vpn vlan-stacking stack-vlan** command to specify a VLAN for a main interface:

- The VLL or VSI using VLAN encapsulation is configured on the two PEs.
- The remote PE accepts packets with one more VLAN tag.
- The local PE is connected to a computer by using a GE interface, XGE interface, 25GE interface, MultiGE interface, 40GE interface, 100GE interface, or Eth-Trunk interface as the AC interface.

  In this scenario, the computer sends and receives all packets. After a VLAN is specified for the main interface, the local PE performs the following operations:
  - The local PE adds VLAN tags to the packets sent by the computer. The VLAN tags are encapsulated in the user packets, and are transparently transmitted to the remote PE.
  - The local PE removes the outer VLAN tags from the packets sent by the remote PE, and forwards the packets to the computer.

Precautions

Before binding the main interface to the VLL or VSI, run the **mpls l2vpn vlan-stacking stack-vlan** command to specify a VLAN for the main interface.

To use an XGE interface, a GE interface, a 25GE interface, a MultiGE interface, a 40GE interface, a 100GE interface, or an Eth-Trunk interface of the device as the AC interface of the PE, run the **undo portswitch** command to change a Layer 2 interface to a Layer 3 interface.

Example

Configure MPLS VLL on the main interface and add VLAN tag 80 to incoming packets.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/13
[HUAWEI-GigabitEthernet0/0/13] undo portswitch
[HUAWEI-GigabitEthernet0/0/13] mpls l2vpn vlan-stacking stack-vlan 80
[HUAWEI-GigabitEthernet0/0/13] mpls l2vc 10.0.0.17 20 tagged
```

10.7.69 mpls l2vpn vsi-pw limit threshold-alarm

Function

The **mpls l2vpn vsi-pw limit threshold-alarm** command configures the upper and lower alarm thresholds for VPLS VCs.

The **undo mpls l2vpn vsi-pw limit threshold-alarm** command restores the default settings.

By default, the upper and lower alarm thresholds are 80% and 70% respectively.

Format

mpls l2vpn vsi-pw limit threshold-alarm upper-limit *upper-limit-value* **lower-limit** *lower-limit-value*

undo mpls l2vpn vsi-pw limit threshold-alarm [**upper-limit** *upper-limit-value* **lower-limit** *lower-limit-value*]

Parameters

Parameter	Description	Value
upper-limit *upper-limit-value*	Specifies the upper alarm threshold.	The value is an integer ranging from 1 to 100.
lower-limit *lower-limit-value*	Specifies the lower alarm threshold.	The value is an integer ranging from 1 to 100. *lower-limit-value* must be smaller than *upper-limit-value*.

Views

MPLS-L2VPN view

Default Level

2: Configuration Level

Usage Guidelines

A device supports only a limited number of VPLS VCs. If a device has too many VPLS VCs, the device performance deteriorates. The **mpls l2vpn vsi-pw limit**

threshold-alarm command allows you to flexibly adjust the upper and lower alarm thresholds for VPLS VCs to control VPLS VC usage.

Note that:

- *upper-limit-value* specifies the upper alarm threshold for VPLS VCs. If the proportion of VPLS VCs created to the maximum VPLS VCs allowed reaches this threshold, a VPLS VC threshold-crossing alarm is reported.
- *lower-limit-value* specifies the lower alarm threshold for VPLS VCs. If the proportion of VPLS VCs created to the maximum VPLS VCs allowed falls below this threshold, a VPLS VC threshold-crossing clear alarm is reported.

Example

Configure the upper and lower alarm thresholds for VPLS VCs as 90% and 70% respectively.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] mpls l2vpn vsi-pw limit threshold-alarm upper-limit 90 lower-limit 70
```

10.7.70 mtu (VSI view)

Function

The **mtu** command sets the MTU of a VSI.

The **undo mtu** command restores the default value.

The default MTU of a VSI is 1500.

Format

mtu *mtu-value*

undo mtu

Parameters

Parameter	Description	Value
mtu-value	Specifies the MTU of a VSI.	The value is an integer that ranges from 328 to 65535.

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the MTUs of the same VSI on two PEs are different, the two PEs cannot exchange information or establish a connection. In this case, you can run the **mtu** command to set the MTU of a VSI so that VSIs created on different PEs for the same VPLS have the same MTU.

Prerequisites

The following operations have been performed before this command is used:

- The **pwsignal bgp** command and the **route-distinguisher (VSI-BGP view)** *route-distinguisher* command have been executed for Kompella VPLS.
- The **pwsignal ldp** command and the **vsi-id** *vsi-id* command have been executed for Martini VPLS.
- The **bgp-ad** command and the **vpls-id** *vpls-id* command have been executed for BGP AD VPLS.

Precautions

When configuring MTUs, note that the MTUs of the VSIs created for the same VPLS on different PEs must be the same.

Devices of some manufacturers cannot perform the MTU matching check on the VSI. When the switch interworks with a non-Huawei device in Kompella mode, you need to perform either of the following configurations to ensure that VCs are Up:

- Set the MTU of the VSI on the PE to be consistent with the MTU of the non-Huawei device.
- Run the **mtu-negotiate disable** command to ignore the check on MTU matching.

Example

Set the MTU of the VSI named **company1**.

```
<HUAWEI> system-view
[HUAWEI] vsi company1 static
[HUAWEI-vsi-company1] pwsignal ldp
[HUAWEI-vsi-company1-ldp] vsi-id 100
[HUAWEI-vsi-company1-ldp] quit
[HUAWEI-vsi-company1] mtu 1600
```

10.7.71 mtu-negotiate disable

Function

The **mtu-negotiate disable** command disables a PE from checking whether the MTUs for the local and remote VSIs match.

The **undo mtu-negotiate disable** command enables a PE to check whether the MTUs for the local and remote VSIs match.

By default, a PE is enabled to check whether the MTUs for the local and remote VSIs match.

Format

mtu-negotiate disable

undo mtu-negotiate disable

Parameters

None

Views

VSI-BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When two PEs that are Huawei and non-Huawei devices use Kompella VPLS to communicate, and their MTUs are different, the VC cannot Up. To resolve this problem, run the **mtu-negotiate disable** command to disable the local PE from checking whether the MTUs for the local and remote VSIs match. Alternatively, run the **mtu** command to change the MTU of the local VSI to be the same as that of the remote VSI.

Precautions

The **mtu-negotiate disable** command and its undo form are valid only for Kompella VPLS.

Example

Disable the device from checking whether the MTUs named **bgp1** for the local and remote VSIs match.

```
<HUAWEI> system-view
[HUAWEI] vsi bgp1
[HUAWEI-vsi-bgp1] pwsignal bgp
[HUAWEI-vsi-bgp1-bgp] mtu-negotiate disable
```

10.7.72 multi-homing-preference

Function

The **multi-homing-preference** command configures the multi-homed priority for a VSI.

The **undo multi-homing-preference** command deletes multi-homed priority for a VSI.

By default, the multi-homed priority for a VSI is 0, which is the lowest priority.

Format

multi-homing-preference *preference-value*

undo multi-homing-preference

Parameters

Parameter	Description	Value
preference-value	Specifies the multi-homed priority of a VSI.	The value is an integer that ranges from 1 to 65535. A large value indicates a high priority.

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In CE dual-homed scenarios, run the **multi-homing-preference** command to specify a primary PE and a backup PE.

Prerequisites

The following operations have been performed before this command is used:

1. A VSI has been created and the automatic member discovery mechanism has been configured using the **vsi** *vsi-name* **auto** command.
2. BGP has been configured as the PW signaling protocol using the **pwsignal bgp** command.
3. The RD has been configured for the VSI using the **route-distinguisher** *route-distinguisher* command.

Precautions

Currently, only Kompella VPLS supports the multi-homed priority for a VSI. In addition, only the dual-homed CE is supported.

If you run the **multi-homing-preference** command for a Kompella VPLS, the configured preference takes effect only after the **bestroute l2vpn-preference vpls** command is run in the BGP-L2VPN-AD address family view.

At present, only one label block can be configured on the VSIs of the two dual-homed PEs. If you want to increase the range, run the **undo site** command to delete the existing site, and then specify a larger range. Only one AC can be configured for the VSIs of the dual-homed PEs.

If the VSIs of two PEs that the dual-homed CE accesses are Up, the PE with higher priority serves as the primary PE, while the PE with lower priority serves as the backup PE. The primary PE is responsible for forwarding the traffic of the CE, while the backup PE is responsible only for checking whether the VSI of the primary PE is Up. After the backup PE is selected, the VSI status of the backup PE turns Down.

If the VSI status of the primary PE turns Down, the primary PE broadcasts Unreach packets. After the backup PE receives the Unreach packets, the backup PE judges that the primary PE is faulty. The backup PE then sends Reach packets to set up a PW with other PEs. The backup PE becomes a primary PE.

If the dual-homed priorities of the two PEs in dual-homed mode are the same, after a session is set up between the PEs, the PEs detect collision. At this time, the VSI of the PE with smaller router ID is Up, while the VSI of the PE with larger router ID is Down.

If a session is set up between PE1 with the priority being "a" and PE2 with the priority being "b", and a is larger than b, the VSI of PE1 is Up and that of PE2 is Down. At this time:

- If the priority of PE1 is changed to "b" (the modification is permitted because PE1 does not have information about remote VCs on PE2), the VSI of PE1 remains Up, while the VSI of PE2 remains Down.
- If the priority of PE2 is changed to "a", the modification is rejected and alarm information is displayed.

After the session turns Down, the PW of the PE with lower priority turns Up. The PW between the two PEs turns Up.

Example

Configure the multi-homed priority of the VSI named **company1** to 100.

```
<HUAWEI> system-view
[HUAWEI] vsi company1 auto
[HUAWEI-vsi-company1] pwsignal bgp
[HUAWEI-vsi-company1-bgp] route-distinguisher 100:1
[HUAWEI-vsi-company1-bgp] quit
[HUAWEI-vsi-company1] multi-homing-preference 100
```

10.7.73 multicast-suppression cir cbs (VSI view)

Function

The **multicast-suppression cir cbs** command enables the multicast suppression function on the VSI.

The **undo multicast-suppression** command disables the multicast suppression function on the VSI.

By default, the multicast traffic function is disabled on a VSI.

Format

multicast-suppression cir *cir-value* **cbs** *cbs-value*

undo multicast-suppression

Parameters

Parameter	Description	Value
cir *cir-value*	Specifies the CIR, that is, the allowed rate at which traffic can pass through.	The value is an integer that ranges from 0 to 10000000, in kbit/s.
cbs *cbs-value*	Specifies the CBS, that is, the traffic that can pass instantly, or the depth of the first token bucket.	The value is an integer that ranges from 10000 to 4294967295, in bytes.

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a VPLS network, the broadcast, multicast, and unknown unicast packets are transmitted in broadcast mode. If large quantities of multicast packets are on the VPLS network, the device has to make a lot of copies of these multicast packets, which wastes bandwidth and resources, and degrades the performance of the system. You can run the **multicast-suppression cir cbs** command to suppress the multicast traffic in the VSI. The rate of multicast traffic on the VPLS network is limited.

Prerequisites

A VSI has been created using the **vsi** *vsi-name* [**auto** | **static**] command.

Example

Set the CIR to 100 kbit/s and the CBS to 18800 bytes for the multicast traffic that can pass in VSI1.

```
<HUAWEI> system-view
[HUAWEI] vsi VSI1
[HUAWEI-vsi-VSI1] multicast-suppression cir 100 cbs 18800
```

10.7.74 npe-upe mac-withdraw enable

Function

The **npe-upe mac-withdraw enable** command enables an SPE to forward the LDP MAC Withdraw messages received from other SPEs to UPEs.

The **undo npe-upe mac-withdraw enable** command disables an SPE from forwarding the LDP MAC Withdraw messages received from other SPEs to UPEs.

By default, an SPE does not forward the LDP MAC Withdraw messages received from other SPEs to UPEs.

Format

npe-upe mac-withdraw enable

undo npe-upe mac-withdraw enable

Parameters

None

Views

VSI-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On enterprise networks, you need to run the **npe-upe mac-withdraw enable** command to enable an SPE to forward the LDP MAC Withdraw messages received from other SPEs to UPEs.

Prerequisites

LDP has been configured as the PW signaling protocol using the **pwsignal ldp** command.

Precautions

The **npe-upe mac-withdraw enable** command is used on SPEs.

- An SPE refers to the network end peer of the local VSI in HVPLS. You can run the **peer** *peer-address* [**negotiation-vc-id** *vc-id*] [**tnl-policy** *policy-name*] command to specify an SPE.
- A UPE refers to the user end peer of the local VSI in HVPLS. You can run the **peer** *peer-address* [**negotiation-vc-id** *vc-id*] [**tnl-policy** *policy-name*] **upe** command to specify a UPE.
- If the local device is not configured with HVPLS, the **npe-upe mac-withdraw enable** command is not required.

Example

Enable the SPE to forward the LDP MAC Withdraw messages received from other SPEs the UPE.

```
<HUAWEI> system-view
[HUAWEI] vsi v1 static
```

```
[HUAWEI-vsi-v1] pwsignal ldp
[HUAWEI-vsi-v1-ldp] npe-upe mac-withdraw enable
```

10.7.75 peer (VSI-LDP view)

Function

The **peer** command configures a peer for a VSI.

The **undo peer** command deletes the peer of a VSI.

By default, no peer is configured for a VSI.

Format

peer *peer-address* [**negotiation-vc-id** *vc-id*] [**tnl-policy** *policy-name*] [**upe**] [**ignore-standby-state**]

undo peer *peer-address* [**negotiation-vc-id** *vc-id*]

Parameters

Parameter	Description	Value
peer-address	Specifies the IPv4 address of the peer. Generally, it is specified as the loopback address of the peer.	The value is in dotted decimal notation.
negotiation-vc-id *vc-id*	Specifies the ID of a VC, which uniquely identifies the VC. Generally, this parameter is specified when the two ends with different VSI IDs need to interconnect.	*vc-id* cannot be the same as the IDs of other local VSIs. The negotiated VC IDs to the same peer must be different. The value is an integer ranging from 1 to 4294967295.
tnl-policy *policy-name*	Specifies the tunnel policy name of the peer.	The value is a string of 1 to 39 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
upe	Identifies whether the peer is a client PE, which applies to Hierarchical Virtual Private LAN Service (HVPLS).	-

Parameter	Description	Value
ignore-standby-state	Configures the created PW to ignore the secondary state sent from the peer device.	-

Views

VSI-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When you configure Martini VPLS, you need to run the **peer** command to configure a peer for the VSI.

Prerequisites

The VSI ID has been configured before you run this command.

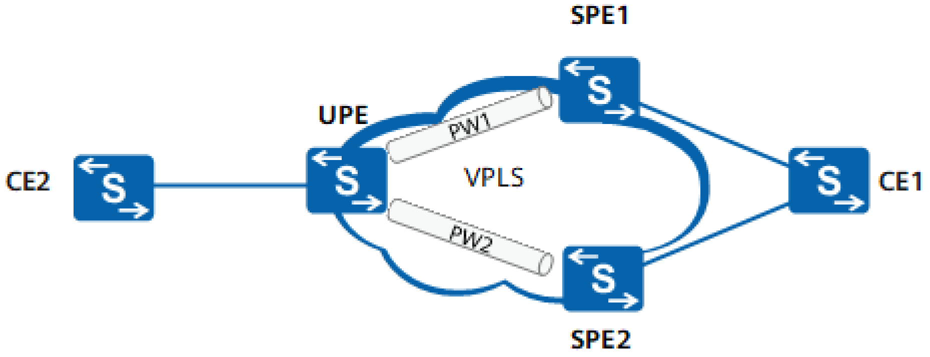
- To configure a Spoke PW on the HVPLS network, you can configure **upe** in the **peer** command. If the specified peer is a UPE, the peer is on the user side, which does not comply with split horizon. If **upe** is not configured, a hub PW is configured, meaning that a VSI peer is specified and the peer is not specified as a UPE. Split horizon applies to hub PWs. Traffic from spoke PWs can be forwarded to spoke PWs and hub PWs, but traffic from hub PWs can only be forwarded to spoke PWs and not to hub PWs.

  NOTE

  Split horizon: The data packets received from the PW on the public network are not forwarded to other PWs, but only forwarded to the private network. On a VPLS network, full mesh and split horizon are used to avoid loops. HVPLS partitions the network, and the devices of different levels forward data to each other without complying with the split horizon scheme.

- To configure a VLL to access a VPLS network, you can adopt one of the following configurations to create a PW:
  - Configure the VSI ID on the VPLS network to be the same as the VC ID of the VLL peer.
  - Configure the value of **negotiation-vc-id** *vc-id* to be the same as the VC ID of the VLL peer.
- The **ignore-standby-state** parameter can be configured for PWs dual-homing a CE to PEs on a PW redundancy network. This setting enables the secondary PW to ignore the Backup state and remain in the Up state, preventing packet loss that occurs during a primary/secondary PW switchover. **Figure 10-2** shows PW redundancy networking with CEs asymmetrically accessing PEs.

Figure 10-2 VPLS PW redundancy networking



If the primary PW1 works properly, it transmits traffic over the path CE1–>SPE1–>UPE–>CE2. If PW1 fails, either of the following situations occurs based on the **ignore-standby-state** setting:

- If **ignore-standby-state** is configured on SPE2, PW2 remains in the Up state. After PW1 fails, SPE2 can forward CE1 traffic over the path CE1–>SPE2–>UPE–>CE2.
- If **ignore-standby-state** is not configured on SPE2, PW2 is in the Backup state before switching to the Up state. After PW1 fails and CE1 sends traffic to SPE2, SPE2 fails to forward traffic to UPE because PW2 does not become Up, causing traffic loss. After PW2 switches to the Up state, SPE2 can forward CE1 traffic over the path CE1–>SPE2–>UPE–>CE2, without traffic loss.

Precautions

After you run the **undo peer** command, all PW configurations created by the peer are deleted.

If the value of **negotiation-vc-id** *vc-id* is different from the value of *vsi-id* configured using the **vsi-id** command, you must configure **negotiation-vc-id** *vc-id* when running the **undo peer** command to delete the VSI peer. Otherwise, the system prompts that the VSI peer cannot be deleted.

Example

Configure the peer for the current VSI.

```
<HUAWEI> system-view
[HUAWEI] vsi company1 static
[HUAWEI-vsi-company1] pwsignal ldp
[HUAWEI-vsi-company1-ldp] vsi-id 1
[HUAWEI-vsi-company1-ldp] peer 10.3.3.3 negotiation-vc-id 10 upe
```

Delete the peer of a VSI.

```
<HUAWEI> system-view
[HUAWEI] vsi company1 static
[HUAWEI-vsi-company1] pwsignal ldp
[HUAWEI-vsi-company1-ldp] vsi-id 1
[HUAWEI-vsi-company1-ldp] peer 10.3.3.3 negotiation-vc-id 10 upe
[HUAWEI-vsi-company1-ldp] undo peer 10.3.3.3 negotiation-vc-id 10
```

10.7.76 peer preference (protect-group view)

Function

The **peer preference** command adds a specified PW to a PW protection group and specifies the priority of the PW.

The **undo peer preference** command deletes a specified PW from a PW protection group.

By default, no PW is added to a PW protection group.

Format

peer *peer-address* [**negotiation-vc-id** *vc-id*] **preference** *preference-value*

undo peer *peer-address* [**negotiation-vc-id** *vc-id*]

Parameters

Parameter	Description	Value
peer-address	Specifies the IPv4 address of the VSI peer. Generally, the loopback address of the peer is used.	-
negotiation-vc-id *vc-id*	Specifies the parameter negotiated with the peer. By default, the VSI ID is used. Generally, this parameter is used in VPLS accessing VLL scenarios in which the VSI IDs of the two ends are inconsistent and the two ends are required to communicate.	The value is an integer that ranges from 1 to 4294967295.
preference-value	Specifies the priority of a peer when the peer joins a PW protection group. The smaller the value, the higher the priority. Among the two peers added to a PW protection group, the one with the higher priority serves as the primary.	The value is an integer ranging from 1 to 32.

Views

protect-group view

Default Level

2. Configuration level

Usage Guidelines

Usage Scenario

After creating a PW protection group and specifying the PW redundancy mode, you can add specified PWs to the group for them to work in backup mode.

Prerequisites

A PW protection group has been created and the PW redundancy mode has been specified.

Precautions

Add PWs to a PW protection group in the descending order of PW priorities. Do not add the PW with a lower priority to the PW protection group first.

If you add the PW with a lower priority to the PW protection group first, a PW switchover will occur after you add the other PW to the PW protection group.

Example

Add a specified PW to a PW protection group and set the priority of the PW to 1.

```
<HUAWEI> system-view
[HUAWEI] vsi vsi1
[HUAWEI-vsi-vsi1] pwsignal ldp
[HUAWEI-vsi-vsi1-ldp] peer 2.2.2.2
[HUAWEI-vsi-vsi1-ldp] protect-group group1
[HUAWEI-vsi-vsi1-ldp-protect-group-group1] peer 2.2.2.2 preference 1
```

10.7.77 peer pw

Function

The **peer pw** creates a PW and displays the PW view.

The **undo peer pw** deletes the created PW.

By default, no PW is created.

Format

peer *peer-address* [**negotiation-vc-id** *vc-id*] **pw** *pw-name*

undo peer *peer-address* [**negotiation-vc-id** *vc-id*] **pw**

Parameters

Parameter	Description	Value
peer *peer-address*	Specifies the IPv4 address of the peer. Generally, it is specified as the loopback address of the peer.	-

Parameter	Description	Value
negotiation-vc-id *vc-id*	Specifies the ID of a VC, which uniquely identifies the VC. Generally, this parameter is specified when the two ends with different VSI IDs need to interconnect.	*vc-id* cannot be the same as the IDs of other local VSIs. The negotiated VC IDs to the same peer must be different. The value is an integer ranging from 1 to 4294967295.
pw *pw-name*	Specifies the name of a PW. The PW name is used to distinguish the PW from other PWs, and must be unique in the same VSI. Nevertheless, the PW name can be used in other VSIs.	The value is a string of 1 to 15 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

VSI-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In Martini VPLS, you need to run the **peer pw** command to configure a PW after specifying a peer.

Prerequisites

The IP address of the peer has been specified using the **peer** *peer-address* command.

Precautions

If the value of **negotiation-vc-id** *vc-id* is different from the value of *vsi-id* configured using the **vsi-id** command, you must configure **negotiation-vc-id** *vc-id* when running the **undo peer pw** command to delete the PW. Otherwise, the PW cannot be deleted.

Example

Create the PW view.

```
<HUAWEI> system-view
[HUAWEI] vsi aa static
[HUAWEI-vsi-aa] pwsignal ldp
[HUAWEI-vsi-aa-ldp] vsi-id 1
[HUAWEI-vsi-aa-ldp] peer 10.1.1.1
[HUAWEI-vsi-aa-ldp] peer 10.1.1.1 pw pw1
[HUAWEI-vsi-aa-ldp-pw-pw1]
```

Delete the PW.

```
<HUAWEI> system-view
[HUAWEI] vsi aa static
[HUAWEI-vsi-aa] pwsignal ldp
[HUAWEI-vsi-aa-ldp] vsi-id 1
[HUAWEI-vsi-aa-ldp] peer 10.1.1.1
[HUAWEI-vsi-aa-ldp] peer 10.1.1.1 pw pw1
[HUAWEI-vsi-aa-ldp-pw-pw1] quit
[HUAWEI-vsi-aa-ldp] undo peer 10.1.1.1 pw
```

10.7.78 peer signaling

Function

The **peer signaling** command configures the signaling mode for a specified peer or peer group.

The **undo peer signaling** command restores the default signaling mode of a specified peer or peer group.

By default, after the **peer enable** command is run in the L2VPN AD address family view, the BGP AD signaling is enabled for all peers or peer groups.

Format

peer { *peer-address* | *group-name* } **signaling** { **vpws** | **vpls** | **vpls-ad disable** }

undo peer { *peer-address* | *group-name* } **signaling** { **vpws** | **vpls** | **vpls-ad disable** }

Parameters

Parameter	Description	Value
peer-address	Specifies an IPv4 address of a peer. The loopback address of the peer is usually used as its IPv4 address.	-
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
vpws	Configures the signaling mode of a specified peer or peer group as VPWS.	-
vpls	Configures the signaling mode of a specified peer or peer group as VPLS.	-
vpls-ad disable	Disables BGP AD signaling for a specified peer or peer group.	-

2: Configuration level

Usage Guidelines

Usage Scenario

In Kompella VLL, Kompella VPLS, and BGP AD VPLS scenarios, configure the signaling mode for peers or peer groups in the L2VPN AD address family view so that peers can advertise routes to each other. The parameters used in different scenarios are described as follows:

- In the Kompella VLL scenario, configure **vpws** in the **peer signaling** command.
- In the Kompella VPLS scenario, configure **vpls** in the **peer signaling** command.
- In the BGP AD VPLS scenario, the BGP AD signaling is enabled for all peers or peer groups in the L2VPN AD address family view by default. Therefore, you need to run the **peer** { *peer-address* | *group-name* } **signaling vpls-ad disable** command to disable BGP AD signaling for a specified peer or peer group in Kompella VLL and Kompella VPLS scenarios.

Prerequisites

The **peer enable** command has been run to create a peer or peer group.

Precautions

For the same peer, the **peer enable** and **peer** { *peer-address* | *group-name* } **signaling** { **vpws** | **vpls** | **vpls-ad disable** } commands run in the L2VPN AD address family view are mutually exclusive with the **peer enable** command run in the VPLS address family view.

For the same peer, the **peer** { *peer-address* | *group-name* } **signaling vpws** command run in the L2VPN AD view is mutually exclusive with the **peer enable** command run in the L2VPN address family view.

The signaling mode configured for a peer is preferred over that configured for the peer group to which the peer belongs.

When a signaling mode is configured for a peer group but not configured for a peer that belongs to the peer group, the peer uses the signaling mode configured for its peer group.

Example

Configure the signaling mode for peer 1.1.1.1 in the L2VPN AD address family view when Kompella VPLS is enabled.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] l2vpn-ad-family
```

```
[HUAWEI-bgp-l2vpn-ad] peer 1.1.1.1 enable
[HUAWEI-bgp-l2vpn-ad] peer 1.1.1.1 signaling vpls
[HUAWEI-bgp-l2vpn-ad] peer 1.1.1.1 signaling vpls-ad disable
```

10.7.79 peer static-npe

Function

The **peer static-npe** command configures the static NPE peer of the VSI in the Hierarchical Virtual Private LAN Service (HVPLS).

The **undo peer static-npe** command deletes the static NPE peer of the VSI in the HVPLS.

By default, the HVPLS has no static NPE peer of the VSI.

Format

peer *peer-address* [**negotiation-vc-id** *vc-id*] [**tnl-policy** *policy-name*] **static-npe trans** *transmit-label* **recv** *receive-label*

undo peer *peer-address* [**negotiation-vc-id** *vc-id*]

Parameters

Parameter	Description	Value
peer-address	Specifies the IPv4 address of the static NPE peer. It is generally specified as the loopback address of the peer.	-
negotiation-vc-id *vc-id*	Indicates the unique ID of a VC. Generally, this parameter is used when the VSI IDs of two ends are inconsistent and the two ends are required to communicate.	*vc-id* cannot be the same as the IDs of other local VSIs. The negotiated VC IDs to the same peer must be different. The value is an integer ranging from 1 to 4294967295.
tnl-policy *policy-name*	Specifies the tunnel-policy name of the static NPE peer.	The value is a string of 1 to 39 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
static-npe	Indicates whether the peer of the static VSI is the PE at the network side.	-

Parameter	Description	Value
trans *transmit-label*	Indicates the outer label that is manually configured and sent from the local device to its peer. It is the outgoing label of the static Layer 2 VC.	The value is an integer ranging from 0 to 1048575.
recv *receive-label*	Indicates the outer label that is manually configured and sent from the peer to the local device. It is the incoming label of the static Layer 2 VC.	The value is an integer that ranges from 16 to 1023.

2: Configuration level

Usage Guidelines

Usage Scenario

On the HVPLS network, you can run the **peer static-npe** command on the local device to configure a static NPE peer.

Prerequisites

The VSI ID has been configured using the **vsi-id** *vsi-id* command.

Precautions

If you specify **negotiation-vc-id** *vc-id* when you configure the peer of the VSI, and the specified *vc-id* and that in the configured **vsi-id** command are inconsistent, to delete the peer of the VSI, you must use the **undo peer** command with **negotiation-vc-id** *vc-id*. Otherwise, the peer cannot be deleted.

Example

Configure the static NPE peer of the current VSI. Configure the received and sent outer labels are 100.

```
<HUAWEI> system-view
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] pwsignal ldp
[HUAWEI-vsi-company1-ldp] vsi-id 1
[HUAWEI-vsi-company1-ldp] peer 3.3.3.3 static-npe trans 100 recv 100
```

10.7.80 peer static-upe

Function

The **peer static-upe** command configures the static UPE peer of the VSI in the HVPLS.

The **undo peer static-upe** command deletes the static UPE peer of the VSI in the HVPLS.

By default, the HVPLS has no static UPE peer of the VSI.

Format

peer *peer-address* [**negotiation-vc-id** *vc-id*] [**tnl-policy** *policy-name*] **static-upe trans** *transmit-label* **recv** *receive-label*

undo peer *peer-address* [**negotiation-vc-id** *vc-id*]

Parameters

Parameter	Description	Value
peer-address	Specifies the IPv4 address of the UPE peer. Generally, it is specified as the loopback address of the peer.	-
negotiation-vc-id *vc-id*	Specifies the ID of a VC, which uniquely identifies the VC. Generally, this parameter is specified when the two ends with different VSI IDs need to interconnect.	*vc-id* cannot be the same as the IDs of other local VSIs. The negotiated VC IDs to the same peer must be different. The value is an integer ranging from 1 to 4294967295.
tnl-policy *policy-name*	Specifies the tunnel-policy name of the static UPE peer.	The value is a string of 1 to 39 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
static-upe	Indicates whether the static UPE is a client PE device. This parameter applies to HVPLS.	-
trans *transmit-label*	Specifies the outer label that sent from the local device to its peer.	It is the outgoing label of the static Layer 2 VC. The value is an integer that ranges from 0 to 1048575.

Parameter	Description	Value
recv *receive-label*	Specifies the outer label manually configured and sent from the peer to the local device. It is the incoming label of the static Layer 2 VC.	The value is an integer that ranges from 16 to 1023.

Usage Guidelines

Usage Scenario

On the HVPLS network, you can run the **peer static-upe** command on the local device to configure a static UPE peer.

Prerequisites

The VSI ID has been configured using the **vsi-id** *vsi-id* command.

Precautions

If **negotiation-vc-id** *vc-id* is used when configuring the VSI peer, and specified *vc-id* is different from *vsi-id* configured using the **vsi-id** command, you must configure **negotiation-vc-id** *vc-id* when running the **undo peer** command to delete the VSI peer. Otherwise, the VSI peer cannot be deleted.

Example

Configure the static UPE peer of the current VSI. The sent and received outer labels are 100.

```
<HUAWEI> system-view
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] pwsignal ldp
[HUAWEI-vsi-company1-ldp] vsi-id 1
[HUAWEI-vsi-company1-ldp] peer 3.3.3.3 static-upe trans 100 recv 100
```

10.7.81 ping vpls

Function

The **ping vpls** command detects the status of the PW and reachability of the peer.

Format

ping vpls [**-c** *echo-number* | **-m** *time-value* | **-s** *data-bytes* | **-t** *timeout-value* | **-r** *reply-mode* | **-exp** *exp-value* | **-v**] * **vsi** *vsi-name local-site-id remote-site-id*

ping vpls [**-c** *echo-number* | **-m** *time-value* | **-s** *data-bytes* | **-t** *timeout-value* | **-r** *reply-mode* | **-exp** *exp-value* | **-v**] * **vsi** *vsi-name* **peer** *peer-address* [**negotiate-vc-id** *vc-id*]

Parameters

Parameter	Description	Value
-c *echo-number*	Specifies the number of sent Echo Request packets.	The value is an integer that ranges from 1 to 4294967295. The default value is 5.
-m *time-value*	Specifies the time to wait before sending the next packet.	The value is an integer that ranges from 1 to 10000, in milliseconds. The default value is 2000 milliseconds.
-s *data-bytes*	Specifies the number of bytes of an Echo Request packet to be sent.	The value is an integer that ranges from 65 to 8100. The default value is 100.
-t *timeout-value*	Specifies the timeout period of sending Echo Request packets.	The value is an integer that ranges from 0 to 65535. The default value is 2000.
-r *reply-mode*	Specifies the mode in which the peer sends MPLS Echo Reply packets. The value is a decimal integer. The values are as follows: ● 1: indicates no reply. ● 2: indicates a reply with an IPv4 or IPv6 UDP datagram. ● 3: indicates a reply with an IPv4 or IPv6 UDP datagram carrying a router alert label. ● 4: indicates a reply through the control channel of the application plane.	The value ranges from 1 to 4. The default value is 2.
-exp *exp-value*	Specifies the EXP value of an Echo Request packet to be sent.	The value is an integer that ranges from 0 to 7.
-v	Displays detailed information.	-
vsi *vsi-name*	Specifies the name of a VSI.	The value is an existing VSI.

Parameter	Description	Value
local-site-id	Specifies the ID of the local CE.	The value is an integer that ranges from 0 to 65534.
remote-site-id	Specifies the ID of the remote CE.	The value is an integer that ranges from 0 to 65534.
peer *peer-address*	Specifies the IP address of the peer PE.	-
negotiate-vc-id *vc-id*	Specifies the ID of the local PW.	The value is an integer that ranges from 1 to 4294967295.

Usage Guidelines

Usage Scenario

After VPLS configurations are complete, you can run the **ping vpls** command to check the PW status and reachability of the peer.

- To check the PW status on a Kompella VPLS network, run the following command:

  ping vpls [**-c** *echo-number* | **-m** *time-value* | **-s** *data-bytes* | **-t** *timeout-value* | **-r** *reply-mode* | **-exp** *exp-value* | **-v**] * **vsi** *vsi-name local-site-id remote-site-id*

  .
- To check the PW status on a Martini or BGP AD VPLS network, run the following command:

  ping vpls [**-c** *echo-number* | **-m** *time-value* | **-s** *data-bytes* | **-t** *timeout-value* | **-r** *reply-mode* | **-exp** *exp-value* | **-v**] * **vsi** *vsi-name* **peer** *peer-address* [**negotiate-vc-id** *vc-id*]

  .

Prerequisites

One of the following operations has been performed before the **ping vpls** command is used:

- Configuring Kompella VPLS
- Configuring Martini VPLS

- Configuring BGP AD VPLS

Precautions

The timeout period specified by **-t** is less than the waiting time specified by **-m**.

Note the following points when configuring VPLS:

- If **negotiate-vc-id** is not specified in the **peer** command, *vc-id* is unique and equal to *vsi-id*. To perform the ping operation, you do not need to specify *vc-id* because the VC is unique when **vsi** *vsi-name* and **peer** *peer-address* are specified. In the same case, however, if **negotiate-vc-id** is specified and it is not equal to the actual *vc-id* (that is, *vsi-id*), an error message is displayed.
- If **negotiate-vc-id** (multiple VC IDs can be specified) in the **peer** command, you need to specify **negotiate-vc-id** in addition to **vsi** *vsi-name* and **peer** *peer-address* when performing the ping. If **negotiate-vc-id** is not found or specified, an error message is displayed.

Example

Run the **ping vpls** command on the PE to check connectivity of the VSI named **bgp1** with remote site ID being 10.

```
<HUAWEI> ping vpls -c 10 -m 10 -s 65 -t 100 -v vsi bgp1 10 10
   Reply from 10.2.2.2: bytes=65 Sequence=1 time=2 ms Return Code 3, Subcode 1
   Reply from 10.2.2.2: bytes=65 Sequence=2 time=2 ms Return Code 3, Subcode 1
   Reply from 10.2.2.2: bytes=65 Sequence=3 time=3 ms Return Code 3, Subcode 1
   Reply from 10.2.2.2: bytes=65 Sequence=4 time=2 ms Return Code 3, Subcode 1
   Reply from 10.2.2.2: bytes=65 Sequence=5 time=3 ms Return Code 3, Subcode 1
   Reply from 10.2.2.2: bytes=65 Sequence=6 time=41 ms Return Code 3, Subcode 1
   Reply from 10.2.2.2: bytes=65 Sequence=7 time=4 ms Return Code 3, Subcode 1
   Reply from 10.2.2.2: bytes=65 Sequence=8 time=4 ms Return Code 3, Subcode 1
   Reply from 10.2.2.2: bytes=65 Sequence=9 time=3 ms Return Code 3, Subcode 1
   Reply from 10.2.2.2: bytes=65 Sequence=10 time=6 ms Return Code 3, Subcode 1

 --- FEC: L2 VPN ENDPOINT. Sender VEID = 10, Remote VEID = 10 ping statistics ---
   10 packet(s) transmitted
   10 packet(s) received
   0.00% packet loss
   round-trip min/avg/max = 2/7/41 ms
```

Table 10-135 Description of the ping vpls command output

Item	Description
Return Code	Return code. Different values have different meanings: ● 0: indicates that no return code is received. ● 1: indicates that an incorrect request is received. ● 2: indicates that an unknown TLV is received. ● 3: indicates that there is the outbound interface of one LSP. ● 4: indicates that there is no mapping on the response router. ● 5: indicates that the mapping does not match that on the downstream device. ● 6: indicates that an unknown upstream interface exists. ● 7: indicates that the field is reserved. ● 8: indicates label switching. ● 9: indicates label switching without MPLS forwarding. ● 10: indicates mapping without labels. ● 11: indicates the entity without labels. ● 12: indicates that no protocol is loaded on the interface. ● 13: indicates that the ping operation terminates because there is only one label.
Subcode	Subcode, indicating the number of layers of the labels. Usually, the value is 1.

Run the **ping vpls** command on the PE to check the connectivity of a PW in the Martini VPLS.

```
<HUAWEI> ping vpls vsi a2 peer 10.2.2.2
   Reply from 10.2.2.2: bytes=100 Sequence=1 time=3 ms
   Reply from 10.2.2.2: bytes=100 Sequence=2 time=6 ms
   Reply from 10.2.2.2: bytes=100 Sequence=3 time=6 ms
   Reply from 10.2.2.2: bytes=100 Sequence=4 time=6 ms
   Reply from 10.2.2.2: bytes=100 Sequence=5 time=6 ms

  --- FEC: FEC 128 PSEUDOWIRE (NEW). Type = vlan, ID = 10 ping statistics ---
   5 packet(s) transmitted
   5 packet(s) received
   0.00% packet loss
   round-trip min/avg/max = 3/4/6 ms
```

Table 10-136 Description of the ping vpls command output

Item	Description
Reply from x.x.x.x	Response from the destination host to each Echo Request packet: ● bytes: indicates the length of the response packet. ● sequence: indicates the sequence number of the response packet. ● time: indicates the response time, in ms. If no response packet is received after the timeout period, the message "Request time out" is displayed.
FEC: FEC 128 PSEUDOWIRE	Check on FEC 128, namely, check on a Martini VPLS PW.
Type = vlan	VLAN encapsulation on packets.
ID = 10	The VSI ID being 10.

Run the **ping vpls** command on the PE to check the connectivity of a PW in the BGP AD VPLS.

```
<HUAWEI> ping vpls vsi ad peer 10.2.2.2
    Reply from 10.2.2.2: bytes=100 Sequence=1 time=30 ms
    Reply from 10.2.2.2: bytes=100 Sequence=2 time=60 ms
    Reply from 10.2.2.2: bytes=100 Sequence=3 time=60 ms
    Reply from 10.2.2.2: bytes=100 Sequence=4 time=60 ms
    Reply from 10.2.2.2: bytes=100 Sequence=5 time=60 ms

 --- FEC: FEC 129 PSEUDOWIRE. Sender = 1.1.1.1, Remote = 10.2.2.2 ping statisti
cs ---

    5 packet(s) received
    0.00% packet loss
    round-trip min/avg/max = 30/54/60 ms
```

Table 10-137 Description of the ping vpls command output

Item	Description
Reply from x.x.x.x	Response from the destination host to each Echo Request packet: ● bytes: indicates the length of the response packet. ● sequence: indicates the sequence number of the response packet. ● time: indicates the response time, in ms. If no response packet is received after the timeout period, the message "Request time out" is displayed.
FEC: FEC 129 PSEUDOWIRE	Check on FEC 129, namely, check on a BGP AD VPLS PW.
Sender = x.x.x.x	Address of the sender.

Item	Description
Remote = x.x.x.x	Address of the destination host.

10.7.82 ping vpls mac vsi

Function

The **ping vpls mac vsi** command checks the connectivity of Layer 2 forwarding links on the VPLS network.

Format

ping vpls mac *mac-address* **vsi** *vsi-name* [**vlan** *vlan-id* | **-c** *count* | **-m** *time-value* | **-s** *packsize* | **-t** *timeout* | **-exp** *exp* | **-r** *replymode* | **-h** *ttl*] *

ping vpls mac *mac-address* **vsi** *vsi-name* **rapid** [**vlan** *vlan-id* | **-c** *count* | **-s** *packsize* | **-t** *timeout* | **-exp** *exp* | **-r** *replymode* | **-h** *ttl*] *

Parameters

Parameter	Description	Value
mac *mac-address*	Specifies the unicast destination MAC address of the VPLS MAC ping, expressed in the format of H-H-H.	An H is a hexadecimal number of 1 to 4 bits, such as 00e0 and fc01. If you enter less than four digits, 0s are padded before the input digits. For example, if e0 is entered, 00e0 is displayed. The value cannot be a broadcast or multicast MAC address.
vsi *vsi-name*	Specifies the name of a VSI.	The value is an existing VSI.
vlan *vlan-id*	Specifies the ID of a VLAN	*vlan-id* specifies the VLAN ID, which is an integer that ranges from 1 to 4094.

Parameter	Description	Value
rapid	Indicates that VPLS MAC ping packets are sent in **rapid** mode. This parameter can be used if each response message is not concerned and multiple ping operations need to be performed within a shot period of time. This configuration allows all packets to be sent at the same time, and only summary statistics are displayed.	-
-c *count*	Specifies the number of VPLS MAC Ping Request packets to be sent.	The value ranges from 1 to 4294967295. The default value is 5.
-m *time-value*	Specifies the time to wait before sending the next VPLS MAC Ping Request packet.	The value ranges from 1 to 10000, in milliseconds. The default value is 2000 ms.
-s *packsize*	Specifies the size of the VPLS MAC Ping Request packet.	The value ranges from 142 to 1442, in bytes. The default value is 142 bytes.
-t *timeout*	Specifies the timeout period for waiting for a Reply packet in response to a VPLS MAC Ping Request packet.	The value ranges from 0 to 65535, in milliseconds. The default value is 2000 ms.
-exp *exp*	Specifies the priority.	The value ranges from 0 to 7. The default value is 0.
-r *replymode*	Specifies the reply mode, that is, the Reply packet is sent from the control layer or the data layer. Enumerated type.	-
-h *ttl*	Specifies the TTL value of an Echo Request packet to be sent.	The value ranges from 1 to 255. The default value is 30.

Usage Guidelines

Using the **ping vpls mac vsi** command, you can check the connectivity of Layer 2 forwarding links on the VPLS network.

Example

On the VPLS network, check whether the device with the MAC address of 00e0-fc12-3456 is reachable.

```
<HUAWEI> ping vpls mac 00e0-fc12-3456 vsi v123
Ping mac 00e0-fc12-3456 vsi v123 : 100 data bytes , press CTRL_C to break
    Reply from 10.1.1.1 : bytes=100 sequence=1 time = 1ms
    Reply from 10.1.1.1 : bytes=100 sequence=2 time = 1ms
    Reply from 10.1.1.1 : bytes=100 sequence=3 time = 2ms
    Reply from 10.1.1.1 : bytes=100 sequence=4 time = 3ms
    Reply from 10.1.1.1 : bytes=100 sequence=5 time = 2ms
    The IP address of the PE is 5.5.5.5 and the interface on the PE is GigabitEthernet0/0/1.

  --- vsi : v123 00e0-5952-6f01 ping statistics ---
    5 packet(s) transmitted
    5 packet(s) received
    0.00% packet loss
    round-trip min/avg/max = 1/2/3 ms
```

10.7.83 ping vpls multicast

Function

The **ping vpls multicast** command starts an MFIB ping test with a specified VSI in the VPLS domain.

Format

ping vpls multicast vsi *vsi-name* [**-a** *source-ip-address* | **-c** *count* | **-s** *packetsize* | **-t** *timeout* | **-m** *interval* | **-r** *replymode* | **-exp** *exp* | **-v**] * *dest-ip-address*

Parameters

Parameter	Description	Value
vsi *vsi-name*	Specifies the name of the VSI on which the operation is performed.	The value is an existing VSI.
-a *source-ip-address*	Specifies the multicast source IP address. By default, the multicast source IP address is the IP address of the initiator. The value is in dotted decimal notation.	-

Parameter	Description	Value
-c *count*	Specifies the number of Echo Request packets to be sent.	The value is an integer that ranges from 1 to 4294967295. The default value is 5.
-s *packetsize*	Specifies the length of the payload in the Echo Request packet, which should be smaller than the MTU value.	The value ranges from 100 to 1442, in bytes. The default value is 100.
-t *timeout*	Specifies the timeout period for waiting for an Echo Reply packet.	The value ranges from 0 to 65535, in milliseconds. The default value is 2000 milliseconds.
-m *interval*	Specifies the time to wait before sending the next Echo Request packet.	The value ranges from 1 to 10000, in milliseconds. The default value is 2000 milliseconds.
-r *replymode*	Specifies the reply mode. The default value is 2. ● 1: indicates that the peer end does not respond to Echo Request packets. ● 2: indicates that the peer end responds to Echo Request packets with IPv4 or IPv6 UDP packets. ● 3: indicates that the peer end responds to Echo Request packets with IPv4 or IPv6 UDP packets carrying the Router Alert option. ● 4: indicates that the peer end responds to Echo Request packets through the control channel of the application program grade. ● 5: indicates that the peer end responds to Echo Request packets with VPLS IPv4 UDP packets. **NOTE** Currently, the switch only supports mode 1, 2, and 5.	-

Parameter	Description	Value
-exp *exp*	Specifies the priority of Echo Request packets to be sent.	The value is an integer that ranges from 0 to 7. The default value is 0.
-v	Specifies the displayed details.	-
dest-ip-address	Specifies the multicast IP address.	-

Usage Guidelines

Usage Scenario

Using the **ping vpls multicast** command, you can start an MFIB ping test with a specified VSI in the VPLS domain and obtain information about the egress that is in the VPLS domain and can normally receive specified IP multicast packets. In addition, you can check whether the IGMP snooping function is normal.

Precautions

- To check whether the IGMP snooping function is normal, enable IGMP snooping of the VSI to trigger the exchange of IGMP Query packets and Report packets between the multicast source and receiver and specify a non-reserved multicast address as the destination address to initiate the VPLS multicast ping.
- The **ping vpls multicast** command does not support BGP AD VPLS.

After receiving a VPLS multicast Ping packet, the egress in the VPLS domain sends a Reply packet to the sender. The sender can determine the connectivity of the egress and the round trip delay according to the received Reply packet.

You can check the IGMP snooping function in the following scenarios:

- If IGMP snooping is enabled on a PE and the **ping vpls multicast** command run on the PE contains the **-v** parameter, the MPLS Echo packet received by the initiator carries information about interfaces at the AC side of the PE. If the initiator does not receive the Echo Reply packet of the PE, it considers the IGMP snooping function faulty.
- If a certain PE is not enabled with the IGMP snooping function, the Echo Reply packet received by the initiator does not carry information about interfaces at the AC side of the PE.

Example

Initiate an MFIB ping test with a specified VSI in the VPLS domain.

```
<HUAWEI> ping vpls multicast vsi aaa -a 11.11.11.1 -c 2 -v 225.0.0.1
ping 225.0.0.1 : 56 data bytes , press CTRL-C to break

round-trip min/avg/max = 10/15/20 ms
```

Table 10-138 Description of the ping vpls multicast command output

Item	Description
Seq	Sequence number of the packet.
Node-id	Response address, which carries the port number if it contains forwarding information about the AC side.
Path	Path. ● Self: indicates that packets are sent from the local end (AC side). ● In-Band: indicates that packets are sent from the data link layer (PW side).
Size	Size of the packet.
RTT	Round trip time.

10.7.84 ping vpn-config

Function

The **ping vpn-config** command checks whether configurations on both ends of a VPN are consistent, which can help you locate faults on the VPN connection.

Format

ping vpn-config peer-address *peer-address* **vsi-name** *vsi-name* [**pw-id** *pw-id*] [**local**] [**remote**]

Parameters

Parameter	Description	Value
peer-address *peer-address*	Specifies the IP address of the peer PE.	-
vsi-name *vsi-name*	Specifies the name of the VSI on which the operation is performed.	The value is an existing VSI.
pw-id *pw-id*	Specifies the ID of the PW.	The value is an integer that ranges from 1 to 4294967295. This parameter cannot be specified in the BGP AD VPLS networking.
local	Indicates that the Request packet is encapsulated in LSP mode.	-
remote	Indicates that the Reply packet is encapsulated in LSP mode.	-

Views

All views

Default Level

0: Visit level

Usage Guidelines

Usage Scenario

Using the **ping vpn-config** command, you can check whether configurations on both ends of a VPN are consistent, which can help you locate faults on the VPN connection.

The **ping vpn-config** command is used to send a Request packet from the local PE to the peer PE to obtain VPN configurations of the peer PE, such as the VSI name, status, PW type, MTU value, and number of CEs. After the local PE receives the VPN configuration of the peer PE, it displays the information on the local. This can help you locate the fault on the VPN.

Precautions

The **ping vpn-config** command is applied to VPLS networks, dynamic PWE3 networks, and VLL accessing the VPLS networks.

NOTE

The timeout period of the **ping vpn-config** command is 10 seconds.

Example

Run the **ping vpn-config** command to ping the peer PE in Martini VPLS networking.

```
<HUAWEI> ping vpn-config peer-address 3.3.3.9 vsi-name a2
VPN-CONFIG PING: Press CTRL_C to break.
Result Detail: Request Sent - Reply Received

Table 10-139 Description of the ping vpn-config command output

Item	Description
Result details	Details of the command operation result.
Local VPN description	Description of the local VPN. To set the value, run the **description** command.
Remote VPN description	Description of the peer VPN.
PW State	Status of a PW.
Local	Configuration of the local PE.
Remote	Configuration of the remote PE.
VPN Type	Type of a VPN.
VSI Name	Name of a VSI.
VSI ID	ID of a VSI. To set the value, run the **vsi-id** command.
Admin State	VSI administration status.
Oper State	VSI operating status.
MTU	MTU of the VSI. In PWE3 networking, it refers to the MTU of an AC interface; in VPLS networking, it refers to the MTU of a VSI.
CE Count	Number of AC links.
Control Word	Whether the control word is enabled: ● Enable ● Disable
Primary Or Secondary	Displayed as a PW on the local end and always displayed as N/A on the remote end.
Actual IP Addr	Actual IP address.
Expect IP Addr	Expected IP address.
SPE	Whether it is a SPE
PW ID	ID of a PW.
VC-Type	Encapsulation type of the VC. ● Ethernet: indicates that the encapsulation type of the VC is Ethernet. ● VLAN: indicates that the encapsulation type of the VC is VLAN.
Egress Label	Outgoing label.

Item	Description
Ingress Label	Incoming label.
VPLS ID	VPLS ID To set the value, run the **vpls-id** command.
RD	Route tag. To set the value, run the **route-distinguisher** command.
Import VPN target	Import VPN target.
Export VPN target	Export VPN target.
LSP Tunnel Used	Whether the packet is encapsulated in LSP mode.

10.7.85 protect-group (VSI-LDP view)

Function

The **protect-group** command creates a PW protection group. If the PW protection group to be created already exists, the PW protection group view is displayed.

The **undo protect-group** command deletes a specified PW protection group.

By default, no PW protection group is created in a VSI.

Format

protect-group *group-name*

undo protect-group *group-name*

Parameters

Parameter	Description	Value
group-name	Specifies the name of a PW protection group.	The value is a string of 1 to 15 case-sensitive characters without spaces or hyphens (-). When double quotation marks are used around the string, spaces are allowed in the string.

Views

VSI-LDP view

Default Level

2. Configuration level

Usage Guidelines

Usage Scenario

Multiple PWs can be created in a VSI.

You can create multiple PW protection groups for a VSI. After you add two PWs to a PW protection group, the two PWs will work in backup mode.

Prerequisites

The VSI ID has been configured using the **vsi-id** *vsi-id* command in the VSI-LDP view.

Follow-up Procedure

After creating PW protection groups, configure the PW redundancy mode of each PW protection group, add PWs to these groups, and configure revertive switching policies for these groups.

Example

Create a PW protection group named group1.

```
<HUAWEI> system-view
[HUAWEI] vsi vsi1
[HUAWEI-vsi-vsi1] pwsignal ldp
[HUAWEI-vsi-vsi1-ldp] vsi-id 10
[HUAWEI-vsi-vsi1-ldp] protect-group group1
```

10.7.86 protect-mode (protect-group view)

Function

The **protect-mode** command specifies the PW redundancy mode of a PW protection group.

The **undo protect-mode** command cancels the PW redundancy mode of a PW protection group.

By default, a PW protection group does not have a PW redundancy mode.

Format

protect-mode pw-redundancy master

undo protect-mode

Parameters

Parameter	Description	Value
pw-redundancy master	Specifies the PW redundancy mode of a PW protection group as master/slave.	-

Views

protect-group view

Default Level

2. Configuration level

Usage Guidelines

Usage Scenario

You can configure PW protection groups to protect PW pairs of a VSI.

In the scenarios, in which the active/standby PWs cannot be determined based on the signaling sent by the remote end, you can create a PW protection group on the UPE, and specify the PW redundancy mode of the group as master/slave. The local UPE determines the active/standby PWs based on the priorities configured using the **peer preference** command.

NOTE

When the mode of the group is master/slave, the local UPE does not determine the active/standby PWs based on the signaling sent by the remote end.

Prerequisites

The PW protection group has been configured using the **protect-group** command.

Precautions

A static hub PW and a static spoke PW cannot be added to the same protection group.

After a PW protection group is configured, you must specify the PW redundancy mode before configuring other parameters. Deleting the PW redundancy mode of a PW protection group will clear all the configurations of the group.

Example

Configure the PW redundancy mode of a PW protection group as PW redundancy master/slave.

```
<HUAWEI> system-view
[HUAWEI] vsi vsi1
[HUAWEI-vsi-vsi1] pwsignal ldp
[HUAWEI-vsi-vsi1-ldp] protect-group group1
[HUAWEI-vsi-vsi1-ldp-protect-group-group1] protect-mode pw-redundancy master
```

10.7.87 protect-switch (protect-group view)

Function

The **protect-switch** command triggers a manual protection switchover or cancels the manual switchover in a protection group.

Format

protect-switch { **manual** | **clear** }

Parameters

Parameter	Description	Value
manual	Forcibly performs a PW switchover to switch traffic from the high-priority primary PW to the low-priority backup PW.	-
clear	Cancels the **manual** PW switchover to switch traffic from the low-priority backup PW back to the high-priority primary PW.	-

Views

protect-group view

Default Level

2. Configuration level

Usage Guidelines

Usage Scenario

If you want to maintain the device where the primary PW in a PW protection group resides, you must use a command to switch traffic from the primary PW to the secondary PW first. After the device where the primary PW resides is stable, you need to use this command to switch traffic back from the secondary PW to the primary PW.

Prerequisites

A PW protection group has been created and the PW redundancy mode is master/slave. The primary and secondary PWs have joined the PW protection group and their status is Up.

Precautions

After you run the **protect-switch manual** command, traffic switches from the primary PW to the secondary PW. After you run the **protect-switch clear** command, traffic switches from the secondary PW to the primary PW.

After you run the **protect-switch manual** command, service traffic is always transmitted over the low-priority backup PW. To enable service traffic to be transmitted over a high-priority PW, run the **protect-switch clear** command to cancel the manual switchover. The manual switchover is also cancelled when the priorities of the primary and backup PWs change in some situations, for example, a PW is Down or you change their priority values. In these situations, the system selects the PW with a higher priority to transmit service traffic.

Example

Forcibly perform an active/standby PW switchover in the current PW protection group.

```
<HUAWEI> system-view
[HUAWEI] vsi vsi1
[HUAWEI-vsi-vsi1] pwsignal ldp
[HUAWEI-vsi-vsi1-ldp] protect-group group1
[HUAWEI-vsi-vsi1-ldp-protect-group-group1] protect-switch manual
```

10.7.88 pw

Function

The **pw** command displays the PW view.

The **undo pw** command deletes the PW view.

By default, the PW view is not displayed.

Format

pw *pw-name*

undo pw *pw-name*

Parameters

Parameter	Description	Value
pw-name	Specifies the name of a PW.	The value is a string of 1 to 15 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

VSI-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a PW is created, you can run the **pw** *pw-name* command to enter the PW view.

Prerequisites

A PW has been created using the **peer** *peer-address* [**negotiation-vc-id** *vc-id*] **pw** *pw-name* command.

Precautions

The PW name must be unique in a VSI, and the PW name can be the same in different VSIs.

Example

Enter the PW view.

```
<HUAWEI> system-view
[HUAWEI] vsi aa static
[HUAWEI-vsi-aa] pwsignal ldp
[HUAWEI-vsi-aa-ldp] vsi-id 1
[HUAWEI-vsi-aa-ldp] peer 10.1.1.1
[HUAWEI-vsi-aa-ldp] peer 10.1.1.1 pw pw1
[HUAWEI-vsi-aa-ldp-pw-pw1] quit
[HUAWEI-vsi-aa-ldp] pw pw1
```

10.7.89 pwsignal

Function

The **pwsignal** command configures the signaling mode for a VSI.

By default, no signaling mode is configured for a VSI.

Format

pwsignal { **bgp** | **ldp** }

Parameters

Parameter	Description	Value
bgp	Uses the BGP signing mode.	-
ldp	Uses the LDP signaling mode.	-

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When configuring the Martini or Kompella VPLS, you need to run the **pwsignal** command to configure a signaling mode for a VSI.

Precautions

If the member discovery mode of the VSI is static, the signaling mode must be LDP. If the member discovery mode of the VSI is automatic, the signaling mode must be BGP.

After the signaling mode is configured successfully for the VSI, it cannot be modified. If you want to change the signaling mode, you must delete the VSI and re-create VSI.

Example

Configure the signaling mode of the VSI as LDP.

```
<HUAWEI> system-view
[HUAWEI] vsi company1 static
[HUAWEI-vsi-company1] pwsignal ldp
[HUAWEI-vsi-company1-ldp]
```

Configure the signaling mode of the VSI as BGP.

```
<HUAWEI> system-view
[HUAWEI] vsi company2 auto
[HUAWEI-vsi-company2] pwsignal bgp
[HUAWEI-vsi-company2-bgp]
```

10.7.90 pw spoke-mode (VSI-BGPAD view)

Function

The **pw spoke-mode** command configures all PWs of a BGP AD VSI as spoke PWs.

The **undo pw spoke-mode** command restores the default setting.

By default, all PWs of a BGP AD VSI are hub PWs.

Format

pw spoke-mode

undo pw spoke-mode

Parameters

None

Views

VSI-BGPAD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a BGP AD VPLS needs to be deployed on a network with a star or tree topology (on which one PE that serves as a server or an authorization device is configured as the hub PE, and other PEs are configured as spoke PEs), all PWs of the VSI on the hub PE must be configured as spoke PWs to disable split horizon of the PWs. Traffic from spoke PWs can be forwarded to spoke PWs and hub PWs, but traffic from hub PWs can only be forwarded to spoke PWs and not to hub PWs.

Prerequisites

The VPLS ID has been configured using the **vpls-id** *vpls-id* command in the VSI-BGPAD view.

Precautions

The **pw spoke-mode** command takes effect on all the PWs of a BGP AD VSI.

After the **pw spoke-mode** command is run, all PWs of the specified VSI become spoke PWs. Split horizon does not function on spoke PWs. This means that packets sent from Spoke PWs can be forwarded to other PWs. If the **undo pw spoke-mode** command is run, all PWs of the VSI will be changed to hub PWs that comply with split horizon rules.

Example

Create a BGP AD VSI named **company1** and configure all the PWs of the VSI as spoke PWs.

```
<HUAWEI> system-view
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] bgp-ad
[HUAWEI-vsi-company1-bgpad] vpls-id 65535:1
[HUAWEI-vsi-company1-bgpad] pw spoke-mode
```

10.7.91 remote-vpn-target refresh

Function

The **remote-vpn-target refresh** command refreshes the remote VPN target manually.

Format

remote-vpn-target refresh

Parameters

None

Views

VSI-BGP view

Default Level

2: Configuration level

Usage Guidelines

When locating a Kompella VPLS fault, you can use the **remote-vpn-target refresh** command to refresh the remote VPN target manually.

Example

Refresh the remote VPN target.

```
<HUAWEI> system-view
[HUAWEI] vsi company2
[HUAWEI-vsi-company2] pwsignal bgp
[HUAWEI-vsi-company2-bgp] remote-vpn-target refresh
```

10.7.92 reroute (protect-group view)

Function

The **reroute** command configures a revertive switching policy for a PW protection group with the master/slave PW redundancy mode.

The **undo reroute** command deletes the revertive switching policy for a PW protection group with the master/slave PW redundancy mode.

The default revertive switching policy for a PW protection group with the master/slave PW redundancy mode is delayed switchback and the default delay is 30s.

Format

reroute { **delay** *delay-time* | **immediately** | **never** }

undo reroute

Parameters

Parameter	Description	Value
delay *delay-time*	Specifies that the revertive switching policy is delayed switchback.	The value is an integer ranging from 10 to 600, in seconds. The default value is 30s.
immediately	Specifies that the revertive switching policy is immediate switchback.	-
never	Specifies that the revertive switching policy is non-revertive. Traffic does not switch back to the primary PW even after the primary PW recovers. Traffic will be switched back to the primary PW only when the secondary PW fails.	-

Views

protect-group view

Default Level

2. Configuration level

Usage Guidelines

Usage Scenario

The **reroute** command can configure revertive switching policies for only PW protection groups with the master/slave PW redundancy mode. The revertive switching policy for PW protection groups with the independent PW redundancy mode is immediate switchback and cannot be modified.

Currently, three types of revertive switching policies are available:

- Delayed switchback: Traffic is switched back to the primary PW after the delay time specified in *delay-time*. After the switchover is performed, the UPE notifies the remote PE on the secondary PW of a fault. On a large-scale network, packet loss caused by incomplete route convergence may occur during the switchback. To prevent this problem, configure traffic to be switched back after a delay.
- Immediate switchback: Traffic is immediately switched back to the primary PW. This revertive switching policy applies to scenarios in which users hope traffic to be restored as soon as possible.
- Non-revertive: Traffic will not be switched back to the primary PW even after the primary PW recovers. Traffic will be switched back to the primary PW only when the secondary PW fails. If you do not want traffic to be frequently switched between the primary and secondary PWs, you can use the non-revertive policy.

Prerequisites

The PW redundancy mode of the PW protection group is master/slave.

Precautions

The revertive switching policy determines the switchback behavior of the traffic after the primary PW recovers.

Example

Configure the primary and secondary PWs in a PW protection group to perform a switchback after a delay of 60s.

```
<HUAWEI> system-view
[HUAWEI] vsi vsi1
[HUAWEI-vsi-vsi1] pwsignal ldp
[HUAWEI-vsi-vsi1-ldp] protect-group group1
[HUAWEI-vsi-vsi1-ldp-protect-group-group1] reroute delay 60
```

10.7.93 reset bgp l2vpn-ad

Function

The **reset bgp l2vpn-ad** command resets the BGP connections associated with L2VPN-AD.

Format

reset bgp l2vpn-ad { **all** | *as-number-plain* | *as-number-dot* | *ipv4-address* | **group** *group-name* | **external** | **internal** } [**graceful**]

Parameters

Parameter	Description	Value
l2vpn-ad	Resets BGP connections associated with L2VPN-AD.	-
all	Resets all the BGP connections.	-
as-number-plain	Integral AS number	The value is an integer ranging from 1 to 4294967295.
as-number-dot	AS number in dotted notation	The value is in the format of *x.y*, where *x* and *y* are integers that range from 1 to 65535 and from 0 to 65535, respectively.
ipv4-address	Resets the connections with a specified BGP peer.	It is in dotted decimal notation.
group *group-name*	Resets the BGP connections with the specified peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
external	Resets all EBGP connections.	-
internal	Resets all IBGP connections.	-
graceful	Specifies to reset BGP connections in GR mode.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

The **reset bgp l2vpn-ad** command is used to make new BGP configurations associated with L2VPN-AD take effect.

⚠ CAUTION

After you run this command, the TCP connection is reset, and the neighbor relationship between two peers is reestablished. So, confirm the action before you use the command.

Example

Reset all BGP L2VPN-AD connections.

```
<HUAWEI> reset bgp l2vpn-ad all
```

10.7.94 reset oam-mac statistics

Function

The **reset oam-mac statistics** command clears the statistics about the number of MAC diagnostic packets.

Format

reset oam-mac statistics { **populate** | **purge** | **purge-register** | **all** }

Parameters

Parameter	Description	Value
populate	Indicates the statistics about the number of populate packets.	-
purge	Indicates the statistics about the number of purge packets.	-
purge-register	Indicates the statistics about the number of purge + register packets.	-
all	Indicates the statistics about the number of MAC diagnostic packets.	-

Views

All views

Default Level

3: Management level

Usage Guidelines

Using the **reset oam-mac statistics** command, you can clear the statistics about the number of MAC diagnostic packets.

NOTICE

The statistics about MAC diagnostic packets cannot be restored once they are cleared. Confirm the action before you run the **reset oam-mac statistics** command.

Example

Display the statistics about the number of all MAC diagnostic packets that are received by the device.

```
<HUAWEI> display oam-mac statistics all
 Received populate packet: 3
 Received purge packet: 1
 Received purge register packet: 2
```

Clear the statistics about the number of MAC diagnostic packets that are received by the device.

```
<HUAWEI> reset oam-mac statistics all
```

Display the statistics about the number of MAC diagnostic packets that are received by the device. It is found that all the statistics are cleared.

```
<HUAWEI> display oam-mac statistics all
 Received populate packet: 0
 Received purge packet: 0
 Received purge register packet: 0
```

10.7.95 reset vpls multicast-ping statistics

Function

The **reset vpls multicast-ping statistics** command clears the statistics on the number of MFIB Ping packets.

Format

reset vpls multicast-ping statistics

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

You can run this command to clear the statistics on the number of sent and received MFIB Ping packets.

Example

Reset the statistics on the number of MFIB Ping packets.

```
<HUAWEI> reset vpls multicast-ping statistics
```

10.7.96 reset vpls multicast-trace statistics

Function

The **reset vpls multicast-trace statistics** command clears the statistics on the number of MFIB Trace packets.

Format

reset vpls multicast-trace statistics

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

The **reset vpls-trace statistics** command clears the statistics about the number of sent and received VPLS MAC Trace packets.

Example

Clear the statistics about the number of VPLS MAC Trace packets.

```
<HUAWEI> reset vpls-trace statistics
```

10.7.99 reset traffic-statistics vsi all

Function

The **reset traffic-statistics vsi all** command clears the statistics about all VPLS PW traffic.

Format

reset traffic-statistics vsi all

Parameters

None

Views

User view

Default Level

2: Configuration level

Usage Guidelines

When the **reset traffic-statistics vsi all** command is run successfully, confirm whether to proceed with the operation. If yes, enter **Y**. If no, enter **N**.

Example

Reset the statistics about all VPLS PW traffic in the user view.

```
<HUAWEI> reset traffic-statistics vsi all
Warning:Traffic-statistics information will be cleared! Continue? [Y/N]:Y
```

10.7.100 reset traffic-statistics vsi name

Function

The **reset traffic-statistics vsi name** command clears the statistics about the public traffic on all VPLS PWs in the specified VSI.

Format

reset traffic-statistics vsi name *vsi-name*

Parameters

Parameter	Description	Value
vsi-name	Specifies the name of the VSI in which traffic statistics are cleared.	The value is an existing VSI.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the VPLS configuration is complete, you can run the **display traffic-statistics vsi** command to view statistics about all PW traffic in the VSI. To view the statistics about the traffic in a specified period, you can run the **reset traffic-statistics vsi name** command to clear the previous statistics.

Precautions

The **reset traffic-statistics vsi name** command is valid only in Martini VPLS.

After you run this command, statistics about all VPLS PW traffic in the VSI are cleared.

Example

Clear the statistics about all VPLS PW traffic in the specified VSI in the user view.

```
<HUAWEI> reset traffic-statistics vsi name newvsi
```

10.7.101 reset traffic-statistics vsi name peer

Function

The **reset traffic-statistics vsi name peer** command clears the statistics about public traffic of the PW in the specified VPLS VSI.

Format

reset traffic-statistics vsi name *vsi-name* **peer** *peer-address*

Parameters

Parameter	Description	Value
vsi-name	Specifies the name of the VSI in which traffic statistics are cleared.	The value is an existing VSI.
peer *peer-address*	Specifies the peer IP address of the PW.	-

Views

User view

Usage Guidelines

Usage Scenario

After the VPLS configuration is complete, you can run the **display traffic-statistics vsi peer** command to view statistics about the traffic of the PW. To view the statistics about the traffic in a specified period, you can run the **reset traffic-statistics vsi name peer** command to clear the previous statistics.

Precautions

The **reset traffic-statistics vsi name peer** command is valid only in Martini VPLS.

After you run this command, statistics about the traffic on the corresponding VPLS PW are cleared.

Example

Clear the statistics about the traffic on the VPLS PW in the user view.

```
<HUAWEI> reset traffic-statistics vsi name newvsi peer 10.1.1.1
```

10.7.102 reset traffic-statistics vsi name peer ldp129

Function

The **reset traffic-statistics vsi name peer ldp129** command clears the statistics about the public traffic on the BGP AD VPLS PW in the specified VSI.

Format

reset traffic-statistics vsi name *vsi-name* **peer** *peer-address* **ldp129**

Parameters

Parameter	Description	Value
name *vsi-name*	Specifies the name of the VSI in which traffic statistics are cleared.	The value is an existing VSI.
peer *peer-address*	Specifies the peer IP address of the PW.	-

Views

Usage Guidelines

Usage Scenario

After the BGP AD VPLS configuration is complete, you can run the **display traffic-statistics vsi peer ldp129** command to view statistics about the PW traffic. To view the statistics about the traffic in a specified period, you can run the **reset traffic-statistics vsi name peer ldp129** command to clear the previous statistics.

Prerequisites

The traffic statistics function has been enabled using the **traffic-statistics enable (VSI-BGPAD view)** command or the **traffic-statistics peer enable (VSI-BGPAD)** command in the VSI-BGPAD view.

Precautions

The **reset traffic-statistics vsi name peer ldp129** command is valid only in BGP AD VPLS.

After you run the **reset traffic-statistics vsi name peer ldp129** command, statistics about the traffic on the corresponding BGP AD VPLS PW are cleared.

Example

Clear the statistics about the traffic on the specified BGP AD VPLS PW in the user view.

```
<HUAWEI> reset traffic-statistics vsi name newvsi peer 10.1.1.1 ldp129
```

10.7.103 reset traffic-statistics vsi name peer negotiation-vc-id

Function

The **reset traffic-statistics vsi name peer negotiation-vc-id** command clears the statistics about the public traffic on the Martini VPLS PW in a specified VSI.

Format

reset traffic-statistics vsi name *vsi-name* **peer** *peer-address* **negotiation-vc-id** *vc-id*

Parameters

Parameter	Description	Value
vsi-name	Specifies the name of a VSI.	The value is an existing VSI.
peer *peer-address*	Specifies the peer IP address of the PW.	-
negotiation-vc-id *vc-id*	Specifies the ID of the PW.	The value is an integer that ranges from 1 to 4294967295.

Usage Guidelines

Usage Scenario

After the Martini VPLS configuration is complete, you can run the **display traffic-statistics vsi peer negotiation-vc-id** command to view the statistics about the traffic on the PW. To view the statistics about the traffic in a specified period, you can run the **reset traffic-statistics vsi name peer negotiation-vc-id** command to clear the previous statistics.

Precautions

The **reset traffic-statistics vsi name peer negotiation-vc-id** command is valid only in Martini VPLS.

After you run the **reset traffic-statistics vsi name peer negotiation-vc-id** command, statistics about the traffic on the corresponding Martini VPLS PW are cleared.

Example

Reset the statistics about the traffic on the Martini VPLS PW in the user view.

```
<HUAWEI> reset traffic-statistics vsi name newvsi peer 10.22.33.20 negotiation-vc-id 2
```

10.7.104 reset traffic-statistics vsi name peer remote-site

Function

The **reset traffic-statistics vsi name peer remote-site** command clears the statistics about the public traffic on the Kompella VPLS PW in the specified VSI.

Format

reset traffic-statistics vsi name *vsi-name* **peer** *peer-address* **remote-site** *site-id*

Parameters

Parameter	Description	Value
name *vsi-name*	Specifies the name of a VSI.	The value is an existing VSI.
peer *peer-address*	Specifies the peer IP address of the PW.	-
remote-site *site-id*	Specifies the remote site ID.	The value is an integer that ranges from 0 to 65534.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the Kompella VPLS configuration is complete, you can run the **display traffic-statistics vsi peer remote-site** command to view the statistics about the traffic on the PW. To view the statistics about the traffic in a specified period, you can run the **reset traffic-statistics vsi name peer remote-site** command to clear the previous statistics.

Prerequisites

The traffic statistics function has been enabled using the **traffic-statistics peer remote-site enable (Kompella)** command in the VSI-BGP view.

Precautions

The **reset traffic-statistics vsi name peer remote-site** command is valid only in Kompella VPLS.

After you run the **reset traffic-statistics vsi name peer remote-site** command, statistics about the traffic on the corresponding Kompella VPLS PW are cleared.

Example

Reset the statistics about the traffic on the Kompella VPLS PW in the user view.

```
<HUAWEI> reset traffic-statistics vsi name newvsi peer 10.22.33.20 remote-site 2
```

10.7.105 route-distinguisher (VSI-BGP view)

Function

The **route-distinguisher** command configures an RD for a VSI.

Format

route-distinguisher *route-distinguisher*

Parameters

Parameter	Description	Value
route-distinguisher	Specifies the value of an RD, which identifies a VSI on a PE.	The formats of an RD are as follows: ● 16-bit AS number:32-bit user-defined number: for example, 101:3. An AS number ranges from 0 to 65535, and a user-defined number ranges from 0 to 4294967295. The AS number and user-defined number cannot be both 0. That is, a VPLS ID cannot be 0:0. ● Integral 4-byte AS number:2-byte user-defined number, for example, 65537:3. An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a VPLS ID cannot be 0:0. ● 4-byte AS number in dotted notation:2-byte user-defined number, for example, 0.0:3 or 0.1:0. A 4-byte AS number in dotted notation is in the format of *x.y*, where *x* and *y* are integers that range from 1 to 65535 and from 0 to 65535, respectively. A user-defined number ranges from 0 to 65535. The AS number and user-

Parameter	Description	Value
		defined number cannot be both 0s. That is, a VPLS ID cannot be 0.0:0. - 32-bit IP address:16-bit user-defined number: for example, 192.168.122.15:1. An IPv4 address ranges from 0.0.0.0 to 255.255.255.255, and a user-defined number ranges from 0 to 65535.

Views

VSI-BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you create a VSI in the Kompella VPLS and use the BGP as the PW signaling protocol, run the **route-distinguisher** command to configure the RD. Other parameters can be configured only after the RD is configured.

Prerequisites

The following operations have been performed before this command is used:

1. A VSI has been created using the **vsi** *vsi-name* [**auto**] command.
2. BGP has been configured as the PW signaling protocol using the **pwsignal bgp** command.

Precautions

On the same PE, different VSIs have different RDs. The IDs of the same VSIs on different PEs can be either the same or different.

The RD does not have a default value. After an RD is configured successfully for the VSI, it cannot be modified. If you want to modify the RD, you need to delete the VSI and re-create a VSI.

Kompella VLL and Kompella VPLS must use different RDs.

Example

Configure an RD in the format of "16-bit ASN:32-bit user-defined number" for the VSI named **company1**.

```
<HUAWEI> system-view
[HUAWEI] vsi company1 auto
[HUAWEI-vsi-company1] pwsignal bgp
[HUAWEI-vsi-company1-bgp] route-distinguisher 101:3
```

Configure an RD in the format of "32-bit IP address:16-bit user-defined number" for the VSI named **company2**.

```
<HUAWEI> system-view
[HUAWEI] vsi company2 auto
[HUAWEI-vsi-company2] pwsignal bgp
[HUAWEI-vsi-company2-bgp] route-distinguisher 2.2.2.2:1
```

Configure an RD in the format of "4-byte AS number in dotted notation:2-byte user-defined number" for the VSI named **company2**.

```
<HUAWEI> system-view
[HUAWEI] vsi company2 auto
[HUAWEI-vsi-company2] pwsignal bgp
[HUAWEI-vsi-company2-bgp] route-distinguisher 22.22:22
```

10.7.106 shutdown (VSI view)

Function

The **shutdown** command disables a VSI.

The **undo shutdown** command enables a VSI.

By default, a VSI is enabled.

Format

shutdown

undo shutdown

Parameters

None

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

For service management such as service debugging or service halting, you can disable a VSI temporarily, and add, cancel, or adjust VSI functions.

Pre-configuration Tasks

Before a VSI is disabled, the PW-Signal must be configured.

Precautions

The **shutdown** command mainly affects PW connections of a VSI. After the command is run, the AC is Down and the Layer 2 forwarding table is deleted.

Example

Disable the current VSI.

```
<HUAWEI> system-view
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] shutdown
```

Enable the current VSI.

```
<HUAWEI> system-view
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] undo shutdown
```

10.7.107 signaling

Function

The **signaling** command configures the signaling mode for all peers or peer groups.

The **undo signaling** command restores the default signaling mode of all peers or peer groups.

By default, after the **peer enable** is run in the L2VPN AD address family view, the BGP AD signaling is enabled for all peers or peer groups.

Format

signaling { **vpws** | **vpls** | **vpls-ad disable** }

undo signaling { **vpws** | **vpls** | **vpls-ad disable** }

Parameters

Parameter	Description	Value
vpws	Configures the signaling mode of all peers or peer groups as VPWS.	-
vpls	Configures the signaling mode of all peers or peer groups as VPLS.	-
vpls-ad disable	Disables BGP AD signaling for all peers or peer groups.	-

Views

L2VPN AD address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In Kompella VLL, Kompella VPLS, and BGP AD VPLS scenarios, configure the signaling mode for peers or peer groups in the L2VPN AD address family view so that peers can advertise routes to each other. The parameters used in different scenarios are described as follows:

In the Kompella VLL scenario, configure **vpws** in the **signaling** command.

In the Kompella VPLS scenario, configure **vpls** in the **signaling** command.

In the BGP AD VPLS scenario, the BGP AD signaling is enabled for all peers or peer groups in the L2VPN AD address family view by default. Therefore, you need to run the **signaling vpls-ad disable** command to disable the BGP AD signaling for all peers or peer groups in Kompella VLL and Kompella VPLS scenarios.

Prerequisites

The **peer enable** command has been run to establish peers or peer groups.

Precautions

The signaling mode configured for a peer is preferred over that configured for the peer group to which the peer belongs. The signaling mode configured for a peer group is preferred over that configured by running the **signaling** command.

When a signaling mode is not configured for a peer or its peer group, the peer and peer group use the signaling mode configured by running the **signaling** command.

Example

Configure the signaling mode for all peers or peer groups in the L2VPN AD address family view when Kompella VPLS is enabled.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] l2vpn-ad-family
[HUAWEI-bgp-l2vpn-ad] signaling vpls
[HUAWEI-bgp-l2vpn-ad] signaling vpls-ad disable
```

10.7.108 site

Function

The **site** command configures a site ID for a VSI.

The **undo site** command deletes a site ID of a VSI.

By default, no site ID is configured for the VSI.

Format

site *site-id* [**range** *site-range*] [**default-offset** { **0** | **1** }]

undo site *site-id*

Parameters

Parameter	Description	Value
site-id	Specifies the site ID of a VSI.	The value is an integer that ranges from 0 to 65534.
range *site-range*	Specifies the range of the number of sites in the VSI. If this parameter is specified, the system reserves the required labels for the VSI.	The value is an integer that ranges from 1 to 8000.
default-offset	Specifies the offset of the initial site ID.	The value is an integer. It can be 0 or 1. The default value is 0.

Views

VSI-BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you configure an RD for the VSI in the Kompella VPLS, run the **site** command to configure site connections.

Prerequisites

The following operations have been performed before this command is used:

1. A VSI has been created using the **vsi** *vsi-name* **auto** command.
2. BGP has been configured as the PW signaling protocol using the **pwsignal bgp** command.
3. The RD of the VSI has been configured using the **route-distinguisher** *route-distinguisher* command.

Precautions

The same VSI on different PEs cannot be configured with the same site ID. *site-id* of the local end must be less than the sum of *site-range* and **default-offset** of the remote end. *site-id* of the local end cannot be less than **default-offset** of the remote end.

A device allocates labels to the ranges of Kompella L2VPN instances and VPLS VSIs from the same label block. Therefore, the ranges of Kompella L2VPN instances and VPLS VSIs cannot be greater than the size of the label block. Otherwise, the system prompts that the required labels exceed the permitted maximum labels, and the labels cannot be allocated. The system fails to create a CE or fails to allocate a site ID to a VSI.

Example

Configure the site ID of the VSI as 1 and the number of connected sites in this VSI as 100.

```
<HUAWEI> system-view
[HUAWEI] vsi company2
[HUAWEI-vsi-company2] pwsignal bgp
[HUAWEI-vsi-company2-bgp] route-distinguisher 10.1.1.1:1
[HUAWEI-vsi-company2-bgp] site 1 range 100
```

10.7.109 stream-dual-receiving

Function

The **stream-dual-receiving** command enables the secondary PW to receive and forward traffic from the peer.

The **undo stream-dual-receiving** command disables the secondary PW from receiving and forwarding traffic from the peer.

By default, the secondary PW does not receive traffic from the peer.

Format

stream-dual-receiving

undo stream-dual-receiving

Parameters

None

Views

protect-group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the network is unstable or a faulty occurs on the device, traffic may switch between the primary and secondary PW. In this case, you need to run the **stream-dual-receiving** command to enable the secondary PW to receive and forward traffic from the peer. This reduces number of packets lost during switching.

Prerequisites

The master/slave mode has been configured as the PW redundancy mode.

Configuration Impact

The secondary PW can forward data but does not forward data before traffic is switched from the primary PW to the secondary PW.

Example

Enable the secondary PW to receive and forward traffic from the peer.

```
<HUAWEI> system-view
[HUAWEI] vsi vsi1
[HUAWEI-vsi-vsi1] pwsignal ldp
[HUAWEI-vsi-vsi1-ldp] protect-group group1
[HUAWEI-vsi-vsi1-ldp-protect-group-group1] stream-dual-receiving
```

10.7.110 tnl-policy (VSI view)

Function

The **tnl-policy** command sets a tunnel policy for a VSI.

The **undo tnl-policy** command deletes the tunnel policy of a VSI.

By default, no tunnel policy is applied to a VSI.

Format

tnl-policy *policy-name*

undo tnl-policy

Parameters

Parameter	Description	Value
policy-name	Specifies the policy name of a tunnel.	The value is a string of 1 to 39 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When configuring the VPLS to use tunnels for packet exchange, run the **tnl-policy** command.

Prerequisites

One of the following operations has been performed before this command is used:

- The **pwsignal bgp** command and the **route-distinguisher** *route-distinguisher* command have been executed for Kompella VPLS.
- The **pwsignal ldp** command and the **vsi-id** *vsi-id* command have been executed for Martini VPLS.
- The **bgp-ad** command and the **vpls-id** *vpls-id* command have been executed for BGP AD VPLS.

Precautions

After the **tnl-policy** command is executed, the configured tunnel policy determines which tunnel between PE devices is preferred to forward traffic and whether load balancing is used. When creating a tunnel policy, specify the sequence of selecting tunnels. If no tunnel policy is configured, the default tunnel policy is used. That is, only LSP tunnels are selected and no load balancing is performed.

Example

Configure the tunnel policy name for the VSI.

```
<HUAWEI> system-view
[HUAWEI] vsi company1 static
[HUAWEI-vsi-company1] pwsignal ldp
[HUAWEI-vsi-company1-ldp] vsi-id 100
[HUAWEI-vsi-company1-ldp] quit
[HUAWEI-vsi-company1] tnl-policy tnlpolicyofcompany1
```

10.7.111 track hub-pw (VSI-LDP-PW view)

Function

The **track hub-pw** associates spoke PW status with hub PW status.

The **undo track hub-pw** deletes the association between spoke PW status and hub PW status.

By default, spoke PW status is not associated with hub PW status.

Format

track hub-pw

undo track hub-pw

Parameters

None

Views

VSI-LDP-PW view

Default Level

2. Configuration level

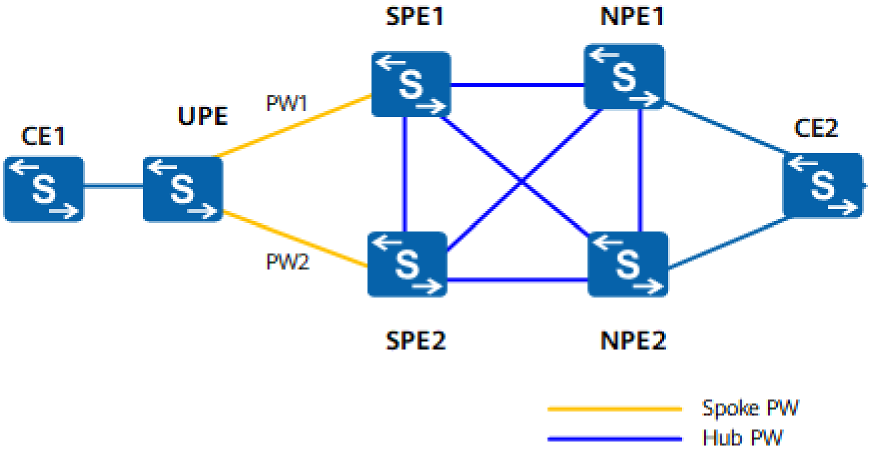
Usage Guidelines

Usage Scenario

Figure 10-3 shows a VPLS PW redundancy scenario. The UPE connects to SPE1 over PW1, a primary PW, and connects to SPE2 over PW2, a secondary PW. PW1 and PW2 work in backup mode. SPEs and NPEs are connected using hub PWs.

Under normal circumstances, if all hub PWs connected to SPE1 go Down but PW1 is Up, the upstream traffic still travels along the primary PW, PW1. As a result, traffic gets lost. To prevent traffic loss, you can run the **track hub-pw** command on SPE1 to associate spoke PW status with hub PW status. After the **track hub-pw** command is configured, SPE1 notifies the UPE of switching traffic to the secondary PW for transmission after detecting that all connected hub PWs go Down.

Figure 10-3 VPLS PW redundancy networking



Prerequisites

The **track hub-pw** command takes effect only if the following conditions are met:

- This command can only be used for a spoke PW to track the status of hub PWs. The **peer** *peer-address* [**negotiation-vc-id** *vc-id*] [**tnl-policy** *policy-name*] **upe** must have been run to create a spoke PW.
- The **peer** *peer-address* [**negotiation-vc-id** *vc-id*] **pw** *pw-name* command must have been run to display the PW view. This is because the **track hub-pw** command can only be run in the VSI-LDP-PW view.

Example

Enable the association between spoke PW status and hub PW status.

```
<HUAWEI> system-view
[HUAWEI] vsi vsi1
[HUAWEI-vsi-vsi1] pwsignal ldp
[HUAWEI-vsi-vsi1-ldp] peer 2.2.2.2 upe
```

```
[HUAWEI-vsi-vsi1-ldp] peer 2.2.2.2 pw 1
[HUAWEI-vsi-vsi1-ldp-pw-1] track hub-pw
```

10.7.112 traffic-statistics enable (VSI-LDP view)

Function

The **traffic-statistics enable** command enables the statistics about the public traffic on all Martini VPLS PWs.

The **undo traffic-statistics enable** command disables the statistics about the public traffic on all Martini VPLS PWs.

By default, the statistics function is disabled.

Format

traffic-statistics enable

undo traffic-statistics enable

Parameters

None

Views

VSI-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the Martini VPLS network is configured, you can run the **traffic-statistics enable** command to enable statistics about the traffic on all PWs.

Prerequisites

The VSI ID has been configured using the **vsi-id** *vsi-id* command in the VSI-LDP view.

Precautions

After this command is executed and the statistics reach the upper limit, a peer can still be configured, but the traffic statistics function does not take effect on this peer. When the configuration needs to be restored after the system is restarted, configured the peer first. If the statistics exceed the upper limit after the **traffic-statistics enable** is executed, the configuration cannot be restored.

The **traffic-statistics enable** command cannot be used together with the **traffic-statistics peer enable (Martini)** command in the VSI-LDP view.

Example

Enable the statistics on all PWs in the VSI 1.

```
<HUAWEI> system-view
[HUAWEI] vsi 1
[HUAWEI-vsi-1] pwsignal ldp
[HUAWEI-vsi-1-ldp] traffic-statistics enable
```

10.7.113 traffic-statistics enable (VSI-BGPAD view)

Function

The **traffic-statistics enable** command enables the statistics about the public traffic on all BGP AD VPLS PWs.

The **undo traffic-statistics enable** command disables the statistics about the public traffic on all BGP AD VPLS PWs.

By default, the statistics function is disabled.

Format

traffic-statistics enable

undo traffic-statistics enable

Parameters

None

Views

VSI-BGPAD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the BGP AD VPLS network is configured, you can run the **traffic-statistics enable** command to enable statistics about the public traffic on all BGP AD VPLS PWs in the corresponding VSI.

Prerequisites

The VPLS ID has been configured using the **vpls-id** *vpls-id* command in the VSI-BGPAD view.

Precautions

The **traffic-statistics enable** command cannot be used together with the **traffic-statistics peer enable (VSI-BGPAD)** command in the VSI-BGPAD view.

Example

Enable global traffic statistics for the VSI named **company1** in the BGP AD VPLS domain.

```
<HUAWEI> system-view
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] bgp-ad
[HUAWEI-vsi-company1-bgpad] vpls-id 100:1
[HUAWEI-vsi-company1-bgpad] traffic-statistics enable
```

10.7.114 traffic-statistics peer remote-site enable (Kompella)

Function

The **traffic-statistics peer remote-site enable** command enables the statistics about the public traffic on a specified Kompella VPLS PW.

The **undo traffic-statistics peer remote-site enable** command disables the statistics about the public traffic on a specified Kompella VPLS PW.

By default, the statistics of the public traffic on the Kompella VPLS PW are disabled.

Format

traffic-statistics peer *peer-address* **remote-site** *site-id* **enable**

undo traffic-statistics peer *peer-address* **remote-site** *site-id* **enable**

Parameters

Parameter	Description	Value
peer *peer-address*	Specifies the peer IP address of the PW.	-
remote-site *site-id*	Specifies the remote site ID.	The value is an integer that ranges from 0 to 65534.

Views

VSI-BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the Kompella VPLS network is configured, you can run the **traffic-statistics peer remote-site enable** command to enable statistics about the traffic on the specified PW. You can specify *peer-address* to enable the statistics about the traffic on the corresponding PW.

Prerequisites

The RD of the VSI has been configured using the **route-distinguisher** *route-distinguisher* command in the VSI-BGP view.

Precautions

After you enable the statistics about the public traffic on the specified Kompella VPLS PW, run the **display traffic-statistics vsi peer remote-site** command to view the statistics about the public traffic on the specified PW.

Example

Enable the statistics about the public traffic on the specified Kompella VPLS PW.

```
<HUAWEI> system-view
[HUAWEI] vsi newvsi auto
[HUAWEI-vsi-newvsi] pwsignal bgp
[HUAWEI-vsi-newvsi-bgp] traffic-statistics peer 10.22.33.20 remote-site 2 enable
```

10.7.115 traffic-statistics peer enable (Martini)

Function

The **traffic-statistics peer enable** command enables the statistics about the public traffic on a specified Martini VPLS PW.

The **undo traffic-statistics peer enable** command disables the statistics about the public traffic on a specified Martini VPLS PW.

By default, the statistics function is disabled.

Format

traffic-statistics peer *peer-address* [**negotiation-vc-id** *vc-id*] **enable**

undo traffic-statistics peer *peer-address* [**negotiation-vc-id** *vc-id*] **enable**

Parameters

Parameter	Description	Value
peer *peer-address*	Specifies the peer IP address of the PW.	-
negotiation-vc-id *vc-id*	Specifies the ID of the PW.	The value is an integer that ranges from 1 to 4294967295.

Views

VSI-LDP view

2: Configuration level

Usage Guidelines

Usage Scenario

After the Martini VPLS network is configured, you can run the **traffic-statistics peer enable** command to enable statistics about the traffic on the specified PW. You can specify *peer-address* to enable the statistics about the traffic on the corresponding PW.

Prerequisites

The VSI ID has been configured using the **vsi-id** *vsi-id* command in the VSI-LDP view.

Precautions

After you enable the statistics about the public traffic on the specified Martini VPLS PW, run the **display traffic-statistics vsi peer negotiation-vc-id** command to view the statistics about the public traffic on the specified PW.

The **traffic-statistics peer enable** command cannot be used together with the **traffic-statistics enable (VSI-LDP view)** command in the VSI-LDP view.

Example

Enable the statistics about the public traffic on the specified Martini VPLS PW.

```
<HUAWEI> system-view
[HUAWEI] vsi newvsi static
[HUAWEI-vsi-newvsi] pwsignal ldp
[HUAWEI-vsi-newvsi-ldp] vsi-id 1
[HUAWEI-vsi-newvsi-ldp] traffic-statistics peer 10.22.33.20 negotiation-vc-id 2 enable
```

10.7.116 traffic-statistics peer enable (VSI-BGPAD)

Function

The **traffic-statistics peer enable** command enables the statistics about the public traffic on a specified BGP AD VPLS PW.

The **undo traffic-statistics peer enable** command disables the statistics about the public traffic on a specified BGP AD VPLS PW.

By default, the statistics about the public traffic on a BGP AD VPLS PW are disabled.

Format

traffic-statistics peer *peer-address* **enable**

undo traffic-statistics peer *peer-address* **enable**

Parameters

Parameter	Description	Value
peer-address	Specifies the peer IP address of the PW.	The value is in dotted decimal notation.

Views

VSI-BGPAD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the BGP AD VPLS network is configured, you can run the **traffic-statistics peer enable** command to enable statistics about the traffic on the specified PW. You can specify *peer-address* to enable the statistics about the traffic on the corresponding PW.

Prerequisites

The VPLS ID has been configured using the **vpls-id** *vpls-id* command in the VSI-BGPAD view.

Precautions

The **traffic-statistics peer enable** command cannot be used together with the **traffic-statistics enable (VSI-BGPAD view)** command in the VSI-BGPAD view.

After you enable the statistics about the public traffic on the specified BGP AD VPLS PW, run the **display traffic-statistics vsi peer ldp129** command to view the statistics about the public traffic on the specified PW.

Example

Configure the BGP AD VPLS VSI named **company1**, and enable the statistics about the public traffic on the PW with the peer at 1.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] bgp-ad
[HUAWEI-vsi-company1-bgpad] vpls-id 100:1
[HUAWEI-vsi-company1-bgpad] traffic-statistics peer 1.1.1.1 enable
```

10.7.117 trace vpls mac vsi

Function

The **trace vpls mac vsi** command checks PE and P devices on the VPLS network which packets pass through from the source to the destination. This command is used to check the connectivity of Layer 2 forwarding links and locate faults on the network.

Format

trace vpls mac *mac-address* **vsi** *vsi-name* [**vlan** *vlan-id*] [**-t** *timeout* | **-f** *first-ttl* | **-m** *max-ttl* | **-exp** *exp* | **-r** *replymode*] *

Parameters

Parameter	Description	Value
mac *mac-address*	Specifies the unicast destination MAC address of the VPLS MAC trace, expressed in the format of H-H-H.	An H is a hexadecimal number of 1 to 4 bits, such as 00e0 and fc01. If you enter less than four digits, 0s are padded before the input digits. For example, if e0 is entered, 00e0 is displayed. The value cannot be a broadcast or multicast MAC address.
vsi *vsi-name*	Specifies the name of a VSI.	The value is an existing VSI.
vlan *vlan-id*	Specifies the ID of a VLAN	*vlan-id* specifies the VLAN ID, which is an integer that ranges from 1 to 4094.
-t *timeout*	Specifies the timeout period for waiting for a Reply packet in response to a VPLS MAC Trace Request packet.	The value is an integer that ranges from 0 to 65535, in milliseconds. The default value is 2000 ms.
-f *first-ttl*	Specifies the initial TTL.	The value is an integer that ranges from 1 to *max-ttl*. The default value is 1.
-m *max-ttl*	Specifies the maximum TTL.	The value is an integer that ranges from *first-ttl* to 255. The default value is 30.
-exp *exp*	Specifies the priority.	The value is an integer that ranges from 0 to 7. The default value is 0.

Parameter	Description	Value
-r *replymode*	Specifies the reply mode, that is, the Reply packet is sent from the control layer or the data layer. - 1: indicates that the peer end does not respond to MPLS MAC Trace Request packets. - 2: indicates that the peer end responds to MPLS MAC Trace Request packets with IPv4 or IPv6 UDP packets. - 3: indicates that the peer end responds to MPLS MAC Trace Request packets with IPv4 or IPv6 UDP packets containing the Router Alert TLV option. - 4: indicates that the peer end responds to MPLS MAC Trace Request packets through the control channel of the application program grade. - 5: indicates that the peer end responds to MPLS MAC Trace Request packets with VPLS IPv4 UDP packets.	Enumerated type. At present, only modes 1, 2, and 5 are supported. When mode 2 is adopted, reply packets are sent from the control layer; when mode 5 is adopted, reply packets are sent from the data layer. The default value is 5.

Usage Guidelines

Usage Scenario

Using the **trace vpls mac vsi** command, you can check the connectivity of Layer 2 forwarding links on the VPLS network, analyze roles of devices, and locate faults on the network.

Prerequisites

Before running this command, ensure that a VSI is configured and the VSI is in the Up state.

Example

On the VPLS network, trace the device with the MAC address 00e0-fc12-3456.

```
<HUAWEI> trace vpls mac 00e0-fc12-3456 vsi a2
 Traceroute to mac 00e0-fc12-3456 vsi a2, 30 hops max, press CTRL_C to break
 TTL  Num     Replier          Time     Type     Downstream              Hit
            LSR-ID          Out Interface
 -------------------------------------------------------------------------
 0    1                              Ingress  10.1.1.1/[3 ]          N
            1.1.1.9          Vlanif1025
 1    1       10.1.1.1        8 ms     Egress                         Y
            3.3.3.9
Info: Succeed in tracing the destination address 00e0-fc12-3456.
```

Table 10-140 Description of the tracert vpls multicast command output

Item	Description
TTL	Time to live.
Num	Sequence number of the packet sent at each hop.
Replier	IP address of the node sending MPLS Echo Reply packets.
Time	Time the packet is processed, that is, period from the time the Request packet is sent from the source node to the time a Reply packet is received by the source node.
Type	Type of the device that sends the Reply packet, which can be: ● Ingress: indicates an ingress node. ● Transit: indicates a transmit node. ● Egress: indicates an egress node.
Downstream	Address and label of the next hop. For example, 10.1.1.1/[3] indicates that the IP address of the next hop is 10.1.1.1 and the label allocated to the next hop is 3.
Hit	Whether the Request packet reaches the destination. ● Y: The Request packet reaches the destination. ● N: The Request packet does not reach the destination.
LSR-ID	ID of the LSR.
Out Interface	Outbound interface through which packets are forwarded.

10.7.118 tracert vpls

Function

The **tracert vpls** command detects the status of a PW or locates an abnormal node on a PW in Down state.

Format

tracert vpls [**-exp** *exp-value* | **-f** *first-ttl* | **-m** *max-ttl* | **-r** *reply-mode* | **-t** *timeout-value*] * **vsi** *vsi-name* { *local-site-id remote-site-id* | **peer** *peer-address* [**negotiate-vc-id** *vc-id*] } [**full-lsp-path**]

Parameters

Parameter	Description	Value
-exp *exp-value*	Specifies the value of the EXP field in the outer label of an MPLS Echo Request packet.	The value is an integer that ranges from 0 to 7.
-f *first-ttl*	Specifies an initial TTL.	The value is an integer that ranges from 1 to 255 and must be smaller than the value of *max-ttl*. The default value is 1.
-m *max-ttl*	Specifies a maximum TTL.	The value is an integer that ranges from 1 to 255 and must be greater than the value of *first-ttl*. The default value is 30.
-r *reply-mode*	Specifies the mode for the peer end to return MPLS Echo Reply packets. The values are as follows: ● 1: indicates no reply. ● 2: indicates a reply with an IPv4 or IPv6 UDP datagram. ● 3: indicates a reply with an IPv4 or IPv6 UDP datagram carrying a router alert label. ● 4: indicates a reply through the control channel of the application plane.	The value is an integer that ranges from 1 to 4. The default value is 2.

Parameter	Description	Value
-t *timeout-value*	Specifies the timeout period for waiting for an MPLS Echo Reply packet.	The value is an integer that ranges from 0 to 65535, in milliseconds. The default value is 5.
vsi *vsi-name*	Specifies the VPN name.	The value is an existing VSI.
local-site-id	Specifies the ID of the local CE.	The value is an integer that ranges from 0 to 65534.
remote-site-id	Specifies the ID of the remote CE.	The value is an integer that ranges from 0 to 65534.
full-lsp-path	Displays the responses from all nodes on the LSP that the MPLS Echo Request packets pass through. If this parameter is not specified, the responses from only the PW nodes along the LSP are displayed.	-
peer *peer-address*	Specifies the IP address of the peer PE.	-
negotiate-vc-id *vc-id*	Specifies the ID of the local PW.	The value is an integer that ranges from 1 to 4294967295.

Usage Guidelines

Usage Scenario

After the VPLS network is configured, if the VSI is in the Down state, you can run the **tracert vpls** command to locate the faulty device on the PW.

The **tracert vpls** command applies to the following networking scenarios:

- VPLS networking

  Based on VPLS types, VPLS PW tracert is classified into:

  - Martini VPLS PW tracert

Martini VPLS PW tracert only supports the label alert mode. On a Hierarchical Virtual Private LAN Service (HVPLS) network, only single-segment PWs can be detected. If a PW ID that is optional is set and specified, the PW with the specified PW ID is detected. If no PW ID is specified, the PW associated with the VSI ID is detected.

- Kompella VPLS PW tracert

  Kompella VPLS PW tracert only supports the label alert mode.

  After a faulty PW is detected using the **ping vc** command, run the **tracert vc** command to locate the fault. The **ping vc** and **tracert vc** commands can efficiently check PW connectivity and locate faults on PWs.

Prerequisites

One of the following operations has been performed before this command is used:

- Configuring Kompella VPLS
- Configuring Martini VPLS
- Configuring BGP AD VPLS

Example

Perform the tracert operation on the VPLS link with the remote site ID being 10.

```
<HUAWEI>tracert vpls vsi test 10 10 full-lsp-path
 TTL   Replier            Time    Type      Downstream
 0                           Ingress   10.1.1.2/[4032 3 ]
 1     10.0.0.181         7 ms    Egress
```

Table 10-141 Description of the tracert vpls command output

Item	Description
TTL	TTL in an MPLS Echo Request packet. It indicates the number of hops through which an MPLS Echo Request packet passes from the source node to this node.
Replier	IP address of the node sending MPLS Echo Reply packets.
Time	Time that the packet is processed.
Type	Type of a node: ● Ingress: indicates an ingress node. ● Transit: indicates a transmit node. ● Egress: indicates an egress node.
Downstream	IP address and label of the downstream node.

Perform the tracert operation to test the connectivity of the BGP AD VPLS PW.

```
<HUAWEI> tracert vpls vsi ad peer 10.2.2.2
 TTL   Replier            Time    Type      Downstream
 0                           Ingress   10.1.1.2/[1025 3 ]
 1     10.2.2.2           30 ms   Egress
```

Table 10-142 Description of the tracert vpls command output

Item	Description
TTL	TTL in an MPLS Echo Request packet. It indicates the number of hops through which an MPLS Echo Request packet passes from the source node to this node.
Replier	IP address of the node sending MPLS Echo Reply packets.
Time	Time the packet is processed. That is, period from the time an MPLS Echo Request packet is sent to the time an MPLS Echo Reply packet is received.
Type	Type of a node: ● Ingress: indicates an ingress node. ● Transit: indicates a transmit node. ● Egress: indicates an egress node.
Downstream	IP address and label of the downstream node. The inner label and the outer label are arranged from left to right, both are outgoing labels.

10.7.119 tracert vpls multicast

Function

The **trace vpls multicast** command starts an MFIB Trace test with a specified VSI in the VPLS domain.

Format

tracert vpls multicast vsi *vsi-name* [**-a** *source-ip-address* | **-t** *timeout* | **-r** *reply-mode* | **-exp** *exp* | **-f** *first-ttl* | **-m** *max-ttl*] * **multicast-address** *multicast-ip-address* **remote-address** *remote-ip-address*

Parameters

Parameter	Description	Value
vsi *vsi-name*	Specifies the name of the VSI on which the operation is performed.	The value is an existing VSI.
-a *source-ip-address*	Specifies the IP address of the multicast source. By default, the multicast source IP address is the IP address of the initiator. The value is in dotted decimal notation.	-

Parameter	Description	Value
-t *timeout*	Specifies the timeout period for waiting for an Echo Reply packet.	The value ranges from 0 to 65535, in milliseconds. The default value is 2000 milliseconds.
-r *reply-mode*	Specifies the reply mode. The default value is 2. ● 1: indicates that the peer end does not respond to Echo Request packets. ● 2: indicates that the peer end responds to Echo Request packets with IPv4 or IPv6 UDP packets. ● 3: indicates that the peer end responds to Echo Request packets with IPv4 or IPv6 UDP packets carrying the Router Alert option. ● 4: indicates that the peer end responds to Echo Request packets through the control channel of the application program grade. ● 5: indicates that the peer end responds to Echo Request packets with VPLS IPv4 UDP packets. **NOTE** Currently, the switch only supports mode 1, 2, and 5.	-
-exp *exp*	Specifies the priority of Echo Request packets to be sent.	The value is an integer that ranges from 0 to 7. The default value is 0.
-f *first-ttl*	Specifies the initial TTL.	The value ranges from 1 to 255.
-m *max-ttl*	Specifies the maximum TTL, which is not smaller than the initial TTL.	The value ranges from 1 to 255.
multicast-address *multicast-ip-address*	Adds a PW to the multicast group with the specified IP address.	-
remote-address *remote-ip-address*	Specifies a unicast IP address.	-

Usage Guidelines

Usage Scenario

You can run the **tracert vpls multicast** command on the PE, SPE, and UPE to implement the monitoring functions:

- The command is used to locate the faulty PE on the VPLS network when IGMP Snooping is enabled.
- The command is used for path discovery on the VPLS network when the IGMP Snooping is disabled.

Precautions

The **trace vpls multicast** command does not support BGP AD VPLS.

Example

Initiate a Trace test in a specified VSI with the multicast address being 226.0.0.1 in the VPLS domain.

```
<HUAWEI> tracert vpls multicast vsi a2 multicast-address 226.0.0.1 remote
-address 10.3.3.9
traceroute to 10.3.3.9 vsi a2, 30 hops max , press CTRL+C to break
-----------------------------------------------------------------
TTL  0
 Num     : 1          Replier: UNKNOWN        Upstream: UNKNOWN
 Time    : 0          Snpg   : N              Version : 2
 Proxy   : N          Port   : N              FW Mode : IP
 Hit Flag: NotInMFIB    PW Info: Y            Alert   : N
 Policy  : Permit       CAC    : N

-----------------------------------------------------------------
TTL  1
 Num     : 1          Replier: 10.3.3.9       Upstream: 10.1.1.9
 Time    : 7          Snpg   : N              Version : 2
 Proxy   : N          Port   : N              FW Mode : IP
 Hit Flag: NotInMFIB    PW Info: N            Alert   : N
 Policy  : Permit       CAC    : N
 Query   : 0          Report : 0              Leave   : 0
-----------------------------------------------------------------
Info: Succeed in tracing the destination address  10.3.3.9
```

Table 10-143 Description of the tracert vpls multicast command output

Item	Description
TTL	Time to live.
Num	Sequence number of the received packet.
Replier	Address of the replier.
Upstream	Address of the PE that sends or forwards the packet.

Item	Description
Time	Time the packet is processed. That is, period from the time the Request packet is sent from the source node to the time a Reply packet is received by the source node.
Snpg	Whether IGMP Snooping is enabled.
Version	Version of IGMP Snooping enabled in the VSI.
Proxy	Whether IGMP Snooping proxy is enabled.
Port	Whether the interface learning function is enabled.
FW Mode	MAC address-based forwarding mode or IP address-based forwarding mode.
Hit Flag	Whether corresponding multicast forwarding information exists in the MFIB.
PW Info	Whether the PWs forwarding the packet can be obtained according to the ingoing label.
Alert	State in which the interface only receives IGMP messages with Router-Alert options.
Policy	Whether the packet meets the deny rule or permit rule according to the ACL.
CAC	Whether connection admission control is configured in the VSI.
Query	The number of Query packets using the current IGMP version received by the replier.
Report	The number of Report packets using the current IGMP version received by the replier.
Leave	The number of Leave packets using the current IGMP version received by the replier.

10.7.120 unknown-frame

Function

The **unknown-frame** command specifies the processing mode for received unknown frames.

By default, the system broadcasts unknown multicast frames.

Format

unknown-frame multicast { **drop** | **broadcast** }

Parameters

Parameter	Description	Value
multicast	Indicates the unknown frames are of the multicast type.	-
drop	Drops the unknown frames.	-
broadcast	Broadcasts the unknown frames.	-

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

After a VSI receives a frame, if an entry that matches the destination address cannot be found in the MAC address table, the frame is regarded as an unknown frame.

Example

Configure the VSI to discard unknown frames.

```
<HUAWEI> system-view
[HUAWEI] vsi company1 auto
[HUAWEI-vsi-company1] unknown-frame multicast drop
```

10.7.121 unknown-unicast-suppression cir cbs (VSI view)

Function

The **unknown-unicast-suppression cir cbs** command enables unknown unicast traffic suppression in the VSI.

The **undo unknown-unicast-suppression** command disables unknown unicast traffic suppression in the VSI.

By default, unknown unicast traffic in a VSI is not suppressed.

Format

unknown-unicast-suppression cir *cir-value* **cbs** *cbs-value*

undo unknown-unicast-suppression

Parameters

Parameter	Description	Value
cir *cir-value*	Specifies the CIR, that is, the allowed rate at which traffic can pass through.	The value is an integer that ranges from 0 to 10000000, in kbit/s.
cbs *cbs-value*	Specifies the CBS, that is, the traffic that can pass instantly, or the depth of the first token bucket.	The value is an integer that ranges from 10000 to 4294967295, in bytes.

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a VPLS network, broadcast packets, multicast packets, and unknown unicast packets are transmitted in broadcast mode and copied to neighboring ACs and PWs. If large quantities of unknown unicast packets are on the VPLS network, the device has to make a lot of copies of these unknown unicast packets, which wastes bandwidth and resources, and deteriorates system performance. You can run the **unknown-unicast-suppression cir cbs** command to suppress the unknown unicast traffic in the VSI. The rate of unknown unicast traffic on the VPLS network is limited.

Prerequisites

A VSI has been created using the **vsi** *vsi-name* [**auto** | **static**] command.

Example

Set the CIR to 100 kbit/s and the CBS to 18800 bytes for the unknown unicast traffic that can pass for VSI1.

```
<HUAWEI> system-view
[HUAWEI] vsi VSI1
[HUAWEI-vsi-VSI1] unknown-unicast-suppression cir 100 cbs 18800
```

10.7.122 upe-npe mac-withdraw enable

Function

The **upe-npe mac-withdraw enable** command enables an SPE to forward the LDP MAC Withdraw messages received from UPEs to other SPEs.

The **undo upe-npe mac-withdraw enable** command disables an SPE from forwarding the LDP MAC Withdraw messages received from UPEs to other SPEs.

By default, an SPE does not forward the LDP MAC Withdraw messages received from UPEs to other SPEs.

Format

upe-npe mac-withdraw enable

undo upe-npe mac-withdraw enable

Parameters

None

Views

VSI-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On enterprise networks, run the **upe-npe mac-withdraw enable** command to enable an SPE to forward the LDP MAC Withdraw messages received from UPEs to other SPEs.

Prerequisites

LDP has been configured as the PW signaling protocol using the **pwsignal ldp** command.

Precautions

The **upe-npe mac-withdraw enable** command is used on SPEs.

- An SPE refers to the network-side peer of the local VSI in HVPLS. You can run the **peer** *peer-address* [**negotiation-vc-id** *vc-id*] [**tnl-policy** *policy-name*] command to specify an SPE.
- A UPE refers to the user-side peer of the local VSI in HVPLS. You can run the **peer** *peer-address* [**negotiation-vc-id** *vc-id*] [**tnl-policy** *policy-name*] **upe** command to specify a UPE.
- If HVPLS is not configured on the local device, the **upe-npe mac-withdraw enable** command is not required.

Example

Enable the SPE to forward the LDP MAC Withdraw messages received from UPEs to other SPEs.

```
<HUAWEI> system-view
[HUAWEI] vsi v1 static
```

```
[HUAWEI-vsi-v1] pwsignal ldp
[HUAWEI-vsi-v1-ldp] upe-npe mac-withdraw enable
```

10.7.123 upe-upe mac-withdraw enable

Function

The **upe-upe mac-withdraw enable** command enables an SPE to forward the LDP MAC Withdraw messages received from a UPE to other UPEs.

The **undo upe-upe mac-withdraw enable** command disables an SPE from forwarding the LDP MAC Withdraw messages received from a UPE to other UPEs.

By default, an SPE does not forward the LDP MAC Withdraw messages received from a UPE to other UPEs.

Format

upe-upe mac-withdraw enable

undo upe-upe mac-withdraw enable

Parameters

None

Views

VSI-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On enterprise networks, run the **upe-upe mac-withdraw enable** command to enable an SPE to forward the LDP MAC Withdraw messages received from a UPE to other UPEs.

Prerequisites

LDP has been configured as the PW signaling protocol using the **pwsignal ldp** command.

Precautions

The **upe-upe mac-withdraw enable** command is used on SPEs.

- An SPE refers to the network-side peer of the local VSI in HVPLS. You can run the **peer** *peer-address* [**negotiation-vc-id** *vc-id*] [**tnl-policy** *policy-name*] command to specify an SPE.
- A UPE refers to the user-side peer of the local VSI in HVPLS. You can run the **peer** *peer-address* [**negotiation-vc-id** *vc-id*] [**tnl-policy** *policy-name*] **upe** command to specify a UPE.

- If HVPLS is not configured on the local device, the **upe-upe mac-withdraw enable** command is not required.

Example

Enable the SPE to forward the LDP MAC Withdraw messages received from a UPE to other UPEs.

```
<HUAWEI> system-view
[HUAWEI] vsi v1 static
[HUAWEI-vsi-v1] pwsignal ldp
[HUAWEI-vsi-v1-ldp] upe-upe mac-withdraw enable
```

10.7.124 vpls bgp encapsulation

Function

The **vpls bgp encapsulation** command specifies the re-encapsulation mode of a VPLS packet after the local PE receives the VPLS packet whose encapsulation type is 19.

By default, the local PE re-encapsulates the received VPLS packet with the encapsulation type as 19 in VLAN mode.

Format

vpls bgp encapsulation { **ethernet** | **vlan** }

Parameters

Parameter	Description	Value
ethernet	Indicates that the received VPLS packet whose encapsulation type is 19 is re-encapsulated in Ethernet mode.	-
vlan	Indicates that the received VPLS packet whose encapsulation type is 19 is re-encapsulated in VLAN mode.	-

Views

MPLS-L2VPN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **vpls bgp encapsulation** command is run only when a Huawei device is connected to a non-Huawei device.

As defined by the latest RFC, the encapsulation type of PW in the Kompella VPLS is 19. Huawei devices support only the Ethernet encapsulation and VLAN encapsulation. If the **vpls bgp encapsulation** command is used, upon receiving a VPLS packet with the encapsulation type as 19, the system re-encapsulates the VPLS packet according to the configuration so that Huawei devices can interwork with non-Huawei devices.

Precautions

Huawei devices can interwork with non-Huawei devices only when the **vpls bgp encapsulation** command is used together with the **ignore-mtu-match** command.

Example

Re-encapsulate the received VPLS packet with the encapsulation type as 19 in Ethernet mode.

```
<HUAWEI> system-view
[HUAWEI] mpls lsr-id 1.1.1.1
[HUAWEI] mpls
[HUAWEI-mpls] quit
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] vpls bgp encapsulation ethernet
```

10.7.125 vpls ignore-ac-state

Function

The **vpls ignore-ac-state** command prevents the status of a VSI from being affected by the status of the Attachment Circuit (AC).

The **undo vpls ignore-ac-state** command restores the default setting.

By default, changes in the status of the AC affect the VSI status.

Format

vpls ignore-ac-state

undo vpls ignore-ac-state

Parameters

None

Views

MPLS-L2VPN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **vpls ignore-ac-state** command is used only before a service switchover between a new network and an old one. Before the devices on an old VPLS network switch to a new network, if you want to check whether the VSI on the new VPLS network can work normally, you can run this command to configure the VSI to ignore the AC status so that the VSI maintains the Up state before the switchover.

Precautions

After the **vpls ignore-ac-state** command is executed, a VSI can keep Up if the VSI PW is Up, and the VSI status is not affected by the AC status.

The AC status refers to the status of the physical or logical interface bound to the VSI.

After the devices on the old network switch to a new network, run the **undo vpls ignore-ac-state** command to restore the default setting.

Example

Configure a VSI to ignore the AC status.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] vpls ignore-ac-state
```

10.7.126 vpls-family

Function

The **vpls-family** command displays the BGP VPLS address family view.

The **undo vpls-family** command deletes all configurations of the BGP VPLS address family.

By default, the BGP VPLS address family is not configured in the BGP view.

Format

vpls-family

undo vpls-family

Parameters

None

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

When configuring Kompella VPLS, you need to enable BGP peers to exchange VPLS information. In this case, run the **vpls-family** command to enter the BGP VPLS address family view.

Example

Enter the VPLS address family view.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] vpls-family
[HUAWEI-bgp-af-vpls]
```

10.7.127 vpls-id

Function

The **vpls-id** command specifies the ID of a VPLS domain to which a VSI belongs.

By default, no VPLS VSI ID is specified.

Format

vpls-id *vpls-id*

Parameters

Parameter	Description	Value
vpls-id	Specifies the ID of a VPLS domain to which multiple VSIs on PEs belong.	A VPLS ID is in one of the following formats: ● 16-bit AS number: a 32-bit user-defined number, for example, 1:3. The AS number ranges from 0 to 65535. The user-defined number ranges from 0 to 4294967295. The AS number and the user-defined number cannot both be 0. That is, a VPN target cannot be 0:0. ● 32-bit IP address: a 16-bit user-defined number, for example, 192.168.122.15:1. The IP address ranges from 0.0.0.0 to 255.255.255.255. The user-defined number ranges from 0 to 65535. ● Integral 4-byte AS number:2-byte user-defined number, for example, 65537:3. An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a VPN target cannot be 0:0. ● 4-byte AS number in dotted notation:2-byte user-defined number, for example, 0.0:3 or 0.1:0. A 4-byte AS number in

Parameter	Description	Value
		dotted notation is in the format of *x.y*, where *x* and *y* are integers that range from 1 to 65535 and from 0 to 65535, respectively. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a VPN target cannot be 0.0:0.

Views

VSI-BGPAD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

VSIs in a BGP AD VPLS domain use BGP signaling to automatically discover members in the same VPLS domain. A VPLS domain is uniquely identified by a VPLS ID. When creating BGP AD VSIs on different PEs, specify the same VPLS ID for the VSIs so that they can join the same VPLS domain. Different BGP AD VSIs on the same PE cannot be added to the same VPLS domain.

Prerequisites

Automatic VPLS member discovery and automatic PW deployment have been configured for the current VSI using the **bgp-ad** command in the VSI view, and the VSI-BGPAD view has been displayed.

Precautions

An ID is specified for the BGP AD VSI. A VPLS domain is uniquely identified by a VPLS ID. Different VPLS IDs must be configured for different VSIs on the same PE. If the VPLS ID specified using the **vpls-id** command for a VSI on a PE has been used by another VSI on that PE, the **vpls-id** command does not take effect and an error message will be displayed. The VSIs that belong to the same VPLS domain and reside on different PEs must be configured with the same VPLS ID.

After a VPLS ID is configured for a VSI, it cannot be directly changed. To change the VPLS ID, you need to delete the VSI, re-create a VSI, and reconfigure the VPLS ID.

Example

Configure a VPLS ID in the format of 16-bit AS number:32-bit user-defined number for the VSI named **company1**.

```
<HUAWEI> system-view
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] bgp-ad
[HUAWEI-vsi-company1-bgpad] vpls-id 101:3
```

Configure a VPLS ID in the format of 32-bit IP address:16-bit user-defined number for the VSI named **company2**.

```
<HUAWEI> system-view
[HUAWEI] vsi company2
[HUAWEI-vsi-company2] bgp-ad
[HUAWEI-vsi-company2-bgpad] vpls-id 2.2.2.2:1
```

Configure a VPLS ID in the format of 32-bit AS number:16-bit user-defined number for the VSI named **company3**.

```
<HUAWEI> system-view
[HUAWEI] vsi company3
[HUAWEI-vsi-company3] bgp-ad
[HUAWEI-vsi-company3-bgpad] vpls-id 16.20:30
```

10.7.128 vpls mac-withdraw loop-detect enable

Function

The **vpls mac-withdraw loop-detect enable** command enables MAC withdraw loop detection.

The **undo vpls mac-withdraw loop-detect enable** command disables MAC withdraw loop detection.

By default, MAC withdraw loop detection is disabled.

Format

vpls mac-withdraw loop-detect enable

undo vpls mac-withdraw loop-detect enable

Parameters

None

Views

MPLS-L2VPN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a dual-homing VPLS or hierarchical VPLS (HVPLS) network, MAC withdraw messages can be forwarded between hub and spoke PWs and between spoke PWs. Incorrect configurations may cause a MAC withdraw message loop, which results in traffic loss. If the loop involves a large number of MAC withdraw messages, denial of service (DoS) attacks may occur. To resolve these problems, run the **vpls mac-withdraw loop-detect enable** command to enable MAC withdraw loop detection. After you enable MAC withdraw loop detection, a PE immediately discards MAC withdraw message when it detects a MAC withdraw message loop.

Prerequisites

MPLS L2VPN has been enabled using the **mpls l2vpn** command.

Example

Enable MAC withdraw loop detection.

```
<HUAWEI> system-view
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] vpls mac-withdraw loop-detect enable
```

10.7.129 vpn-target (VSI-BGP view)

Function

The **vpn-target** command associates a VSI with one or more VPN targets.

The **undo vpn-target** command deletes a VPN target associated with a VSI.

By default, a VSI is not associated with any VPN target.

Format

vpn-target *vpn-target* &<1-16> [**both** | **export-extcommunity** | **import-extcommunity**]

undo vpn-target { **all** | *vpn-target* &<1-16> } [**both** | **export-extcommunity** | **import-extcommunity**]

Parameters

Parameter	Description	Value
vpn-target	Specifies a VPN target that is added to a VSI.	You can choose one of the following formats to express a VPN target: ● 16-bit AS number: a 32-bit user-defined number, for example, 1:3. The AS number ranges from 0 to 65535. The user-defined number ranges from 0 to 4294967295. The AS number and the user-defined number cannot both be 0. That is, a VPN target cannot be 0:0. ● 32-bit IP address: a 16-bit user-defined number, for example, 192.168.122.15:1. The IP address ranges from 0.0.0.0 to 255.255.255.255. The user-defined number ranges from 0 to 65535. ● Integral 4-byte AS number:2-byte user-defined number, for example, 65537:3. An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a VPN target cannot be 0:0. ● 4-byte AS number in dotted notation:2-byte user-defined number, for example, 0.0:3 or 0.1:0. A 4-

Parameter	Description	Value
		byte AS number in dotted notation is in the format of *x.y*, where *x* and *y* are integers that range from 0 to 65535. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a VPN target cannot be 0.0:0.
export-extcommunity	Indicates the extended community attributes carried in the data to be sent.	-
import-extcommunity	Indicates the extended community attributes carried in the received data.	-
both	Indicates the import routing information from the extended community of the destination VPN and the export routing information sent to the extended community of the destination VPN.	-
all	Deletes all attributes of VPN targets.	-

Views

VSI-BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When sending routing information to other PE devices according to the VSI, a PE device adds export VPN targets to the routing information. When receiving routing information from other PE devices, the PE determines whether to add the data to the VSI according to import VPN targets. Therefore, VPN targets can be used to control the route advertisement between nodes.

Prerequisites

The RD of the VSI has been configured using the **route-distinguisher** *route-distinguisher* command.

Example

Associate the current VSI with a VPN target.

```
<HUAWEI> system-view
[HUAWEI] vsi company2
[HUAWEI-vsi-company2] pwsignal bgp
[HUAWEI-vsi-company2-bgp] route-distinguisher 2.2.2.2:1
[HUAWEI-vsi-company2-bgp] vpn-target 3:3 export-extcommunity
[HUAWEI-vsi-company2-bgp] vpn-target 4:4 import-extcommunity
[HUAWEI-vsi-company2-bgp] vpn-target 5:5 both
```

10.7.130 vpn-target (VSI-BGPAD view)

Function

The **vpn-target** command associates a VSI in a BGP AD VPLS domain with one or more VPN targets.

The **undo vpn-target** command removes the VPN targets associated with the VSI.

By default, a VSI is not associated with any VPN target. The association must be configured when a VSI is created.

Format

vpn-target *vpn-target* &<1-16> [**both** | **export-extcommunity** | **import-extcommunity**]

undo vpn-target { **all** | *vpn-target* &<1-16> } [**both** | **export-extcommunity** | **import-extcommunity**]

Parameters

Parameter	Description	Value
vpn-target	Associates a VPN target with a VSI.	The format of a VPN target can be one of the following: - 16-bit AS number:32-bit user-defined number. For example, 1:3. The AS number ranges from 0 to 65535, and the user-defined number ranges from 0 to 4294967295. The AS number and user-defined number cannot be both 0. This means that the VPN target value cannot be 0:0. - 32-bit IP address:16-bit user-defined number. For example, 192.168.122.15:1. The IP address ranges from 0.0.0.0 to 255.255.255.255, and the user-defined number ranges from 0 to 65535. - Integral 4-byte AS number:2-byte user-defined number, for example, 65537:3. An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a VPN target cannot be 0:0. - 4-byte AS number in dotted notation: 2-byte user-defined number, for example, 0.0:3 or 0.1:0. A 4-byte AS number in dotted notation is in the format of *x.y*, where *x* and *y* are integers that range from 0 to 65535. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a VPN target cannot be 0.0:0.
both	Specifies the extended community attributes of the received and sent routing information.	-

Parameter	Description	Value
export-extcommunity	Specifies the extended community attributes carried in routing information to be sent.	-
import-extcommunity	Receives routing information carrying specified extended community attributes.	-
all	Deletes all VPN targets.	-

Views

VSI-BGPAD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

VPN targets can be used in a BGP AD VPLS domain to control the route advertisement and communication between nodes. When a PE advertises routing information to other PEs of different VSIs, it adds export VPN targets to the routing information. When the PE receives routing information from other PEs, it uses import VPN targets to determine whether to import the routing information to the VSIs on it.

Prerequisites

The VPLS ID has been configured using the **vpls-id** *vpls-id* command in the VSI-BGPAD view.

Precautions

A PW can be set up between two VSIs in a BGP AD VPLS domain only when the import VPN target associated with a VSI is the same as the export VPN target associated with the other VSI.

After the **vpn-target** command is run, the PE only advertises the routing information that contains the export VPN targets and imports the routing information that contains the import VPN targets. Two PEs are allowed to communicate with each other only when the VPN targets carried in their exchanged routing information match.

Example

Configure a VSI named **company2**, and associate the VSI with import VPN targets 4:4 and 5:5 and with export VPN targets 3:3 and 5:5.

```
<HUAWEI> system-view
[HUAWEI] vsi company2
[HUAWEI-vsi-company2] bgp-ad
[HUAWEI-vsi-company2-bgpad] vpls-id 100:1
[HUAWEI-vsi-company2-bgpad] vpn-target 3:3 export-extcommunity
[HUAWEI-vsi-company2-bgpad] vpn-target 4:4 import-extcommunity
[HUAWEI-vsi-company2-bgpad] vpn-target 5:5 both
```

10.7.131 vsi

Function

The **vsi** command creates a VSI or displays the VSI view.

The **undo vsi** command deletes a VSI.

By default, no VSI is created.

Format

vsi *vsi-name* [**auto** | **static**]

undo vsi *vsi-name*

Parameters

Parameter	Description	Value
vsi-name	Specifies the name of a VSI.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string. Names of the VSIs on one device cannot be identical.
auto	Indicates that the automatic member discovery mode is used in the VSI.	-
static	Indicates that the static member discovery mode is used in the VSI.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure VPLS, you need to create VSIs first. Each device in a VPLS domain needs to be configured with a VSI that belongs to the domain.

On a Martini or Kompella VPLS network, the VPLS member discovery mode for a created VSI can be set to static or auto. You can set the signaling mode using the **pwsignal** { **bgp** | **ldp** } command after a VSI is created. Use the LDP signaling mode if the static member discovery mode is used. Use the BGP signaling mode if the automatic member discovery mode is used. The member discovery mode cannot be modified. To modify the member discovery mode of the VSI, you need to delete the VSI. Then, re-create a VSI and specify the member discovery mode.

When creating a BGP AD VSI, do not specify a member discovery mode of the VSI. A VSI without a specified member discovery mode can be configured to use the LDP, BGP, or BGP AD signaling mode.

If you have specified a member discovery mode for a VSI, specify the same member discovery mode in the **vsi** command when you want to re-enter the VSI view. If the member discovery mode in the **vsi** command is different from the member discovery mode specified for the VSI, you cannot enter the VSI view.

Prerequisites

The MPLS L2VPN function has been enabled on the device.

Precautions

Note the following points when configuring VSIs in a VPLS domain:

- VSIs on different PEs can have different names.
- A VSI on a PE must be configured with a unique VSI ID or VPLS ID.
- Multiple peers can be specified for a VSI on a PE.

If the specified VSI exists, you can use the **vsi** command to enter the VSI view.

After VPLS configurations are complete, VPLS packets are forwarded based on VSIs. Exercise caution when using the **undo vsi** command because VPLS traffic will be interrupted.

Example

Create a Martini VPLS VSI named **company1**.

```
<HUAWEI> system-view
[HUAWEI] mpls lsr-id 10.1.1.1
[HUAWEI] mpls
[HUAWEI-mpls] quit
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] quit
[HUAWEI] vsi company1 static
[HUAWEI-vsi-company1] pwsignal ldp
```

Create a Kompella VPLS VSI named **company2**.

```
<HUAWEI> system-view
[HUAWEI] mpls lsr-id 10.1.1.1
[HUAWEI] mpls
[HUAWEI-mpls] quit
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] quit
[HUAWEI] vsi company2 auto
[HUAWEI-vsi-company2] pwsignal bgp
```

Create a BGP AD VPLS VSI named **company3**.

```
<HUAWEI> system-view
[HUAWEI] mpls lsr-id 10.1.1.1
[HUAWEI] mpls
[HUAWEI-mpls] quit
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] quit
[HUAWEI] vsi company3
```

Create a Martini VPLS VSI named **company4**, and do not specify the VSI member discovery mode.

```
<HUAWEI> system-view
[HUAWEI] mpls lsr-id 10.1.1.1
[HUAWEI] mpls
[HUAWEI-mpls] quit
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] quit
[HUAWEI] vsi company4
[HUAWEI-vsi-company4] pwsignal ldp
```

Create a Martini Kompella VPLS VSI named **company5**, and do not specify the VSI member discovery mode.

```
<HUAWEI> system-view
[HUAWEI] mpls lsr-id 10.1.1.1
[HUAWEI] mpls
[HUAWEI-mpls] quit
[HUAWEI] mpls l2vpn
[HUAWEI-l2vpn] quit
[HUAWEI] vsi company5
[HUAWEI-vsi-company5] pwsignal bgp
```

10.7.132 vsi-id

Function

The **vsi-id** command sets an ID for a VSI.

By default, no VSI ID is set.

Format

vsi-id *vsi-id*

Parameters

Parameter	Description	Value
vsi-id	Specifies the unique ID of a VSI.	The value is an integer that ranges from 1 to 4294967295.

Views

VSI-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you create a VSI in the Martini VPLS and use the LDP as the PW signaling protocol, run the **vsi-id** command to configure the VSI ID. Other parameters can be configured only after the VSI ID is configured.

Precautions

Different VSIs have different IDs.

VSI IDs on all devices in the same VPLS domain must be the same.

The VSI ID cannot be changed after being set. If you want to change the VSI ID, you need to delete the VSI and re-create a VSI.

Example

Set the ID of the current VSI to 1.

```
<HUAWEI> system-view
[HUAWEI] vsi company1 static
[HUAWEI-vsi-company1] pwsignal ldp
[HUAWEI-vsi-company1-ldp] vsi-id 1
```

10.8 L2VPN Access to L3VPN Configuration Commands

10.8.1 Command Support

Only the following switch models support L2VPN access to L3VPN:

S5731-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-H, and S6730-H

10.8.2 display virtual-ethernet ve-group

Function

The **display virtual-ethernet ve-group** command displays the binding relationship between Virtual Ethernet (VE) interfaces and a VE group.

Format

display virtual-ethernet ve-group [*ve-group-id*]

Parameters

Parameter	Description	Value
ve-group-id	Specifies the ID of a VE group.	The value is an integer ranging from 1 to 8.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If a device is configured with many VE groups, you can use this command to view the relationship between VE interfaces and VE groups.

Example

Display the binding relationship between all VE interfaces and VE groups on a switch.

```
<HUAWEI> display virtual-ethernet ve-group
 Ve-groupID    TerminateVE                 AccessVE
 1             Virtual-Ethernet0/0/1(L2)   Virtual-Ethernet0/0/2(L3)
Total 1, 1 printed
```

Table 10-144 Description of the **display virtual-ethernet ve-group** command output

Item	Description
Ve-groupID	ID of a VE group.
TerminateVE	L2VE interface terminating an L2VPN.
AccessVE	L3VE interface accessing an L3VPN.
Total 1, 1 printed	Total number of VE groups.

10.8.3 display mpls l2vpn track route

Function

The **display mpls l2vpn track route** command displays information about the PWs that track VPNv4 route status.

Format

display mpls l2vpn track route [*ipv4-address* { *mask* | *mask-length* } **vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
ipv4-address	Specifies the destination IP address of a VPNv4 route.	The value is in dotted decimal notation.
mask	Specifies a mask in dotted decimal notation.	The value is in dotted decimal notation.
mask-length	Specifies the mask length.	The value is an integer ranging from 0 to 32.
vpn-instance *vpn-instance-name*	Specifies the VPN instance name.	The value must be an existing VPN instance name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

In an L2VPN access to L3VPN scenario, if all L3VPN-side links of an NPE become unavailable, a black-hole route comes into existence. The user-side UPE cannot detect the link failures and still sends traffic to the NPE. As a result, traffic loss occurs. To prevent traffic loss, run the **mpls l2vpn track route** command to configure the PW to track VPNv4 route status. Then, after the NPE detects that all its L3VPN-side links become unavailable, the NPE instructs the UPE to switch traffic to the secondary PW.

To check information about the PWs that track VPNv4 route status, run the **display mpls l2vpn track route** command.

Example

Display information about all PWs that track VPNv4 route status.

```
<HUAWEI> display mpls l2vpn track route
Total route number:1      reachable:0      unreachable:1
--------------------------------------------------------------

VPN instance name : vpna
Route             : 10.1.1.1/32
Route status      : reachable
PW number         : 1
VC ID      VC Type               Peer IP             VC State
--------------------------------------------------------------
101        VLAN                  10.1.1.2            up
```

Table 10-145 Description of the **display mpls l2vpn track route** command output

Item	Description
Total route number	Total number of VPNv4 routes tracked by a PW.
reachable	Number of reachable VPNv4 routes.
unreachable	Number of unreachable VPNv4 routes.
VPN instance name	VPN instance name.
Route	Destination IP address of a VPNv4 route.
Route status	VPNv4 route status: ● reachable ● unreachable
VC ID	ID of a VC, which uniquely identifies the VC.
VC Type	Encapsulation type of the VC: ● VLAN ● Ethernet
Peer IP	Peer IP address.
VC State	VC status: ● up: The VC is established. ● Down: The VC is not established.

10.8.4 mpls l2vpn track route

Function

The **mpls l2vpn track route** command configures a PW to track VPNv4 route status.

The **undo mpls l2vpn track route** command configures a PW not to track VPNv4 route status.

By default, a PW does not track VPNv4 route status.

Format

mpls l2vpn track route *ipv4-address* { *mask* | *mask-length* } **vpn-instance** *vpn-instance-name*

undo mpls l2vpn track route

Parameters

Parameter	Description	Value
ipv4-address	Specifies the destination IP address of a VPNv4 route.	The value is in dotted decimal notation.
mask	Specifies a mask in dotted decimal notation.	The value is in dotted decimal notation.
mask-length	Specifies the mask length.	The value is an integer ranging from 0 to 32.
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.

Views

VE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

In an L2VPN access to L3VPN scenario, if all L3VPN-side links of an NPE become unavailable, a black-hole route comes into existence. The user-side UPE cannot detect the link failures and still sends traffic to the NPE. As a result, traffic loss occurs. To prevent traffic loss, run the **mpls l2vpn track route** command to configure the PW to track VPNv4 route status. Then, after the NPE detects that all its L3VPN-side links become unavailable, the NPE instructs the UPE to switch traffic to the secondary PW.

Example

Configure a PW to track VPNv4 route status.

```
<HUAWEI> system-view
[HUAWEI] interface virtual-ethernet 0/0/1
[HUAWEI-Virtual-Ethernet0/0/1] ve-group 1 l2-terminate
[HUAWEI-Virtual-Ethernet0/0/1] quit
[HUAWEI] interface virtual-ethernet 0/0/1.1
[HUAWEI-Virtual-Ethernet0/0/1.1] mpls l2vc 10.1.1.2 101
[HUAWEI-Virtual-Ethernet0/0/1.1] mpls l2vpn track route 10.1.1.1 32 vpn-instance vpna
```

10.8.5 statistic enable (VE interface view)

Function

The **statistic enable** command enables the traffic statistics collection function on a Virtual Ethernet (VE) interface.

The **undo statistic enable** command disables the traffic statistics collection function on a VE interface.

By default, the traffic statistics collection function is disabled on a VE interface.

Format

statistic enable { **both** | **inbound** | **outbound** }

undo statistic enable { **both** | **inbound** | **outbound** }

Parameters

Parameter	Description	Value
both	Enables the traffic statistics collection function for incoming and outgoing traffic.	-
inbound	Enables the traffic statistics collection function for incoming traffic.	-
outbound	Enables the traffic statistics collection function for outgoing traffic.	-

Views

VE interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can enable the traffic statistics collection function on the VE interfaces if you want to check the network status or troubleshoot network faults.

Prerequisites

The VE interfaces have been bound to VE groups by using the **ve-group** command. Otherwise, the **statistic enable** command does not take effect.

Precautions

- After you run the **undo statistic enable** command on a VE interface, the switch stops collecting traffic statistics on the VE interface and the collected traffic statistics will be deleted.
- The switch uses ACL resources when collecting traffic statistics. If the traffic statistics collection function is enabled on too many VE interfaces, other services may fail to obtain ACL resources.

- The switch can only collect statistics of unicast, multicast, and broadcast packets on VE interfaces.
- On the VE interface enabled with the traffic statistics collection function, the packets such as ping packets sent from the switch cannot be counted.

Example

Enable the traffic statistics collection function for incoming and outgoing traffic on the VE interface.

```
<HUAWEI> system-view
[HUAWEI] interface virtual-ethernet 0/0/1
[HUAWEI-Virtual-Ethernet0/0/1] ve-group 1 l2-terminate
[HUAWEI-Virtual-Ethernet0/0/1] statistic enable both
```

10.8.6 ve-group

Function

The **ve-group** command configures a VE interface to work in multi-service access mode and binds the VE interface to a specified VE group.

The **undo ve-group** command restores a VE interface to common mode.

By default, a VE interface works in common mode.

Format

ve-group *ve-group-id* { **l2-terminate** | **l3-access** }

undo ve-group

Parameters

Parameter	Description	Value
ve-group-id	Specifies the ID of a VE group.	The value is an integer ranging from 1 to 8.
l2-terminate	Sets the VE interface to an L2VE interface that terminates the L2VPN.	-
l3-access	Sets the VE interface to an L3VE interface that accesses the L3VPN.	-

Views

VE interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In L2VPN access to L3VPN scenarios:

- To change a VE interface to an L2VE interface, run the **ve-group** *ve-group-id* **l2-terminate** command.
- To change a VE interface to an L3VE interface, run the **ve-group** *ve-group-id* **l3-access** command.

Precautions

- A VE group has only one L2VE interface and one L3VE interface.
- The two VE interfaces in a VE group must be on the same chassis.
- Multiple sub-interfaces can be created for each L2VE or L3VE interface to provide access for different VLAN services.

Example

Set Virtual-Ethernet 0/0/1 to an L2VE interface.

```
<HUAWEI> system-view
[HUAWEI] interface virtual-ethernet 0/0/1
[HUAWEI-Virtual-Ethernet0/0/1] ve-group 1 l2-terminate
```

Set Virtual-Ethernet 0/0/2 to an L3VE interface.

```
<HUAWEI> system-view
[HUAWEI] interface virtual-ethernet 0/0/2
[HUAWEI-Virtual-Ethernet0/0/2] ve-group 1 l3-access
```

11 WLAN-AC Commands

11.1 WLAN Service Configuration Commands

11.1.1 Command Support

WLAN-AC commands are supported only by the following models: S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.

11.1.2 ac sysnetid

Function

The **ac sysnetid** command configures an NE name for an AC.

The **undo ac sysnetid** command deletes the NE name of an AC.

By default, no NE name is configured for an AC.

Format

ac sysnetid *ac-sysnetid*

undo ac sysnetid

Parameters

Parameter	Description	Value
ac-sysnetid	Specifies the NE name of an AC.	The value is a string of 1 to 32 case-sensitive characters. The value beginning and ending with double quotation marks (" ") can contain spaces. The value can contain digits, letters, and special characters such as the asterisk (*) and number sign (#).

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The administrator can run the **ac sysnetid** command to configure a unique NE name for an AC. This facilitates AC management.

Configuration Impact

If you run the **ac sysnetid** command multiple times, only the latest configuration takes effect.

Example

Set the NE name of an AC to **ABC123**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ac sysnetid ABC123
```

11.1.3 active-dull-client enable

Function

The **active-dull-client enable** command enables the function of preventing terminals from entering the power-saving mode.

The **undo active-dull-client enable** command disables the function.

By default, the function of preventing terminals from entering the power-saving mode is disabled.

Format

active-dull-client enable

undo active-dull-client enable

Parameters

None

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Due to individual reasons, some terminals may not run services normally when entering the power-saving mode. You can run the **active-dull-client enable** command to enable the function of preventing terminals from entering the power-saving mode. After that, an AP frequently sends QoS data frames to these terminals to prevent them from entering the power-saving mode, ensuring normal services. This function does not take effect for some terminals and cannot prevent the terminals from entering the power-saving mode. For details, see *Test Report on Terminal Compatibility*.

Precautions

After the function is enabled, the terminals consume more power and extra bandwidth. If no terminal unexpectedly enters the power-saving state, you are advised to disable the function.

Example

Enable the function of preventing terminals from entering the power-saving mode.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] active-dull-client enable
```

11.1.4 active-dull-client force enable

Function

The **active-dull-client force enable** command enables the function of forcibly preventing terminals from entering the power-saving mode.

The **undo active-dull-client force enable** command disables the function of forcibly preventing terminals from entering the power-saving mode.

By default, the function of forcibly preventing terminals from entering the power-saving mode is disabled.

Format

active-dull-client force enable

undo active-dull-client force enable

Parameters

None

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the function of preventing terminals from entering the power-saving mode is enabled, some special terminals still enter the power-saving mode, causing service packet loss. In this case, you can enable the function of forcibly preventing terminals from entering the power-saving mode to wake up these terminals and prevent them from entering the power-saving mode.

Precautions

Enabling this function increases terminal power consumption and occupies extra bandwidth. Therefore, it is recommended that this function be enabled only when there are such special terminals.

Example

Enable the function of forcibly preventing terminals from entering the power-saving mode.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] active-dull-client force enable
```

11.1.5 advertise-ap-name enable

Function

The **advertise-ap-name enable** command enables Beacon frames to carry the AP name.

The **undo advertise-ap-name enable** disables Beacon frames from carrying the AP name.

By default, Beacon frames do not carry the AP name.

Format

advertise-ap-name enable

undo advertise-ap-name enable

Parameters

None

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

In certain scenarios, you can run the **advertise-ap-name enable** command to enable Beacon frames to carry the AP name. In this way, you can quickly locate and identify APs by identifying the AP name carried in an SSID or display the AP name on STAs that can receive and resolve the host name carried in SSIDs of multiple APs.

Example

Enable Beacon frames to carry the AP name in the SSID profile **ssid1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] advertise-ap-name enable
```

11.1.6 agile-antenna-polarization

Function

The **agile-antenna-polarization enable** command enables self-adaptive polarization for agile antennas.

The **undo agile-antenna-polarization enable** command disables self-adaptive polarization for agile antennas.

By default, self-adaptive polarization is disabled for agile antennas.

Format

agile-antenna-polarization enable

undo agile-antenna-polarization enable

Parameters

None

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Self-adaptive polarization for agile antennas can reduce interference between transmit signals of antennas, and increase the transmit power of antennas and the demodulation SNR of STAs. When providing wireless coverage, you can enable this function when the following types of STA exist:

- STA with one transmit antenna and one receive antenna in 1x1 mode
- STA with two transmit antennas and two receive antennas in 2x2 mode

After this function is enabled, the AP uses two mutually orthogonal antennas to communicate with STAs but not a third antenna.

Prerequisites

Dual-polarized antennas have been connected to radio ports A and B on the same frequency band.

Example

Enable self-adaptive polarization for agile antennas in a 2G radio profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] agile-antenna-polarization enable
```

11.1.7 antenna-gain

Function

(AP group radio view) The **antenna-gain** command configures the antenna gain for all specified AP radios in an AP group.

(AP group radio view) The **undo antenna-gain** command restores the default antenna gain of all specified AP radios in an AP group.

(AP radio view) The **antenna-gain** command configures the antenna gain for an AP radio.

(AP radio view) The **undo antenna-gain** command restores the antenna gain of an AP radio to that configured in the AP group radio view.

By default, no antenna gain is configured for AP radios. The antenna gains of AP radios depend on AP types and operating channels of AP radios. To check the default antenna gains of radios on different AP types, run the **display ap-type** { **id** *type-id* | **type** *ap-type* } command.

Format

antenna-gain *antenna-gain*

undo antenna-gain

Parameters

Parameter	Description	Value
antenna-gain	Specifies the antenna gain.	The value is an integer that ranges from –10 to +30, in dB.

Views

AP radio view, AP group radio view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The antenna gain is the ratio of the power density produced by an antenna to the power density that should be obtained at the same point if the power accepted by the antenna were radiated equally. It can measure the capability for an antenna to receive and send signals in a specified direction, which is one of the most important parameters to select a BTS antenna. Under the same condition, a higher antenna gain indicates a longer transmission distance.

Precautions

- The regulatory requirements for the strength of radio signals vary in different countries and regions. Therefore, when APs and external antennas are used together, run the **antenna-gain** command to set the antenna gain based on the actual antenna specifications. Then the device software controls the transmit power based on the configured antenna gain within the range allowed by the country code.
- The antenna gain of an AP radio configured using the command takes effect only for external antennas.
- The maximum transmit power of a radio must comply with local laws and regulations. For details, see *WLAN Country Codes and Channels Compliance*. You can obtain this table at Huawei technical support website.
  - Enterprise technical support website: **https://support.huawei.com/enterprise**
  - Carrier technical support website: **https://support.huawei.com**
- The configuration in the AP radio view has a higher priority than that in the AP group radio view.
- When the antenna gain of an AP is not an integer, the AC rounds the value off and delivers the integer antenna gain. For example, if the 2.4 GHz antenna gain of an AP is 2.5 dB, the 2.4 GHz antenna gain of 3 dB is displayed on the AC.

Example

Set the antenna gain of radio 0 on AP 1 to 4.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 1
[HUAWEI-wlan-ap-1] radio 0
[HUAWEI-wlan-radio-1/0] antenna-gain 4
```

11.1.8 ap auth-mode

Function

The **ap auth-mode** command configures the AP authentication mode.

The **undo ap auth-mode** command restores the default AP authentication mode.

By default, the AP authentication mode is MAC address authentication. In the CloudCampus Solution, for an AC in NETCONF mode, the AP authentication mode is SN authentication.

Format

ap auth-mode { **mac-auth** | **no-auth** | **sn-auth** }

undo ap auth-mode

Parameters

Parameter	Description	Value
mac-auth	Indicates the MAC address authentication mode.	-
no-auth	Indicates the none authentication mode.	-
sn-auth	Indicates the SN authentication mode.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

After this command is executed, the device authenticates APs using the configured mode.

NOTE

The none authentication mode brings security risks. You are advised to set the authentication mode to MAC address or SN authentication, which is more secure.

Example

Set the AP authentication mode to MAC address authentication.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] ap auth-mode mac-auth
Warning: The authentication mode is switched to MAC address authentication. Ensu
re that the APs added offline have MAC address information. Otherwise, configura
tions of these APs may be lost after the device restarts. Continue? [Y/N]:Y
```

11.1.9 ap blacklist

Function

The **ap blacklist** command adds APs to the AP blacklist.

The **undo ap blacklist** command deletes APs from the AP blacklist.

By default, no APs exist in the AP blacklist.

Format

ap blacklist mac *ap-mac1* [**to** *ap-mac2*]

undo ap blacklist mac { *ap-mac1* [**to** *ap-mac2*] | **all** }

Parameters

Parameter	Description	Value
mac *ap-mac1*	Specifies the MAC address of an AP.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.
to *ap-mac2*	Specifies the end MAC address during the batch operation. The value of *ap-mac2* must be larger than *ap-mac1*, and *ap-mac1* and *ap-mac2* together specify a range. A maximum of 128 MAC addresses are supported during the batch operation.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.
all	Deletes all MAC addresses from the blacklist.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

APs in the blacklist cannot go online. Online APs will be disconnected after it is blacklisted.

Precautions

The AP blacklist and whitelist can both be configured. However, the MAC address of an AP cannot be added to both of them.

If the AP whitelist and blacklist are both configured, the system checks an AP against the blacklist first.

Example

Add the AP with the MAC address of 00e0-fc07-8280 to the AP blacklist.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap blacklist mac 00e0-fc07-8280
```

Add MAC addresses from 00e0-fc07-8270 to 00e0-fc07-8276 to the AP blacklist.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap blacklist mac 00e0-fc07-8270 to 00e0-fc07-8276
```

11.1.10 ap data-collection enable

Function

The **ap data-collection enable** command enables the AP data caching function.

The **undo ap data-collection enable** command disables the AP data caching function and clears cached data.

By default, the AP data caching function is disabled.

Format

ap data-collection enable

undo ap data-collection enable

Parameters

None

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The AC needs to query performance statistics (such as AP and radio performance statistics, and STA association information on APs) from APs. The **ap data-collection enable** command can enable an AC to periodically query data on APs and cache obtained data. Upon the next data query, the AC can directly search for cached data without the need to wait for APs to return data. This greatly reduces timeout for querying AP-related statistics.

If there are a large number of APs and STAs on the AC, this function may occupy many memory resources and affect performance. Therefore, it is recommended that this function be disabled when statistics query is not required.

Precautions

After the **undo ap data-collection enable** command is executed, data of all APs is cleared. However, common Fit APs periodically report performance statistics. Therefore, even if the data cached on the device is cleared, the data can be queried after the APs periodically report data.

Example

Enable the AP data caching function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap data-collection enable
```

11.1.11 ap data-collection interval

Function

The **ap data-collection interval** command sets the AP data buffer duration.

The **undo ap data-collection interval** command restores the default AP data buffer duration.

By default, the device buffers AP data for 5 minutes.

Format

ap data-collection interval *interval*

undo ap data-collection interval

Parameters

Parameter	Description	Value
interval	Specifies the buffer duration.	The value is an integer that ranges from 5 to 60, in minutes.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to set the AP buffer duration on the device.

Example

Enable the device to buffer AP data and set the buffer duration.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap data-collection enable
[HUAWEI-wlan-view] ap data-collection interval 57
```

11.1.12 ap modify

Function

The **ap modify** command changes information about an AP.

Format

ap modify *ap-id* **mac** *ap-mac*

Parameters

Parameter	Description	Value
ap-id	Specifies the ID of the AP to be replaced.	The AP ID must exist.
mac *ap-mac*	Specifies the MAC address of a new AP.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When AP hardware needs to be replaced, you can configure new AP information for an existing AP ID to prevent repetitive data configurations. In this way, the new

AP goes online using the ID of the original AP so that all data configurations of the original AP directly take effect on the new AP.

By default, you can run the **display ap** command to view the MAC address of an AP.

Precautions

This configuration enables the new AP to go online on the AC and interrupts services of the original AP.

The type of the new AP must be the same as that of the original AP.

Example

Specify the MAC address **00e0-fc12-3456** of a new AP for the AP ID 0.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap modify 0 mac 00e0-fc12-3456
Warning: Modify AP will influence the service that has published in AP, Whether to continue? [Y/N]y
```

11.1.13 ap rtu load

Function

The **ap rtu load** command unzips a right-to-use (RTU) license package and automatically delivers the unzipped RTU licenses to the corresponding APs.

NOTE

The RTU License is not supported by the following models.

- AirEngine x76x (Excluding the AirEngine 5760-51, AirEngine 6760-X1, AirEngine 6760-X1E)
- AirEngine x77x
- The cemtral AP (including matching RUs)
- AirEngine 9700D-S (including matching ORUs)

Format

ap rtu load filename *filename*

Parameters

Parameter	Description	Value
filename *filename*	Specifies the name of an RTU license package.	The value is a string of 1 to 64 case-sensitive characters. The package must be a .zip package and have the same name as the existing RTU license package.

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

RTU is an authorization mode for selling hardware capabilities in installments, such as the number of spatial streams, capacity, and ports. An RTU license cannot be migrated after being bound to a device. As a part of hardware value, RTU licenses have the same lifecycle and the same entitlement as the hardware. The quantities of spatial streams, antennas, and service ports have always been the indicators for a WLAN in the industry, among which the quantity of spatial streams is the most basic indicator. RTU licensing allows basic AP models to support features such as dual-band, three-radio, and independent scanning radio.

After applying for RTU licenses in batches, you will obtain an RTU license package. You need to manually upload the RTU license package to the AC, and then run this command to unzip the package and automatically deliver the RTU licenses to the corresponding APs.

Prerequisites

An RTU license package has been manually uploaded to the AC.

Configuration Impact

Executing this command will unzip the RTU license package locally on the device, with a list of RTU license files generated.

Precautions

To ensure that RTU-granted functions work properly, license files in the RTU license package must meet the following requirements:

- License files are .dat files downloaded from the Electronic Software Delivery Platform (ESDP).
- The name of a license file (including the file name extension) cannot exceed 64 characters.

Follow-up Procedure

Manually restart the APs to which the RTU licenses have been delivered so that these licenses can take effect.

Example

Unzip an RTU license package and automatically deliver the unzipped RTU licenses to the corresponding APs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap rtu load filename rtu.zip
Info: This operation may take a few seconds. Please wait for a moment....done.
Info: Valid license file(s):2048, invalid license file(s):0
Warning: After the RTU file is downloaded to the AP, restart the AP to make RTU take effect.
```

11.1.14 ap whitelist

Function

The **ap whitelist** command adds APs to the AP whitelist.

The **undo ap whitelist** command deletes APs from the AP whitelist.

By default, no APs exist in the AP whitelist.

Format

ap whitelist { **mac** *ap-mac1* [**to** *ap-mac2*] | **sn** *ap-sn1* [**to** *ap-sn2*] }

undo ap whitelist { **mac** { *ap-mac1* [**to** *ap-mac2*] | **all** } | **sn** { *ap-sn1* [**to** *ap-sn2*] | **all** } }

Parameters

Parameter	Description	Value
mac *ap-mac1*	Specifies the MAC address of an AP.	The value is in H-H-H format. An H is a 4-digit hexadecimal number.
to *ap-mac2*	Specifies the end MAC address during the batch operation. The value of *ap-mac2* must be larger than *ap-mac1*, and *ap-mac1* and *ap-mac2* together specify a range.	The value is in H-H-H format. An H is a 4-digit hexadecimal number.
sn *ap-sn1*	Specifies the SN of an AP.	The value is a string of 1 to 31 characters.
to *ap-sn2*	Specifies the end SN during the batch operation. The value of *ap-sn2* must be larger than *ap-sn1*, and *ap-sn1* and *ap-sn2* together specify a range.	The value is a string of 1 to 31 characters.
mac all	Deletes all MAC addresses from the whitelist.	-
sn all	Deletes all SNs from the whitelist.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

- In MAC address authentication mode configured using the **ap auth-mode** command, if the MAC address of an AP exists in the whitelist, the AP automatically goes online, without the need of manual confirmation. If the MAC address of an AP is not in the whitelist and the AP has not been imported, the AP cannot automatically go online. In this case, you need to run the **ap-confirm** command to confirm the AP.
- When the AP authentication mode is set to SN authentication using the **ap auth-mode** command, if the SN of an online AP exists in the whitelist, the AP automatically goes online, without the need of manual confirmation. If the SN of an AP is not in the whitelist and the AP has not been imported, the AP cannot automatically go online. In this case, you need to run the **ap-confirm** command to confirm the AP.

Prerequisites

The AP authentication mode has been set to MAC address or SN authentication using the **ap auth-mode** command.

Precautions

When adding multiple SNs to the whitelist, ensure that the start SN length and the end SN length are the same.

Example

Add the AP with the MAC address of 00e0-fc07-8280 to the AP whitelist.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap whitelist mac 00e0-fc07-8280
```

Add MAC addresses from 00e0-fc07-8270 to 00e0-fc07-8290 to the AP whitelist.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap whitelist mac 00e0-fc07-8270 to 00e0-fc07-8290
```

Add the SN 08PE56430071 to the AP whitelist.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap whitelist sn 08PE56430071
```

Add SNs from 08PE56430076 to 08PE56430081 to the AP whitelist.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap whitelist sn 08PE56430076 to 08PE56430081
```

11.1.15 ap-confirm

Function

The **ap-confirm** command confirms unauthenticated APs and allows them to go online.

Format

ap-confirm { **all** | **mac** *ap-mac* | **sn** *ap-sn* }

Parameters

Parameter	Description	Value
all	Confirms all APs.	-
mac *ap-mac*	Confirms the AP with the specified MAC address.	The value is in H-H-H format. An H is a 4-digit hexadecimal number.
sn *ap-sn*	Confirms the AP with the specified SN.	The value is a string of 1 to 31 characters.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

After viewing unauthenticated APs using the **display ap unauthorized record** command, you can run the **ap-confirm** command to confirm these unauthenticated APs if you want to connect them to the AC. After confirmation, the APs are allowed to go online, automatically added to the default region, and bound to the default AP profiles.

Example

Confirm the AP with the MAC address 00e0-fc12-3456.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-confirm mac 00e0-fc12-3456
```

Confirm all APs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-confirm all
```

11.1.16 ap-id

Function

The **ap-id** command imports an AP or displays the AP view.

By default, no AP is imported.

Format

ap-id *ap-id* [[**type-id** *type-id* | **ap-type** *ap-type*] { **ap-mac** *ap-mac* | **ap-sn** *ap-sn* | **ap-mac** *ap-mac* **ap-sn** *ap-sn* }]

Parameters

Parameter	Description	Value
ap-id	Specifies an AP ID.	The value is an integer that ranges from 0 to 1023.
type-id *type-id*	Specifies an AP type ID.	The value is an integer that ranges from 0 to .
ap-type *ap-type*	Specifies an AP type.	The value is a string of 1 to 31 characters.
ap-mac *ap-mac*	Specifies the MAC address of an AP.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.
ap-sn *ap-sn*	Specifies an AP SN.	The value is a string of 1 to 31 characters, and can only contain letters and digits.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to set parameters for an AP imported successfully before it goes online. The parameter settings then take effect when the AP goes online.

To delete an AP, run the **undo ap** command.

Precautions

To add an AP, you must enter the MAC address, SN, or MAC address+SN of the AP. In MAC address authentication mode, enter the MAC address of the AP. In SN authentication mode, enter the SN of the AP.

To enter the AP view, you only need to enter the AP ID.

Example

Import an AP with the ID of 11, type ID of 125, and MAC address of 00e0-fc07-8270.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 11 type-id 125 ap-mac 00e0-fc07-8270
```

11.1.17 ap-mac

Function

The **ap-mac** command imports an AP or displays the AP view.

By default, no AP is imported.

Format

ap-mac *ap-mac* [**type-id** *type-id* | **ap-type** *ap-type*] [**ap-id** *ap-id*] [**ap-sn** *ap-sn*]

Parameters

Parameter	Description	Value
ap-mac	Specifies the MAC address of an AP.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.
type-id *type-id*	Specifies an AP type ID.	The value is an integer that ranges from 0 to .
ap-type *ap-type*	Specifies an AP type.	The value is a string of 1 to 31 characters.
ap-id *ap-id*	Specifies an AP ID.	The value is an integer that ranges from 0 to 1023.
ap-sn *ap-sn*	Specifies an AP SN.	The value is a string of 1 to 31 characters, and can only contain letters and digits.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to set parameters for an AP imported successfully before it goes online. The parameter settings then take effect when the AP goes online.

Precautions

When importing an AP, you must enter the MAC address of the AP. If the AP authentication mode is SN authentication, you also need to enter the SN of the AP.

To enter the AP view, you only need to enter the MAC address of the AP. If the specified MAC address does not exist, the system adds a new AP and displays the AP view.

The **ap-mac** *ap-mac* [[**type-id** *type-id* | **ap-type** *ap-type*] [**ap-id** *ap-id*] [**ap-sn** *ap-sn*]] and **ap-id** *ap-id* [[**type-id** *type-id* | **ap-type** *ap-type*] { **ap-mac** *ap-mac* | **ap-sn** *ap-sn* | **ap-mac** *ap-mac* **ap-sn** *ap-sn* }] commands have the same function. You can use either one according to the actual situation.

Example

Import the AP with the MAC address of 00e0-fc07-8260.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-mac 00e0-fc07-8260
```

11.1.18 association-timeout

Function

The **association-timeout** command configures the association aging time for STAs.

The **undo association-timeout** command restores the default association aging time of STAs.

By default, the association aging time of STAs is 5 minutes.

Format

association-timeout *association-timeout*

undo association-timeout

Parameters

Parameter	Description	Value
association-timeout	Specifies the association aging time of STAs.	The value is an integer that ranges from 1 to 30, in minutes.

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The administrator can run this command to set the association aging time for STAs. If the AP receives no data packet from a STA in a specified time, the STA goes offline after the association aging time expires.

Precautions

Changing the association aging time of a STA may interrupt the STA services.

Example

Set the association aging time of STAs to 15 minutes in the SSID profile **ssid1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] association-timeout 15
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.1.19 auto-off service

Function

The **auto-off service** command enables the scheduled VAP auto-off function and sets the time range within which the VAP is disabled.

The **undo auto-off service** command disables the scheduled VAP auto-off function.

By default, the scheduled VAP auto-off function is disabled.

Format

auto-off service start-time *start-time* **end-time** *end-time*

undo auto-off service

Parameters

Parameter	Description	Value
start-time *start-time*	Specifies the time when a VAP starts to be disabled.	The time is in hh:mm:ss format. hh indicates the hour that is an integer ranging from 0 to 23. mm indicates the minute that is an integer ranging from 0 to 59. ss indicates the second that is an integer ranging from 0 to 59.
end-time *end-time*	Specifies the time when a VAP stops being disabled.	The time is in hh:mm:ss format. hh indicates the hour that is an integer ranging from 0 to 23. mm indicates the minute that is an integer ranging from 0 to 59. ss indicates the second that is an integer ranging from 0 to 59.

Views

VAP profile view, 2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an enterprise does not want employees to access the internal WLAN from 01:00 to 05:00, the administrator can run the **auto-off service** command to enable the scheduled VAP auto-off function.

Precautions

- After the service mode of a VAP is enabled using the **undo service-mode disable** command, you can run the **auto-off service** command to configure the scheduled VAP auto-off function. In the scheduled time, the VAP is disabled and cannot be enabled using the **undo service-mode disable** command. To enable the VAP, run the **undo auto-off service** command.
- The scheduled VAP auto-off function takes effect in the scheduled time only after the **undo service-mode disable** command is executed. If the service mode of a VAP is disabled using the **service-mode disable** command, the VAP auto-off function does not take effect.

- The scheduled VAP auto-off function enabled in a VAP profile view takes effect only on the APs using the VAP profile, and the scheduled VAP auto-off function enabled in a radio profile view takes effect only on the APs using the radio profile.

Example

Configure the scheduled VAP auto-off function in the VAP profile **vap1**, and configure the VAP to be disabled from 1:00:00 to 7:00:00.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] auto-off service start-time 1:00:00 end-time 7:00:00
```

11.1.20 beacon-2g-rate

Function

The **beacon-2g-rate** command sets the transmit rate of 2.4 GHz management frames (including Beacon frames, Probe Response frames, Assoc/Reassoc Response frames, and Auth frames).

The **undo beacon-2g-rate** command restores the default transmit rate of 2.4 GHz management frames.

By default, the transmit rate of 2.4 GHz management frames is 5.5 Mbit/s.

Format

beacon-2g-rate *beacon-2g-rate*

undo beacon-2g-rate

Parameters

Parameter	Description	Value
beacon-2g-rate	Specifies the transmit rate of management frames.	The value is of the enumerated type: ● 1: 1 Mbit/s ● 2: 2 Mbit/s ● 5.5: 5.5 Mbit/s ● 6: 6 Mbit/s ● 9: 9 Mbit/s ● 11: 11 Mbit/s ● 12: 12 Mbit/s ● 18: 18 Mbit/s ● 24: 24 Mbit/s ● 36: 36 Mbit/s ● 48: 48 Mbit/s ● 54: 54 Mbit/s

Views

SSID profile view, Mesh profile view, WDS profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In high-density wireless scenarios, too many management frames occupy a large number of wireless resources. To reduce wireless resource occupation of management frames and improve channel utilization, you can run the **beacon-2g-rate** command to set a high transmit rate for 2.4 GHz management frames.

Precautions

The 802.11b protocol supports only 1 Mbit/s, 2 Mbit/s, 5.5 Mbit/s, and 11 Mbit/s. If you set the transmit rate of management frames to a rate not supported by the 802.11b protocol, STAs supporting only 802.11b cannot connect to the wireless network.

If you run the **radio-type dot11b** command in the 2G radio profile view to set the radio type to **dot11b**, and the 2G radio profile is applied to an AP, *beacon-2g-rate* that takes effect on the 2 GHz radio of the AP is fixed as 1 Mbit/s, and *beacon-2g-rate* configured in the SSID profile view does not take effect on the AP.

Example

Set the transmit rate of 2.4 GHz management frames to 18 Mbit/s in the SSID profile **ssid1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] beacon-2g-rate 18
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.1.21 beacon-5g-rate

Function

The **beacon-5g-rate** command sets the transmit rate of 5 GHz management frames (including Beacon frames, Probe Response frames, Assoc/Reassoc Response frames, and Auth frames).

The **undo beacon-5g-rate** command restores the default transmit rate of 5 GHz management frames.

By default, the transmit rate of 5 GHz management frames is 6 Mbit/s.

Format

beacon-5g-rate *beacon-5g-rate*

undo beacon-5g-rate

Parameters

Parameter	Description	Value
beacon-5g-rate	Specifies the transmit rate of management frames.	The value is of the enumerated type: • 6: 6 Mbit/s • 9: 9 Mbit/s • 12: 12 Mbit/s • 18: 18 Mbit/s • 24: 24 Mbit/s • 36: 36 Mbit/s • 48: 48 Mbit/s • 54: 54 Mbit/s

Usage Guidelines

Usage Scenario

In high-density wireless scenarios, too many management frames occupy a large number of wireless resources. To reduce wireless resource occupation of management frames and improve channel utilization, you can run the **beacon-5g-rate** command to set a high transmit rate for 5 GHz management frames.

Example

Set the transmit rate of 5 GHz management frames to 18 Mbit/s in the SSID profile **ssid1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] beacon-5g-rate 18
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.1.22 beacon-6g-rate

Function

The **beacon-6g-rate** command sets the transmit rate of 6 GHz management frames (including Beacon frames, Probe Response frames, Assoc/Reassoc Response frames, and Auth frames).

The **undo beacon-6g-rate** command restores the default transmit rate of 6 GHz management frames.

By default, the transmit rate of 6 GHz management frames is 6 Mbit/s.

Format

beacon-6g-rate *beacon-6g-rate*

undo beacon-6g-rate

Parameters

Parameter	Description	Value
beacon-6g-rate	Specifies the transmit rate of management frames.	The value is of the enumerated type: ● 6: 6 Mbit/s ● 9: 9 Mbit/s ● 12: 12 Mbit/s ● 18: 18 Mbit/s ● 24: 24 Mbit/s ● 36: 36 Mbit/s ● 48: 48 Mbit/s ● 54: 54 Mbit/s

Usage Scenario

In high-density wireless scenarios, too many management frames occupy a large number of wireless resources. To reduce wireless resource occupation of management frames and improve channel utilization, you can run the **beacon-6g-rate** command to set a high transmit rate for 6 GHz management frames.

Example

Set the transmit rate of 6 GHz management frames to 18 Mbit/s in the SSID profile **ssid1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] beacon-6g-rate 18
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.1.23 beacon-interval

Function

The **beacon-interval** command sets the interval for sending Beacon frames.

The **undo beacon-interval** command restores the default interval for an AP to send Beacon frames.

By default, the interval for sending Beacon frames is 100 TUs.

Format

beacon-interval *beacon-interval*

undo beacon-interval

Parameters

Parameter	Description	Value
beacon-interval	Specifies the interval for sending Beacon frames.	The value is an integer that ranges from 60 TUs to 1000 TUs. TU is a time unit equal to 1024 microseconds.

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

An AP broadcasts Beacon frames at intervals to notify STAs of an existing 802.11 network. After receiving a Beacon frame, a STA can modify parameters used to connect to the 802.11 network.

A long interval for sending Beacon frames lengthens the dormancy time of STAs, while a short interval for sending Beacon frames increases air interface costs. Therefore, you are advised to set the interval for sending Beacon frames for an AP based on the VAP quantity. The following intervals for sending Beacon frames are recommended for APs with different VAP quantities on a single radio:

- No more than 4 VAPs: about 100 TUs
- 5 to 8 VAPs: about 200 TUs
- 9 to 12 VAPs: about 300 TUs
- 13 to 16 VAPs: about 400 TUs

Ensure that the air scan interval meets the following condition: scan-interval ≥ beacon-interval + 100 ms

Example

Set the interval for sending Beacon frames to 200 TUs in the 2G radio profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] beacon-interval 200
```

11.1.24 beamforming disable

Function

The **beamforming disable** command disables the beamforming function.

The **undo beamforming disable** command enables the beamforming function.

By default, the beamforming function is enabled.

NOTE

This configuration takes effect only on APs running V200R019C10 or later.

Format

beamforming disable

undo beamforming disable

Parameters

None

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Beamforming is a signal processing technique that controls signal transmission direction, and transmission and reception of radio signals. The transmit end uses weight to transmit signals. The signals are transmitted to the destination as narrow beams. Beamforming increases the demodulation signal-to-noise ratio (SNR) for the destination device.

Precautions

If nodes on a Mesh network are fixed and distant from each other, enable the beamforming function to increase the demodulation SNR of Mesh links. Mobile nodes may cause a low demodulation SNR of Mesh links in Mesh scenarios. Therefore, it is recommended that the beamforming function be disabled.

To use the MU-MIMO function, enable the beamforming function.

Example

Disable the beamforming function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name default
[HUAWEI-wlan-ssid-prof-default] beamforming disable
```

11.1.25 beamforming enable

Function

The **beamforming enable** command enables the beamforming function.

The **undo beamforming enable** command disables the beamforming function.

By default, the beamforming function is disabled.

NOTE

This configuration takes effect only on APs running V200R019C00 or earlier.

Format

beamforming enable

undo beamforming enable

Parameters

None

Views

2G radio profile view, 5G radio profile view

2: Configuration level

Usage Guidelines

Usage Scenario

Beamforming is a signal processing technique that controls signal transmission direction, and transmission and reception of radio signals. The transmit end uses weight to transmit signals. The signals are transmitted to the destination as narrow beams. Beamforming increases the demodulation signal-to-noise ratio (SNR) for the destination device.

Precautions

If nodes on a WDS or Mesh network are fixed and distant from each other, enable the beamforming function to increase the demodulation SNR of WDS or Mesh links. Mobile nodes may cause a low demodulation SNR of WDS or Mesh links in WDS or Mesh scenarios. Therefore, it is recommended that the beamforming function be disabled.

Example

Enable the beamforming function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] beamforming enable
```

11.1.26 capwap control-link-priority

Function

The **capwap control-link-priority** command configures the priority of CAPWAP management packets.

The **undo capwap control-link-priority** command restores the default priority of CAPWAP management packets.

The default priority of CAPWAP management packets is 7.

Format

capwap control-link-priority { **local** | **remote** } *priority-value*

undo capwap control-link-priority { **local** | **remote** }

Parameters

Parameter	Description	Value
local	Specifies the priority of CAPWAP management packets from the AC to the APs. The priority of CAPWAP management packets determines the reliability of links from the AC to APs.	-
remote	Priority of CAPWAP management packets from APs to the AC. The priority of CAPWAP management packets determines the reliability of links from APs to the AC.	-
priority-value	Specifies the priority of CAPWAP management packets.	The value is an integer that ranges from 0 to 7. The value 0 indicates the lowest priority, and the value 7 indicates the highest priority.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to configure the DSCP priority of CAPWAP management packets. A higher priority indicates a more reliable link between the AC and APs.

The configuration of the priority of CAPWAP management packets from the AC to APs takes effect immediately. After the priority of CAPWAP management packets from an AP to the AC is changed, if the AP is online, the AC sends the priority to the AP in the Echo packet. If the AP is not online, the priority is delivered to the AP in the Echo packet when the AP goes online. The new priority takes effect immediately when the AP receives it.

Precautions

NOTICE

When setting the parameter **local** *priority-value* to configure the priority of CAPWAP management packets from the AC to APs, ensure that the value is in the range of 4 to 7 to prevent the management channel from being interrupted in case of heavy service traffic.

Example

Set the priority of CAPWAP management packets from the AC to APs to 6.

```
<HUAWEI> system-view
[HUAWEI] capwap control-link-priority local 6
```

11.1.27 capwap dtls control-link encrypt

Function

The **capwap dtls control-link encrypt** command configures DTLS encryption for CAPWAP control tunnels.

The **undo capwap dtls control-link encrypt** command restores the default configuration of DTLS encryption for CAPWAP control tunnels.

By default, DTLS encryption for CAPWAP control tunnels is disabled.

Format

capwap dtls control-link encrypt

undo capwap dtls control-link encrypt

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In the Discovery phase of the CAPWAP tunnel establishment between the AP and AC, the AP obtains the AC IP address using the discovery mechanism. Then in the DTLS negotiation phase, a CAPWAP tunnel is established between the AP and AC based on this IP address. During this process, UDP packets transmitted over the CAPWAP tunnel are encrypted using DTLS.

After DTLS encryption is enabled on the local end, the local end authenticates the peer end using the configured authentication mode. After authentication succeeds, the local end negotiates a DTLS encryption key with the peer end based on the authentication mode to protect packets transmitted over the CAPWAP control tunnel. If the DTLS negotiation fails, the CAPWAP tunnel cannot be established.

Configuration Impact

After the configuration is modified, the AP and AC re-establish a CAPWAP tunnel.

Precautions

Before enabling this function, run the **capwap dtls psk** command to configure a PSK.

If this function is enabled on the peer end, authentication and DTLS encryption negotiation are still performed on the local end even if the function is disabled on the local end. If the local end fails the verification of the peer end, the CAPWAP tunnel fails to be established. To temporarily disable DTLS encryption on the local and peer ends, you can configure the function of establishing CAPWAP DTLS sessions in none authentication mode. However, this function brings security risks. Ensure that the peer and local ends are in a secure and trusted network environment. After the CAPWAP link is established, disable the function of establishing CAPWAP DTLS sessions in none authentication mode so that the local and peer ends reestablish a CAPWAP link in secure mode.

Example

Enable DTLS encryption for CAPWAP control tunnels.

```
<HUAWEI> system-view
[HUAWEI] capwap dtls control-link encrypt
Warning: This operation may cause devices using CAPWAP connections to reset or go offline. Continue?
[Y/N]:y
```

11.1.28 capwap dtls cert-mandatory-match disable

Function

The **capwap dtls cert-mandatory-match disable** command disables the function of establishing CAPWAP DTLS sessions through the initial certificate.

The **undo capwap dtls cert-mandatory-match disable** command enables the function of establishing CAPWAP DTLS sessions through the initial certificate.

By default, the function of establishing CAPWAP DTLS sessions through the initial certificate is enabled.

Format

capwap dtls cert-mandatory-match disable

undo capwap dtls cert-mandatory-match disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If DTLS encryption for CAPWAP control tunnels has been enabled, when adding an AP running V200R021C00 or later, you can enable APs to establish DTLS sessions through the initial certificate so that they can properly go online. After the APs go online, they obtain new DTLS certificates to initiate DTLS sessions and go online again in secure mode. If high security is required, you can disable this function and use PSK authentication.

If an AP has been online on another WAC where the PSK for DTLS encryption is configured, the AP will fail to go online after being steered to the local WAC. In this case, you need to enable APs to establish DTLS sessions through the initial certificate so that they can properly go online. After the AP goes online, it obtains a new DTLS credential to establish a DTLS session and go online again in secure mode. Then, disable this function.

Example

Disable the function of establishing CAPWAP DTLS sessions through the initial certificate.

```
<HUAWEI> system-view
[HUAWEI] capwap dtls cert-mandatory-match disable
```

11.1.29 capwap dtls no-auth enable

Function

The **capwap dtls no-auth enable** command enables the function of establishing CAPWAP DTLS sessions in none authentication mode.

The **undo capwap dtls no-auth enable** command disables the function of establishing CAPWAP DTLS sessions in none authentication mode.

By default, the function of establishing CAPWAP DTLS sessions in none authentication mode is disabled.

Format

capwap dtls no-auth enable

undo capwap dtls no-auth enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If DTLS encryption for CAPWAP control tunnels has been enabled, when adding an AP running a version earlier than V200R021C00, you can run this command to enable the AP to establish a DTLS session in none authentication mode so that the AP can properly go online. After the AP goes online, it obtains a new DTLS certificate to initiate a DTLS session in secure mode and go online again. To ensure network security, disable this function immediately after the AP goes online again to prevent unauthorized APs from accessing the network.

Example

Disable the function of establishing CAPWAP DTLS sessions in none authentication mode.

```
<HUAWEI> system-view
[HUAWEI] undo capwap dtls no-auth enable
```

11.1.30 capwap dtls psk

Function

The **capwap dtls psk** command configures a pre-shared key (PSK) used for DTLS encryption.

By default, no PSK used for DTLS encryption is configured.

Format

capwap dtls psk *psk-value*

Parameters

Parameter	Description	Value
psk-value	Specifies a PSK used for DTLS encryption.	The value is string of 48 or 68 characters in ciphertext (for example, **%^%#u(Oz:BL,QKYZw%-JWC*P8aGC,="C&M'OI*Gmt.V(%^%#**) or a string of 8 to 32 characters in plaintext (for example, **YsHsjx_202206**). The key must contain at least two types of the following: uppercase letters, lowercase letters, digits, and special characters except the question mark (?) and space.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During CAPWAP tunnel establishment, an AP establishes a DTLS session with an AC. If DTLS encryption has been enabled for CAPWAP control, sent management packets will be encrypted using DTLS. When the PSK is used for DTLS encryption, this command can be used to modify the PSK value in the DTLS session.

Follow-up Procedure

Run the **capwap dtls control-link encrypt** command to enable DTLS encryption for CAPWAP control tunnels.

Precautions

After the **capwap dtls psk** command configuration is complete, the new PSK will be automatically synchronized to the online APs that are working properly, but the previous PSK still takes effect. The new PSK takes effect after these APs go online again.

Example

Set the PSK used for DTLS encryption to **YsHsjx_202206**.

```
<HUAWEI> system-view
[HUAWEI] capwap dtls psk YsHsjx_202206
```

11.1.31 capwap echo

Function

The **capwap echo** command sets the CAPWAP heartbeat detection interval and the number of CAPWAP heartbeat detections.

The **undo capwap echo** command restores the default CAPWAP heartbeat detection interval and the number of CAPWAP heartbeat detections.

By default, the CAPWAP heartbeat detection interval is 25s and the number of CAPWAP heartbeat detections is 6.

If dual-link backup is enabled, the default number of CAPWAP heartbeat detections changes to 3.

Format

capwap echo { **interval** *interval-value* | **times** *times-value* } *

undo capwap echo { **interval** | **times** }

Parameters

Parameter	Description	Value
interval *interval-value*	Specifies the CAPWAP heartbeat detection interval, at which a detection packets are sent.	The value is an integer that ranges from 2 to 300, in seconds.
times *times-value*	Specifies the number of CAPWAP heartbeat detections. If no response is received after the specified number of times, the link is considered disconnected.	The value is an integer that ranges from 3 to 120.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

As defined by CAPWAP, the AP and AC send handshake packets periodically to maintain the data channel and management channel between them. If the AP does not receive packets from the peer end within the specified number of heartbeat detection times, the AP considers that the link with the peer end is disconnected. The AP resets and releases the IP address. Then, the AP and AC reestablish a link. If the AC does not receive packets from the peer end within the specified number of heartbeat detection times, the AC disconnects the link and reports an error to the AP. After this command is executed, the AP and AC perform heartbeat detection based on the new configurations (including the detection interval and number of detections).

Precautions

If dual-link backup is enabled in a WDS scenario, the CAPWAP heartbeat detection interval is 25s and the number of CAPWAP heartbeat detections is 3. In this case, the WDS link is unstable and cannot ensure normal user access. You need to run this command to set the CAPWAP heartbeat detection interval to 25 seconds and the number of CAPWAP heartbeat detections to 6.

After the CAPWAP heartbeat detection interval and the number of CAPWAP heartbeat detections are configured, the interval and the number of times for sending Echo packets are configured.

Radio traffic statistics packets are sent and received together with Echo packets.

If you set the CAPWAP heartbeat detection interval and the number of CAPWAP heartbeat detections smaller than the default values, the CAPWAP link reliability is degraded. If the two parameters are set too high, APs can go online only after a heartbeat timeout. Exercise caution when you set the values. The default values are recommended.

Example

Set the CAPWAP heartbeat detection interval to 30s and the number of CAPWAP heartbeat detections to 3.

```
<HUAWEI> system-view
[HUAWEI] capwap echo interval 30 times 3
```

11.1.32 capwap dtls cbc

Function

The **capwap dtls cbc enable** command configures the CAPWAP DTLS server to establish DTLS sessions with DTLS clients running earlier versions using the CBC cipher suite.

The **capwap dtls cbc disable** command disables the CAPWAP DTLS server from using the CBC cipher suite to establish DTLS sessions with DTLS clients running earlier versions.

By default, CAPWAP DTLS compatibility with the CBC cipher suite is disabled.

Format

capwap dtls cbc enable

capwap dtls cbc disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In versions earlier than V200R021C00, CAPWAP clients support only the DTLS CBC cipher suite, which poses security risks. To establish CAPWAP DTLS sessions with these clients, run this command to enable compatibility with earlier versions.

Precautions

This function can be used only after the weak-encryption-algorithm plug-in is installed.

After this function is enabled, the TLS1_TXT_PSK_WITH_AES_256_CBC_SHA algorithm suite is used to set up DTLS sessions with CAPWAP DTLS clients running a version earlier than V200R021C00, which poses security risks.

After this function is disabled, CAPWAP links established based on earlier DTLS versions are disconnected, which may interrupt services.

Example

Enable CAPWAP DTLS compatibility with the CBC cipher suite.

```
<HUAWEI> system-view
[HUAWEI] capwap dtls cbc enable
```

11.1.33 capwap dtls version1.0

Function

The **capwap dtls version1.0 enable** command configures the CAPWAP DTLS server to establish DTLS 1.0 sessions with DTLS clients running earlier versions.

The **capwap dtls version1.0 disable** command disables the CAPWAP DTLS server from establishing DTLS 1.0 sessions with DTLS clients running earlier versions.

By default, CAPWAP compatibility with DTLS 1.0 is disabled.

Format

capwap dtls version1.0 enable

capwap dtls version1.0 disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In versions earlier than V200R021C00, CAPWAP clients support only the DTLS 1.0 version, which poses security risks. To establish CAPWAP DTLS sessions with clients that support only DTLS 1.0, run this command to enable compatibility with earlier versions.

Precautions

This function can be used only after the weak-encryption-algorithm plug-in is installed.

After this function is enabled, the DTLS 1.0 version is used to set up DTLS sessions with CAPWAP DTLS clients running a version earlier than V200R021C00, which poses security risks.

After this function is disabled, CAPWAP links established based on earlier DTLS versions are disconnected, which may interrupt services.

Example

Enable CAPWAP compatibility with DTLS 1.0.

```
<HUAWEI> system-view
[HUAWEI] capwap dtls version1.0 enable
```

11.1.34 capwap echo-timeout trace logging

Function

The **capwap echo-timeout trace logging** command enables the Echo packet process trace and diagnostic log record functions upon AP Echo packet timeout.

The **undo capwap echo-timeout trace logging** command disables the Echo packet process trace and diagnostic log record functions upon AP Echo packet timeout.

By default, the Echo packet process trace and diagnostic log record functions are enabled upon AP Echo packet timeout.

Format

capwap echo-timeout trace logging

undo capwap echo-timeout trace logging

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

After you run the **capwap echo-timeout trace logging** command, the Echo packet process is traced and diagnostic logs are recorded upon AP Echo packet timeout.

Example

s

Enable the Echo packet process trace and diagnostic log record functions upon AP Echo packet timeout.

```
<HUAWEI> system-view
[HUAWEI] capwap echo-timeout trace logging
```

11.1.35 capwap message-integrity psk

Function

The **capwap message-integrity psk** command configures a PSK used for checking integrity of CAPWAP packets.

The **undo capwap message-integrity psk** command restores the default PSK used for checking integrity of CAPWAP packets.

The default username and password are available in *WLAN Default Usernames and Passwords* (**Enterprise Network** or **Carrier**). If you have not obtained the access permission of the document, see **Help** on the website to find out how to obtain it.

Format

capwap message-integrity psk *psk-value*

undo capwap message-integrity psk

Parameters

Parameter	Description	Value
psk-value	Specifies the PSK used for checking integrity of CAPWAP packets.	The value is string of 48 or 68 characters in ciphertext (for example, **%^%#u(Oz:BL,QKYZw%-JWC*P8aGC,="C&M'OI*Gmt.V(%^%#**) or a string of 6 to 32 characters in plaintext (for example, **YsHsjx_202206**). The key must contain at least two types of the following: uppercase letters, lowercase letters, digits, and special characters except the question mark (?) and space.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

CAPWAP packets are transmitted between the AC and APs. To prevent the packets from being forged or tampered with and prevent malformed packet attacks, you can configure integrity check of CAPWAP packets. When a PSK is used to check integrity of CAPWAP packets, you can run this command on the AC to configure a PSK.

NOTE

It is recommended that you change the PSK in a timely manner to ensure device security.

Follow-up Procedure

Run the **undo capwap message-integrity check disable** command to enable integrity check of CAPWAP packets.

Configuration Impact

After the configuration is complete, all online APs on the AC go offline.

Example

Set the PSK used for checking integrity of CAPWAP packets to **YsHsjx_202206**.

```
<HUAWEI> system-view
[HUAWEI] capwap message-integrity psk YsHsjx_202206
Warning: In a backup scenario, the PSK and status of CAPWAP message integrity check must be the same
between the master and backup e
nds. This operation may cause devices using CAPWAP connections to reset or go offline. Continue? [Y/N]:y
```

11.1.36 capwap message-integrity check disable

Function

The **capwap message-integrity check disable** command disables integrity check of CAPWAP packets.

The **undo capwap message-integrity check disable** command enables integrity check of CAPWAP packets.

By default, integrity check of CAPWAP packets is enabled.

Format

capwap message-integrity check disable

undo capwap message-integrity check disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

CAPWAP packets are transmitted between the AC and APs. To prevent the packets from being forged or tampered with and prevent malformed packet attacks, you can configure integrity check of CAPWAP packets.

Configuration Impact

After the configuration is modified, all online APs on the AC go offline.

Example

Enable integrity check of CAPWAP packets.

```
<HUAWEI> system-view
[HUAWEI] capwap message-integrity check disable
Warning: In a backup scenario, the PSK and status of CAPWAP message integrity check must be the same
between the master and backup e
nds. This operation may cause devices using CAPWAP connections to reset or go offline. Continue? [Y/N]:y
```

11.1.37 capwap sensitive-info psk

Function

The **capwap sensitive-info psk** command configures a PSK used for encrypting sensitive information.

The **undo capwap sensitive-info psk** command restores the default PSK used for encrypting sensitive information.

The default username and password are available in *WLAN Default Usernames and Passwords* (**Enterprise Network** or **Carrier**). If you have not obtained the access permission of the document, see **Help** on the website to find out how to obtain it.

Format

capwap sensitive-info psk *psk-value*

undo capwap sensitive-info psk

Parameters

Parameter	Description	Value
psk-value	Specifies the PSK used for encrypting sensitive information.	The value is string of 48 or 68 characters in ciphertext (for example, **%^%#u(Oz:BL,QKYZw%-JWC*P8aGC,="C&M'OI*Gmt.V(%^%#**) or a string of 6 to 32 characters in plaintext (for example, **YsHsjx_202206**). The key must contain at least two types of the following: uppercase letters, lowercase letters, digits, and special characters except the question mark (?) and space.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Sensitive information exchanged between the AC and APs is encrypted, such as the FTP user name/password, AP login user name/password, and service configuration-related keys. You can run this command to modify the PSK used for encrypting sensitive information.

NOTE

It is recommended that you change the PSK in a timely manner to ensure device security.

After the configuration is complete, all online APs on the AC go offline and online again.

Precautions

In dual-link HSB and cold backup scenarios, ensure that the PSKs configured on the active and standby ACs are the same. Otherwise, APs cannot establish

CAPWAP tunnels with the standby ACs, causing the APs to go offline after an active/standby switchover.

When an AP is being upgraded on the AC, the PSK used for encrypting sensitive information cannot be changed.

Example

Set the PSK for encrypting sensitive information to **YsHsjx_202206**.

```
<HUAWEI> system-view
[HUAWEI] capwap sensitive-info psk YsHsjx_202206
Warning: This operation may cause devices using CAPWAP connections to go offline. Continue? [Y/N]:y
```

11.1.38 capwap source interface

Function

The **capwap source interface** command configures the interface used by the AC to establish a CAPWAP tunnel as the source interface of the AC.

The **undo capwap source interface** command disables the AC from using an interface as the source interface.

By default, no source interface is configured for the AC.

Format

capwap source interface { **loopback** *loopback-number* | **vlanif** *vlan-id* }

undo capwap source interface { **loopback** *loopback-number* | **vlanif** *vlan-id* }

Parameters

Parameter	Description	Value
loopback *loopback-number*	Configures a loopback interface as the source interface.	The value is an integer that ranges from 0 to 1023.
vlanif *vlan-id*	Configures a VLANIF interface as the source interface.	The value is an integer that ranges from 1 to 4094.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The source IP address must be specified for each AC so that all access devices connected to the AC can learn this IP address for communication.

When the CAPWAP source interface or address is configured for the first time, the system checks whether security-related configurations exist, including the PSK for DTLS encryption, PSK for DTLS encryption of inter-AC tunnels, user name and password for logging in to the AP, and password for logging in to the global offline management VAP. The CAPWAP source interface or address can be successfully configured only when all these configurations exist; otherwise, the system prompts you to complete related configurations first.

Prerequisites

An IP address has been assigned to the specified loopback or VLANIF interface.

Precautions

A maximum of eight source interfaces can be configured.

If SVF is enabled, only one source interface can be configured.

When multiple source interfaces are configured, the management VLAN of the APs must be within the VLAN range corresponding to the source interfaces. Otherwise, the APs cannot go online.

The source interface cannot be bound to a VPN instance.

Changing the source interface configuration will clear statistics about CAPWAP packets in CPU attack defense.

Example

Configure a loopback interface as the source interface.

```
<HUAWEI> system-view
[HUAWEI] interface loopback 20
[HUAWEI-LoopBack20] ip address 192.168.10.1 24
[HUAWEI-LoopBack20] quit
[HUAWEI] capwap source interface loopback 20
Set the DTLS PSK(contains 6-32 plain-text characters, or 48 or 68 cipher-text characters that must be a
combination of at least two of the following: lowercase letters a to z, uppercase letters A to Z, digits, and
special characters):******

Set the DTLS inter-controller PSK(contains 6-32 plain-text characters, or 48 or 68 cipher-text characters that
must be a combination of at least two of the following: lowercase letters a to z, uppercase letters A to Z,
digits, and special characters):******

Set the user name for FIT APs(contains 4-31 plain-text characters, which can only include letters, digits and
underlines. And the first character must be a letter):admin

Set the password for FIT APs(plain-text password of 8-128 characters or cipher-text password of 48-188
characters that must be a combination of at least three of the following: lowercase letters a to z, uppercase
letters A to Z, digits, and special characters):********

Set the global temporary-management psk(contains 8-63 plain-text characters, or 48-108 cipher-text
characters that must be a combination of at least two of the following: lowercase letters a to z, uppercase
letters A to Z, digits, and special characters):********
```

Table 11-1 Description of the command output

Item	Description
Set the DTLS PSK	Configures the PSK for DTLS encryption.
Set the DTLS inter-controller PSK	Configures the PSK for DTLS encryption of inter-AC tunnels.
Set the user name for FIT APs Set the password for FIT APs	Configures the user name and password for logging in to the Fit AP.
Set the global temporary-management psk	Configures the password for logging in to the global offline management VAP, allowing users to connect to the offline management SSID in wireless mode.

11.1.39 channel

Function

(AP group radio view) The **channel** command configures the working bandwidth and channel for specified radios on all APs in an AP group.

(AP group radio view) The **undo channel** command restores the default working bandwidth and channel for specified radios on all APs in an AP group.

(AP radio view) The **channel** command configures the working bandwidth and channel for specified radios on an AP.

(AP radio view) The **undo channel** command restores the working bandwidth and channel on specified radios of an AP to those configured in the AP group radio view.

By default, the working bandwidth of a radio is 20 MHz, and no working channel is configured for a radio.

Format

channel { **20mhz** | **40mhz-minus** | **40mhz-plus** | **80mhz** | **160mhz** | **320mhz** } *channel*

channel 80+80mhz *channel1 channel2*

undo channel

Parameters

Parameter	Description	Value
20mhz	Sets the working bandwidth of a radio to 20 MHz.	-
40mhz-minus	Sets the working bandwidth of a radio to 40 MHz Minus.	-
40mhz-plus	Sets the working bandwidth of a radio to 40 MHz Plus.	-
80mhz	Sets the working bandwidth of a radio to 80 MHz.	-
160mhz	Sets the working bandwidth of a radio to 160 MHz.	-
320mhz	Sets the working bandwidth of a radio to 320 MHz.	-
80+80mhz	Sets the working bandwidth of a radio to 80+80 MHz.	-
channel/ channel1/ channel2	Specifies the working channel of a radio.	The parameter is an enumeration value. The value range is determined based on the country code and radio mode.

Views

AP radio view, AP group radio view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Different radios use different channels. Channels for radios also vary in different countries and regions. Select channels based on the actual situations.

Precautions

The channel parameter settings must match the radio frequency band. For details about mappings between channel parameters and frequency bands, see *Country Codes & Channels Compliance*. You can obtain this table at Huawei technical support website.

- Enterprise technical support website: **https://support.huawei.com/enterprise**

- Carrier technical support website: **https://support.huawei.com**

The configured channels must be supported by STAs; otherwise, the STAs cannot discover radio signals.

If an AP detects radar signals on a channel, the channel cannot be configured as the radio channel of the AP in 30 minutes. However, the channel can be configured as the radio channel of other APs that do not detect radar signals on it.

The configuration in the AP radio view has a higher priority than that in the AP group radio view.

If two radios of an AP work on the 5 GHz frequency band, the operating channels of the two 5 GHz radios must be separated by at least one channel to avoid interference. If two radios of an AP work on the 5 GHz and 6 GHz frequency bands, respectively, pay attention to channel planning as follows:

- For the model AirEngine 6761-22T: Do not use a 5 GHz high-frequency channel (149–165) and a 6 GHz low-frequency channel (80 MHz channels 1–13, 160 MHz channels 1–29) at the same time.
- For the model AirEngine 8771-X1T: Do not use a 5 GHz high-frequency channel (20 MHz channels 153–165, 40 MHz channels 132–161, 80 MHz channels 132–161, 160 MHz channels 100–128, 320 MHz channels 100–144) and a 6 GHz channel (160 MHz channels 1–29, 320 MHz channels 1–61) at the same time.

For example, a country supports 40 MHz+ 5G channels 36, 44, 52, and 60. When deploying 5 GHz radio channels, if one radio is deployed to work on channel 36, it is recommended that channel 52 or 60 be configured for the other radio. Channel 44 is not recommended in this case.

NOTE

- You can configure the 80 MHz, 160 MHz, 320 MHz, or 80+80 MHz bandwidth only in the 5G radio view. When 320 MHz bandwidth is configured on the 5 GHz frequency band, the available channels are fixed at 100–144 that operate with 240 MHz bandwidth.

Example

Set the working bandwidth to 20 MHz and channel to 6 for radio 0 of AP 1.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 1
[HUAWEI-wlan-ap-1] radio 0
[HUAWEI-wlan-radio-1/0] channel 20mhz 6
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.1.40 channel-switch announcement disable

Function

The **channel-switch announcement disable** command disables an AP from sending an announcement when the channel is switched.

The **undo channel-switch announcement disable** command enables an AP to send an announcement when the channel is switched.

By default, an AP sends an announcement when the channel is switched.

Format

channel-switch announcement disable

undo channel-switch announcement disable

Parameters

None

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

When the AP works on a Depth First Select (DFS) channel, a radar detection is performed. The AP automatically switches to another channel because the DFS channel frequency may interfere with the radar frequency.

After the **undo channel-switch announcement disable** command is run, if the AP channel switches, the AP sends an Action frame to instruct STAs to switch channels after multiple Beacon intervals. The AP also switches the channel after the same intervals. The AP and STAs switch channels at the same time to prevent STA reassociations and ensure rapid service recovery.

NOTE

The channel switching announcement function must be supported by both the AP and STA.

The following APs do not send Action frames during channel switching announcement. Instead, these APs carry information in Beacon frames to instruct STAs to switch channels.

- AirEngine 9700D-S (including matching ORUs)
- AirEngine X77X
- AirEngine X76X

Example

Disable the AP from sending an announcement after the channel is switched.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] channel-switch announcement disable
```

11.1.41 channel-switch mode

Function

The **channel-switch mode** command configures an announcement mode for channel switching.

The **undo channel-switch mode** command restores the default announcement mode for channel switching.

By default, data transmission from STAs continues on the current channel when the channel is switched.

Format

channel-switch mode { **stop-transmitting** | **continue-transmitting** }

undo channel-switch mode

Parameters

Parameter	Description	Value
stop-transmitting	Stops data transmission from STAs on the current channel during channel switching.	-
continue-transmitting	Continues data transmission from STAs on the current channel during channel switching.	-

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

During channel switching, STA communication is interrupted. The administrator can stop an associated STA sending data on the current channel until channel switching is complete. Alternatively, data transmission from STAs can be continued on the current channel before channel switching is complete.

Example

Stop data transmission from STAs on the current channel during channel switching.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] channel-switch mode stop-transmitting
```

11.1.42 copy-from

Function

The **copy-from** command copies data to the current profile from a profile of the same type.

Format

copy-from *profile-name*

Parameters

Parameter	Description	Value
profile-name	Specifies the name of the profile from which data is copied.	The profile name must already exist.

Views

All WLAN profile views except the WIDS profile, WIDS whitelist profile, and WIDS spoof SSID profile

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **copy-from** command to copy data to the current profile from a profile of the same type. This simplifies profile configuration and improves configuration efficiency.

- To create a profile that has the same configuration as an existing profile, enter the view of the profile to be created and run the **copy-from** command to copy data from the existing profile.
- To create a profile that has most configurations the same as an existing profile, enter the view of the new profile, run the **copy-from** command to copy data from the existing profile, and modify the different configurations.

Precautions

If the current profile is referenced by another profile, you cannot run the command to copy data to the current profile.

When the WAPI certificate or private key configuration exists in the security profile, you must manually perform the configuration instead of using this command to copy data.

When you copy a location profile, if the protocol used by APs to report information is set to HTTPS and the SSL policy (**private report-protocol https ssl-policy** *ssl-policy*) is specified, the configuration will not be copied.

Example

Create the VAP profile **test** and copy data from the profile **sample**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name test
[HUAWEI-wlan-vap-prof-test] copy-from sample
```

11.1.43 country-code

Function

The **country-code** command configures a country code.

The **undo country-code** command restores the default country code.

The default country code is **CN**.

Format

country-code *country-code*

undo country-code

Parameters

Parameter	Description	Value
country-code	Specifies a country code.	The value is a string of characters in enumerated type. For specific values, see **Table 11-2**.

Views

Regulatory domain profile view

Default Level

2: Configuration level

Usage Guidelines

Table 11-2 Country codes supported by ACs

Country Code	Country/Region
AE	United Arab Emirates
AM	Armenia
AR	Argentina
AT	Austria
AU	Australia
AZ	Azerbaijan
BE	Belgium
BG	Bulgaria
BH	Bahrain
BN	Brunei Darussalam
BO	Bolivia
BR	Brazil
BY	Belarus
BZ	Belize
CA	Canada
CH	Switzerland
CL	Chile
CN	China (default)
CO	Colombia
CR	Costa Rica
CY	Cyprus
CZ	Czech Republic
DE	Germany
DK	Denmark
DO	Dominican Republic
EC	Ecuador
EE	Estonia
EG	Egypt

Country Code	Country/Region
ES	Spain
FI	Finland
FR	France
GB	United Kingdom
GE	Georgia

TR	Türkiye
TT	Trinidad and Tobago
TW	Taiwan, China
UA	Ukraine
US	United States
UY	Uruguay
UZ	Uzbekistan
VE	Venezuela
VN	Vietnam
YE	Yemen
ZA	South Africa
ZW	Zimbabwe

Usage Scenario

When an AC controls APs in different countries or regions, different country codes can be configured based on the regulatory domain profile to meet different radio requirements, such as power and channel specifications, in different countries or regions.

Configuration Impact

After the country code is changed in a regulatory domain profile, APs using the regulatory domain profile automatically restart if they run versions earlier than V200R020C00.

Example

Set the country code to **US** in the regulatory domain profile **region1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] regulatory-domain-profile name region1
[HUAWEI-wlan-regulate-domain-region1] country-code us
Warning: Modifying the country code will clear the channel and power configurations of radios, and
requires the APs to be restarted if they run V200R019C10 or earlier. Continue?[Y/N]:y
```

11.1.44 coverage distance

Function

(AP group radio view) The **coverage distance** command configures the radio coverage distance parameter for all specified radios in an AP group.

(AP group radio view) The **undo coverage distance** command restores the default radio coverage distance parameter for all specified radios in an AP group.

(AP radio view) The **coverage distance** command configures the radio coverage distance parameter for an AP radio.

(AP radio view) The **undo coverage distance** command restores the configuration of the radio coverage distance parameter on an AP radio to that configured in the AP group radio view.

By default, the radio coverage distance parameter is 3 (unit: 100 m) for all radios.

Format

coverage distance *distance*

undo coverage distance

Parameters

Parameter	Description	Value
distance	Specifies the radio coverage distance parameter. Each distance parameter corresponds to a group of **slottime**, **acktimeout**, and **ctstimeout** values. You can configure the radio coverage distance based on the AP distance, so that APs adjust the **slottime**, **acktimeout**, and **ctstimeout** values accordingly.	The value is an integer that ranges from 1 to 400, in the unit of 100 meters.

Views

AP radio view, AP group radio view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In practice, two APs may be deployed at a spacing of dozens of meters to dozens of kilometers. Therefore, the time to wait for ACK frames from the peer AP varies depending on the AP spacing. A proper ACK timeout setting can improve data transmission efficiency between APs.

You can configure the radio coverage distance parameter based on distances between APs. Based on this parameter, the APs can automatically adjust the values of **slottime**, **acktimeout**, and **ctstimeout** to improve data transmission efficiency.

Precautions

The configuration in the AP radio view has a higher priority than that in the AP group radio view.

Example

Set the radio coverage distance parameter to 2 for radio 0 of AP 0.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 0
[HUAWEI-wlan-ap-1] radio 0
[HUAWEI-wlan-radio-1/0] coverage distance 2
```

11.1.45 cpe-tunnel-profile (WLAN view)

Function

The **cpe-tunnel-profile** command creates a CPE tunnel profile and displays the CPE tunnel profile view, or displays the view of an existing CPE tunnel profile.

The **undo cpe-tunnel-profile** command deletes a CPE tunnel profile.

No default CPE tunnel profile is available in the system.

Format

cpe-tunnel-profile name *profile-name*

undo cpe-tunnel-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a CPE tunnel profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all CPE tunnel profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An EoGRE tunnel established between an AP and a CPE is also known as a CPE tunnel. A CPE tunnel profile is used to specify the parameters including the VLAN, GRE key, and GRE checksum used by the CPE tunnel.

Follow-up Procedure

Run the **cpe-tunnel-profile** command in the VAP profile view to bind the CPE tunnel profile to a VAP profile and run the **vap-profile** command to bind the VAP profile to an AP group, AP, AP radio, or AP group radio so that the CPE tunnel profile can take effect.

Precautions

- A CPE tunnel profile bound to a VAP profile cannot be deleted. To delete such a CPE tunnel profile, unbind it from the VAP profile first.

Example

Create the CPE tunnel profile **cpe1** and display the CPE tunnel profile view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] cpe-tunnel-profile name cpe1
[HUAWEI-wlan-cpe-tunnel-prof-cpe1]
```

11.1.46 cpe-tunnel-profile (VAP profile view)

Function

The **cpe-tunnel-profile** command binds a CPE tunnel profile to a VAP profile.

The **undo cpe-tunnel-profile** command unbinds a CPE tunnel profile from a VAP profile.

By default, no CPE tunnel profile is bound to a VAP profile.

Format

cpe-tunnel-profile *profile-name*

undo cpe-tunnel-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a CPE tunnel profile.	The CPE tunnel profile must exist.

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Prerequisites

The EoGRE tunnel encapsulation function has been enabled on a CPE.

Usage Scenario

After a CPE tunnel profile is bound to a VAP profile, data packets of wired terminals connected to a CPE are transparently transmitted to the upper-layer wired network through the CPE tunnel.

Example

Create the CPE tunnel profile **cpe1** and bind it to the VAP profile **vap1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] cpe-tunnel-profile name cpe1
[HUAWEI-wlan-cpe-tunnel-prof-cpe1] quit
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] cpe-tunnel-profile cpe1
```

11.1.47 deny-broadcast-probe enable

Function

The **deny-broadcast-probe enable** command configures an AP not to respond to broadcast Probe Request frames.

The **undo deny-broadcast-probe enable** command configures an AP to respond to broadcast Probe Request frames.

By default, an AP responds to broadcast Probe Request frames.

Format

deny-broadcast-probe enable

undo deny-broadcast-probe enable

Parameters

None

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In high-density wireless scenarios, too many Probe Response frames occupy a large number of wireless resources. To reduce wireless resource occupation of the frames and improve channel usage efficiency, you can run the **deny-broadcast-probe enable** command to configure an AP not to respond to broadcast Probe Request frames.

Precautions

Configuring an AP not to respond to broadcast Probe Request frames may reduce channel scan efficiency of some STAs.

Example

Configure an AP not to respond to broadcast Probe Request frames.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] deny-broadcast-probe enable
```

11.1.48 destination (soft GRE profile view)

Function

The **destination** command configures the destination IP address for a soft GRE tunnel.

The **undo destination** command restores the default destination IP address of a soft GRE tunnel.

By default, no destination IP address is configured for a soft GRE tunnel.

Format

destination { **ip-address** *destination-ip-address* | **ipv6-address** *destination-ipv6-address* }

undo destination

Parameters

Parameter	Description	Value
ip-address *destination-ip-address*	Specifies the destination IPv4 address of a soft GRE tunnel.	The value is in dotted decimal notation.
ipv6-address *destination-ipv6-address*	Specifies the destination IPv6 address of a soft GRE tunnel.	The value is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.

Views

Soft GRE profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When configuring the soft GRE forwarding mode, you need to configure the destination IP address of the soft GRE tunnel, that is, the peer IP address of the tunnel, so that service data can be forwarded to the specified destination IP address.

Precautions

Ensure that the route between the AP and the destination IP address of the soft GRE tunnel is reachable.

The destination IP address of a soft GRE tunnel must be configured in a soft GRE profile. The destination IP addresses of different soft GRE profiles cannot be the same.

If the IP address type of the AP is different from the destination IP address type configured in the soft GRE profile, the AP cannot establish a soft GRE tunnel.

If this command is run more than once, the latest configuration overrides the previous one.

Example

Set the destination IP address of a soft GRE tunnel to 10.10.1.1.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] softgre-profile name soft1
[HUAWEI-wlan-softgre-prof-soft1] destination ip-address 10.10.1.1
```

11.1.49 dhcp client option12

Function

The **dhcp client option12** command enables or disables DHCP packets sent by APs to carry the Option 12 field and specifies AP information contained in the Option 12 field.

The **undo dhcp client option12** command restores the default AP information in the Option 12 field carried in DHCP packets sent by APs.

By default, the Option 12 field carried in DHCP packets sent by an AP contains the AP type and MAC address.

Format

dhcp client option12 { **ap-name** | **ap-type ap-mac** | **disable** }

undo dhcp client option12

Parameters

Parameter	Description	Value
ap-name	Enables DHCP packets sent by APs to carry the Option 12 field that contains the AP name.	-
ap-type ap-mac	Enables DHCP packets sent by APs to carry the Option 12 field that contains the AP type and MAC address.	-
disable	Disables DHCP packets sent by APs from carrying the Option 12 field.	-

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After an AP (DHCP client) obtains an IP address through DHCP, this function enables the DHCP Discover and DHCP Request packets sent by the AP to carry the Option 12 field. The Option 12 field can contain the AP type, MAC address or the AP name. After the AP obtains an IP address through DHCP, you can check information about the AP with this IP address on the DHCP server that supports display of DHCP client host information.

Precautions

This function is valid only for the APs that obtain IP addresses through DHCP.

Example

Configure the AP name contained in the Option 12 field carried in DHCP packets sent by APs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] dhcp client option12 ap-name
```

11.1.50 dhcp option82 insert enable

Function

The **dhcp option82 insert enable** command enables the function of adding the Option 82 field to DHCP packets sent by STAs.

The **undo dhcp option82 insert enable** command disables the function of adding the Option 82 field to DHCP packets sent by STAs.

By default, the function of adding the Option 82 field to DHCP packets sent by STAs is disabled.

Format

dhcp option82 insert enable

undo dhcp option82 insert enable

Parameters

None

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After going online, a STA obtains the IP address through DHCP. When the DHCP Request packet from the STA reaches an AP, the AP adds the Option 82 field to the packet and sends the packet to the DHCP server. The Option 82 field contains the MAC address or SSID of the associated AP. Therefore, the DHCP server knows the AP on which the STA goes online.

Prerequisites

Before enabling the function of adding the Option 82 field to DHCP packets sent by STAs, run the **undo learn-client-address disable** command to enable the STA IP address learning. By default, STA IP address learning is enabled.

Example

Enable the function of adding the Option 82 field to DHCP packets sent by STAs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] dhcp option82 insert enable
```

11.1.51 dhcp option82 format (VAP profile view)

Function

The **dhcp option82 format** command configures the format of the Option 82 field in DHCP messages sent from STAs.

The **undo dhcp option82 format** command restores the default format of the Option 82 field in DHCP messages sent from STAs.

By default, the format of the Option 82 field in DHCP messages sent from STAs is **ap-mac**.

Format

dhcp option82 { **circuit-id** | **remote-id** } **format** { **ap-mac** [**mac-format** { **normal** | **compact** | **hex** | **colon** }] [**user-defined** *text*] | **ap-mac-ssid** [**mac-format** { **normal** | **compact** | **colon** }] [**user-defined** *text*] | **user-defined** *text* | **ap-name** [**user-defined** *text*] | **ap-name-ssid** [**user-defined** *text*] | **ap-location** [**user-defined** *text*] | **ap-location-ssid** [**user-defined** *text*] }

dhcp option82 { **remote-id** | **circuit-id** } **format** { **ap-group-ap-mac** | **ap-group-ap-mac-ssid** } **mac-format** { **normal** | **compact** | **colon** } [**user-defined** *text*]

dhcp option82 { **remote-id** | **circuit-id** } **format** { **ap-group** | **ap-group-ap-name** | **ap-group-ap-name-ssid** | **ap-group-ap-location** | **ap-group-ap-location-ssid** } [**user-defined** *text*]

undo dhcp option82 { **circuit-id** | **remote-id** } **format**

Parameters

Parameter	Description	Value
circuit-id	Specifies the circuit-ID in the Option 82 field.	-
remote-id	Specifies the remote-ID in the Option 82 field.	-

Parameter	Description	Value
ap-mac	Indicates that Option 82 contains the AP's MAC address.	-
ap-mac-ssid	Indicates that Option 82 contains the AP's MAC address and SSID.	-
mac-format	Specifies the format of the AP's MAC address in Option 82.	-
normal	Sets the MAC address format to xx-xx-xx-xx-xx-xx.	-
compact	Sets the MAC address format to xxxx-xxxx-xxxx.	-
hex	Sets the MAC address format to XXXXXXXXXXXX in hexadecimal notation.	-
colon	Sets the MAC address format to xx:xx:xx:xx:xx:xx.	-
user-defined *text*	Specifies the user-defined format of Option 82.	The value is a string of 1 to 255 characters.
ap-name	Indicates that Option 82 contains the AP name.	-
ap-name-ssid	Indicates that Option 82 contains the AP name and SSID.	-
ap-location	Indicates that Option 82 contains the AP location.	-
ap-location-ssid	Indicates that Option 82 contains the AP location and SSID.	-
ap-group	Indicates that Option 82 contains the AP group name.	-
ap-group-ap-mac	Indicates that Option 82 contains the AP group name and AP's MAC address.	-
ap-group-ap-mac-ssid	Indicates that Option 82 contains the AP group name, AP's MAC address, and SSID.	-

Parameter	Description	Value
ap-group-ap-name	Indicates that Option 82 contains the AP group name and AP name.	-
ap-group-ap-name-ssid	Indicates that Option 82 contains the AP group name, AP name, and SSID.	-
ap-group-ap-location	Indicates that Option 82 contains the AP group name and AP location.	-
ap-group-ap-location-ssid	Indicates that Option 82 contains the AP group name, AP location, and SSID.	-

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

After the function of adding the Option 82 field to DHCP messages sent from STAs, you can run the **dhcp option82 format** command to configure the format of the Option 82 field.

You can use the following keywords to define the Option 82 field:

- ap-mac: indicates the AP's MAC address. After DHCP messages from a STA reach an AP, the AP inserts its MAC address into the Option 82 field of the DHCP messages.
- ap-mac-ssid: indicates the MAC address and SSID of the AP. After DHCP messages from a STA reach an AP, the AP inserts its MAC address and SSID associated with the STA into the Option 82 field of the DHCP messages.
- ap-name: indicates the AP name. After DHCP messages from a STA reach an AP, the AP inserts its name into the Option 82 field of the DHCP messages.
- ap-name-ssid: indicates the AP name and SSID. After DHCP messages from a STA reach an AP, the AP inserts its name and associated SSID into the Option 82 field of the DHCP messages.
- ap-location: indicates the AP location. After DHCP messages from a STA reach an AP, the AP inserts its location into the Option 82 field of the DHCP messages.
- ap-location-ssid: indicates the AP location and SSID. After DHCP messages from a STA reach an AP, the AP inserts its location and associated SSID into the Option 82 field of the DHCP messages.
- ap-group: indicates the AP group name. After DHCP messages from a STA reach an AP, the AP inserts the name of the AP group to which it belongs into the Option 82 field of the DHCP messages.

- ap-group-ap-mac, ap-group-ap-mac-ssid, ap-group-ap-name, ap-group-ap-name-ssid, ap-group-ap-location, ap-group-ap-location-ssid: indicates the combination of the AP group name and other keywords. After DHCP messages from a STA reach an AP, the AP inserts the name of the AP group to which it belongs and information specified by other keywords into the Option 82 field of the DHCP messages.

If **mac-format** is not specified in the **dhcp option82** { **circuit-id** | **remote-id** } **format** { **ap-mac** | **ap-mac-ssid** } command, the AP's MAC address in the Option 82 field is **XXXXXXXXXXXX** in ASCII format.

The total length of the **circuit-id** and **remote-id** options in the Option 82 field cannot exceed 255 bytes. Otherwise, some Option 82 information may be lost. Note that a Chinese character may occupy 2 or 3 bytes.

Example

Set the format of the remote-ID suboption in Option 82 carried in DHCP messages sent from STAs to **ap-mac-ssid**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] dhcp option82 remote-id format ap-mac-ssid
```

11.1.52 display ac global configuration

Function

The **display ac global configuration** command displays AC global configuration.

Format

display ac global configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view AC global information.

Example

Display AC global configuration.

```
<HUAWEI> display ac global configuration
------------------------------------------------------------------------------
AC sysnetid                    : AC
------------------------------------------------------------------------------
```

Table 11-3 Description of the **display ac global configuration** command output

Item	Description
AC sysnetid	NE name of an AC. To configure the NE name for an AC, run the **ac sysnetid** command.

11.1.53 display ap

Function

The **display ap** command displays AP information.

Format

display ap { **all** | **ap-group** *ap-group* }

display ap [**ap-group** *ap-group*] **by-ssid** *ssid*

display ap by-state *state* [**ap-group** *ap-group*]

Parameters

Parameter	Description	Value
all	Displays information about all APs.	-
ap-group *ap-group*	Specifies the AP group to which an AP belongs.	The AP group must exist.
by-ssid *ssid*	Specifies an SSID.	The SSID must exist.

Parameter	Description	Value
by-state *state*	Displays the status of an AP.	The value is of the enumerated type: - **commit-failed**: Displays information about APs in configuration commitment failed state. - **committing**: Displays information about APs in configuration committing state. - **config**: Displays information about APs in configuration initialization state. - **config-failed**: Displays information about APs in initialization failed state. - **download**: Displays information about APs in system software downloading state. - **fault**: Displays information about APs that failed to go online. - **idle**: Displays information about APs in initialization state before the link is established for the first time.

Parameter	Description	Value
		- **name-conflicted**: Displays information about APs having duplicate names. - **normal**: Displays information about APs in normal state. - **standby**: Displays information about APs in standby state. - **ver-mismatch**: Displays information about APs with versions that do not match the AC version. - **countrycode-mismatch**: Displays information about APs with country codes that do not match the AC's country code. - **type-mismatch**: Displays information about APs with types that are different from the actual types.

Item	Description
	- **D: data link exception**: indicates that data links of RUs have not been established. Check the network connection between the AC and RUs.
Scene	Effective scenario profile on the AP. To configure this parameter, run the **scene** command. **-** indicates that no scenario profile is configured.
Total	Total number of queried APs.

Table 11-5 AP state list

AP State	Description	Possible Cause	Handling Suggestion
commit-failed (cmtfa)	WLAN service configurations fail to be delivered to an AP after the AP goes online on an AC.	After an AP goes online on the AC, WLAN service configurations are performed for the AP. If the link between the AP and AC is disconnected or the peer end has no response, the AP enters the commit-failed state.	Check the network connection.
committing (cmt)	WLAN service configurations are being delivered to an AP after the AP goes online on an AC.	After an AP goes online on the AC, WLAN service configurations are being delivered to the AP. During this process, the AP is in committing state.	This is a normal state, and no action is required.
config (cfg)	WLAN service configurations are being delivered to an AP when the AP is going online on an AC.	After an AP establishes a link with the AC, WLAN service configurations are delivered to the AP. During this process, the AP is in config state.	This is a normal state, and no action is required.

AP State	Description	Possible Cause	Handling Suggestion
config-failed (cfgfa)	WLAN service configurations fail to be delivered to an AP when the AP is going online on an AC.	After an AP establishes a link with the AC, WLAN service configurations are delivered to the AP. If the configuration delivery fails due to various reasons (such as link disconnection), the AP enters the config-failed state.	Check the network connection.
download (dload)	An AP is in upgrade state.	When an AP is performing an upgrade, it enters the download state.	When the AP upgrade is complete, check the AP state.
fault	An AP fails to go online.	An AP fails to go online, which is usually caused by the following: ● The AP fails to obtain an IP address or obtains an incorrect IP address. ● The network between the AP and AC is faulty. ● The AP fails to be authenticated. ● The number of APs on an AC has reached the maximum value. ● The AP is faulty. ● In dual-link cold backup or N+1 backup scenario, if the link between the active and standby ACs is established properly, an AP that goes online on the active AC is in fault state on the standby AC.	Handle the AP online failure. For details, see **An AP Fails to Go Online on the AC** in the *Troubleshooting Guide*.

AP State	Description	Possible Cause	Handling Suggestion
idle	It is the initialization state of an AP before it establishes a link with the AC for the first time.	When an AP has not established a CAPWAP link with the AC, the MAC address and SN of an AP that is added offline are different from the actual MAC address and SN of the AP, or the AC cannot manage an AP due to license resource insufficiency, the AP enters the idle state.	Perform the following operations. Check whether the AP is connected to the network. If the AP connection is normal, go to next step. Check the MAC address and SN of the AP that is added offline are different from the actual MAC address and SN of the AP. If not, perform the following operations: 1. Run the **display ap all** command to check AP information. 2. Run the **undo ap** { **ap-name** *ap-name* | **ap-id** *ap-id* | **ap-mac** *ap-mac* | **ap-group** *group-name* | **all** } command to delete the AP. 3. Run the **ap-id** *ap-id* [[**type-id** *type-id* | **ap-type** *ap-type*] { **ap-mac** *ap-mac* | **ap-sn** *ap-sn* | **ap-mac** *ap-mac* **ap-sn** *ap-sn* }] or **ap-mac** *ap-mac* [**type-id** *type-id* | **ap-type** *ap-type*] [**ap-id** *ap-id*] [**ap-sn** *ap-sn*] command to add correct AP information. If the fault persists, expand the license capacity. Note that RUs managed by the AC do not occupy

AP State	Description	Possible Cause	Handling Suggestion
			license resources of the AC.
name-conflicted (namec)	The name of an AP conflicts with that of an existing AP.	The name of an AP conflicts with the name of another AP that has been online on the same AC.	Run the **ap-rename ap-id** *ap-id* **new-name** *ap-new-name* command to change the AP name.
normal (nor)	An AP is working properly.	An AP successfully goes online on an AC.	This is a normal state, and no action is required.
standby (stdby)	An AP is in normal state on the standby AC.	In the HSB scenario, if the link between the master and backup ACs is established properly, an AP is in standby state on the backup AC and in normal state on the master AC.	This is a normal state, and no action is required.
ver-mismatch (vmiss)	The version of an AP does not match that of an AC on which the AP is about to go online.	The versions of the AP and AC do not match.	Log in to Huawei technical support website and download the release notes. Based on the version mapping, upgrade the AP or AC to the matching version. ● Enterprise technical support website: **https://support.huawei.com/enterprise** ● Carrier technical support website: **https://support.huawei.com**

AP State	Description	Possible Cause	Handling Suggestion
countryCode-mismatch (cmiss)	The country codes of the AP and AC do not match.	The AP's current version does not support the country code configured on the AC. The country code of the AP is locked, and the country code configured on the AC is not supported.	The AP does not support the country code. Upgrade the AP or modify the country code configuration on the AC. The country code of the AP is locked. Replace the AP or change the country code on the AC to be the same as that of the AP.
type-mismatch (tmiss)	The AP type does not match that configured on the AC.	The AP type configured on the AC did not match the actual AP type.	Change the AP type configured on the AC.
unauth	An AP is not authenticated.	The AP fails to be authenticated.	Run the **display ap unauthorized record** command to query authenticated APs. Run the **ap-confirm** command to confirm unauthenticated APs and allow them to go online.

11.1.54 display ap blacklist

Function

The **display ap blacklist** command displays the AP blacklist.

Format

display ap blacklist

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command displays APs in the blacklist. These APs are not allowed to go online on the AC. If an AP is online on the AC but is in the blacklist, the AP is brought offline.

Example

Display the AP blacklist.

```
<HUAWEI> display ap blacklist
--------------------------------------------------------------------------------
ID     MAC
--------------------------------------------------------------------------------
0      xxxx-xxxx-xxxx
--------------------------------------------------------------------------------
Total: 1
```

Table 11-6 Description of the **display ap blacklist** command output

Item	Description
ID	ID of the MAC address in the AP blacklist. The ID is generated automatically when the MAC address is specified.
MAC	MAC addresses of the APs that are not allowed to connect to the AC. To configure this parameter, run the **ap blacklist** command.

11.1.55 display ap config-info

Function

The **display ap config-info** command displays AP configuration.

Format

display ap config-info { **ap-name** *ap-name* | **ap-id** *ap-id* }

Parameters

Parameter	Description	Value
ap-name *ap-name*	Displays configuration of the AP with a specified name.	The AP name must exist.

Parameter	Description	Value
ap-id *ap-id*	Displays configuration of the AP with a specified ID.	The AP ID must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ap config-info** command to view AP configuration information, including the basic configuration, radio configuration, VAP configuration, and profile configuration.

Example

Display the configuration of the AP **ap1**.

```
<HUAWEI> display ap config-info ap-name ap1
------------------------------------------------------------------------------------
AP MAC                           : 00e0-fcxx-xxxx

Table 11-7 Description of the **display ap config-info** command output

Item	Description
AP MAC	MAC address of an AP.
AP SN	SN of an AP.
AP type	AP type.
AP name	AP name. To configure this parameter, run the **ap-name (AP view)** or **ap-rename** command.
Domain name	Default domain name suffix of the AP. To configure this parameter, run the **ip domain-name** command.
AP group	AP group. To configure this parameter, run the **ap-group (AP view)** or **ap-regroup** command.
Country code	Country code. To configure this parameter, run the **country-code** command.
Scene	Effective scenario profile on the AP. To configure this parameter, run the **scene** command.
Radio x configurations	Radio configuration.
Radio enable	Whether a radio is enabled. To configure this parameter, run the **radio disable** command.
Work mode	Working mode of a radio. To configure this parameter, run the **work-mode** command.
WDS mode	WDS mode. To configure this parameter, run the **wds-mode** command.
Mesh mode	Mesh role of a radio. To configure this parameter, run the **mesh-role** command.

Item	Description
Radio band	Frequency band of a radio. To configure this parameter, run the **frequency** command.
Radio type	Protocol type of a radio.
Flexible radio switch	Whether the DFA function of a radio is enabled. To configure this parameter, run the **calibrate flexible-radio disable** command.
Config channel/bandwidth	Configured AP channel and bandwidth. To configure this parameter, run the **channel** command.
Actual channel/bandwidth	Actual AP channel and bandwidth.
Config EIRP	Transmit power of a radio configured in the radio profile. To configure this parameter, run the **eirp** command.
Actual EIRP	Actual transmit power of a radio.
Maximum EIRP	Maximum transmit power of a radio.
Radio Calibration DCA 5G bandwidth	5 GHz radio calibration bandwidth configuration obtained from the bound scenario profile. To configure this parameter, run the **scene** command.
Radio Calibration TPC threshold(dBm)	Radio calibration power configuration obtained from the bound scenario profile. To configure this parameter, run the **scene** command.
Radio Calibrate grouping interference threshold(dBm)	Interference threshold of a calibration group obtained from the bound scenario profile. To configure this parameter, run the **scene** command.
CCA threshold(dBm)	CCA threshold for AP radios. To configure this parameter, run the **cca-threshold** command.

Item	Description
RX sensitivity(dBm)	Receiver sensitivity. To configure this parameter, run the **rx-sensitivity** command.
Beacon interval(TUs)	Interval at which an AP sends Beacon frames. To configure this parameter, run the **beacon-interval** command.
Dynamic EDCA	Enabling status of dynamic EDCA obtained from the bound scenario profile. To configure this parameter, run the **scene** command.
Station load balance sta-number start threshold	Start threshold for dynamic load balancing based on the number of STAs. To configure this parameter, run the **sta-load-balance dynamic sta-number start-threshold** command.
Station load balance sta-number gap threshold(number)	Load difference threshold for dynamic load balancing based on the number of STAs. To configure this parameter, run the **sta-load-balance dynamic sta-number gap-threshold** command.
Smart roam standing SNR threshold(dB)	SNR threshold for smart roaming. To configure this parameter, run the **smart-roam roam-threshold { snr | rate }** command.
Smart roam SNR quick-kickoff-threshold(dB)	SNR threshold for quickly disconnecting STAs. To configure this parameter, run the **smart-roam quick-kickoff-threshold** command.
Radio Calibration maximum 2.4G calibration TX power(dBm)	Maximum transmit power that can be adjusted through 2.4 GHz radio calibration. To configure this parameter, run the **calibrate max-tx-power** command.

Item	Description
Radio Calibration maximum 5G calibration TX power(dBm)	Maximum transmit power that can be adjusted through 5 GHz radio calibration. To configure this parameter, run the **calibrate max-tx-power radio-5g** command.
Radio Calibration minimum 2.4G calibration TX power(dBm)	Minimum transmit power that can be adjusted through 2.4 GHz radio calibration. To configure this parameter, run the **calibrate min-tx-power** command.
Radio Calibration minimum 5G calibration TX power(dBm)	Minimum transmit power that can be adjusted through 5 GHz radio calibration. To configure this parameter, run the **calibrate min-tx-power radio-5g** command.
VAP configurations	VAP configuration. VAP configuration is displayed only after a VAP profile is referenced by the AP.
WLAN ID 1	WLAN ID of a VAP. To configure this parameter, run the **vap-profile** command.
SSID	SSID name. To configure this parameter, run the **ssid** command.
Forward mode	Forwarding mode. To configure this parameter, run the **forward-mode** command.
Authen mode	Authentication mode.
Encrypt mode	Encryption mode.
Service vlan	Effective service VLAN.
Deny-broadcast-probe	Whether an AP is configured not to respond to broadcast Probe Request frames. To configure this parameter, run the **deny-broadcast-probe enable** command.

Item	Description
Active dull client	Whether the function of preventing terminals from entering energy-saving mode is enabled. To configure this parameter, run the **active-dull-client enable** command.
Force active dull client	Whether the function of forcibly preventing terminals from entering power-saving mode is enabled. To configure this parameter, run the **active-dull-client force enable** command.
Association timeout(min)	Specifies the association aging time of STAs. To configure this parameter, run the **association-timeout** command.
AP system profile	Name of the referenced AP system profile. To configure this parameter, run the **ap-system-profile (AP group view and AP view)** command.
Regulatory domain profile	Name of the referenced regulatory domain profile. To configure this parameter, run the **regulatory-domain-profile** command.
WIDS profile	Name of the referenced WIDS profile.
BLE profile	Name of the referenced BLE profile. To configure this parameter, run the **ble-profile (AP group view and AP view)** command.
AP location	Installation position of an AP. To configure this parameter, run the **location** command.
UUID	UUID of a BLE broadcast frame sent by the AP's built-in Bluetooth module. To configure this parameter, run the **broadcasting-content (AP view)** command.

Item	Description
Major	Major field of a BLE broadcast frame sent by the AP's built-in Bluetooth module. To configure this parameter, run the **broadcasting-content (AP view)** command.
Minor	Minor field of a BLE broadcast frame sent by the AP's built-in Bluetooth module. To configure this parameter, run the **broadcasting-content (AP view)** command.
Reference RSSI	Reference RSSI of a BLE broadcast frame sent by the AP's built-in Bluetooth module. To configure this parameter, run the **broadcasting-content (AP view)** command.
Ap pki profile	Bound AP PKI realm profile. To configure this parameter, run the **ap-pki-profile** command.
AP wired port profile	Name of the referenced AP wired port profile. To configure this parameter, run the **wired-port-profile (AP group view and AP view)** command.
Interface *interface-name*	Interface name and number.
Radio x	Radio.
Radio 2.4G profile	Name of the referenced 2G radio profile. To configure this parameter, run the **radio-2g-profile** command.
Radio 5G profile	Name of the referenced 5G radio profile. To configure this parameter, run the **radio-5g-profile** command.

Item	Description
VAP profile	Name of the referenced VAP profile. The displayed format is "VAP ID:VAP profile name (service VLAN defined when binding to the VAP profile, single VLAN, or VLAN pool)." To configure this parameter, run the **vap-profile** command.
Mesh profile	Name of the referenced Mesh profile. To configure this parameter, run the **mesh-profile radio** command.
WDS profile	Name of the referenced WDS profile. To configure this parameter, run the **wds-profile radio** command.
Mesh whitelist profile	Mesh whitelist profile referenced by an AP group. To configure this parameter, run the **mesh-whitelist-profile (AP group radio view or AP radio view)** command.
WDS whitelist profile	WDS whitelist profile referenced by an AP group. To configure this parameter, run the **wds-whitelist-profile (AP group radio view or AP radio view)** command.
Location profile	Name of the referenced location profile. To configure this parameter, run the **location-profile** command.
Radio switch	Whether a radio is enabled. To configure this parameter, run the **radio disable** command.
Channel	Working channel of a radio. To configure this parameter, run the **channel** command.
Channel bandwidth	Working bandwidth of a radio. To configure this parameter, run the **channel** command.
EIRP(dBm)	Transmit power of a radio, in dBm. To configure this parameter, run the **eirp** command.

Item	Description
Antenna gain(dB)	Antenna gain of a radio, in dB. To configure this parameter, run the **antenna-gain** command.
Coverage distance(100 m)	Radio coverage distance parameter, in the unit of 100 m. To configure this parameter, run the **coverage distance** command.
Work mode	Working mode of an AP. To configure this parameter, run the **work-mode** command.
Radio frequency	Working frequency band of a radio. To configure this parameter, run the **frequency** command.
Spectrum analysis	Whether spectrum analysis is enabled. To configure this parameter, run the **spectrum-analysis enable** command.
Channel monitor	Whether the function of monitoring the status of all channels is enabled. To configure this parameter, run the **channel-monitor enable** command.
WIDS device detect	Whether wireless device detection is enabled. To configure this parameter, run the **wids device detect enable** command.
WIDS attack detect	Whether attack detection is enabled. To configure this parameter, run the **wids attack detect** command.
WIDS contain switch	Whether rogue device containment is enabled. To configure this parameter, run the **wids contain enable** command.
Auto channel select	Whether automatic channel selection is enabled. To configure this parameter, run the **calibrate auto-channel-select** command.

Item	Description
Auto bandwidth select	Whether automatic bandwidth selection is enabled. To configure this parameter, run the **calibrate auto-bandwidth-select** command.
Auto transmit power select	Whether automatic transmit power selection is enabled. To configure this parameter, run the **calibrate auto-txpower-select** command.
Reference data-analysis	Whether big data calibration is enabled. To configure this parameter, run the **calibrate reference data-analysis { disable | enable }** command.
Reference 3d-data	Whether 3D radio calibration is enabled. To configure this parameter, run the **calibrate reference 3d-data { disable | enable }** command.
Interference visualization	Whether the interference visualization function is enabled. To configure this parameter, run the **interference-visualization enable** command.
Card 1/Card 2/Card 3/Card usb	IoT card.
Card connect type	Communication connection type between IoT cards and APs. To configure this parameter, run the **card connect-type** command.
Baud rate	Baud rate used for communication between an IoT card and the AP. To configure this parameter, run the **baud-rate** command.
Wired port profile	Bound AP wired port profile. To configure this parameter, run the **wired-port-profile (IoT card interface view)** command.

Item	Description
Iot profile	Bound IoT profile. To configure this parameter, run the **iot-profile (IoT card interface view)** command.
Protocol Type	Communication protocol between the AP and host computer.
First Port	Source port for the first channel.
Extended Port	Source port for the extended channel.

11.1.56 display ap configurable channel

Function

The **display ap configurable channel** command displays the configurable channels supported by a specified AP.

Format

display ap configurable channel { **ap-name** *ap-name* | **ap-id** *ap-id* } [**radio** *radio-id*]

Parameters

Parameter	Description	Value
ap-name *ap-name*	Displays configurable channels supported by the AP with the specified name.	The AP name must exist.
ap-id *ap-id*	Displays configurable channels supported by the AP with the specified ID.	The AP ID must exist.
radio *radio-id*	Displays configurable channels supported by the specified radio.	The radio ID must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Available wireless channels and power levels vary in different countries or regions. The country code configuration allows you to specify channels that can available on WLANs in the local country or region. You can run this command to view configurable channels supported by a specified AP.

Example

Display configurable channels supported by the AP named **test**.

```
<HUAWEI> display ap configurable channel ap-name test
2.4G 20M : 1,2,3,4,5,6,7,8,9,10,11,12,13.
2.4G 40M+: 1,2,3,4,5,6,7,8,9.
2.4G 40M-: 5,6,7,8,9,10,11,12,13.
5G   20M : 36,40,44,48,52,56,60,64,100,104,108,112,116,120,124,128,132,136,140,149,153,157,161,165.
5G   40M+: 36,44,52,60,100,108,116,124,132,149,157.
5G   40M-: 40,48,56,64,104,112,120,128,136,153,161.
5G   80M : 36,40,44,48,52,56,60,64,100,104,108,112,116,120,124,128,149,153,157,161.
5G  160M : 36,40,44,48,52,56,60,64,100,104,108,112,116,120,124,128.
5G 80+80M: 36+106, 36+122, 36+155, 40+106, 40+122, 40+155, 44+106, 44+122,

Table 11-8 Description of the **display ap configurable channel** command output

Item	Description
2.4G 20M	Configurable 20 MHz channels supported by the AP on the 2.4 GHz frequency band.
2.4G 40M+	Configurable 40 MHz Plus channels supported by the AP on the 2.4 GHz frequency band.
2.4G 40M-	Configurable 40 MHz Minus channels supported by the AP on the 2.4 GHz frequency band.
5G 20M	Configurable 20 MHz channels supported by the AP on the 5 GHz frequency band.
5G 40M+	Configurable 40 MHz Plus channels supported by the AP on the 5 GHz frequency band.
5G 40M-	Configurable 40 MHz Minus channels supported by the AP on the 5 GHz frequency band.

Item	Description
5G 80M	Configurable 80 MHz channels supported by the AP on the 5 GHz frequency band.
5G 160M	Configurable 160 MHz channels supported by the AP on the 5 GHz frequency band.
5G 80+80M	Configurable 80+80 MHz channels supported by the AP on the 5 GHz frequency band.
5G 320M	Configurable 320 MHz channels supported by the AP on the 5 GHz frequency band.
6G 20M	Configurable 20 MHz channels supported by the AP on the 6 GHz frequency band.
6G 40M+	Configurable 40 MHz Plus channels supported by the AP on the 6 GHz frequency band.
6G 40M-	Configurable 40 MHz Minus channels supported by the AP on the 6 GHz frequency band.
6G 80M	Configurable 80 MHz channels supported by the AP on the 6 GHz frequency band.
6G 160M	Configurable 160 MHz channels supported by the AP on the 6 GHz frequency band.
6G 320M	Configurable 320 MHz channels supported by the AP on the 6 GHz frequency band.

11.1.57 display ap global configuration

Function

The **display ap global configuration** command displays AP global configuration.

Format

display ap global configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view AP global information.

Example

Display AP global configuration.

```
<HUAWEI> display ap global configuration
------------------------------------------------------------------------------
AP auth-mode                        : MAC-auth
AP LLDP switch                      : disable
AP username/password                : -/******
AP data collection                  : disable
AP data collection interval(minute): 5
------------------------------------------------------------------------------
```

Table 11-9 Description of the **display ap global configuration** command output

Item	Description
AP auth-mode	AP authentication mode. To configure this parameter, run the **ap auth-mode** command.
AP LLDP switch	Whether LLDP is enabled on an AP. To configure this parameter, run the **ap lldp enable** command.
AP username/password	User name and password for logging in to an AP. To configure this parameter, run the **ap username** command.
AP data collection	Whether data buffering is enabled on an AP. To configure this parameter, run the **ap data-collection enable** command.
AP data collection interval(minute)	AP data buffering interval. To configure this parameter, run the **ap data-collection interval** command.

11.1.58 display ap non-factory all

Function

The **display ap non-factory all** command displays Fat APs and cloud APs on the network.

Format

display ap non-factory all

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

If the working mode of a Fit AP is switched to the Fat or cloud mode, the AP cannot be managed by the device. Fat or cloud APs detected on the current network can be displayed. Based on AP information, check whether the AP mode is switched by mistake.

Follow-up Procedure

If so, run the **ap manufacturer-config** command to switch the working mode of the AP to Fit.

Precautions

The device can detect Fat APs and cloud APs only when the following conditions are met:

- The IP address of an AP in non-Fit mode is not obtained through DHCP, or its IP address is obtained through DHCP but the AP does not obtain the AC address through the option field. In this scenario, the device can detect the AP as a non-Fit AP by the device when the AP is in the same LAN as the device.
- The IP address of an AP in non-Fit mode is obtained through DHCP, and the AP does not obtain the AC address through the option field. In this scenario, the device can detect the AP as a non-Fit AP by the device when the address for the device to manage the Fit AP is the same as the address specified in the option field.

Example

Display APs that operate in non-Fit mode on the network.

```
<HUAWEI> display ap non-factory all
Cnt: Manage FIT AP count
Mode: Actual mode/Config mode
----------------------------------------------------------------------------------------------------------------------------------------
-------
MAC           SN              IP              Type                 Mode        Cnt   Operate State     Record time
----------------------------------------------------------------------------------------------------------------------------------------
-------
00e0-fc11-2222  **********1        10.1.1.11         AirEngine8760-X1-PRO   FAT/-        1     waiting deliver
2023-07-22 17:23:17
```

```
00e0-fc11-2233  **********2        10.1.1.12        AirEngine8760-X1-PRO   CLOUD/CLOUD  0     -
2023-07-22 17:33:17
00e0-fc11-3344  **********3        10.1.1.13        AirEngine8760-X1-PRO   CLOUD/-      0     delivered
2023-07-22 17:33:17
----------------------------------------------------------------------------------------------------------------------------
-------
Total: 3
```

Table 11-10 Description of the **display ap non-factory all** command output

Item	Description
MAC	MAC address of an AP in non-Fit mode.
SN	SN of an AP in non-Fit mode.
IP	IP address of an AP in non-Fit mode.
Type	Type of an AP in non-Fit mode.
Mode	Current mode and configuration mode of an AP in non-Fit mode. The configuration mode refers to the specified mode information received by the AP through DHCP Option 148. When the configuration mode is not empty, the Fit mode cannot be restored.
Cnt	Number of managed Fit APs when the AP in non-Fit mode is the leader AP.
Operate State	State of receiving the **ap manufacturer-config** command on an AP in non-Fit mode. ● waiting deliver: The command has been delivered but has not been received on the AP. ● delivered: The AP has received the command. ● -: The command is not delivered.
Record time	Latest time when the AP is detected.
Total	Total number of times APs in non-Fit mode are detected.

11.1.59 display ap offline-record

Function

The **display ap offline-record** command displays AP offline records.

Format

display ap offline-record { **all** | **mac** *mac-address* }

Parameters

Parameter	Description	Value
all	Displays offline records of all APs.	-
mac *mac-address*	Displays offline records of the AP with the specified MAC address.	The AP's MAC address must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command displays AP offline records, helping the maintenance personnel manage and maintain the APs.

After the number of AP offline records reaches the maximum that can be stored, new records overwrite existing ones.

A maximum of five offline records can be stored for each AP.

Example

Display offline records of all APs.

```
<HUAWEI> display ap offline-record all
------------------------------------------------------------------------------
MAC              Last offline time       Reason
------------------------------------------------------------------------------
00e0-fc24-0080    2015-01-31/16:21:50    The AP name is modified.
00e0-fc76-e360    2015-01-31/14:02:35    The AP is replaced.
------------------------------------------------------------------------------
Total records: 2
```

Table 11-11 Description of the **display ap offline-record** command output

Item	Description
MAC	MAC address of an AP.
Last offline time	Time when the AP went offline last time.

Item	Description
Reason	Reason why the AP goes offline. For the description of offline reasons and handling suggestions, see **Table 11-12**. For more troubleshooting methods, see **An AP Goes Offline Unexpectedly** in the *Troubleshooting Guide*.

Table 11-12 Possible reasons and suggestions for APs to go offline

Reason Why an AP Goes Offline	Suggestion
The AC country code is modified.	The AP goes offline due to normal configuration changes, and no action is required.
The AP is replaced.	The AP goes offline due to normal configuration changes, and no action is required.
Reboot by ap update reset command. The AP is reset automatically after the upgrade.	The AP resets to load the new version file after the upgrade, and no action is required.
A command is delivered to reboot an AP.	The AC delivers a reboot command to the AP, and no action is required.
An AP is deleted.	The AP is deleted on the AC, and no action is required.
The license expires.	Apply for a new license. For details, see *WLAN License Usage Guide*.
Insufficient license resources.	Choose one of the following handling suggestions based on the networking: ● If license control is deployed, check whether the link between the license server and client is disconnected. If so, restore the link. ● If N+1 or dual-link backup is deployed, check whether the active and standby link is disconnected. If so, restore the link. ● If the number of APs on the network exceeds the total number of license resources, apply for a new license.
The AP is added to the blacklist.	Check whether the AP needs to be added to the blacklist.

Reason Why an AP Goes Offline	Suggestion
A CAPWAP tunnel is faulty (due to inconsistent link IDs).	The AP will automatically attempt to recover the link, and no action is required.
The DTLS configuration of the CAPWAP tunnel changes.	The AP goes offline due to normal configuration changes, and no action is required.
The AP's factory settings are restored.	The AP goes offline due to normal configuration changes, and no action is required.
The radio type is inconsistent between the AC and AP.	Run the **display ap config-info** command to verify the AP radio configuration.
Heartbeat packet transmission for the CAPWAP data tunnel between the AC and AP times out.	Check the intermediate network between the AP and AC.
Heartbeat packet transmission for the CAPWAP control tunnel between the AC and AP times out.	Check the intermediate network between the AP and AC.
The dual-link networking configuration is modified.	The configuration change causes the AP to automatically reboot, and no action is required.
The AP name is modified.	The AP goes offline due to normal configuration changes, and no action is required.
The AP group name is modified.	The AP goes offline due to normal configuration changes, and no action is required.
The management VLAN is modified.	The AP goes offline due to normal configuration changes, and no action is required.
AP provisioning parameters are set.	The AP goes offline due to normal configuration changes, and no action is required.
The CAPWAP source IP address is deleted.	The AP goes offline due to normal configuration changes, and no action is required.
The central AP goes offline.	Check the reason why the central AP goes offline.
The central AP proactively reboots RUs.	The AP goes offline due to normal configuration changes, and no action is required.

Reason Why an AP Goes Offline	Suggestion
The AP is powered off and restarts.	If the AP restarts repeatedly, check whether the AP power supply mode matches the actual power supply.
An internal error (KP) occurs.	Contact technical support personnel.
An internal error (VOS signal error) occurs.	Contact technical support personnel.
An internal error (forwarding error monitored by MFPI) occurs.	Contact technical support personnel.
An internal error (PKO error monitored by MSC) occurs.	Contact technical support personnel.
An internal error (reset due to timer expiration) occurs.	Contact technical support personnel.
An internal error (reset of the write CPLD register) occurs.	Contact technical support personnel.
The reset button is pressed to reset the AP.	Check whether the AP is manually reset.
The AP restarts due to a CANBUS reset.	Contact technical support personnel.
The AP restarts due to AP interference.	Contact technical support personnel.
The AP restarts due to a chip exception. The AP restarts due to a firmware exception.	Contact technical support personnel.
The CAPWAP sensitive-info PSK is modified.	The configuration change causes the AP to automatically reboot, and no action is required.
The CAPWAP integrity-check PSK is modified.	The configuration change causes the AP to automatically reboot, and no action is required.
The country code is inconsistent on the AC and AP.	Check the country code configuration on the AC and AP.

Reason Why an AP Goes Offline	Suggestion
The AP is forcibly disconnected.	Check the fault based on the possible causes, which may be: ● CAPWAP resources are insufficient. ● The access interface of the AP is changed. ● The Eth-Trunk connected to the AP is deleted. If the fault persists, contact technical support personnel.
The wideband status change.	The AP goes offline due to normal configuration changes, and no action is required.
Reset for a configuration delivery failure.	Check network connectivity. If no problem is found, contact technical support personnel.
Reboot for the branch group of AP change.	The AP goes offline due to normal configuration changes, and no action is required.
The AC license expires.	Re-activate the AC license.
A CAPWAP tunnel is faulty (due to a CAPWAP link entry verification failure).	The AP will automatically attempt to recover the link, and no action is required.
Batch delete	Check whether the active AC runs properly. When the active AC is restored, the AP switches to this active AC to go online.
Switch service radio to proxy scanning radio.	The configuration change causes the AP to automatically reboot, and no action is required.
Switch proxy scanning radio to service radio.	The configuration change causes the AP to automatically reboot, and no action is required.
The AP cloud license expires.	Purchase a new license and load it to iMaster NCE-Campus.
The device has been disconnected from the iMaster NCE-Campus for more than 90 days.	Verify the iMaster NCE-Campus address configured on the AC, and check network connectivity.
The device is deleted from the iMaster NCE-Campus.	No action is required.

Reason Why an AP Goes Offline	Suggestion
The iMaster NCE-Campus does not deliver AP information.	1. Verify that AP information is correctly added to iMaster NCE-Campus, the AP is associated with the AC, and the AC is online. 2. Verify the iMaster NCE-Campus address configured on the AC, and check network connectivity. 3. Check whether iMaster NCE-Campus fails to deliver AP information. If so, manually deliver AP information again.
An internal error (Reset for firmware abnormal) occurs.	Contact technical support personnel.
An internal error (Reset for abnormal network port self-healing) occurs.	Contact technical support personnel.
An internal error (Reset for the forcible AP disconnection in specific scenarios) occurs.	Contact technical support personnel.
An internal error (Reset for slow task switching) occurs.	Contact technical support personnel.
An internal error (Reset for MFPI detect CAP PBUF use out) occurs.	Contact technical support personnel.
An internal error (Reset for ap abnormal self-healing) occurs.	Contact technical support personnel.
An internal error (Reset for exception(redis-server exit)) occurs.	Contact technical support personnel.
An internal error (Reset for exception(confd exit)) occurs.	Contact technical support personnel.
An internal error (Reset for exception(callhome exit)) occurs.	Contact technical support personnel.
An internal error (Reset for an abnormal process) occurs.	Contact technical support personnel.
N+1 switchover of APs.	No action is required.
An internal error (Reset for an NP heartbeat message exception) occurs	Contact technical support personnel.
An internal error (exceed the extreme temperature) occurs.	Take proper measures to lower the ambient temperature, for example, by lowering the air conditioner temperature and ventilate the equipment room.

Reason Why an AP Goes Offline	Suggestion
An internal error (memory use out) occurs.	Contact technical support personnel.
An internal error (dophi-server exit) occurs.	Contact technical support personnel.
An internal error (Wi-Fi SDK self-healing failure) occurs.	Contact technical support personnel.
Reconnect by command.	No action is required.
Reset for the radio mode change.	No action is required.
Reset for RTU license activation.	No action is required.
Reset for an overdue demo license.	No action is required.
Reset for insufficient power supply.	Contact technical support personnel.
An internal error (Reset for an unexpected exit of the WPC process) occurs.	Contact technical support personnel.
Cloud licenses expire, and local license resources are insufficient	Expand the license capacity (RUs do not occupy license resources).
Incompatible DTLS version or encryption algorithm	Upgrade the AP version, or run the **capwap dtls version1.0 enable** and **capwap dtls cbc enable** commands to enable compatibility with earlier DTLS versions.
The CAPWAP DTLS authentication configuration of the AP is changed	The AP goes offline due to configuration changes, and no action is required.

11.1.60 display ap online-fail-record

Function

The **display ap online-fail-record** command displays AP online failure records.

Format

display ap online-fail-record { **all** | **mac** *mac-address* }

Parameters

Parameter	Description	Value
all	Displays online failure records of all APs.	-

Parameter	Description	Value
mac *mac-address*	Displays online failure records of the AP with the specified MAC address.	The AP's MAC address must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If an AP fails to go online on the AC, you can run this command to check the failure reason, which helps locate the fault.

After the number of AP online failure records reaches the maximum that can be stored, new records overwrite existing ones.

A maximum of five online failure records can be stored for each AP.

Example

Display online failure records about the AP with the MAC address 00e0-fcb1-56a0.

```
<HUAWEI> display ap online-fail-record mac 00e0-fcb1-56a0
------------------------------------------------------------------------------
MAC             Last fail time       Reason
------------------------------------------------------------------------------
00e0-fcb1-56a0  2015-01-20/15:48:06  The AP is added to the AP blacklist.
------------------------------------------------------------------------------
Total records: 1
```

Table 11-13 Description of the **display ap online-fail-record** command output

Item	Description
MAC	MAC address of the AP that fails to go online.
Last fail time	Time of the AP online failure.
Reason	Reason why the AP fails to go online. For details about going-online failure causes and handling suggestions, see **Table 11-14**. For more troubleshooting methods, see **An AP Fails to Go Online on the AC** in the *Troubleshooting Guide*.

Table 11-14 Possible causes and suggestions for APs' failures to go online

Reason Why an AP Fails to Go Online	Suggestion
Insufficient license resources.	Expand the license capacity. Note that RUs do not occupy license resources of the AC. For details, see *WLAN License Usage Guide*.
The AP is not in the SN whitelist.	Run the **ap whitelist sn** *ap-sn1* [**to** *ap-sn2*] command to add the AP to the whitelist or run the **ap-confirm** command to enable the AP to pass authentication.
The AP is not in the MAC whitelist.	Run the **ap whitelist mac** *ap-mac1* [**to** *ap-mac2*] command to add the AP to the whitelist or run the **ap-confirm** command to enable the AP to pass authentication.
The AP is added to the AP blacklist.	Check whether the AP needs to be added to the blacklist. To delete the AP from the blacklist, run the **undo ap blacklist** command.
The MAC address and SN of the AP do not match.	Check whether the MAC address and SN of the AP match.
DTLS negotiation for CAPWAP tunnel setup fails.	Check whether the PSK used for DTLS encryption is correctly configured.
DTLS negotiation failed, because of negotiation timeout or inconsistent PSKs on two ends.	● Check whether the shared keys of the AC and AP are the same. If not, change them to the same. Alternatively, enable the function of establishing CAPWAP DTLS sessions in none authentication mode so that the APs can obtain security credentials. After the APs go online, disable this function immediately in order to prevent unauthorized APs from going online. ● Check whether ping packets are normal on the network. If not, negotiation timeout occurs because of a network exception during the DTLS negotiation. In this case, check the network. ● If this fault persists, contact technical support personnel.

Reason Why an AP Fails to Go Online	Suggestion
CAPWAP tunnel negotiation fails.	Check network connectivity. If no problem is found, contact technical support personnel.
APs cannot go online during data backup.	Wait until backup is complete.
The upgrade fails.	Run the **display ap update configuration** command to check whether the AP's upgrade file is correct. If so, rectify the fault by referring to **Fit AP Upgrade Fails** in the *Troubleshooting Guide*.
The CAPWAP tunnel fails to be established.	Check network connectivity. If no problem is found, contact technical support personnel.
The configuration fails to be delivered.	The device attempts to deliver the configuration again. If the failure persists: 1. Check whether the AC and AP can ping each other. If the network is disconnected or a large number of packets are lost, check the intermediate network. 2. Check whether the MTU between the AC and AP is correctly configured. Assume that the MTU of the intermediate network is 1500 bytes. Run the **ping** **-a** <*AC CAPWAP source IP*> **-s** *1472* **-f** <*AP IP*> command on the AC to check whether the ping operation succeeds. If packet loss occurs, run the **mtu** (AP system profile view) command to change the MTU of the AP to be the same as the MTU of the intermediate network. 3. Check whether the AC and AP can properly send and receive packets, whether the queue usage exceeds the threshold, and whether packet loss or any loop occurs on interfaces. If this fault persists, contact technical support personnel.

Reason Why an AP Fails to Go Online	Suggestion
The versions of the AP and AC do not match.	Log in to Huawei technical support website and download the release notes. Based on the version mapping, upgrade the AP or AC to the matching version. - Enterprise technical support website: **https://support.huawei.com/enterprise** - Carrier technical support website: **https://support.huawei.com**
- The AC does not support the AP type. - Unsupported AP type, AC version may need to be upgraded.	Replace the AP with that supported by the AC or replace the AC with one that supports this AP type. To enable an AC to manage APs that are new in a later version, you can manually add AP types. For details, see **Enabling a WAC to Manage New APs Running Later Versions**.
The AP name conflicts.	Run the **ap-rename** command to rename the AP.
The number of central APs reaches the upper limit.	Check whether the number of central APs reaches the maximum value.
The number of common APs reaches the upper limit.	Check whether the number of common APs reaches the maximum value. If the number of normal APs is smaller than the maximum, to allow the AP to go online, run the **undo ap** command to delete APs that are not in normal state to release resources.
The central AP is not in normal state.	Run the **display ap** command to check the central AP status and take measures accordingly.
The CAPWAP sensitive-info PSK is different on the two ends of the CAPWAP tunnel.	Ensure that the PSK for encrypting CAPWAP sensitive information is the same on the AP and AC. Alternatively, enable the AP to set up a DTLS session with the AC using the default PSK.
The CAPWAP integrity-check PSK is different on the two ends of the CAPWAP tunnel.	Ensure that the PSK for checking CAPWAP packet integrity is the same on the AP and AC. Alternatively, enable the AP to set up a DTLS session with the AC using the default PSK.

Reason Why an AP Fails to Go Online	Suggestion
The configured and reported AP types are different. The real AP type is *XXXX*. The type ID carried by the AP is different from that configured on the AC.	After the **undo AP** command is run to delete an AP, the system cannot obtain the AP type and displays a message "The configured and reported AP types are different." In this case, ensure that the configured AP type is the same as the reported one.
The AC license is not active.	Activate the AC license.
Too many APs go online concurrently, leading to a failure to create sufficient DBSS interfaces.	No action is required. The APs will attempt to go online again. If the APs still fail to go online, contact technical support personnel.
The country codes of the AP and AC are inconsistent, and the country code of the AP is locked.	The country code of some AP models cannot be modified. For example, an AP model with the suffix -US is used only in the United States, and its country code is fixed as US. Configure the country code on the AC to be the same as that on the AP.
The AP cloud license expires.	Purchase a new license and load it to iMaster NCE-Campus.
The device has been disconnected from the iMaster NCE-Campus for more than 90 days.	Verify the iMaster NCE-Campus address configured on the AC, and check network connectivity.
The device is deleted from the iMaster NCE-Campus.	No action is required.
The iMaster NCE-Campus does not deliver AP information.	1. Verify that AP information is correctly added to iMaster NCE-Campus, the AP is associated with the AC, and the AC is online. 2. Verify the iMaster NCE-Campus address configured on the AC, and check network connectivity. 3. Check whether iMaster NCE-Campus fails to deliver AP information. If so, manually deliver AP information again.
Configuration synchronization is in progress, leading to the system busy.	No action is required.
Backing up HA data.	Wait till HA data backup ends.

Reason Why an AP Fails to Go Online	Suggestion
Insufficient LPU resources.	All the resources of the card are occupied. Go online through another card.
Invalid port on the switch connected to the AP.	Check whether a card does not support AP access or the cards are in different working groups.
Insufficient trunk resources.	The trunk resources are released.
The number of distribute APs reaches the upper limit of the central AP.	Re-plan the network and expand the network capacity by adding central APs.
The number of CAPWAP tunnels reaches the upper limit.	Run the **display as** command to check whether any online AS occupies CAPWAP resources. If so, properly allocate CAPWAP resources.
This AP type is not supported. Add it or upgrade the AC version.	Add the AP type or upgrade the AC version.
Inconsistent type IDs on the AP and AC. (Type ID reported by the AP: *xx*; AP type: *yy*)	Modify the AP type ID to be the same as that on the AC. The method is as follows: 1. Run the **undo ap** { **ap-name** *ap-name* | **ap-id** *ap-list* | **ap-mac** *ap-mac* } command to delete all the APs using this type ID. 2. Run the **undo ap-type** *type-description* command to delete the AP type configuration. 3. Run the **ap-type** *type-description* **type-id** *type-id* command to configure the AP type correctly.
The AC version is not supported by the AP.	Upgrade the AC version.
Failed to add the reported AP type parameters.	Upgrade the AC version.
The AP is forcibly disconnected.	iMaster NCE-Campus responds with a registration failure message. In this case, add the AP on iMaster NCE-Campus.
This AP type is not supported.	Replace the AP.

Reason Why an AP Fails to Go Online	Suggestion
DTLS negotiation failed by using the preset certificate.	The function of verifying the CN field in AC certificates is configured on the AP. In an AC replacement scenario, if the CN field of the new AC is not added, APs cannot go online on the new AC. In this case, you need to add the CN field of the new AC for APs on the original AC. If the original AC is faulty and does not support the configuration, log in to each AP that fails to go online and run the **capwap dtls server-auth disable** command to disable the AC authentication function for the AP or restore the factory settings of each AP.
The AP automatic replacement function is enabled, and the AP does not carry LLDP neighbor information.	Check whether LLDP is enabled on the device connected to the AP's uplink interface.
Cloud licenses expire, and local license resources are insufficient	Expand the license capacity. (RUs do not consume license resources.)
Incompatible DTLS version or encryption algorithm	Upgrade the AP version, or run the **capwap dtls version1.0 enable** and **capwap dtls cbc enable** commands to enable compatibility with earlier DTLS versions.
Negotiation DTLS data tunnel failed	Check whether the PSK used for DTLS encryption is correctly configured.
Access through VPN is rejected	The AP cannot go online through a VPN. Ensure that no VPN configuration exists on the interface connecting the upstream device to the AP.
The radio type is inconsistent between the AC and AP	No action is required. The AP automatically restarts and the new configuration takes effect.
The total number of APs and tunnel APs reaches the maximum number of APs that can be managed	Run the **display ap all** and **display tunnel-ap all** commands to check the number of APs and the number of tunnel APs, respectively. Plan APs properly or expand the capacity based on the maximum number of APs that can be managed.

11.1.61 display ap radio-mode all

Function

The **display ap radio-mode all** command displays the effective radio mode of online APs.

Format

display ap radio-mode all

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After switching the radio mode of an AP using the **radio-mode** command, you can run the **display ap radio-mode all** command to query the effective radio mode of the AP.

Example

Display the effective radio mode of online APs.

```
<HUAWEI> display ap radio-mode all
--------------------------------------------
ID      Mode
--------------------------------------------
0       2radio-standard
--------------------------------------------
Total: 1
```

Table 11-15 Description of the **display ap radio-mode all** command output

Item	Description
ID	AP ID.

Item	Description
Mode	Radio mode. ● 2radio-standard: standard dual-radio mode ● 2radio-2g-enhanced: 2G enhanced dual-radio mode ● 2radio-5g-enhanced: 5G enhanced dual-radio mode ● 2radio-independent-scan: dual-radio + independent scanning mode ● 3radio: three-radio mode ● -: The AP has not reported the radio mode switching message. **NOTE** The AirEngine 6761-21, AirEngine 6761-21E, and AirEngine 6761S-21 have a dedicated radio for scanning and can perform radio scanning even in **2radio-standard** mode.

11.1.62 display ap-rtu-status all

Function

The **display ap-rtu-status all** command displays the RTU license loading status of all APs.

NOTE

The RTU License is not supported by the following models.

- AirEngine x76x (Excluding the AirEngine 5760-51, AirEngine 6760-X1, AirEngine 6760-X1E)
- AirEngine x77x
- The cemtral AP (including matching RUs)
- AirEngine 9700D-S (including matching ORUs)

Format

display ap-rtu-status all

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After loading RTU licenses to APs, you can run this command to check the RTU license loading status.

Precautions

If the number of RTU licenses exceeds the maximum number of RTU licenses supported by an AC, the excess RTU licenses cannot be displayed in the command output. To check information about these RTU licenses, run the **dir rtu/** command in the user view.

Example

Display the RTU license loading status of all APs.

```
<HUAWEI> display ap-rtu-status all
Info: This operation may take a few seconds. Please wait for a moment.done.
Active: [1] The RTU license is activated on the AP.
Activating(Init):[1] The AC has not delivered the RTU file to the AP.
Activating(Need reboot): [1] The AP has downloaded the RTU license and needs a restart for the license to
take effect.
Active fail(Flash memory not enough): [1] The flash memory on the AP is insufficient for storing the license
file. Manually clear the flash space on the AP.
Active fail(Invalid license): [1] Invalid license file. Verify that the license file is correct.
No RTU license: [1] The license file of the AP does not exist on the AC. Upload the RTU package available
for this AP and run the ap rtu load command to decompress the package.
Not support RTU:[2] The AP version or model does not support the RTU license.
Not active:[3] The RTU license on the AC does not have the corresponding AP.
------------------------------------------------------------
AP ID  AP name    RTU license SN            RTU status
------------------------------------------------------------
1      AP-1       2102351TYRW0KB001030      Active
2      AP-2       2102353KCN10L1000053      Activating(Need reboot)
3      AP-3       2102353GSF10KC00002       No license on AP
4      AP-4       -                         No RTU license
5      AP-5       2102353GSF10KC00003       Active fail(Flash memory not enough)
6      AP-6       2102353GSF10KC00004       Active fail(Invalid license)
7      AP-7       2102353GSF10KC00005       Not support RTU
8      AP-8       -                         Not support RTU
9      AP-9       2102353GSF10KC00006       Activating(Init)
-      -          2102353GSF10KC10005       Not active
-      -          2102353GSF10KC20005       Not active
-      -          2102353GSF10KC30005       Not active
------------------------------------------------------------
Total: 12
```

Table 11-16 Description of the **display ap-rtu-status all** command output

Item	Description
AP ID	AP ID.
AP name	AP name.

Item	Description
RTU license SN	ESN in the RTU license file, which is not the ESN of the AP. If no ESN or an invalid ESN is contained in a license file, the file is considered invalid and this field is displayed as -. If the license file does not contain the RTU license file for the AP, this field is displayed as -.
RTU status	RTU license loading status. ● Active: The RTU license has been activated on an AP. ● Activating(Init): The AC has not delivered the RTU license file to an AP. ● Activating(Need reboot): An AP has downloaded and stored the RTU license file, and needs a restart for the file to take effect. ● No RTU license: The AC does not have the RTU license file for an AP. You need to upload the RTU license package containing the RTU license for the AP and run the **ap rtu load** command to unzip the package. ● Active fail(Flash memory not enough): The flash memory on an AP has insufficient space to store the RTU license file. You need to manually clear the flash memory on the AP. ● Active fail(Invalid license): The RTU license file is invalid. Verify that the file is correct. ● Not support RTU: The model software version or model of an AP does not support the RTU license. ● Not active: The AC has the RTU license but the corresponding AP is not online on the AC. ● -: An AP goes online on the standby AC. Query the RTU license on the active AC.

11.1.63 display ap sta-signal strength

Function

The **display ap sta-signal strength** command displays the average signal strength of STAs connected to an AP.

Format

display ap sta-signal strength { **ap-name** *ap-name* | **ap-id** *ap-id* } [**radio** *radio-id*]

Parameters

Parameter	Description	Value
ap-name *ap-name*	Displays the average signal strength of STAs connected to the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Displays the average signal strength of STAs connected to the AP with a specified ID.	The AP ID must exist.
radio *radio-id*	Displays the average signal strength of STAs connected to a specified AP radio.	The radio ID must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view the average signal strength of STAs connected to an AP.

Example

Display the average signal strength of STAs connected to AP **test**.

```
<HUAWEI> display ap sta-signal strength ap-name test
Station signal strength(dBm): 0
```

Table 11-17 Description of the **display ap sta-signal strength** command output

Item	Description
Station signal strength(dBm)	Average signal strength of STAs.

11.1.64 display ap statistics

Function

The **display ap statistics** command displays AP type statistics.

Format

display ap statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Various types of APs can be added on the device. You can run this command to view types of APs added on the device and the number of APs of various types.

Example

Display statistics about AP types.

```
<HUAWEI> display ap statistics
------------------------------------------------------------------------------
Type                Number
------------------------------------------------------------------------------
AP4050DN              1
AP5030DN              1
------------------------------------------------------------------------------
```

Table 11-18 Description of the **display ap statistics** command output

Item	Description
Type	AP type.
Number	Number of APs of a type.

11.1.65 display ap unauthorized record

Function

The **display ap unauthorized record** command displays information about unauthenticated APs.

Format

display ap unauthorized record

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If the MAC address or SN authentication mode is configured for an AP but the AP is neither imported nor added to the whitelist, the AC does not allow this AP to access. You can run the **display ap unauthorized record** command to view information about unauthorized APs.

Example

Display information about unauthorized APs.

```
<HUAWEI> display ap unauthorized record
Unauthorized AP record:
Total number: 1
--------------------------------------------------------------------------------
AP type: AirEngine8760-X1-PRO
AP SN: xxxxxxxxxxxxxxxxx
AP MAC address: xxxx-xxxx-xxxx
AP IP address: 192.168.109.252
Record time: 2020-01-22 17:23:17
--------------------------------------------------------------------------------
```

Table 11-19 Description of the **display ap unauthorized record** command output

Item	Description
Unauthorized AP record	Records about unauthenticated APs.
Total number	Total number of unauthenticated APs.
AP type	AP type.
AP SN	AP SN.
AP MAC address	AP's MAC address.
AP IP address	AP's IP address.
Record time	Time when an unauthorized AP was recorded.

11.1.66 display ap whitelist

Function

The **display ap whitelist** command displays AP whitelist information.

Format

display ap whitelist { **mac** | **sn** }

Parameters

Parameter	Description	Value
sn	Displays SNs in the AP whitelist.	-
mac	Displays MAC addresses in the AP whitelist.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When the AP authentication mode is set to MAC address or SN authentication using the **ap auth-mode** command, you can run the **ap whitelist** command to configure an AP whitelist. Only RUs on the whitelist are allowed to go online. To check information about RUs in the whitelist, run the **display ap whitelist** command.

Example

Display MAC addresses in the AP whitelist.

```
<HUAWEI> display ap whitelist mac
--------------------------------------------------------------------------------
Index  MAC
--------------------------------------------------------------------------------
0      00e0-fcb1-56a0
1      00e0-fc24-0080
2      00e0-fc9d-0bb0
--------------------------------------------------------------------------------
Total: 3
```

Table 11-20 Description of the **display ap whitelist mac** command output

Item	Description
Index	Index.
MAC	MAC address of an AP. To add a MAC address to the AP whitelist, run the **ap whitelist mac** *ap-mac1* [**to** *ap-mac2*] command.

Display SNs in the AP whitelist.

```
<HUAWEI> display ap whitelist sn
--------------------------------------------------------------------------------
Index  SN
--------------------------------------------------------------------------------
0      210235449210CB000011
1      S0001
2      210235568010D1000032
--------------------------------------------------------------------------------
Total: 3
```

Table 11-21 Description of the **display ap whitelist sn** command output

Item	Description
Index	Index.
SN	SN of an AP. To add an SN to the AP whitelist, run the **ap whitelist sn** *ap-sn1* [**to** *ap-sn2*] command.

11.1.67 display ap-group

Function

The **display ap-group** command displays configuration and reference information about an AP groups.

Format

display ap-group { **all** | **name** *group-name* }

Parameters

Parameter	Description	Value
all	Displays information about all AP groups.	-
name *group-name*	Displays information about a specified AP group.	The AP group must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ap-group** command to view configuration and reference information about AP groups.

Example

Display information about all AP groups.

```
<HUAWEI> display ap-group all
------------------------------------------------------------
Name                              APs
------------------------------------------------------------
default                          1
------------------------------------------------------------
Total: 1
```

Table 11-22 Description of the **display ap-group all** command output

Item	Description
Name	Name of an AP group.
APs	Number of APs in an AP group.

Display information about the AP group **default**.

Table 11-23 Description of the **display ap-group name** command output

Item	Description
AP system profile	AP system profile referenced by an AP group. To configure this parameter, run the **ap-system-profile (AP group view and AP view)** command.
Regulatory domain profile	Regulatory domain profile referenced by an AP group. To configure this parameter, run the **regulatory-domain-profile** command.
WIDS profile	WIDS profile referenced by an AP group.

Item	Description
BLE profile	BLE profile referenced by an AP group. To configure this parameter, run the **ble-profile (AP group view and AP view)** command.
UUID	UUID of a BLE broadcast frame sent by the AP's built-in Bluetooth module. To configure this parameter, run the **broadcasting-content (AP group view)** command.
AP location	Installation position of an AP in the AP group. To configure this parameter, run the **location** command.
Domain name	Default domain name suffix of the AP. To configure this parameter, run the **ip domain-name** command.
Scene	Scenario profile bound to an AP group. To configure this parameter, run the **scene** command.
Ap pki profile	Bound AP PKI realm profile. To configure this parameter, run the **ap-pki-profile** command.
AP wired port profile	AP wired port profile referenced by an AP group. To configure this parameter, run the **wired-port-profile (AP group view and AP view)** command.
Interface *Interface-name*	Interface name.
Radio 0/Radio 1/Radio 2	Radio ID.
Radio 2.4G profile	2G radio profile referenced by an AP group. To configure this parameter, run the **radio-2g-profile** command.
Radio 5G profile	5G radio profile referenced by an AP group. To configure this parameter, run the **radio-5g-profile** command.

Item	Description
VAP profile	VAP profile referenced by an AP group. The displayed format is "VAP ID:VAP profile name (service VLAN defined when binding to the VAP profile, single VLAN, or VLAN pool)." To configure this parameter, run the **vap-profile** command.
Mesh profile	Mesh profile referenced by an AP group. To configure this parameter, run the **mesh-profile radio** command.
WDS profile	WDS profile referenced by an AP group. To configure this parameter, run the **wds-profile radio** command.
Mesh whitelist profile	Mesh whitelist profile referenced by an AP group. To configure this parameter, run the **mesh-whitelist-profile (AP group radio view or AP radio view)** command.
WDS whitelist profile	WDS whitelist profile referenced by an AP group. To configure this parameter, run the **wds-whitelist-profile (AP group radio view or AP radio view)** command.
Location profile	Location profile referenced by an AP group. To configure this parameter, run the **location-profile** command.
Radio switch	Whether a radio is enabled. To configure this parameter, run the **radio disable** command.
Channel	Working channel of a radio. To configure this parameter, run the **channel** command.
Channel bandwidth	Working bandwidth of a radio. To configure this parameter, run the **channel** command.

Item	Description
EIRP(dBm)	Transmit power of a radio, in dBm. To configure this parameter, run the **eirp** command.
Antenna gain(dB)	Antenna gain of a radio, in dB. To configure this parameter, run the **antenna-gain** command.
Coverage distance(100 m)	Radio coverage distance parameter, in the unit of 100 m. To configure this parameter, run the **coverage distance** command.
Work mode	Working mode of a radio. To configure this parameter, run the **work-mode** command.
Flexible radio switch	Whether the DFA function of a radio is enabled. To configure this parameter, run the **calibrate flexible-radio disable** command.
Radio frequency	Working frequency band of a radio. To configure this parameter, run the **frequency** command.
Spectrum analysis	Whether spectrum analysis is enabled. To configure this parameter, run the **spectrum-analysis enable** command.
Channel monitor	Whether the function of monitoring the status of all channels is enabled. To configure this parameter, run the **channel-monitor enable** command.
WIDS device detect	Whether wireless device detection is enabled. To configure this parameter, run the **wids device detect enable** command.
WIDS attack detect	Whether attack detection is enabled. To configure this parameter, run the **wids attack detect** command.
WIDS contain switch	Whether rogue device containment is enabled. To configure this parameter, run the **wids contain enable** command.

Item	Description
Auto channel select	Whether automatic channel selection is enabled. To configure this parameter, run the **calibrate auto-channel-select** command.
Auto bandwidth select	Whether automatic bandwidth selection is enabled. To configure this parameter, run the **calibrate auto-bandwidth-select** command.
Auto transmit power select	Whether automatic transmit power selection is enabled. To configure this parameter, run the **calibrate auto-txpower-select** command.
Reference data-analysis	Whether big data calibration is enabled. To configure this parameter, run the **calibrate reference data-analysis { disable | enable }** command.
Reference 3d-data	Whether 3D radio calibration is enabled. To configure this parameter, run the **calibrate reference 3d-data { disable | enable }** command.
Beacon switch	Whether RUs are enabled to send Beacon frames. To configure this parameter, run the **beacon disable** command.
CTS switch	Whether RUs are enabled to respond to STAs with CTS packets. To configure this parameter, run the **cts disable** command.
CTS delay time(us)	Delay time after which RUs respond to STAs with CTS packets. To configure this parameter, run the **cts delay** command.
Card 1/Card 2/Card 3/Card usb	IoT card.

Item	Description
Card connect type	Communication connection type between IoT cards and APs. To configure this parameter, run the **card connect-type** command.
Baud rate	Baud rate used for communication between an IoT card and the AP. To configure this parameter, run the **baud-rate** command.
Wired port profile	AP wired port profile referenced by an AP group. To configure this parameter, run the **wired-port-profile (IoT card interface view)** command.
Iot profile	Bound IoT profile. To configure this parameter, run the **iot-profile (IoT card interface view)** command.
Protocol Type	Communication protocol between the AP and host computer.
First Port	Source port for the first channel.
Extended Port	Source port for the extended channel.
Traffic policy outbound	Traffic policy applied to an AP group.

11.1.68 display capwap configuration

Function

The **display capwap configuration** command displays the CAPWAP configuration.

Format

display capwap configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view the interval for sending Keepalive packets, number of times for sending Keepalive packets, and priority of CAPWAP management packets.

Example

Display the CAPWAP configuration.

```
<HUAWEI> display capwap configuration
 ------------------------------------------------------------------
 Source interface                                : -
 Echo interval(seconds)                          : 25
 Echo times                                      : 6

 DTLS version1.0 status                          : disable
 DTLS cbc status                                 : disable
 ------------------------------------------------------------------
```

Table 11-24 Description of the **display capwap configuration** command output

Item	Description
Source interface	Source interface of the AC. To configure this parameter, run the **capwap source interface** command.
Echo interval(seconds)	Interval for sending Keepalive packets. To configure this parameter, run the **capwap echo interval** *interval-value* command.
Echo times	Number of times for sending Keepalive packets. If no response is received after the specified number of times, the link is considered disconnected. To configure this parameter, run the **capwap echo times** *times-value* command.

Item	Description
Control priority(server to client)	Priority of CAPWAP management packets from the AC to the APs. To configure this parameter, run the **capwap control-link-priority local** *priority-value* command.
Control priority(client to server)	Priority of CAPWAP management packets from the APs to the AC. To configure this parameter, run the **capwap control-link-priority remote** *priority-value* command.
Control-link DTLS encrypt	Whether DTLS encryption for CAPWAP control tunnels is enabled. To configure this parameter, run the **capwap dtls control-link encrypt** command.
DTLS PSK value	PSK for DTLS encryption. To configure this parameter, run the **capwap dtls psk** command.
Control-link inter-controller DTLS encrypt	Whether DTLS encryption is enabled for control tunnels between ACs. To configure this parameter, run the **capwap dtls inter-controller control-link encrypt** command.
Inter-controller DTLS PSK value	PSK for DTLS encryption of an inter-AC tunnel. To configure this parameter, run the **capwap dtls inter-controller psk** command.
Message-integrity PSK value	PSK for checking integrity of CAPWAP packets. To configure this parameter, run the **capwap message-integrity psk** command.
Message-integrity check switch	Whether integrity check of CAPWAP packets is enabled. To configure this parameter, run the **capwap message-integrity check disable** command.
Sensitive-info PSK value	PSK for encrypting sensitive information. To configure this parameter, run the **capwap sensitive-info psk** command.

Item	Description
Sensitive-info inter-controller PSK value	PSK for encrypting sensitive information between ACs. To configure this parameter, run the **capwap inter-controller sensitive-info psk** command.
DTLS no-auth status	Whether the function of establishing CAPWAP DTLS sessions in none authentication mode is enabled. To configure this parameter, run the **capwap dtls no-auth enable** command.
DTLS cert-mandatory-match status	Whether the function of establishing CAPWAP DTLS sessions through the initial certificate is enabled. To configure this parameter, run the **capwap dtls cert-mandatory-match disable** command.
DTLS version1.0 status	Whether compatibility with DTLS 1.0 is enabled. To configure this parameter, run the **capwap dtls version1.0 enable** command.
DTLS CBC status	Whether compatibility with the DTLS CBC cipher suite is enabled. To configure this parameter, run the **capwap dtls cbc enable** command.

11.1.69 display cpe-tunnel-profile

Function

The **display cpe-tunnel-profile** command displays configuration and reference information about CPE tunnel profiles.

Format

display cpe-tunnel-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays information about all CPE tunnel profiles.	-
name *profile-name*	Displays information about a specified CPE tunnel profile.	The CPE tunnel profile must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check configuration and reference information about CPE tunnel profiles.

Example

Display information about all CPE tunnel profiles.

```
<HUAWEI> display cpe-tunnel-profile all
------------------------------------------------------------------------------------------------------------
Profile name         Reference
------------------------------------------------------------------------------------------------------------
default              1
cpe-tunnel-profile1  0
------------------------------------------------------------------------------------------------------------
Total: 2
```

Table 11-25 Description of the **display cpe-tunnel all** command output

Item	Description
Profile name	Name of a CPE tunnel profile.
Reference	Number of times a CPE tunnel profile is referenced.

Display information about the CPE tunnel profile **cpe1**.

```
<HUAWEI> display cpe-tunnel-profile name cpe1
--------------------------------------------------------------------------------
PVID VLAN                          : 100
GRE checksum                       : disable
GRE key                            : disable
Allow-pass VLAN                    : 1 100
Forward mode                       : tunnel
Wlan-slice high-reliability traffic filter info:
```

```
AppliedRecord:
----------------------------------------------------------------------------------
```

Table 11-26 Description of the **display cpe-tunnel-profile name** command output

Item	Description
PVID VLAN	PVID of the interface corresponding to the CPE tunnel.
GRE checksum	Whether the checksum function is enabled for the CPE tunnel. To configure this parameter, run the **gre checksum (CPE tunnel profile view)** command.
GRE key	GRE key status of the CPE tunnel. To configure this parameter, run the **gre key (CPE tunnel profile view)** command.
Allow-pass VLAN	VLANs from which packets are allowed to pass through the CPE tunnel.
Forward mode	Forwarding mode of the CPE tunnel. ● direct-forward: direct forwarding ● tunnel: tunnel forwarding To configure this parameter, run the **forward-mode (CPE tunnel profile view)** command.
AppliedRecord(Wlan-slice high-reliability traffic filter info)	ACL-based rule records for air interface slicing. To configure this parameter, run the **wlan-slice high-reliability acl** command.

11.1.70 display radio

Function

The **display radio** command displays AP radio information.

Format

display radio { **all** | **ap-group** *ap-group-name* | **ap-name** *ap-name* | **ap-id** *ap-id* }

Parameters

Parameter	Description	Value
all	Displays radio information about all APs.	-
ap-group *ap-group-name*	Displays radio information about all APs in a specified AP group.	The AP group must exist.
ap-name *ap-name*	Displays radio information about the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Displays radio information about the AP with a specified ID.	The AP ID must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view the working status of AP radios.

Example

Display radio information about all APs.

```
<HUAWEI> display radio all
CH/BW:Channel/Bandwidth
CE:Current EIRP (dBm)
ME:Max EIRP (dBm)
CU:Channel utilization
ST:Status
WM:Working Mode (normal/monitor/monitor dual-band-scan/monitor proxy dual-band-scan)
-------------------------------------------------------------------------------------
 AP ID Name           RfID  Band  Type   ST  CH/BW    CE/ME   STA    CU    WM
-------------------------------------------------------------------------------------
 0     00e0-fc76-e360  0     2.4G  bgn    on  6/20M    24/24   0      55%   normal
 0     00e0-fc76-e360  1     5G    an     on  56/20M   25/25   0      3%    normal
-------------------------------------------------------------------------------------
Total:2
```

Table 11-27 Description of the **display radio** command output

Item	Description
AP ID	AP ID.
Name	AP name.
RfID	Radio ID.

Item	Description
Band	Operating frequency band of an AP radio.
Type	Protocol type of an AP radio. ● b: 802.11b radio type ● bg: 802.11b/g radio type ● bgn: 802.11b/g/n radio type ● a: 802.11a radio type ● an: 802.11a/n radio type ● an11ac: 802.11a/n/ac radio type ● 11ax: 802.11b/g/n/ax radio type for a 2.4 GHz radio; 802.11a/n/ac/ax radio type for a 5 GHz radio; or 802.11ax radio type for a 6 GHz radio ● 11be: 802.11b/g/n/ax/be radio type for a 2.4 GHz radio; 802.11a/n/ac/ax/be radio type for a 5 GHz radio; or 802.11ax/be radio type for a 6 GHz radio
ST	Working status of an AP radio.
CH/BW	Channel/Bandwidth of an AP radio. If no VAP profile is bound to the radio, a hyphen (-) is displayed.
CE/ME	Current transmit power of an AP radio/ Maximum transmit power of an AP radio. If no VAP profile is bound to the radio, a hyphen (-) is displayed. **NOTE** The value is calculated based on the typical gain of the antenna used by the AP.
STA	Number of STAs connected to an AP radio.

Item	Description
CU	Channel utilization. When an AP radio works in monitor mode, this parameter is displayed as **-**. ● In the AC+central AP+RU networking: RUs do not proactively report the channel utilization to the AC. To query the channel utilization of RUs, enable the data buffer function on the AC. **NOTE** The **ap data-collection enable** command enables the data buffer function on the AC. After this command is executed, a large data buffer occupies the device memory and affects device performance. It is recommended that the **undo ap data-collection enable** command be executed to disable data buffer after the query. ● In the AC+Fit AP networking: A Fit AP periodically reports the channel utilization to the AC. Therefore, the AC does not need to query the channel utilization of APs.
WM	Working mode of an AP radio. ● normal ● monitor ● monitor dual-band-scan: inter-band scanning mode ● monitor proxy dual-band-scan: proxy inter-band scanning mode

11.1.71 display radio-2g-profile

Function

The **display radio-2g-profile** command displays configuration and reference information about a 2G radio profile.

Format

display radio-2g-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays information about all 2G radio profiles.	-
name *profile-name*	Displays information about a specified 2G radio profile.	The 2G radio profile must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view configuration and reference information about a 2G radio profile.

Example

Display information about all 2G radio profiles.

```
<HUAWEI> display radio-2g-profile all
--------------------------------------------------------------------
Profile name  Config Reference  Reference radios
--------------------------------------------------------------------
default       10                4
--------------------------------------------------------------------
Total: 1
```

Table 11-28 Description of the **display radio-2g-profile all** command output

Item	Description
Profile name	Name of a 2G radio profile.
Config Reference	Number of times a 2G radio profile is referenced.
Reference radios	Number of radios that reference a 2G radio profile.

Display information of the 2G radio profile **default**.

```
<HUAWEI> display radio-2g-profile name default
------------------------------------------------------------
Radio type                        : 802.11n

------------------------------------------------------------
```

Table 11-29 Description of the **display radio-2g-profile name** command output

Item	Description
Radio type	Radio type. To configure this parameter, run the **radio-type (2G radio profile view)** command.

Item	Description
Power auto adjust	Whether automatic per packet power adjustment is enabled. To configure this parameter, run the **power auto-adjust enable** command.
Beacon interval(TUs)	Interval at which an AP sends Beacon frames, in TUs. To configure this parameter, run the **beacon-interval** command.
Beamforming switch	Whether the beamforming function is enabled. To configure this parameter, run the **beamforming enable** command. This configuration takes effect only on APs running V200R019C00 or earlier.
Support short preamble	Whether the short preamble is supported. To configure this parameter, run the **short-preamble disable** command.
Fragmentation threshold(Byte)	Packet fragmentation threshold, in bytes. To configure this parameter, run the **fragmentation-threshold** command.
Channel switch announcement	Whether channel switch announcement is enabled. To configure this parameter, run the **channel-switch announcement disable** command.
Channel switch mode	Channel switch announcement mode. To configure this parameter, run the **channel-switch mode** command.
Guard interval mode	802.11n/ac GI mode. To configure this parameter, run the **guard-interval-mode** command.
802.11ax Guard interval mode	802.11ax/be GI mode. ● dot8: 0.8us ● 1dot6: 1.6us ● 3dot2: 3.2us To configure this parameter, run the **guard-interval-mode** command.

Item	Description
A-MPDU switch	Whether the MPDU aggregation function is enabled. To configure this parameter, run the **a-mpdu disable** command.
HT A-MPDU length limit	Maximum length of the aggregated MPDU frame. To configure this parameter, run the **ht a-mpdu max-length-exponent** command.
A-MSDU switch	Whether to enable the function of sending 802.11 packets in A-MSDU mode. To configure this parameter, run the **a-msdu enable** command.
RTS-CTS-mode	RTS/CTS mode. To configure this parameter, run the **rts-cts-mode** command.
RTS-CTS-threshold	RTS/CTS threshold. To configure this parameter, run the **rts-cts-threshold** command.
802.11bg basic rate	802.11bg basic rate set. To configure this parameter, run the **dot11bg basic-rate** command.
802.11bg support rate	802.11bg supported rate set. To configure this parameter, run the **dot11bg supported-rate** command.
Multicast rate 2.4G	Multicast rate of wireless packets on the 2.4 GHz radio. To configure this parameter, run the **multicast-rate** command.
Interference detect switch	Whether interference detection is enabled. To configure this parameter, run the **interference detect-enable** command.
Co-channel frequency interference threshold(%)	Alarm threshold for co-channel interference. To configure this parameter, run the **interference co-channel threshold** command.

Item	Description
Adjacent-channel frequency interference threshold(%)	Alarm threshold for adjacent-channel interference. To configure this parameter, run the **interference adjacent-channel threshold** command.
Station interference threshold	Alarm threshold for STA interference. To configure this parameter, run the **interference station threshold** command.
WMM switch	Whether the WMM function is enabled. To configure this parameter, run the **wmm disable** command.
Mandatory switch	Whether to allow STAs that do not support WMM to connect to a WMM-enabled AP. To configure this parameter, run the **wmm mandatory enable** command.
Auto-off start time	Start time for scheduled VAP auto-off. To configure this parameter, run the **auto-off service** command.
Auto-off end time	End time for scheduled VAP auto-off. To configure this parameter, run the **auto-off service** command.
Wifi-light mode	Information reflected by the blinking frequency of the Wireless LED. To configure this parameter, run the **wifi-light** command.
Rrm-profile	Name of the RRM profile referenced by a radio profile. To configure this parameter, run the **rrm-profile (radio profile view)** command.
Air-scan-profile	Name of the air scan profile referenced by a radio profile. To configure this parameter, run the **air-scan-profile (radio profile view)** command.

Item	Description
Smart-antenna	Status of the smart antenna function. To configure this parameter, run the **smart-antenna { enable | disable }** command.
Agile-antenna-polarization	Status of the self-adaptive polarization for agile antennas. To configure this parameter, run the **agile-antenna-polarization** command.
CCA threshold(dBm)	CCA threshold for APs. To configure this parameter, run the **cca-threshold** command.
RX sensitivity(dBm)	Receiver sensitivity threshold. To configure this parameter, run the **rx-sensitivity** command.
AGC high threshold(dBm)	Upper AGC threshold. To configure this parameter, run the **agc-threshold** command.
High PER threshold(%)	Upper valid PER threshold in the smart antenna algorithm. To configure this parameter, run the **smart-antenna valid-per-scope** command.
Low PER threshold(%)	Lower valid PER threshold in the smart antenna algorithm. To configure this parameter, run the **smart-antenna valid-per-scope** command.
Training interval(s)	Smart antenna training interval. To configure this parameter, run the **smart-antenna training-interval** command.
Training mpdu num	Number of MPDUs sent by an AP to STAs during smart antenna training. To configure this parameter, run the **smart-antenna training-mpdu-number** command.

Item	Description
Throughput trigger training threshold (%)	Sudden performance change threshold that triggers smart antenna training. To configure this parameter, run the **smart-antenna throughput-triggered-training** command.
VIP user bandwidth reservation ratio (%)	Percentage of bandwidth reserved for VIP users. To configure this parameter, run the **vip-user bandwidth reservation-ratio** command.
Legacy signal length compatible	Whether the L-SIG field length compatibility function of the 802.11n protocol is enabled. To configure the parameter, run the **dot11n legacy-signal-length-compatible enable** command.
RX STBC	Whether the STBC encoding function in the receive direction is enabled. To configure this parameter, run the **rx-stbc disable** command.
Fastpass users	Number of FastPass users. This parameter is valid only for DAPs. To configure this parameter, run the **fastpass users** command.
Fastpass period(ms)	FastPass scheduling period. This parameter is valid only for DAPs. To configure this parameter, run the **fastpass users** command.
Fastpass ratio(%)	Percentage of FastPass users in the scheduling period. This parameter is valid only for DAPs. To configure this parameter, run the **fastpass users** command.
Radio reload time-range	Time range during which radios are reloaded as scheduled. To configure this parameter, run the **radio-reload time-range** command.
Utmost power switch	Whether a radio is enabled to send packets at maximum power. To configure this parameter, run the **utmost-power** command.

Item	Description
AP EDCA parameters	EDCA parameters and ACK policy on an AP. To configure this parameter, run the **wmm edca-ap** command.
AC_VO	AC_VO packets. To configure this parameter, run the **wmm edca-ap** command.
AC_VI	AC_VI packets. To configure this parameter, run the **wmm edca-ap** command.
AC_BE	AC_BE packets. To configure this parameter, run the **wmm edca-ap** command.
AC_BK	AC_BK packets. To configure this parameter, run the **wmm edca-ap** command.
ECWmax	Exponent form of the maximum contention window. ECWmin and ECWmax determine the average backoff time. To configure this parameter, run the **wmm edca-ap** command.
ECWmin	Exponent form of the minimum contention window. ECWmin and ECWmax determine the average backoff time. To configure this parameter, run the **wmm edca-ap** command.
AIFSN	Arbitration inter frame spacing number (AIFSN), which determines the channel idle time. To configure this parameter, run the **wmm edca-ap** command.
TXOPLimit(32us)	Transmission opportunity limit (TXOPLimit), which determines the maximum duration in which a STA can occupy a channel. A larger value indicates a longer duration. To configure this parameter, run the **wmm edca-ap** command.

Item	Description
Ack-Policy	ACK policy. It includes: - **normal**: During 802.11 packet exchange, the receiver sends an ACK packet to confirm the receiving of a packet from the sender. - **noack**: The receiver sends no ACK packet to confirm the receiving of a packet from the sender. It applies to scenarios where communication quality is good and interference is low. To configure this parameter, run the **wmm edca-ap** command.

11.1.72 display radio-5g-profile

Function

The **display radio-5g-profile** command displays configuration and reference information about a 5G radio profile.

Format

display radio-5g-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays information about all 5G radio profiles.	-
name *profile-name*	Displays information about a specified 5G radio profile.	The 5G radio profile must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view configuration and reference information about a 5G radio profile.

Example

Display information about all 5G radio profiles.

```
<HUAWEI> display radio-5g-profile all
-------------------------------------------------------------------------
Profile name  Config Reference  Reference radios
-------------------------------------------------------------------------
default       10                4
-------------------------------------------------------------------------
Total: 1
```

Table 11-30 Description of the **display radio-5g-profile all** command output

Item	Description
Profile name	Name of a 5G radio profile.
Config Reference	Number of times a 5G radio profile is referenced.
Reference radios	Number of radios that reference a 5G radio profile.

Display information of the 5G radio profile **default**.

```
<HUAWEI> display radio-5g-profile name default
------------------------------------------------------------
Radio type                                 : 802.11ac
Power auto adjust                          : disable
Beacon interval(TUs)                       : 100
Beamforming switch                         : disable
Fragmentation threshold(Byte)              : 2346
Channel switch announcement                : enable
Channel switch mode                        : continue

```

Table 11-31 Description of the **display radio-5g-profile name** command output

Item	Description
Radio type	Radio type. To configure this parameter, run the **radio-type (5G radio profile view)** command.
Power auto adjust	Whether automatic per packet power adjustment is enabled. To configure this parameter, run the **power auto-adjust enable** command.
Beacon interval(TUs)	Interval at which an AP sends Beacon frames, in TUs. To configure this parameter, run the **beacon-interval** command.
Beamforming switch	Whether the beamforming function is enabled. To configure this parameter, run the **beamforming enable** command. This configuration takes effect only on APs running V200R019C00 or earlier.
Fragmentation threshold(Byte)	Packet fragmentation threshold, in bytes. To configure this parameter, run the **fragmentation-threshold** command.

Item	Description
Channel switch announcement	Whether channel switch announcement is enabled. To configure this parameter, run the **channel-switch announcement disable** command.
Channel switch mode	Channel switch announcement mode. To configure this parameter, run the **channel-switch mode** command.
Guard interval mode	802.11n/ac GI mode. To configure this parameter, run the **guard-interval-mode** command.
802.11ax guard interval mode	802.11ax/be GI mode. ● dot8: 0.8us ● 1dot6: 1.6us ● 3dot2: 3.2us To configure this parameter, run the **guard-interval-mode** command.
A-MPDU switch	Whether the MPDU aggregation function is enabled. To configure this parameter, run the **a-mpdu disable** command.
HT A-MPDU length limit	Maximum length of the aggregated MPDU frame. To configure this parameter, run the **ht a-mpdu max-length-exponent** command.
VHT A-MPDU length limit	Maximum length of the frame aggregated in A-MPDU mode. To configure this parameter, run the **vht a-mpdu max-length-exponent** command.
A-MSDU switch	Whether to enable the function of sending 802.11 packets in A-MSDU mode. To configure this parameter, run the **a-msdu enable** command.
VHT A-MSDU Max frame number	Maximum number of subframes that can be aggregated into an A-MSDU. To configure this parameter, run the **vht a-msdu max-frame-num** command.

Item	Description
RTS-CTS-mode	RTS/CTS mode. To configure this parameter, run the **rts-cts-mode** command.
RTS-CTS-threshold	RTS/CTS threshold. To configure this parameter, run the **rts-cts-threshold** command.
802.11a basic rate	802.11a basic rate set. To configure this parameter, run the **dot11a basic-rate** command.
802.11a support rate	802.11a supported rate set. To configure this parameter, run the **dot11a supported-rate** command.
Multicast rate 5G	Multicast rate of wireless packets on the 5 GHz radio. To configure this parameter, run the **multicast-rate** command.
VHT mcs	Maximum MCS value corresponding to a specific number of 802.11ac spatial streams. To configure this parameter, run the **vht mcs-map** command.
Interference detect switch	Whether interference detection is enabled. To configure this parameter, run the **interference detect-enable** command.
Co-channel frequency interference threshold(%)	Alarm threshold for co-channel interference. To configure this parameter, run the **interference co-channel threshold** command.
Adjacent-channel frequency interference threshold(%)	Alarm threshold for adjacent-channel interference. To configure this parameter, run the **interference adjacent-channel threshold** command.
Station interference threshold	Alarm threshold for STA interference. To configure this parameter, run the **interference station threshold** command.

Item	Description
WMM switch	Whether the WMM function is enabled. To configure this parameter, run the **wmm disable** command.
Mandatory switch	Whether to allow STAs that do not support WMM to connect to a WMM-enabled AP. To configure this parameter, run the **wmm mandatory enable** command.
Auto-off start time	Start time for scheduled VAP auto-off. To configure this parameter, run the **auto-off service** command.
Auto-off end time	End time for scheduled VAP auto-off. To configure this parameter, run the **auto-off service** command.
WiFi-light mode	Information reflected by the blinking frequency of the Wireless LED. To configure this parameter, run the **wifi-light** command.
Rrm-profile	Name of the RRM profile referenced by a radio profile. To configure this parameter, run the **rrm-profile (radio profile view)** command.
Air-scan-profile	Name of the air scan profile referenced by a radio profile. To configure this parameter, run the **air-scan-profile (radio profile view)** command.
Utmost power switch	Whether a radio is enabled to send packets at maximum power. To configure this parameter, run the **utmost-power** command.
Smart-antenna	Status of the smart antenna function. To configure this parameter, run the **smart-antenna { enable | disable }** command.

Item	Description
Agile-antenna-polarization	Status of the self-adaptive polarization for agile antennas. To configure this parameter, run the **agile-antenna-polarization** command.
CCA threshold(dBm)	CCA threshold for APs. To configure this parameter, run the **cca-threshold** command.
RX sensitivity(dBm)	Receiver sensitivity threshold. To configure this parameter, run the **rx-sensitivity** command.
AGC high threshold(dBm)	Upper AGC threshold. To configure this parameter, run the **agc-threshold** command.
High PER threshold(%)	Upper valid PER threshold in the smart antenna algorithm. To configure this parameter, run the **smart-antenna valid-per-scope** command.
Low PER threshold(%)	Lower valid PER threshold in the smart antenna algorithm. To configure this parameter, run the **smart-antenna valid-per-scope** command.
Training interval(s)	Smart antenna training interval. To configure this parameter, run the **smart-antenna training-interval** command.
Training mpdu num	Number of MPDUs sent by an AP to STAs during smart antenna training. To configure this parameter, run the **smart-antenna training-mpdu-number** command.
Throughput trigger training threshold (%)	Sudden performance change threshold that triggers smart antenna training. To configure this parameter, run the **smart-antenna throughput-triggered-training** command.

Item	Description
VIP user bandwidth reservation ratio (%)	Percentage of bandwidth reserved for VIP users. To configure this parameter, run the **vip-user bandwidth reservation-ratio** command.
Legacy signal length compatible	Whether the L-SIG field length compatibility function of the 802.11n protocol is enabled. To configure the parameter, run the **dot11n legacy-signal-length-compatible enable** command.
RX STBC	Whether the STBC encoding function in the receive direction is enabled. To configure this parameter, run the **rx-stbc disable** command.
Radio reload time-range	Time range during which radios are reloaded as scheduled. To configure this parameter, run the **radio-reload time-range** command.
DFS radar-filter sensitivity	Sensitivity level of correction for false radar detection. To configure this parameter, run the **dfs radar-filter sensitivity** command.
AP EDCA parameters	EDCA parameters and ACK policy on an AP. To configure this parameter, run the **wmm edca-ap** command.
AC_VO	AC_VO packets. To configure this parameter, run the **wmm edca-ap** command.
AC_VI	AC_VI packets. To configure this parameter, run the **wmm edca-ap** command.
AC_BE	AC_BE packets. To configure this parameter, run the **wmm edca-ap** command.
AC_BK	AC_BK packets. To configure this parameter, run the **wmm edca-ap** command.

Item	Description
ECWmax	Exponent form of the maximum contention window. ECWmin and ECWmax determine the average backoff time. To configure this parameter, run the **wmm edca-ap** command.
ECWmin	Exponent form of the minimum contention window. ECWmin and ECWmax determine the average backoff time. To configure this parameter, run the **wmm edca-ap** command.
AIFSN	Arbitration inter frame spacing number (AIFSN), which determines the channel idle time. To configure this parameter, run the **wmm edca-ap** command.
TXOPLimit(32us)	Transmission opportunity limit (TXOPLimit), which determines the maximum duration in which a STA can occupy a channel. A larger value indicates a longer duration. To configure this parameter, run the **wmm edca-ap** command.
Ack-Policy	ACK policy. It includes: ● **normal**: During 802.11 packet exchange, the receiver sends an ACK packet to confirm the receiving of a packet from the sender. ● **noack**: The receiver sends no ACK packet to confirm the receiving of a packet from the sender. It applies to scenarios where communication quality is good and interference is low. To configure this parameter, run the **wmm edca-ap** command.

11.1.73 display references radio-2g-profile

Function

The **display references radio-2g-profile** command displays reference information about a 2G radio profile.

Format

display references radio-2g-profile name *profile-name*

Parameters

Parameter	Description	Value
name *profile-name*	Displays reference information about a specified 2G radio profile.	The 2G radio profile must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display references radio-2g-profile** command to view reference information about a 2G radio profile.

Example

Display reference information about the 2G radio profile **default**.

```
<HUAWEI> display references radio-2g-profile name default
----------------------------------------------------------------------
Reference type  Reference name                Reference radio
----------------------------------------------------------------------
AP-group        ap-group1                     Radio-0
----------------------------------------------------------------------
Total:1
```

Table 11-32 Description of the **display references radio-2g-profile** command output

Item	Description
Reference type	Type of the profile by which a 2G radio profile is referenced.
Reference name	Name of the profile by which a 2G radio profile is referenced.
Reference radio	Radio to which a 2G radio profile is referenced.

11.1.74 display references radio-5g-profile

Function

The **display references radio-5g-profile** command displays reference information about a 5G radio profile.

Format

display references radio-5g-profile name *profile-name*

Parameters

Parameter	Description	Value
name *profile-name*	Displays reference information about a specified 5G radio profile.	The 5G radio profile must exist.

Views

All views

Default Level

Usage Guidelines

You can run the **display references radio-5g-profile** command to view reference information about a 5G radio profile.

Example

Display reference information about the 5G radio profile **default**.

```
<HUAWEI> display references radio-5g-profile name default
---------------------------------------------------------------------
Reference type  Reference name                  Reference radio
---------------------------------------------------------------------
AP-group        ap-group1                       Radio-0
---------------------------------------------------------------------
Total:1
```

Table 11-33 Description of the **display references radio-5g-profile** command output

Item	Description
Reference type	Type of the profile by which a 5G radio profile is referenced.

Item	Description
Reference name	Name of the profile by which a 5G radio profile is referenced.
Reference radio	Radio to which a 5G radio profile is referenced.

11.1.75 display references regulatory-domain-profile

Function

The **display references regulatory-domain-profile** command displays reference information about a regulatory domain profile.

Format

display references regulatory-domain-profile name *profile-name*

Parameters

Parameter	Description	Value
name *profile-name*	Displays reference information about a specified regulatory domain profile.	The regulatory domain profile must exist.

Views

All views

Default Level

Usage Guidelines

You can run the **display references regulatory-domain-profile** command to view reference information about a regulatory domain profile.

Example

Display reference information about the regulatory domain profile **default**.

```
<HUAWEI> display references regulatory-domain-profile name default
------------------------------------------------------------
Reference type           Reference name
------------------------------------------------------------
AP-group                default
AP-group                1
```

```
------------------------------------------------------------
Total: 2
```

Table 11-34 Description of the **display references regulatory-domain-profile** command output

Item	Description
Reference type	Type of the profile by which a regulatory domain profile is referenced.
Reference name	Name of the profile by which a regulatory domain profile is referenced.

11.1.76 display references softgre-profile

Function

The **display references softgre-profile** command displays reference information about a soft GRE profile.

Format

display references softgre-profile name *profile-name*

Parameters

Parameter	Description	Value
name *profile-name*	Displays reference information about a specified soft GRE profile.	The specified soft GRE profile must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view reference information about a soft GRE profile.

Example

Display reference information about the soft GRE profile **soft1**.

```
<HUAWEI> display references softgre-profile name soft1
------------------------------------------------------------------------
Reference type              Reference name
------------------------------------------------------------------------
VAP profile                 vap1
------------------------------------------------------------------------
Total: 1
```

Item	Description
Reference type	Type of the profile by which a soft GRE profile is referenced.
Reference name	Name of the profile by which a soft GRE profile is referenced.

11.1.77 display references ssid-profile

Function

The **display references ssid-profile** command displays reference information about an SSID profile.

Format

display references ssid-profile name *profile-name*

Parameters

Parameter	Description	Value
name *profile-name*	Displays reference information about a specified SSID profile.	The SSID profile must exist.

Views

```
<HUAWEI> display references vap-profile name default
------------------------------------------------------------------------------
Reference type     Reference name                     Reference radio  WLAN ID
------------------------------------------------------------------------------
AP group          group1                        Radio-0          1
------------------------------------------------------------------------------
Total: 1
```

Table 11-37 Description of the **display references vap-profile** command output

Item	Description
Reference type	Type of the profile by which a VAP profile is referenced.
Reference name	Name of the profile by which a VAP profile is referenced.
Reference radio	AP radio by which a VAP profile is referenced.
WLAN ID	WLAN ID of a VAP.

11.1.79 display references vlan pool

Function

The **display references vlan pool** command displays reference information about a VLAN pool.

Format

display references vlan pool *pool-name*

Parameters

Parameter	Description	Value
pool-name	Displays reference information about a specified VLAN pool.	The VLAN pool must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view profiles that reference a VLAN pool.

Example

Display reference information about the VLAN pool **pool1**.

```
<HUAWEI> display references vlan pool pool1
--------------------------------------------------------------------------------
Reference type   Reference name                    Reference radio  WLAN ID
--------------------------------------------------------------------------------
AP group         default                           Radio-0          1
AP group         default                           Radio-1          1
AP group         default                           Radio-2          1
AP group         default                           Radio-0          2
AP group         default                           Radio-1          2
AP group         default                           Radio-2          2
AP ID            0                                 Radio-0          2
AP ID            0                                 Radio-1          2
VAP profile      1
user group       123
--------------------------------------------------------------------------------
Total: 10
```

Table 11-38 Description of the **display references vlan pool** command output

Item	Description
Reference type	Type of a profile that references a VLAN pool.
Reference name	Name of a profile that references a VLAN pool.
Reference radio	Radio that references a VLAN pool. This item is displayed only when a VLAN pool is configured as the service VLAN for a VAP profile applied in the AP group radio view or AP radio view.
WLAN ID	WLAN ID that references a VLAN pool. This item is displayed only when a VLAN pool is configured as the service VLAN for a VAP profile applied in the AP group radio view or AP radio view.

11.1.80 display regulatory-domain-profile

Function

The **display regulatory-domain-profile** command displays configuration and reference information about a regulatory domain profile.

Format

display regulatory-domain-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays information about all regulatory domain profiles.	-
name *profile-name*	Displays information about a specified regulatory domain profile.	The regulatory domain profile must exist.

Views

1: Monitoring level

Usage Guidelines

You can run the **display regulatory-domain-profile** command to view configuration and reference information about a regulatory domain profile.

Example

Display information about all regulatory profiles.

```
<HUAWEI> display regulatory-domain-profile all
------------------------------------------------------------
Profile name        Reference
------------------------------------------------------------
default             6
------------------------------------------------------------
Total: 1
```

Table 11-39 Description of the **display regulatory-domain-profile all** command output

Item	Description
Profile name	Regulatory domain profile name.
Reference	Number of times a regulatory domain profile is referenced.

Display information about the regulatory domain profile **default**.

```
<HUAWEI> display regulatory-domain-profile name default
------------------------------------------------------------
```

```
Profile name           : default
Country code           : CN
2.4G dca channel-set  : 1,6,11
5G dca bandwidth       : 20mhz
5G dca channel-set    : 149,153,157,161,165
6G dca bandwidth       : 20mhz
6G dca channel-set    : -
Wideband switch       : enable
Channel load mode     : outdoor
------------------------------------------------------------
```

Table 11-40 Description of the **display regulatory-domain-profile name** command output

Item	Description
Profile name	Regulatory domain profile name.
Country code	Country code. To configure the parameter, run the **country-code** command.
2.4G dca channel-set	2.4G radio calibration channel set. To configure the parameter, run the **dca-channel channel-set** command.
5G dca bandwidth	5G radio calibration bandwidth. To configure the parameter, run the **dca-channel bandwidth** command.
5G dca channel-set	5G radio calibration channel set. To configure the parameter, run the **dca-channel channel-set** command.
6G dca bandwidth	6G radio calibration bandwidth. To configure the parameter, run the **dca-channel bandwidth** command.
6G dca channel-set	6G radio calibration channel set. To configure the parameter, run the **dca-channel channel-set** command.
Wideband switch	Indicates whether the wideband function, that is, the 4.9 GHz frequency band, of the regulatory domain profile is enabled. ● enable: The wideband function is enabled. ● disable: The wideband function is disabled. To configure this parameter, run the **wideband enable** command.

Item	Description
Channel load mode	Channel load mode. ● outdoor: outdoor mode ● indoor: indoor mode To configure this parameter, run the **channel-load-mode indoor** command.

11.1.81 display softgre-profile

Function

The **display softgre-profile** command displays configuration and reference information about a soft GRE profile.

Format

display softgre-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays information about all soft GRE profiles.	-
name *profile-name*	Displays information about a specified soft GRE profile.	The specified soft GRE profile must exist.

Usage Guidelines

You can run this command to check configuration and reference information about soft GRE profiles.

Example

Display information about all soft GRE profiles.

```
<HUAWEI> display softgre-profile all
--------------------------------------------------------------------------------
Profile name                     Reference     IP address
--------------------------------------------------------------------------------
soft1                          0              10.10.1.1
--------------------------------------------------------------------------------
Total: 1
```

Table 11-41 Description of the **display softgre-profile all** command output

Item	Description
Profile name	Name of a soft GRE profile.
Reference	Number of times a soft GRE profile is referenced.
IP address	Tunnel destination address configured in the soft GRE profile.

Display information about the soft GRE profile **soft1**.

```
<HUAWEI> display softgre-profile name soft1
------------------------------------------------------------------------
Destination IP-address : 10.10.1.1
Keepalive               : enable
Keepalive period        : 5(s)
Keepalive retry-times  : 3
Untagged VLAN           : 101
------------------------------------------------------------------------
```

Table 11-42 Description of the **display softgre-profile name** command output

Item	Description
Destination IP-address	Destination IP address of the soft GRE tunnel. To configure this parameter, run the **destination (soft GRE profile view)** command.
Keepalive	Whether Keepalive detection is enabled for the soft GRE tunnel. To configure this parameter, run the **keepalive** command.
Keepalive period	Interval for sending Keepalive packets. To configure this parameter, run the **keepalive period** *period* command.
Keepalive retry-times	Unreachable counter. To configure this parameter, run the **keepalive period** *period* **retry-times** *retry-times* command.

Item	Description
Untagged VLAN	VLAN tag removed from the soft GRE tunnel packets sent by an AP. To configure this parameter, run the **untagged vlan (soft GRE profile view)** command.

11.1.82 display softgre-tunnel-status

Function

The **display softgre-tunnel-status** command displays soft GRE tunnel information on a specified AP.

Format

display softgre-tunnel-status { **ap-name** *ap-name* | **ap-id** *ap-id* }

Parameters

Parameter	Description	Value
ap-name *ap-name*	Displays soft GRE tunnel information on the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Displays soft GRE tunnel information on the AP with a specified ID.	The AP ID must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check the soft GRE tunnel status and Keepalive information.

Example

Display soft GRE tunnel information on the AP named **area_1**.

```
<HUAWEI> display softgre-tunnel-status ap-name area_1
----------------------------------------------------------------------------------------------------
Destination IP-address              Status      Keepalive    Request     Response
----------------------------------------------------------------------------------------------------
```

```
10.10.1.1                          UP          enable        1           0
------------------------------------------------------------------------------------------------------
```

Table 11-43 Description of the **display softgre-tunnel-status** command output

Item	Description
Destination IP-address	Destination IP address of the soft GRE tunnel. To configure this parameter, run the **destination (soft GRE profile view)** command.
Status	Status of a soft GRE tunnel. ● DOWN: When Keepalive detection is enabled, the device detects that the peer end is unreachable and sets the soft GRE tunnel status to **DOWN**. ● UP: When Keepalive detection is disabled or Keepalive detection is enabled and the peer is reachable, the device sets the soft GRE tunnel status to **UP**.
Keepalive	Whether Keepalive detection is enabled for the soft GRE tunnel. To configure this parameter, run the **keepalive (soft GRE profile view)** command.
Request	Number of Keepalive request packets sent by the AP.
Response	Number of Keepalive response packets received by the AP.

11.1.83 display ssid-profile

Function

The **display ssid-profile** command displays configuration and reference information about SSID profiles.

Format

display ssid-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays information about all SSID profiles.	-
name *profile-name*	Displays information about a specified SSID profile.	The SSID profile must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ssid-profile** command to view configuration and reference information about SSID profiles.

Example

Display information about all SSID profiles.

```
<HUAWEI> display ssid-profile all
------------------------------------------------------------------
Profile name  Beacon 2.4G/5G/6G rate(Mbps)  Reference  SSID
------------------------------------------------------------------
default       1/6                           2          GUEST-WLAN
------------------------------------------------------------------
Total: 1
```

Table 11-44 Description of the **display ssid-profile all** command output

Item	Description
Profile name	SSID profile name.
Beacon 2.4G/5G/6G rate(Mbps)	Rate of management frames on each frequency band.
Reference	Number of times an SSID profile is referenced.
SSID	SSID name.

Display information about the SSID profile **default**.

```
<HUAWEI> display ssid-profile name default
------------------------------------------------------------------
Profile ID                    : 0
```

```
SSID                                  : GUEST-WLAN

```

Table 11-45 Description of the **display ssid-profile name** command output

Item	Description
Profile ID	ID of an SSID profile.
SSID	SSID name. To configure this parameter, run the **ssid** command.
SSID hide	SSID hiding. To configure this parameter, run the **ssid-hide enable** command.
Association timeout(min)	Association timeout period. To configure this parameter, run the **association-timeout** command.
Max STA number	Maximum number of users. To configure this parameter, run the **max-sta-number (SSID profile view)** command.
Action upon reaching the max STA number	Action to take when the number of access users reaches the maximum. ● SSID hide: hiding the SSID ● SSID broadcast: broadcasting the SSID ● priority-based STA replacement: allowing access of VIP users instead of non-VIP users based on priorities To configure this parameter, run the **reach-max-sta** command.
Legacy station	Whether to permit access of non-HT STAs. To configure this parameter, run the **legacy-station disable** command.
DTIM interval	DTIM interval. To configure this parameter, run the **dtim-interval** command.
Beacon 2.4G rate(Mbps)	Rate at which 2.4 GHz management frames are sent. To configure this parameter, run the **beacon-2g-rate** command.
Beacon 5G rate(Mbps)	Rate at which 5 GHz management frames are sent. To configure this parameter, run the **beacon-5g-rate** command.

Item	Description
Beacon 6G rate(Mbps)	Rate at which 6 GHz management frames are sent. To configure this parameter, run the **beacon-6g-rate** command
802.11bg basic rate	802.11b/g basic rate set. If no information is displayed, no configuration is available and the configuration in the radio profile takes effect. To configure this parameter, run the **dot11bg basic-rate** (SSID profile view) command.
802.11bg support rate	802.11b/g supported rate set. If no information is displayed, no configuration is available and the configuration in the radio profile takes effect. To configure this parameter, run the **dot11bg supported-rate** (SSID profile view) command.
802.11a basic rate	802.11a basic rate set. If no information is displayed, no configuration is available and the configuration in the radio profile takes effect. To configure this parameter, run the **dot11a basic-rate** (SSID profile view) command.
802.11a support rate	802.11a supported rate set. If no information is displayed, no configuration is available and the configuration in the radio profile takes effect. To configure this parameter, run the **dot11a supported-rate** (SSID profile view) command.
Deny-broadcast-probe	Whether an AP is configured not to respond to broadcast Probe Request frames. To configure this parameter, run the **deny-broadcast-probe enable** command.

Item	Description
Probe-response-retry num	Number of times Probe Response packets are retransmitted. To configure this parameter, run the **probe-response-retry** command.
802.11r	802.11r roaming. To configure this parameter, run the **dot11r enable** command.
802.11r authentication	802.11r authentication mode. To configure this parameter, run the **dot11r enable** command.
802.11r proprietary	Whether Huawei's proprietary 802.11r function is enabled. To configure this parameter, run the **dot11r proprietary** command.
802.11r reassociation timeout (s)	802.11r reassociation timeout interval. To configure this parameter, run the **dot11r reassociate-timeout** command.
QOS CAR inbound CIR(kbit/s)	CIR in the QoS CAR profile applied to the inbound direction of an interface, which is the allowed rate at which traffic can pass through. To configure this parameter, run the **qos car (SSID profile view)** command.
QOS CAR inbound PIR(kbit/s)	PIR in the QoS CAR profile applied to the inbound direction of an interface, which is the maximum rate of traffic that can pass through an interface. To configure this parameter, run the **qos car (SSID profile view)** command.
QOS CAR inbound CBS(byte)	CBS in the QoS CAR profile applied to the inbound direction of an interface, which is the average volume of burst traffic that can pass through an interface. To configure this parameter, run the **qos car (SSID profile view)** command.

Item	Description
QOS CAR inbound PBS(byte)	PBS in the QoS CAR profile applied to the inbound direction of an interface, which is the maximum volume of burst traffic that can pass through an interface. To configure this parameter, run the **qos car (SSID profile view)** command.
U-APSD	Whether the U-APSD function is enabled. To configure this parameter, run the **u-apsd enable** command.
Active dull client	Whether the function of preventing terminals from entering energy-saving mode is enabled. To configure this parameter, run the **active-dull-client enable** command.
Force active dull client	Whether the function of forcibly preventing terminals from entering power-saving mode is enabled. To configure this parameter, run the **active-dull-client force enable** command.
MU-MIMO	Whether downlink MU-MIMO scheduling is enabled. To configure this parameter, run the **mu-mimo disable** command.
MU-MIMO optimize	Whether the MU-MIMO optimization function is enabled. To configure this parameter, run the **mu-mimo optimize enable** command.
TWT switch	Whether the TWT function is enabled. To configure this parameter, run the **twt enable** command.
QBSS load	Whether the QBSS load function is enabled. To configure this parameter, run the **qbss-load enable** command.

Item	Description
Single txchain	Whether to enable the single-antenna transmission mode. To configure this parameter, run the **single-txchain enable** command.
Advertise AP name	Whether Beacon frames are enabled to carry the AP name. To configure this parameter, run the **advertise-ap-name enable** command.
Service guarantee	Service guarantee mode. To configure this parameter, run the **service-guarantee** command.
Inter-AC roam switch	Whether inter-AC roaming is enabled. To configure this parameter, run the **inter-ac roam disable** command.
Game-turbo switch	Whether the game turbo function is enabled. To configure this parameter, run the **game-turbo disable** command.
VHT tx mcs-map nss value	Maximum number of spatial streams sent in 802.11ac. To configure this parameter, run the **vht mcs-map (SSID profile view)** command.
VHT tx mcs-map map value	Maximum MCS value of spatial streams sent in 802.11ac. To configure this parameter, run the **vht mcs-map (SSID profile view)** command.
VHT rx mcs-map nss value	Maximum number of spatial streams received in 802.11ac. To configure this parameter, run the **vht mcs-map (SSID profile view)** command.
VHT rx mcs-map map value	Maximum MCS value of spatial streams received in 802.11ac. To configure this parameter, run the **vht mcs-map (SSID profile view)** command.

Item	Description
HE tx mcs-map nss value	Maximum number of spatial streams sent in 802.11ax. To configure this parameter, run the **he mcs-map (SSID profile view)** command.
HE tx mcs-map map value	Maximum MCS value of spatial streams sent in 802.11ax. To configure this parameter, run the **he mcs-map (SSID profile view)** command.
HE rx mcs-map nss value	Maximum number of spatial streams received in 802.11ax. To configure this parameter, run the **he mcs-map (SSID profile view)** command.
HE rx mcs-map map value	Maximum MCS value of spatial streams received in 802.11ax. To configure this parameter, run the **he mcs-map (SSID profile view)** command.
Beamforming switch	Whether the beamforming function is enabled. To configure this parameter, run the **beamforming disable** command. This configuration takes effect only on APs running V200R019C10 or later.
OFDMA downlink switch	Whether downlink OFDMA is enabled. To configure this parameter, run the **ofdma downlink disable** command.
OFDMA uplink switch	Whether uplink OFDMA is enabled. To configure this parameter, run the **ofdma uplink disable** command.
ER-SU	Whether the extended-range single-user (ER SU) function is enabled. To configure this parameter, run the **er-su disable** command.
WMM EDCA client parameters	WMM parameters for STAs. To configure this parameter, run the **wmm edca-client (SSID profile view)** command.
AC_VO	AC_VO packets.

Item	Description
AC_VI	AC_VI packets.
AC_BE	AC_BE packets.
AC_BK	AC_BK packets.
ECWmax	Exponent form of the maximum contention window. ECWmin and ECWmax determine the average backoff time.
ECWmin	Exponent form of the minimum contention window. ECWmin and ECWmax determine the average backoff time.
AIFSN	Arbitration inter frame spacing number (AIFSN), which determines the channel idle time.
TXOPLimit(32us)	Transmission opportunity limit (TXOPLimit), which determines the maximum duration in which a STA can occupy a channel. A larger value indicates a longer duration.
WMM MUEDCA client parameters	MU EDCA parameters for STAs. To configure this parameter, run the **wmm mu-edca-client (SSID profile view)** command.
MUEDCA Timer(8TUs)	MU EDCA timer, which indicates the validity duration of MU EDCA parameters. When the timer is 0, the conventional EDCA parameters take effect.

11.1.84 display sta-offline-delay configuration

Function

The **display sta-offline-delay configuration** command displays the STA offline delay configuration.

Format

display sta-offline-delay configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view the STA offline delay configuration.

Example

Display the STA offline delay configuration.

```
<HUAWEI> display sta-offline-delay configuration
------------------------------------------------------------------------------
Enable switch                    : disable
Aging time(s)                    : 180
Full station reject switch         : disable
Max number                        : 2048
------------------------------------------------------------------------------
```

Table 11-46 Description of the **display sta-offline-delay configuration** command output

Item	Description
Enable switch	Whether to enable the STA offline delay function. To configure the parameter, run the **sta-offline-delay enable** command.
Aging time(s)	Aging time of the STA offline delay state To configure the parameter, run the **sta-offline-delay aging-time** command.
Full station reject switch	Whether to force STAs in offline delay state to go offline and allow new STAs to go online after the number of STAs reaches the maximum. To configure the parameter, run the **sta-offline-delay full-sta-reject enable** command.
Max number	Maximum number of STAs that are allowed to delay going offline. To configure the parameter, run the **sta-offline-delay max-number** command.

11.1.85 display station

Function

The **display station** command displays access information about STAs.

Format

display station { **ap-group** *ap-group-name* | **ap-name** *ap-name* | **ap-id** *ap-id* | **ssid** *ssid* | **sta-mac** *sta-mac-address* | **vlan** *vlan-id* | **all** }

Parameters

Parameter	Description	Value
ap-group *ap-group-name*	Displays STA access information about a specified AP group.	The AP group must exist.
ap-name *ap-name*	Displays STA access information about the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Displays STA access information about the AP with a specified ID.	The AP ID must exist.
ssid *ssid*	Displays STA access information about a specified SSID.	The SSID must exist. To specify an SSID starting with a space, include the SSID with double quotation marks (" "). For example, in the SSID **" hello"**, the double quotation marks at the start and end of the SSID occupy two characters. To specify an SSID starting with a double quotation mark ("), enter an escape character (\) before the double quotation mark. For example, in the SSID **\"hello**, the escape character (\) occupies one character.

Parameter	Description	Value
sta-mac *sta-mac-address*	Displays access information about a STA with the specified MAC address.	The STA's MAC address must exist. STA information can be displayed only when the AP associated with the STA is in normal state.
vlan *vlan-id*	Displays STA access information about a specified VLAN.	-
all	Displays access information about all STAs.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display station** command to view access information about STAs. You can run the **display access-user** command to view access information about online wired and wireless users. The information includes users' authentication, authorization, and accounting information.

Capabilities of a STA displayed in the **display station sta-mac** *sta-mac-address* command output are negotiated between the STA and AP and are affected by both their capabilities, which may be different from the actual STA capabilities.

Example

Display access information about all STAs.

```
<HUAWEI> display station all
Rf/WLAN: Radio ID/WLAN ID
Rx/Tx: link receive rate/link transmit rate(Mbps)
-------------------------------------------------------------------------------------------------------------------
STA MAC          AP ID Ap name        Rf/WLAN  Band  Type  Rx/Tx      RSSI  VLAN  IP address    SSID
Status
-------------------------------------------------------------------------------------------------------------------
00e0-fc12-3456   0     00e0-fc07-6f80 0/2      2.4G  11n   3/8        -70   10    10.10.10.253  tap1      Normal
-------------------------------------------------------------------------------------------------------------------
Total: 1 2.4G: 1 5G: 0 6G: 0
```

Table 11-47 Description of the **display station all** command output

Item	Description
STA MAC	MAC address of a STA.
AP ID	AP ID.
Ap name	AP name.
Rf/WLAN	Radio ID/VAP ID.
Band	Frequency band of a radio.
Type	Protocol type of a radio.
Rx/Tx	Rate at which the AP receives packets from the STA/Rate at which the AP sends packets to the STA.
RSSI	RSSI of signals received by an AP from a STA.
VLAN	VLAN ID of a STA.
IP address	IP address of a STA.
SSID	SSID name.
Status	Status of a STA. **Normal** indicates that the STA is in normal state, and **Delay** indicates that the STA is in offline delay state. This item is displayed only when the STA offline delay function is enabled. To enable the STA offline delay function, run the **sta-offline-delay enable** command.

Display access information about a specified STA.

```
<HUAWEI> display station sta-mac 00e0-fcb4-2689

Table 11-48 Description of the **display station sta-mac** *sta-mac-address* command output

Item	Description
Station MAC-address	MAC address of a STA.
Station IP-address	IP address of a STA.
Station gateway	Gateway address of a STA. **NOTE** If the device obtains the STA's gateway address through DHCP, the parameter displays as the obtained gateway address; otherwise, the parameter displays as 0.0.0.0.
Associated SSID	SSID of a service set with which a STA is associated.
Station online time(ddd:hh:mm:ss)	Online duration of a STA, in the format of ddd:hh:mm:ss.
The upstream SNR(dB)	SNR of a STA received by an AP, in dB.
The upstream aggregate receive power(dBm)	Transmit power of a STA received by an AP, in dBm.
Station connect rate(Mbps)	Connection rate of a STA, in Mbit/s. Affected by wireless environments, antenna angles, and other factors, the actual connection rate of a STA cannot reach the upper limit.
Station connect channel	Channel used by a STA.
Station inactivity time(ddd:hh:mm:ss)	Idle duration of a STA, in the format of ddd:hh:mm:ss.
Station current state	Current status of a STA.
Authorized for data transfer	Whether a STA is authenticated.
QoS enabled	Whether QoS is enabled on a STA.
HT rates enabled	Whether 802.11n is enabled on a STA.
Power save mode enabled	Whether the power saving mode is enabled on a STA.

Item	Description
Auth reference held	Whether the authentication reference flag is set.
UAPSD enabled	Whether UAPSD is enabled.
UAPSD triggerable	UAPSD can be triggered, waiting for a STA to send a trigger frame to the AP.
UAPSD SP in progress	Whether the UAPSD mode is in the service period (SP).
This is an ATH node	Whether the wireless network adapter uses the Atheros chip.
WDS workaround req	Whether the AP uses a patch used to fix bugs of Atheros Owl series chips in WDS scenarios. This item indicates whether the AP uses the patch.
WDS link	STA that is a node on the WDS link.
PMF negotiation	Whether a STA implements the PMF negotiation.
Station's HT capability	HT capability of a STA. ● A: Advanced coding ● W: HT40 channel width ● P: MIMO power save disabled ● Q: Static MIMO power save ● R: Dynamic MIMO power save ● G: Greenfield preamble ● S: Short GI enabled (HT40) ● D: Delayed block ACK ● M: Max A-MSDU size
Station capabilities	Capabilities of a STA. ● E: ESS ● I: IBSS ● c: CF Pollable ● C: CF-Poll Request ● P: Privacy ● S: Short Preamble ● B: PBCC ● A: Channel Agility ● s: Short Slot Time ● D: DSSS-OFDM

Item	Description
Station PMF capabilities	PMF capability of a STA. **PMFC** indicates whether the optional mode is used, and **PMFR** indicates whether the mandatory mode is used. - PMFC=0,PMFR=0: PMF is not supported. - PMFC=1,PMFR=0: PMF in optional mode is used. - PMFC=1,PMFR=1: PMF in mandatory mode is used.
Station VHT capabilities	Whether a STA supports 802.11ac.
256QAM capabilities	Whether a STA supports 256-QAM.
VHT explicit beamforming capabilities	Whether a STA supports 802.11ac explicit beamforming.
MU-MIMO capabilities	Whether a STA supports MU-MIMO.
Station HE capabilities	Whether a STA supports 802.11ax.
OFDMA capabilities	Whether a STA supports OFDMA.
BSS color capabilities	Whether a STA supports BSS Color.
OFDMA RA capabilities	Whether a STA supports OFDMA RA.
TRS capabilities	Whether a STA can receive frames with the TRS field.
BSR capabilities	Whether a STA can receive frames with the BSR field.
DL MU-MIMO partialband capabilities	Whether a STA supports partial-bandwidth downlink MU-MIMO.
UL MU-MIMO fullband capabilities	Whether a STA supports full-bandwidth uplink MU-MIMO.
UL MU-MIMO partialband capabilities	Whether a STA supports partial-bandwidth uplink MU-MIMO.
Dynamic SMPS capabilities	Whether a STA supports Spatial Multiplexing Power Save (SMPS).
HE SU beamformee capabilities	Whether a STA supports HE beamforming.
Station's RM capabilities	Radio management capability of a STA.
Neighbor Report	Whether a STA can obtain information about neighboring APs.

Item	Description
Beacon Passive Measurement	Whether a STA can report information about neighboring APs in passive mode.
Beacon Active Measurement	Whether a STA can report information about neighboring APs in active mode.
Beacon Table Measurement	Whether a STA can report information about neighboring APs in Beacon table mode.
Link Measurement	Whether a STA supports link measurement. ● Yes: supported ● No: not supported
Transmit Power Adaptation	Whether a STA supports TPC. ● Yes: supported ● No: not supported
Station EHT capabilities	802.11be radio management capability of a STA.
MRU capabilities	Whether a STA supports MRU.
BE SU beamformee capabilities	Whether a STA supports SU beamformee.
DL MU-MIMO Partial Bandwidth	Whether a STA supports downlink MU-MIMO.
UL MU-MIMO Partial Bandwidth	Whether a STA supports uplink MU-MIMO.
MLO capabilities	Whether a STA supports MLO.
Station's RSSI(dBm)	RSSI of signals received by an AP from a STA, in dBm.
Station's radio mode	Radio mode of a STA.
Station's AP ID	AP ID associated with a STA.
Station's AP Name	Name of the AP which a STA associates with.
Station's ORU ID	ID of the ORU associated with a STA in a distributed AP scenario. Particularly, if the STA associates with the 2.4 GHz radio, two ORU IDs are displayed, with one of which the STA actually associates.
Station's Radio ID	Radio ID of a STA.

Item	Description
Station's Authentication Method	Authentication mode of a STA.
Station's Cipher Type	Encryption mode of a STA.
Station's User Name	User name of a STA.
Station's Vlan ID	VLAN ID of a STA.
Station's Channel Band-width	Channel bandwidth of a STA.
Station's asso BSSID	BSSID with which a STA is associated.
Station's state	Status of the STA.
Station's QoS Mode	QoS mode of the STA.
Station's HT Mode	HT mode of the STA. ● EHT: 802.11be ● HE: 802.11ax ● VHT: 802.11ac ● HT: 802.11n ● -: 802.11a/b/g
Station's MCS value	The maximum MCS value of the STA.
Station's NSS value	NSS value of the STA. If the STA does not support NSS or the NSS value is 0, a hyphen (-) is displayed.
Station's Short GI	Whether the STA supports the short GI.
Station's roam state	Roaming state of a STA.
HAC CAPWAP IP	CAPWAP IP address for inter-AC communication.
HAP CAPWAP IP	CAPWAP IP address for AP access.
Supported band	Frequency bands supported by the STA.
Supported 2.4G channels Supported 5G channels Supported 6G channels	Channel set supported by a STA. **NOTE** If - is displayed, possible causes include: ● The AP version is too early to report channels supported by STAs. ● The STA cannot report the support channels IE field.
802.11k support	Whether a STA supports 802.11k.
802.11r support	Whether a STA supports 802.11r.

Item	Description
802.11r proprietary support	Whether the STA supports Huawei proprietary 802.11r over-the-DS roaming.
802.11v support	Whether a STA supports 802.11v.
Available for roaming	Whether a STA can trigger the roaming process.
Sticky station or not	Whether a STA is a sticky terminal.
Station device type	Identified STA type.
Aimless roaming support in sticky state	Whether a STA is forced to roam to the target AP.
Station identify info	STA information identified by the device.
Category name	STA category identified by the device.
Vendor name	STA vendor identified by the device.
Model name	STA model identified by the device.
OS	STA operating system identified by the device.
U-APSD list	U-APSD list.
AC-VI	Whether U-APSD takes effect on AC_VI packets.
AC-VO	Whether U-APSD takes effect on AC_VO packets.
AC-BE	Whether U-APSD takes effect on AC_BE packets.
AC-BK	Whether U-APSD takes effect on AC_BK packets.

11.1.86 display station assoc-info ap-offline-record

Function

The **display station assoc-info ap-offline-record** command displays information about STAs that connect to the APs in fault state.

Format

display station assoc-info ap-offline-record { **all** | { **ap-name** *ap-name* | **ap-id** *ap-id* } [**radio** *radio-id*] }

Parameters

Parameter	Description	Value
all	Displays information about STAs that connect to all APs in fault state.	-
ap-name *ap-name*	Displays information about STAs that go online on the AP with a specified name in fault state.	The AP name must exist.
ap-id *ap-id*	Displays information about STAs that go online on the AP with a specified ID in fault state.	The AP ID must exist.
radio *radio-id*	Displays information about STAs that connect to a specified radio of an AP in fault state.	The radio ID must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

When link faults occur between the APs and AC, the APs in fault state allow access of new STAs and log the STA information. When the link between the APs and AC is re-established, the APs disconnect these STAs and send the STA information to the AC. You can run the **display station assoc-info ap-offline-record** command on the AC to check information about the STAs that connect to the APs in fault state.

Prerequisite

The APs in fault state have been enabled to allow access of new STAs using the **keep-service enable allow new-access** command.

Example

Display information about STAs that connect to all APs in fault state.

```
<HUAWEI> display station assoc-info ap-offline-record all
Offline Station information list:
------------------------------------------------------------------------------
STA MAC          AP name   RADIO ID  SSID
------------------------------------------------------------------------------
00e0-fc12-3456   ap1       0         SSID_MYWLAN
------------------------------------------------------------------------------
Total: 1
```

Table 11-49 Description of the **display station assoc-info ap-offline-record** command output

Item	Description
STA MAC	MAC address of a STA.
AP name	Name of the AP that the STA connects to.
RADIO ID	ID of the radio that the STA connects to.
SSID	SSID that the STA connects to.

11.1.87 display station online-fail-record

Function

The **display station online-fail-record** command displays records of STAs' failures to go online.

Format

display station online-fail-record { **all** | **ap-name** *ap-name* | **ap-id** *ap-id* | **sta-mac** *sta-mac-address* }

Parameters

Parameter	Description	Value
all	Displays going-online failure records of all STAs.	-
ap-name *ap-name*	Displays records of STAs' failures to go online on the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Displays records of STAs' failures to go online on the AP with a specified ID.	The AP ID must exist.
sta-mac *sta-mac-address*	Displays online failure records of the STA with the specified MAC address.	The STA's MAC address must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If a STA fails to go online, you can run the command to check the failure reason, which helps locate the fault.

After the number of records of STAs' failures to go online reaches the maximum that can be stored, new records overwrite existing ones.

Example

Display online failure records of all STAs.

```
<HUAWEI> display station online-fail-record all
Reason distribution
----------------------------------------------------------------------------------------

Table 11-50 Description of the **display station online-fail-record** command output

Item	Description
Reason distribution	Distribution of STA going-online failure reasons. All the reasons after the reasons listed in **Table 11-51** are counted as **Other Reasons**. - The authentication request times out.
Count	Number of times that a reason is displayed.
Percent	Percentage of a reason.
Recent records	Recent records of reasons for the STA's failures to go online.
Radio ID/WLAN ID	ID of the radio/VAP to which the STA fails to connect.
STA MAC	MAC address of the STA that fails to go online.

Item	Description
AP ID	ID of the AP on which the STA fails to go online.
Ap name	Name of the AP on which the STA fails to go online.
Last record time	Last time when the STA failed to go online.
Reason	Reason for the STA's failure to go online. For details about STA online failure reasons and handling suggestions, see **Table 11-51**. For reasons of access authentication failures, see **Common Causes for Access Authentication Failures** in *Huawei S Series Campus Switches Troubleshooting Guide*. For troubleshooting methods, see **STAs Fail to Associate with a WLAN** in the *Troubleshooting Guide*.

Table 11-51 STAs' going-online failure reasons and handling suggestions

Reason Why a STA Fails to Go Online	Suggestion
The number of STAs exceeds the physical specifications allowed by the AP.	Expand the network capacity or retain the current configuration as required.
The number of associated STAs exceeds the maximum allowed by the AC.	Expand the WLAN capacity.
The STA associates with a heavily loaded radio.	Check whether the load balancing configuration is proper.
The STA is in the dynamic blacklist.	Check the attack records and check whether the STA has initiated attacks.
The STA's SNR is below the user CAC threshold.	Check whether the SNR-based user CAC threshold is properly set. To modify this threshold, run the **uac client-snr threshold** command and reassociate the STA with the WLAN. Alternatively, determine the STA location and provide coverage to the location.

Reason Why a STA Fails to Go Online	Suggestion
The number of STAs exceeds the maximum allowed by the AP.	Configure load balancing or expand the network capacity.
The number of STAs exceeds the maximum allowed in the VAP reported by the AP.	Increase the maximum number of users on the VAP or expand the WLAN capacity.
The STA does not send an authentication request before associating with the network.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The key is incorrect or the STA uses the cached PMK.	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Failed to receive the handshake packet (2/4) from the STA.	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Failed to receive the handshake packet (4/4) from the STA.	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Re-authentication fails (start negotiation failure).	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Authentication fails (MAC address authentication failure).	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (WPA key negotiation failure).	Verify that the correct password is entered on the STA. If this fault persists, contact technical support personnel.
The authentication request times out.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
STA authentication times out.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Invalid association request packet.	Reassociate the STA with the network. If this fault persists, the STA may be incompatible. Contact technical support personnel.

Reason Why a STA Fails to Go Online	Suggestion
The encryption mode is inconsistent on the STA and AP.	Check whether the encryption mode is consistent on the STA and AP.
Authentication fails in the association stage.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The STA is not authenticated.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The AP does not support the rate set specified in the association request packet of the STA.	Modify the basic rate set and supported rate set in the radio profile and reassociate the STA with the network.
The encryption algorithm is inconsistent on the STA and AP.	Check whether the encryption algorithm is consistent on the STA and AP.
Failed to decrypt the challenge packet.	Reassociate the STA with the network or check whether the STA works properly. If this fault persists, contact technical support personnel.
Access from legacy STAs is denied.	Check whether the configuration for denying access of legacy STAs is required. To modify this configuration, run the **undo legacy-station disable** command to permit access of legacy STAs.
The WMM capability of the STA and VAP does not match.	Check whether WMM is forcibly enabled in the radio profile or check the specified configuration of the STA.
STAs have a compatibility issue(Incorrect network type flag carried by STAs) .	Check whether the STA works properly. If so, reassociate the terminal with the network. If this fault persists, contact technical support personnel.
STAs have a compatibility issue(STAs do not support short timeslots).	Check whether the STA supports the 802.11g protocol.
STAs have a compatibility issue(STAs do not support DFS.)	Check whether the STA supports the 802.11h protocol.
The STA is not in the global whitelist.	Check whether the STA needs to be added to the global whitelist.
The STA is in the global blacklist.	Check whether the STA needs to be added to the global blacklist.

Reason Why a STA Fails to Go Online	Suggestion
The STA is not in the VAP's whitelist.	Check whether the STA needs to be added to the VAP's whitelist.
The STA is in the VAP's blacklist.	Check whether the STA needs to be added to the VAP's blacklist.
The association or reassociation packet check fails.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The number of users exceeds the maximum allowed on the VAP defined by the AC.	Expand the network capacity or run the **max-sta-number** command to increase the maximum number of STAs associated with the VAP.
The Navi AC status is abnormal.	Check the configuration and the network to Navi AC.
VAP configurations on the Local AC and Navi AC are different.	Check the VAP configurations on the Local AC and Navi AC. Check items are as follows: ● STA authentication access mode. ● SSID.
The number of associated STAs exceeds the maximum specifications of the Navi AC.	Expand the WLAN capacity.
Failed to check the configuration during STA association.	Contact technical support personnel.
Batch backup is in progress. STA access is denied.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
STA access failed due to other reasons.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Reassociation denied.	No action is required.
During roaming association, the SSID is inconsistent with that before roaming.	Check whether the SSID is the same before and after roaming. If this fault persists, contact technical support personnel.
During roaming association, the authentication mode is inconsistent with that before roaming.	Check whether the authentication mode is the same before and after roaming. If this fault persists, contact technical support personnel.

Reason Why a STA Fails to Go Online	Suggestion
During roaming association, the STA status is abnormal.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The STA fails the roaming check due to other reasons.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The STA uses a static IP address.	Check whether the static IP address is configured by the user. If so, configure the STA to dynamically obtain an IP address.
The number of STAs exceeds the UAC threshold of the radio.	Check whether the CAC threshold based on the number of users is properly set. To modify this threshold, run the **uac client-number threshold** command and reassociate the STA with the WLAN.
The channel utilization of the radio has reached the upper threshold.	Check whether the user CAC threshold based on the channel utilization is properly set. To modify this threshold, run the **uac channel-utilization threshold** command and reassociate the STA with the WLAN.
Exceeded the maximum number of users on the central AP.	Expand the WLAN capacity.
Authentication fails.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The encryption mode used by STAs is different from that used by the VAP.	Check the encryption modes used by STAs and the VAP.
The possible cause is that the STA configuration is incorrect, the signal quality on the air interface is low, or the AC forces the STA to reassociate with the network to ensure uninterrupted STA services.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The client capability does not match.	The client capability does not meet the requirements. Upgrade the client version or Wi-Fi version.
Compatibility problems exist on the wireless client. (The HT capability carried by the client is incorrect).	Upgrade the STA version or Wi-Fi module version, or run the **undo legacy-station disable** command to permit access of non-HT STAs.

Reason Why a STA Fails to Go Online	Suggestion
The client access is restricted temporarily.	To allow a wireless client to access a better AP, temporarily restrict the client to access this AP. It is normal if the terminal can connect to a better AP. If a client fails to connect to an AP for multiple consecutive times, check whether APs need to be added.
Received an Authentication frame with authentication transaction sequence number out of expected sequence.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Invalid RSNE capabilities.	Forget the network and reassociate the STA with the network. If this fault persists, contact technical support personnel.
Cipher suite rejected because of security policy.	Check whether the encryption mode and key configurations on the wireless terminal are correct. If this fault persists, contact technical support personnel.
Invalid pairwise master key identifier(PMKID).	Forget the network and reassociate the STA with the network. If this fault persists, contact technical support personnel.
Invalid group cipher.	Forget the network and reassociate the STA with the network. If this fault persists, contact technical support personnel.
Invalid pairwise cipher.	Forget the network and reassociate the STA with the network. If this fault persists, contact technical support personnel.
Invalid MDE.	Forget the network and reassociate the STA with the network. If this fault persists, contact technical support personnel.
Invalid FTE.	Forget the network and reassociate the STA with the network. If this fault persists, contact technical support personnel.
Others reason.	Contact technical support personnel.

Reason Why a STA Fails to Go Online	Suggestion
802.11r EAPOL Msg 2/4 did not contain R1 name.	Check whether the station has some compatibility problems and please disable dot1x reauthenticate when enable 802.11r. If this fault persists, contact technical support personnel.
Key negotiation fails(the length of the key data is invalid).	Verify that the correct password is entered on the STA. If this fault persists, contact technical support personnel.
Key negotiation fails(the length of the key data(2/4) is invalid).	Verify that the correct password is entered on the STA. If this fault persists, contact technical support personnel.
Key negotiation fails(the length of the key data(4/4) is invalid).	Verify that the correct password is entered on the STA. If this fault persists, contact technical support personnel.
Key negotiation fails(fail to send the handshake packet).	Verify that the correct password is entered on the STA. If this fault persists, contact technical support personnel.
The MAC address of the access user is different from that configured for the PPSK account.	Run the **display wlan ppsk-user all** command to check whether any PPSK account allows the access from this MAC address. If so, use this PPSK account for access. If not, configure a PPSK account mapping this MAC address and use the new PPSK account for access.
The PPSK account does not exist.	Run the **display wlan ppsk-user all** command to check whether any PPSK account maps the access SSID. If not, create the PPSK account and bind it to the SSID.
The number of PPSK users exceeds the maximum value.	Run the **display wlan ppsk-user all** command to query the maximum number of access users supported by the PPSK account, and then modify the maximum number of access users as required.
The PPSK account expires.	Run the **display wlan ppsk-user all** command to check the timeout period of the PPSK account, and change it to a valid time.

Reason Why a STA Fails to Go Online	Suggestion
Key negotiation fails (message 2/4 processing error).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (message 4/4 processing error).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (message 1/2 processing error).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (start unicast negotiation fails because of incorrect input parameters).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (start multicast negotiation fails because of incorrect input parameters).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (message 2/4 authentication mode or encryption type mismatch).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (message 4/4 authentication mode or encryption type mismatch).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid length of the message 2/2).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid length of WPA data packets).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid length of the message 2/4).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.

Reason Why a STA Fails to Go Online	Suggestion
Key negotiation fails (invalid length of the message 4/4).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (mismatched packet descriptor of the message 2/4).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (mismatched packet descriptor of the message 4/4).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (mismatched packet descriptor of the message 2/2).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid length of the message 4/4 packet key).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid length of the message 2/2 packet key).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid key information in the message 2/4 packet).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid key information in the message 4/4 packet).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid key information in the message 2/2 packet).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (message 2/4 handshake status mismatch).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.

Reason Why a STA Fails to Go Online	Suggestion
Key negotiation fails (message 4/4 handshake status mismatch).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (message 2/2 handshake status mismatch).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid number of message 2/4 replay times).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid number of message 4/4 replay times).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid number of message 2/2 replay times).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (message 4/4 MIC verification failure).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (message 2/2 MIC verification failure).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (packet length calculation failure).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (the EAP packet length is 0).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (the EAP packet is too long).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.

Reason Why a STA Fails to Go Online	Suggestion
Key negotiation fails (the key body length of EAP packets is 0).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid length of the EAP packet key).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (incorrect EAP packet descriptor).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid EAP packet type).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (PMK parse failure).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (mismatch between the PMK and PMKR1Name).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (the type is not FTIE).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid FTIE length).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (mismatch between Anonce and FTIE).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (mismatch between Snonce and FTIE).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.

Reason Why a STA Fails to Go Online	Suggestion
Key negotiation fails (MIC generation failure).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (failure to modify the rsnie field).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (failure to fill FTIE data).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
WAPI authentication times out.	Check the network quality or reassociate the STA with the network. If this fault persists, contact technical support personnel.
WAPI authentication fails.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Re-authentication fails (re-authentication failure).	Check the intermediate network between the AP and AC or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Re-authentication fails (failure to fill the start negotiation message).	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Authentication fails (authentication failure).	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Authentication fails (failure to fill the start negotiation message).	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Authentication fails (start negotiation failure).	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Authentication fails (failure to receive EAP key packets).	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Authentication fails (MAC address authentication processing error).	Reassociate the STA with the network. If this fault persists, contact technical support personnel.

Reason Why a STA Fails to Go Online	Suggestion
Key negotiation fails (access security processing failure).	Verify that the correct password is entered on the STA. If this fault persists, contact technical support personnel.
Key negotiation fails.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Authentication is rejected because an Anti-CloggingToken is required.	Forget the network and reassociate the STA with the network. If this fault persists, contact technical support personnel.
Authentication is rejected because the offered finite cyclic group is not supported.	Forget the network and reassociate the STA with the network. If this fault persists, contact technical support personnel.
Robust management frame policy violation	Check whether the encryption mode and pmf configuration are correct on the client.
High-reliability air interface slicing is enabled but is not supported by STA.	Associate the STA with an SSID on which high-reliability air interface slicing is not enabled.

11.1.88 display station offline-record

Function

The **display station offline-record** command displays STAs' going-offline records.

Format

display station offline-record { **all** | **ap-name** *ap-name* | **ap-id** *ap-id* | **sta-mac** *sta-mac* }

Parameters

Parameter	Description	Value
all	Displays all STAs' going-offline records.	-
ap-name *ap-name*	Displays STAs' going-offline records on the AP with a specified name.	The AP name must exist.

Parameter	Description	Value
ap-id *ap-id*	Displays STAs' going-offline records on the AP with a specified ID.	The AP ID must exist.
sta-mac *sta-mac*	Displays the going-offline records of a specified STA.	The STA's MAC address must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After a STA goes offline, you can use this command to check the reason why the STA goes offline.

A maximum of three going-offline records can be stored for each STA.

Example

Display all STAs' going-offline records.

```
<HUAWEI> display station offline-record all

Table 11-52 Description of the **display station offline-record** command output

Item	Description
Reason distribution	Distribution of reasons of STAs going offline. All the reasons after the reasons listed in **Table 11-53** are counted as **Other Reasons**. - The STA ages out.
Count	Number of times that a reason is displayed.
Percent	Percentage of a reason.
Recent records	Recent reason records of STAs' going-offline.
STA MAC	MAC address of a STA.
AP ID	ID of the AP from which STAs go offline.
Ap name	Name of the AP from which STAs go offline.
Radio ID/WLAN ID	ID of the radio or WLAN ID of the VAP from which a STA goes offline.
Last record time	Time when the STA went offline last time.
Reason	Reason why the STA went offline. For description of offline reasons and handling suggestions, see **Table 11-53**.For reasons of access authentication failures, see **Common Causes for Access Authentication Failures** in *Huawei S Series Campus Switches Troubleshooting Guide*. For troubleshooting methods, see **A STA Goes Offline Unexpectedly** in the *Troubleshooting Guide*.
Total stations	Total number of STAs.
Total records	Total number of STA offline records.

Table 11-53 Possible reasons and suggestions for STAs to go offline

Reason Why a STA Goes Offline	Suggestion
STA entry addition times out or fails.	Check the intermediate network between the AP and AC or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Authentication fails in the association stage.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The configuration is modified.	Check whether configuration modification records exist.
Roaming check failed(on the eSAP).	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Roaming failed(because of a roaming entry failure on the forwarding side or a failure to obtain the configuration).	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The AP is faulty.	Check the reason why the AP goes offline, and rectify the fault accordingly. For reasons why an AP goes offline, see **display ap offline-record**.
The AP is deleted.	No action is required.
Failed to synchronize user entries between the AP and AC.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Failed to synchronize user entries in a mobility group.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
A tunnel between ACs goes Down.	Check the network between the ACs.
The home AP goes offline or a network fault occurs.	Reassociate the STA with another AP. If this fault persists, contact technical support personnel.
The home AP is deleted.	Reassociate the STA with another AP. If this fault persists, contact technical support personnel.
The home VAP is deleted.	Reassociate the STA with another VAP. If this fault persists, contact technical support personnel.
The AC forcibly disconnects idle STAs.	Check whether this function is required. If so, no action is required. If not, run the **undo idle-cut** command in the service scheme view to modify the configuration.

Reason Why a STA Goes Offline	Suggestion
Roaming check failed because the user left the current AC during inter-AC roaming.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The keepalive packet on the home AP times out.	Check the intermediate network between the AP and AC or reassociate the STA with the network. If this fault persists, contact technical support personnel.
The keepalive packet between ACs times out.	Check the intermediate network between the AP and AC or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Layer 3 roaming is disabled.	Reassociate the STA with the network or enable Layer 3 roaming.
The STA MAC is added to the STA blacklist.	Verify that the STA needs to be added to the blacklist.
The STA disassociates with the network.	Check whether the STA actively goes offline or whether the STA is faulty.
The STA is deauthenticated.	Check whether the STA actively goes offline or whether the STA is faulty.
The VAP goes down because the configuration is modified.	Check whether configuration change records exist in the log.
The STA is added to the dynamic blacklist.	Check whether the STA is an attacker.
The signal strength is too low.	Check whether the threshold for quickly disconnecting STAs by smart roaming is correctly configured, and check whether the WLAN coverage area is sufficient.
No control entry exists.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
No Wi-Fi entry exists.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The STA roams between ACs.	No action is required.

Reason Why a STA Goes Offline	Suggestion
The STA associates or reassociates with the network but does not send a DHCP Discover message. The STA reassociates with the network but does not send a DHCP request message.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The STA ages out.	No action is required.
A STA goes offline properly.	No action is required.
Failed to synchronize user entries between WMP and eSAP.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The STA roams out of the device.	No action is required.
A STA goes offline unexpectedly.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
During inter-AC roaming, the SSID is inconsistent with that before roaming.	Check whether the SSID is the same before and after roaming. If this fault persists, contact technical support personnel.
The STA fails the roaming security check.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The STA fails the roaming status check.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The STA fails the roaming check due to other reasons.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Failed to add FPI item.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The device in NAT mode does not support roaming.	Reassociate the STA with the network or reconfigure the network mode.
Layer 3 roaming is disabled(delay offline).	Reassociate the STA with the network or enable Layer 3 roaming.
Fail to send IPC to UCM reporting auth request.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Fail to send IPC to UCM reporting roam request.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Station roam between normal and backup AP.	No action is required.

Reason Why a STA Goes Offline	Suggestion
The PPSK configuration is modified.	Check whether the modification record can be found in the log.
Exceeded the maximum number of login STAs supported by the PPSK account.	Check the maximum number of login STAs supported by the PPSK account.
Failed to synchronize user entries between Local AC and Navi AC.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The remotely authenticated STA is disconnected after an active/standby switchover in the Local AC dual-link networking.	No action is required.
VAP configurations on the Navi AC is modified.	No action is required.
Inter-ac roaming is disabled.	No action is required.
Users go offline due to WDS link disconnection or other unknown reasons (reported by Wi-Fi).	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The number of users exceeds the specifications (insufficient key slots).	Expand the AP capacity or reassociate the STA with another AP.
A user exception is detected.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The STA does not respond.	Check whether the STA works properly.
The STA rate is too low.	Check whether the threshold for quickly disconnecting STAs by smart roaming is correctly configured, and check whether the WLAN coverage area is sufficient.
The STA uses a bogus IP address.	Configure the STA to automatically obtain an IP address.
The AP goes online again.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Multicast key handshake failure.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.

Reason Why a STA Goes Offline	Suggestion
Reporting the PMK negotiation result to the AC times out.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The STA disassociates with the network (delay offline).	Check whether the STA actively goes offline or whether the STA is faulty.
The STA is deauthenticated (delay offline).	Check whether the STA actively goes offline or whether the STA is faulty.
The STA ages out (delay offline).	No action is required.
The STA IP address changes after roaming.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
AP restores connection from escape mode.	No action is required.
The soft-GRE tunnel goes down.	Check the connectivity to the peer end of the soft-GRE tunnel. If this fault persists, contact technical support personnel.
Higher-priority STAs access the network.	Configure the STA as a high-priority STA, or increase the user CAC threshold or the maximum number of STAs on a VAP.
The number of STAs reached the CAC or VAP threshold.	Increase the user CAC threshold or the maximum number of STAs on a VAP.
The possible cause is that the STA configuration is incorrect, the signal quality on the air interface is low, or the AC forces the STA to reassociate with the network to ensure uninterrupted STA services.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The key is incorrect or the STA uses the cached PMK.	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Failed to receive the handshake packet (2/4) from the STA.	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Failed to receive the handshake packet (4/4) from the STA.	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.

Reason Why a STA Goes Offline	Suggestion
802.11r EAPOL Msg 2/4 did not contain R1 name.	Check whether the station has some compatibility problems and please disable dot1x reauthenticate when enable 802.11r. If this fault persists, contact technical support personnel.
Key negotiation fails(the length of the key data is invalid).	Verify that the correct password is entered on the STA. If this fault persists, contact technical support personnel.
Key negotiation fails(the length of the key data(2/4) is invalid).	Verify that the correct password is entered on the STA. If this fault persists, contact technical support personnel.
Key negotiation fails(the length of the key data(4/4) is invalid).	Verify that the correct password is entered on the STA. If this fault persists, contact technical support personnel.
Key negotiation fails(fail to send the handshake packet).	Verify that the correct password is entered on the STA. If this fault persists, contact technical support personnel.
The MAC address of the access user is different from that configured for the PPSK account.	Run the **display wlan ppsk-user all** command to check whether any PPSK account allows the access from this MAC address. If so, use this PPSK account for access. If not, configure a PPSK account mapping this MAC address and use the new PPSK account for access.
The PPSK account does not exist.	Run the **display wlan ppsk-user all** command to check whether any PPSK account maps the access SSID. If not, create the PPSK account and bind it to the SSID.
The number of PPSK users exceeds the maximum value.	Run the **display wlan ppsk-user all** command to query the maximum number of access users supported by the PPSK account, and then modify the maximum number of access users as required.
The PPSK account expires.	Run the **display wlan ppsk-user all** command to check the timeout period of the PPSK account, and change it to a valid time.
Key negotiation fails (message 2/4 processing error).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (message 4/4 processing error).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (message 1/2 processing error).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.

Reason Why a STA Goes Offline	Suggestion
Key negotiation fails (start unicast negotiation fails because of incorrect input parameters).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (start multicast negotiation fails because of incorrect input parameters).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (message 2/4 authentication mode or encryption type mismatch).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (message 4/4 authentication mode or encryption type mismatch).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid length of the message 2/2).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid length of WPA data packets).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid length of the message 2/4).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid length of the message 4/4).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (mismatched packet descriptor of the message 2/4).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (mismatched packet descriptor of the message 4/4).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (mismatched packet descriptor of the message 2/2).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.

Reason Why a STA Goes Offline	Suggestion
Key negotiation fails (invalid length of the message 4/4 packet key).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid length of the message 2/2 packet key).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid key information in the message 2/4 packet).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid key information in the message 4/4 packet).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid key information in the message 2/2 packet).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (message 2/4 handshake status mismatch).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (message 4/4 handshake status mismatch).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (message 2/2 handshake status mismatch).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid number of message 2/4 replay times).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid number of message 4/4 replay times).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid number of message 2/2 replay times).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (message 4/4 MIC verification failure).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (message 2/2 MIC verification failure).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.

Reason Why a STA Goes Offline	Suggestion
Key negotiation fails (packet length calculation failure).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (the EAP packet length is 0).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (the EAP packet is too long).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (the key body length of EAP packets is 0).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid length of the EAP packet key).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (incorrect EAP packet descriptor).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid EAP packet type).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (PMK parse failure).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (mismatch between the PMK and PMKR1Name).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (the type is not FTIE).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (invalid FTIE length).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (mismatch between Anonce and FTIE).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (mismatch between Snonce and FTIE).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.

Reason Why a STA Goes Offline	Suggestion
Key negotiation fails (MIC generation failure).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (failure to modify the rsnie field).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (failure to fill FTIE data).	Check whether the key is correct or reassociate the STA with the network. If this fault persists, contact technical support personnel.
WAPI authentication times out.	Check the network quality or reassociate the STA with the network. If this fault persists, contact technical support personnel.
WAPI authentication fails.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Re-authentication fails (re-authentication failure).	Check the intermediate network between the AP and AC or reassociate the STA with the network. If this fault persists, contact technical support personnel.
Re-authentication fails (failure to fill the start negotiation message).	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Re-authentication fails (start negotiation failure).	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Authentication fails (authentication failure).	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Authentication fails (failure to fill the start negotiation message).	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Authentication fails (start negotiation failure).	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Authentication fails (failure to receive EAP key packets).	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Authentication fails (MAC address authentication processing error).	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Authentication fails (MAC address authentication failure).	Reassociate the STA with the network. If this fault persists, contact technical support personnel.

Reason Why a STA Goes Offline	Suggestion
The authentication request times out.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
Key negotiation fails (WPA key negotiation failure).	Verify that the correct password is entered on the STA. If this fault persists, contact technical support personnel.
Key negotiation fails (access security processing failure).	Verify that the correct password is entered on the STA. If this fault persists, contact technical support personnel.
Key negotiation fails.	Reassociate the STA with the network. If this fault persists, contact technical support personnel.
The AAA deletes the STA.	Check whether the AAA configuration and STA authentication information are both correct. If this fault persists, contact technical support personnel.
High-reliability air interface slicing is enabled or disable.	Associate the STA with an SSID on which high-reliability air interface slicing is not enabled.
Service tunnel VLAN is changed.	No action is required.

11.1.89 display station online-track

Function

The **display station online-track** command displays online time information about a STA.

Format

display station online-track *sta-mac-address*

Parameters

Parameter	Description	Value
sta-mac-address	Displays online time information about the STA with a specified MAC address.	The specified MAC address must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view online time information about a STA.

Example

Display online time information about a specified STA.

```
<HUAWEI> display station online-track 00e0-fc08-9abf
----------------------------------------------------------------------------
Event        Event Start(hh:mm:ss)      Event End(hh:mm:ss)      Cost(ms)
----------------------------------------------------------------------------
Association   14:20:28                 14:20:28                10
Auth         14:20:28                 14:20:30                2240
WPA          14:20:30                 14:20:31                330
DHCP         14:20:31                 14:20:31                10
----------------------------------------------------------------------------
Total cost: 2590ms
```

Table 11-54 Description of the **display station online-track** *sta-mac-address* command output

Item	Description
Event	Event type. The values are as follows: - Association: STA association - Auth: STA authentication - WPA: WPA key negotiation - DHCP: STAs obtaining IP addresses through DHCP
Event Start(hh:mm:ss)	Time when the event starts.
Event End(hh:mm:ss)	Time when the event ends.
Cost(ms)	Duration of the event.
Total cost	Total duration of all events.

11.1.90 display station statistics

Function

The **display station statistics** command displays statistics information about STAs.

Format

display station statistics [**sta-mac** *sta-mac-address* | **ap-name** *ap-name* | **ap-id** *ap-id*]

Parameters

Parameter	Description	Value
sta-mac *sta-mac-address*	Displays statistics information about a STA with a specified MAC address.	The STA's MAC address must exist.
ap-name *ap-name*	Displays statistics information about STAs on the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Displays statistics information about STAs on the AP with a specified ID.	The AP ID must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run the **display station statistics** command to view statistics information about STAs.

- If no parameter is specified, statistics information about all STAs associated with the AC is displayed.
- If an AP is specified by **ap-name** or **ap-id**, the number of STAs associated with, disassociated from, and reassociated with the AP is displayed.
- If a STA is specified by **sta-mac**, the number of packets and packet transmission rate between the STA and an AP are displayed.

Prerequisites

- To view statistics information about a STA specified by **sta-mac**, ensure that the STA has been associated with an AP.
- To view statistics information about STAs associated with an AP specified by **ap-name** or **ap-id**, ensure that the AP has been added to the AC and is in normal state.

Example

Display statistics information about all STAs.

```
<HUAWEI> display station statistics
--------------------------------------------------------------------------------
 Successful associations on the AC                              :0
 AC authentication failures due to a password error             :0
 AC authentication failures due to an invalid algorithm         :0
 AC authentication failures due to timeout                      :0
 AC authentication failures due to rejection                    :0
 AC authentication failures due to other reasons                :0
 Sticky STAs detected                                           :0
```

```
Online sticky STAs                                          :0
Sticky STA rate(%)                                          :-
Total number of roamings triggered by sticky STAs                 :0
Number of roamings triggered by sticky STAs                       :0
Sticky STA-triggered roaming success rate(%)                      :-
Unavailable to trigger roam number                              :0
Unavailable to trigger roam rate(%)                             :-
STAs supporting neighbor report                               :0
STAs supporting beacon report                                 :0
    Beacon passive measurement                                 :0
    Beacon active measurement                                  :0
    Beacon table measurement                                   :0
2.4G-only STAs                                              :0
5G-only STAs                                                :0
6G-only STAs                                                :0
2.4G and 5G STAs                                              :0
2.4G, 5G and 6G STAs                                            :0
Online STAs                                                 :0
    STAs associated with 2.4G band                             :0
    STAs associated with 5G band                               :0
    STAs associated with 6G band                               :0
------------------------------------------------------------------------------
```

Table 11-55 Description of the **display station statistics** command output

Item	Description
Successful associations on the AC	Total number of successful link authentications on the AC. Every time a STA initiates a link authentication request and passes the authentication, the counter is incremented by 1. If the same STA initiates multiple authentication requests and passes all authentications, the counter is incremented cumulatively.
AC authentication failures due to a password error	Number of authentication failures due to the incorrect password.
AC authentication failures due to an invalid algorithm	Number of authentication failures due to the invalid authentication algorithm.
AC authentication failures due to timeout	Number of authentication failures due to timeout.
AC authentication failures due to rejection	Number of authentication failures due to rejected access to the AC.
AC authentication failures due to other reasons	Number of authentication failures due to other reasons.
Sticky STAs detected	Number of sticky STAs.
Online sticky STAs	Number of online sticky STAs.
Sticky STA rate(%)	Ratio of the number of sticky STAs to the total number of STAs.

Item	Description
Total number of roamings triggered by sticky STAs	Total number of the triggered smart roaming times.
Number of roamings triggered by sticky STAs	Number of the successfully triggered smart roaming times.
Sticky STA-triggered roaming success rate(%)	Success rate of triggered smart roaming.
Unavailable to trigger roam number	Number of STAs that cannot roam on the AC.
Unavailable to trigger roam rate(%)	Ratio of the number of sticky STAs that cannot roam to the total number of STAs on the AC.
STAs supporting neighbor report	Number of STAs that can obtain information about neighboring APs.
STAs supporting beacon report	Number of STAs that can report information about neighboring APs through the Beacon Report mechanism.
Beacon passive measurement	Number of STAs that can report information about neighboring APs in passive mode.
Beacon active measurement	Number of STAs that can report information about neighboring APs in active mode.
Beacon table measurement	Number of STAs that can report information about neighboring APs in Beacon table mode.
2.4G-only STAs	Number of STAs that support only the 2.4 GHz frequency band.
5G-only STAs	Number of STAs that support only the 5 GHz frequency band.
6G-only STAs	Number of STAs that support only the 6 GHz frequency band.
2.4G and 5G STAs	Number of STAs that support only the 2.4 GHz and 5 GHz frequency bands.
2.4G, 5G and 6G STAs	Number of STAs that support the 2.4 GHz, 5 GHz, and 6 GHz frequency bands.
Online STAs	Number of online STAs.

Item	Description
STAs associated with 2.4G band	Number of STAs associated with the 2.4 GHz radio. The number of STAs of different types is displayed, including 802.11b, 802.11g, 802.11be 20 MHz, 802.11be 40 MHz, 802.11ax 20 MHz, 802.11ax 40 MHz, 802.11n 20 MHz, and 802.11n 40 MHz STAs.
STAs associated with 5G band	Number of STAs associated with the 5 GHz radio. The number of STAs of different types is displayed, including 802.11a, 802.11n 20 MHz, 802.11n 40 MHz, 802.11be 20 MHz, 802.11be 40 MHz, 802.11be 80 MHz, 802.11be 160 MHz, 802.11be 320 MHz, 802.11ax 20 MHz, 802.11ax 40 MHz, 802.11ax 80 MHz, 802.11ax 160 MHz, 802.11ac 20 MHz, 802.11ac 40 MHz, 802.11ac 80 MHz, and 802.11ac 160 MHz STAs.
STAs associated with 6G band	Number of STAs associated with the 6 GHz radio. The number of STAs of different types is displayed, including 802.11be 20 MHz, 802.11be 40 MHz, 802.11be 80 MHz, 802.11be 160 MHz, 802.11be 320 MHz, 802.11ax 20 MHz, 802.11ax 40 MHz, 802.11ax 80 MHz, and 802.11ax 160 MHz STAs.

Display statistics information about the STA with the MAC address 00e0-fc33-4455.

```
<HUAWEI> display station statistics sta-mac 00e0-fc33-4455
------------------------------------------------------------------
 Packets sent to the station                          : 7
 Packets received from the station                    : 40
 Bytes sent to the station                            : 1170
 Bytes received from the station                      : 3911
 Wireless data rate sent to the station(kbps)         : 0
 Wireless data rate received from the station(kbps)   : 0
 Trigger roam total                                   : 0
 Trigger roam failed                                  : 0
 STA power save percent                               : 0%
------------------------------------------------------------------------------
```

Table 11-56 Description of the **display station statistics sta-mac** *sta-mac-address* command output

Item	Description
Packets sent to the station	Number of packets sent to the STA.

Item	Description
Packets received from the station	Number of packets received from the STA.
Bytes sent to the station	Number of bytes sent to the STA.
Bytes received from the station	Number of bytes received from the STA.
Wireless data rate sent to the station(kbps)	Rate at which packets are sent to the STA, in kbit/s.
Wireless data rate received from the station(kbps)	Rate at which packets are received from the STA, in kbit/s.
Trigger roam total	Total number of smart roaming times.
Trigger roam failed	Number of smart roaming failures.
STA power save percent	Percentage of power saved on the STA.

Display STA statistics information of a specified AP.

```
<HUAWEI> display station statistics ap-name N1-1

 Load balancing status between dual bands                     :-
 Sticky STAs detected                                    :0
------------------------------------------------------------------------------
```

Table 11-57 Description of the **display station statistics ap-name** *ap-name* command output

Item	Description
Total online time of STAs (seconds)	Total online duration of all STAs, in seconds.
STAs associated with the AP	Number of STAs currently associated with the AP, not including the number of STAs in aging status.
Association requests	Number of association requests sent to the AP.
Successful association requests	Number of successful associations.
Rejected association requests	Number of association requests rejected by the AP.
Failed association requests	Number of failed associations.
Repeated association requests	Number of times STAs repeatedly send association requests to the AP.
Reassociation requests	Number of reassociation requests sent to the AP.
Successful reassociation requests	Number of successful reassociations.
Rejected reassociation requests	Number of reassociation requests rejected by the AP.
Failed reassociation requests	Number of failed reassociations.
Repeated reassociation requests	Number of times STAs repeatedly send reassociation requests to the AP.
Disassociations initiated by STAs	Number of times STAs are disassociated from the AP because users go offline.
Disassociations due to STA roaming	Number of times STAs are disassociated from the AP because users roam to other regions.
Disassociations because STAs go offline unexpectedly	Number of times STAs are disassociated from the AP because users go offline unexpectedly.
Disassociations due to other reasons	Number of times STAs are disassociated from the AP for other reasons.

Item	Description
Disassociations due to a link authentication failure	Number of times STAs are disassociated from the AP due to link authentication failures.
Authentication requests	Number of times link authentication requests are sent.
Deauthentication requests	Number of times link deauthentication requests are sent.
STAs in power saving mode	Number of STAs working in power saving mode.
STAs in HT mode	Number of STAs working in HT mode.
STAs in B mode	Number of STAs working in 802.11b mode.
STAs in G mode	Number of STAs working in 802.11g mode.
STAs in A mode	Number of STAs working in 802.11a mode.
STAs in N mode	Number of STAs working in 802.11n mode.
STAs in AC mode	Number of STAs working in 802.11ac mode.
STAs in AX mode	Number of STAs working in 802.11ax mode.
STAs in BE mode	Number of STAs working in 802.11be mode.
2.4G-only STAs	Number of STAs that support only the 2.4 GHz frequency band.
5G-only STAs	Number of STAs that support only the 5 GHz frequency band.
6G-only STAs	Number of STAs that support only the 6 GHz frequency band.
2.4G and 5G STAs	Number of STAs that support only the 2.4 GHz and 5 GHz frequency bands.
2.4G, 5G and 6G STAs	Number of STAs that support 2.4 GHz, 5 GHz, and 6 GHz frequency bands.
2.4G and 5G STAs associated with 5G	Number of STAs that support both 2.4 and 5 GHz frequency bands and are associated with the 5 GHz radio.

Item	Description
STAs associated with 2.4G band	Number of STAs associated with the 2.4 GHz radio.
STAs associated with 5G band	Number of STAs associated with the 5 GHz radio.
STAs associated with 6G band	Number of STAs associated with the 6 GHz radio.
Band steer success rate(%)	Band steering success rate.
Load balancing status between dual bands	Status of load balancing between different frequency bands.
Sticky STAs detected	Number of the detected sticky STAs.

11.1.91 display vap

Function

The **display vap** command displays information about service VAPs.

Format

display vap { **ap-group** *ap-group-name* | { **ap-name** *ap-name* | **ap-id** *ap-id* } [**radio** *radio-id*] } [**ssid** *ssid*]

display vap { **all** | **ssid** *ssid* }

Parameters

Parameter	Description	Value
ap-group *ap-group-name*	Displays information about all service VAPs in a specified AP group.	The AP group must exist.
ap-name *ap-name*	Displays information about service VAPs on the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Displays information about service VAPs on the AP with a specified ID.	The AP ID must exist.
radio *radio-id*	Displays information about service VAPs on a specified radio.	The value is an integer that ranges from 0 to 2.
ssid *ssid*	Displays information about service VAPs with a specified SSID.	The SSID must exist.
all	Displays information about all service VAPs.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view information about service VAPs.

Example

Display information about all service VAPs.

```
<HUAWEI> display vap all
WID : WLAN ID
---------------------------------------------------------------------------
AP ID AP name        RfID WID  BSSID          Status  Auth type  STA   SSID
---------------------------------------------------------------------------
3     ap1            0    1    00e0-fc12-3456 ON      Open       0     GUEST-WLAN
---------------------------------------------------------------------------
Total: 1
```

Table 11-58 Description of the **display vap** command output

Item	Description
AP ID	AP ID.
AP name	AP name.
RfID	Radio ID.
WID	WLAN ID of a VAP.
SSID	SSID name.
BSSID	MAC address of a VAP.
Status	Current status of a VAP. ● ON: The VAP service is enabled. ● OFF: The VAP service is disabled. ● -: This is the state of a VAP on the standby AC in a dual-link cold backup scenario.
Auth type	Authentication mode of a VAP.
STA	Number of STAs connected to a VAP.

11.1.92 display vap create-fail-record

Function

The **display vap create-fail-record** command displays records about VAP creation failures.

Format

display vap create-fail-record { **ap-mac** *ap-mac* | **all** }

Parameters

Parameter	Description	Value
ap-mac *ap-mac*	Displays records about VAP creation failures on an AP with the specified MAC address.	The AP's MAC address must exist.
all	Displays records about VAP creation failures on all APs.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display vap create-fail-record** command to check records about VAP creation failures.

Example

Display all records about VAP creation failures.

```
<HUAWEI> display vap create-fail-record all
Rf/WLAN: Radio ID/WLAN ID
-------------------------------------------------------------------------------
AP MAC          Rf/WLAN  Profile Name  Source Type
VAP Type        Reason
-------------------------------------------------------------------------------
00e0-fc76-e360  0/4      1             ap-group
Service         Preshared key is not configured.
00e0-fc76-e370  1/4      1             ap-group
Service         Preshared key is not configured.
00e0-fc76-e360  0/6      1             ap-group
Service         Preshared key is not configured.
00e0-fc76-e370  1/6      1             ap-group
Service         Preshared key is not configured.
-------------------------------------------------------------------------------
Total records: 4
```

Table 11-59 Description of the **display vap create-fail-record all** command output

Item	Description
AP MAC	MAC address of an AP.
Rf/WLAN	Radio ID/WLAN ID.
Profile Name	VAP profile name.
Source Type	Object to which the VAP is bound, including: - ap-group: AP group - ap-id: AP
VAP Type	VAP type, including: - Service: Service VAP - WDS: WDS VAP - Mesh: Mesh VAP
Reason	Reason why the VAP fails to be created. **Table 11-60** describes detailed reasons.

Table 11-60 Reasons for VAP creation failures

Reason for VAP Creation Failures	Remarks	Suggestion
The VAPs using WEP encryption on an AP cannot use the same key ID.	-	Check the configuration of the VAP profile or security profile.
Invalid WEP key index.	-	Check whether the security profile is configured correctly.
Preshared key is not configured.	-	Configure a pre-shared key.
Only one management VAP profile can be bound.	-	Delete the management VAP that has been configured.
The bridge is enabled. Please undo first.	WLAN IDs 13 and 14 are used to set up a WDS bridge. Select other WLAN IDs or delete the WDS configuration.	Select another WLAN ID or delete the WDS configuration.

Reason for VAP Creation Failures	Remarks	Suggestion
WLAN ID(16) is used. Please undo first.	WLAN ID 16 is used to set up a Mesh link. Select another WLAN ID or delete the Mesh configuration.	Select another WLAN ID or delete the Mesh configuration.
Only one temporary management vap-profile can be bound to an AP.	-	Delete the offline management VAP that has been configured.
The current country code does not support 5GHz frequency band.	-	Change the country code, or do not create a 5 GHz VAP.
The current country code does not support 2.4GHz frequency band.	-	Change the country code, or do not create a 2.4 GHz VAP.
The AP type does not support the wlan id.	-	Delete unused VAPs.
This AP type does not support WDS function.	-	Replace the AP with one supporting WDS.
This AP type or version does not support Mesh function.	-	Replace the AP with a Mesh-capable AP or upgrade the AP to a Mesh-capable version.
The number of VAPs has reached the upper limit.	-	Delete excess VAPs.
The AP does not support 5GHz frequency band.	-	Change the AP, or do not create a 5 GHz VAP.
The AP does not support 2.4GHz frequency band.	-	Change the AP, or do not create a 2.4 GHz VAP.
The AP does not support 802.1X+WEP.	-	Replace the AP with one in compliance with 802.11ac Wave 2.
SFN roaming can be configured only on one VAP of each radio.	-	Create a VAP on another radio or delete the SFN roaming VAP on the current radio.
The AP does not support SFN.	-	Replace the AP with one supporting SFN roaming.

Reason for VAP Creation Failures	Remarks	Suggestion
The 5G radio of the AP does not support SFN. The radio frequency band of the AP does not support SFN.	-	Replace the AP or modify the radio configuration.
The number of VAPs has reached the card specific.	-	Reduce the number of VAPs on a card, or enable the AP to go online on another card of the switch and create VAPs.
The AP in this version does not support PPSK authentication.	-	Replace the AP with an AP that supports PPSK authentication or upgrade the AP to a version that supports PPSK authentication.
The AP in this version does not support the WPA3-Enterprise transition mode.	-	Upgrade the AP to V200R023C00 or later.
The AP in this version does not support Navi-AC VAPs.	-	Replace the AP with an AP that supports Navi AC VAPs or upgrade the AP to a version that supports Navi AC VAPs.
Unknown reason, error code is 0x%x.	-	Contact technical support personnel.
The number of WDS VAPs has reached the upper limit.	-	Delete redundant WDS VAPs.
The number of Mesh VAPs has reached the upper limit.	-	Delete redundant Mesh VAPs.
The frequency band of this radio is inconsistent with that supported by the current country code.	-	Change the country code, or do not create a VAP for the current radio.

Reason for VAP Creation Failures	Remarks	Suggestion
The AP in this version does not support the Mesh configuration on radio 2.	-	Replace the AP with an AP on which radio 2 supports Mesh or upgrade the AP to a version that supports Mesh on radio 2 of an AP.
The AP does not support OWE.	-	Replace the AP with an OWE-capable AP or upgrade the AP to an OWE-capable version.
No security policy is configured.	-	Configure a security policy.
No PSK is configured.	-	Configure a WEP key.
The 6GHz frequency band supports only the open, OWE and WPA3 security policies.	-	Modify the security policy configuration of the VAP.
The current country code does not support 6GHz frequency band.	-	Change the country code, or do not create a 6 GHz VAP.
The AP does not support 6GHz frequency band.	-	Change the AP, or do not create a 6 GHz VAP.
The 6G radio of the AP does not support SFN.	-	Replace the AP or modify the 6 GHz radio configuration.
The 6 GHz frequency band does not support WAPI, WPA, WPA2, and WEP.	-	Modify the encryption configuration of the VAP.
The AP in this version does not support RPSK authentication.	-	Replace the AP with an AP that supports RPSK authentication or upgrade the AP to a version that supports RPSK authentication.
The AP in this version does not support 802.1X +WPA3+AES.	-	Upgrade the AP to V200R023C00SPC100 or later.

11.1.93 display vap-profile

Function

The **display vap-profile** command displays configuration and reference information about VAP profiles.

Format

display vap-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays information about all VAP profiles.	-
name *profile-name*	Displays information about a specified VAP profile.	The VAP profile must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check configuration and reference information about VAP profiles.

Example

Display information about all VAP profiles.

```
<HUAWEI> display vap-profile all
FMode   : Forward mode
STA U/D : Rate limit client up/down
VAP U/D : Rate limit VAP up/down
BR2G/5G/6G : Beacon 2.4G/5G/6G rate
-----------------------------------------------------------------------------------------------------------------------
Name         FMode    Type     VLAN    AuthType  STA U/D(Kbps)  VAP U/D(Kbps)  BR2G/5G/6G(Mbps)
Reference  SSID
-----------------------------------------------------------------------------------------------------------------------
default      direct   service   VLAN 1  Open      -/-          -/-          5.5/6/6         0        GUEST-WLAN
vap-profile1  direct   service   VLAN 1  Open      -/-          -/-          5.5/6/6         0        GUEST-WLAN
-----------------------------------------------------------------------------------------------------------------------
Total: 2
```

Table 11-61 Description of the **display vap-profile all** command output

Item	Description
Name	VAP profile name.
FMode	Service data forwarding mode.
Type	VAP profile type. ● service ● management AP ● service-backup ap-offline ● service-backup auth-server-down ● service-backup distribute
VLAN	Service VLAN ID.
AuthType	User authentication mode.
STA U/D(Kbps)	Uplink/downlink rate limit of a single STA.
VAP U/D(Kbps)	Uplink/downlink rate limit of all STAs on a specified VAP.
BR2G/5G/6G(Mbps)	Rate of Beacon frames on each frequency band.
Reference	Number of times a VAP profile is referenced.
SSID	SSID profile referenced by a VAP profile.

Display information about the VAP profile **default**.

```
<HUAWEI> display vap-profile name default

Table 11-62 Description of the **display vap-profile name** command output

Item	Description
Profile ID	VAP profile ID.
Service mode	Whether the VAP service is enabled. To configure this parameter, run the **service-mode disable** command.
Type	VAP type. ● service: service type ● ap-management: management AP type ● ap-offline: AP-offline backup service type ● service-backup distribute: distributed-AP backup service type To configure this parameter, run the **type (VAP profile view)** command.
Forward mode	Service data forwarding mode. ● direct-forward: direct forwarding ● tunnel: tunnel forwarding ● Soft-GRE: soft GRE forwarding To configure this parameter, run the **forward-mode** command.
Split tunnel ACL	Split tunneling ACL number. In this manner, packets matching the ACL rules can be forwarded in direct mode when the tunnel forwarding mode is configured. To configure this parameter, run the **split-tunnel** command.
Offline management	Whether the offline management VAP and antenna alignment VAP are enabled. To configure this parameter, run the **temporary-management enable (VAP profile view)** command.
Service VLAN ID	Service VLAN ID. To configure this parameter, run the **service-vlan (VAP profile view)** command.

Item	Description
Service VLAN Pool	VLAN pool to which a service VLAN belongs. To configure this parameter, run the **service-vlan (VAP profile view)** command.
Permit VLAN ID	VLAN from which packets are allowed to pass through when the authorization VLAN verification function is enabled.
Auto off service switch	Whether the scheduled VAP auto-off function is enabled. To configure this parameter, run the **auto-off service** command.
Auto off starttime	Start time for scheduled VAP auto-off. To configure this parameter, run the **auto-off service** command.
Auto off endtime	End time for scheduled VAP auto-off. To configure this parameter, run the **auto-off service** command.
Auto off track link	Whether to automatically disable VAPs upon disconnection of the uplink of a cloud AP. After this function is enabled through the iMaster NCE-Campus, the SSID is automatically disabled when the uplink of the cloud AP is disconnected. Only cloud APs support this parameter.
STA access mode	STA access control mode. To configure this parameter, run the **sta-access-mode** command.
STA blacklist profile	STA blacklist profile. To configure this parameter, run the **sta-access-mode** command.
STA whitelist profile	STA whitelist profile. To configure this parameter, run the **sta-access-mode** command.
Keep service	Whether service holding upon CAPWAP link disconnection is enabled. To configure this parameter, run the **keep-service enable (VAP profile view)** command.

Item	Description
Keep service allow new access	Whether new STAs are allowed to go online when APs are offline. To configure this parameter, run the **keep-service enable (VAP profile view)** command.
Keep service allow new access no auth	Whether offline APs allow Portal or MAC address authentication STAs to go online without authentication. To configure this parameter, run the **keep-service enable (VAP profile view)** command.
Band steer	Whether the band steering function is enabled. To configure this parameter, run the **band-steer disable** command.
Sta network detect(reassoc)	Whether network detection upon STA reassociation is enabled. To configure this parameter, run the **sta-network-detect disable** command.
Sta network detect(assoc)	Whether network detection upon STA association is enabled. To configure this parameter, run the **sta-network-detect assoc enable** command.
Learn client IPv4 address	Whether STA IPv4 address learning is enabled. To configure this parameter, run the **learn-client-address disable (VAP profile view)** command.
Learn client DHCP strict	Whether strict STA IP address learning through DHCP is enabled. To configure this parameter, run the **learn-client-address dhcp-strict** command.
Learn client DHCP blacklist	Whether to add STAs with bogus IP addresses to a dynamic blacklist. To configure this parameter, run the **learn-client-address dhcp-strict** command.

Item	Description
Learn client IPv6 address	Whether STA IPv6 address learning is enabled. To configure this parameter, run the **learn-client-address disable (VAP profile view)** command.
Learn client DHCPv6 strict	Whether strict STA IP address learning through DHCPv6 is enabled. To configure this parameter, run the **learn-client-address dhcpv6-strict** command.
Learn client DHCPv6 blacklist	Whether to add STAs with bogus IPv6 addresses to a dynamic blacklist. To configure this parameter, run the **learn-client-address dhcpv6-strict** command.
Learn client DHCPv6 SLAAC	Whether STA IPv6 address learning only through DHCPv6 or SLAAC is enabled. To configure this parameter, run the **learn-client-address dhcpv6-slaac** command.
Learn client DHCPv6 SLAAC blacklist	Whether to add STAs with bogus IPv6 addresses to a dynamic blacklist. To configure this parameter, run the **learn-client-address dhcpv6-slaac** command.
IP source check	Whether IPSG is enabled. To configure this parameter, run the **ip source check user-bind enable** command.
ARP anti-attack check	Whether DAI is enabled. To configure this parameter, run the **arp anti-attack check user-bind enable** command.
DHCP option82 insert	Whether to enable APs to add the Option 82 field to DHCP packets sent by STAs. To configure this parameter, run the **dhcp option82 insert enable** command.

Item	Description
DHCP option82 remote id format	Format of the remote-ID in the Option 82 field added to DHCP packets sent by STAs. To configure this parameter, run the **dhcp option82 format (VAP profile view)** command.
DHCP option82 circuit id format	Format of the circuit-ID in the Option 82 field added to DHCP packets sent by STAs. To configure this parameter, run the **dhcp option82 format (VAP profile view)** command.
MAC format	Format of the AP MAC address in the Option 82 field. To configure this parameter, run the **dhcp option82 format (VAP profile view)** command.
DHCP option82 remote id pattern	Field separator of remote-id suboptions for Option 82 in DHCP packets sent by STAs. To configure this parameter, run the **dhcp option82 pattern (VAP profile view)** command.
DHCP option82 circuit id pattern	Field separator of circuit-id suboptions for Option 82 in DHCP packets sent by STAs. To configure this parameter, run the **dhcp option82 pattern (VAP profile view)** command.
User defined text	User-defined format of Option 82's suboptions in DHCP packets sent by STAs. To configure this parameter, run the **dhcp option82 format (VAP profile view)** command.
ND trust port	Whether the ND trusted interface function is enabled. To configure this parameter, run the **nd trust port** command.
SFN roam	Whether agile distributed SFN roaming is enabled. To configure this parameter, run the **sfn-roam enable** command.

Item	Description
Anti attack flood	Flood detection and prevention.
ARP flood switch	Whether ARP flood detection is enabled. ● enable ● disable To configure this parameter, run the **anti-attack flood disable** command.
ARP flood STA rate threshold	Rate threshold for ARP flood detection. To configure this parameter, run the **anti-attack flood sta-rate-threshold** command.
ARP flood blacklist	Whether the ARP flood blacklist function is enabled. ● enable ● disable To configure this parameter, run the **anti-attack flood blacklist enable** command.
ND flood switch	Whether ND flood detection is enabled. ● enable ● disable To configure this parameter, run the **anti-attack flood disable** command.
ND flood STA rate threshold	Rate threshold for ND flood detection. To configure this parameter, run the **anti-attack flood sta-rate-threshold** command.
ND flood blacklist	Whether the ND flood blacklist function is enabled. ● enable ● disable To configure this parameter, run the **anti-attack flood blacklist enable** command.

Item	Description
IGMP flood switch	Whether IGMP flood detection is enabled. ● enable ● disable To configure this parameter, run the **anti-attack flood disable** command.
IGMP flood STA rate threshold	Rate threshold for IGMP flood detection. To configure this parameter, run the **anti-attack flood sta-rate-threshold** command.
IGMP flood blacklist	Whether the IGMP flood blacklist function is enabled. ● enable ● disable To configure this parameter, run the **anti-attack flood blacklist enable** command.
DHCP flood switch	Whether DHCP flood detection is enabled. ● enable ● disable To configure this parameter, run the **anti-attack flood disable** command.
DHCP flood STA rate threshold	Rate threshold for DHCP flood detection. To configure this parameter, run the **anti-attack flood sta-rate-threshold** command.
DHCP flood blacklist	Whether the DHCP flood blacklist function is enabled. To configure this parameter, run the **anti-attack flood blacklist enable** command. ● enable ● disable

Item	Description
DHCPv6 flood switch	Whether DHCPv6 flood detection is enabled. ● enable ● disable To configure this parameter, run the **anti-attack flood disable** command.
DHCPv6 flood STA rate threshold	Rate threshold for DHCPv6 flood detection. To configure this parameter, run the **anti-attack flood sta-rate-threshold** command.
DHCPv6 flood blacklist	Whether the DHCPv6 flood blacklist function is enabled. ● enable ● disable To configure this parameter, run the **anti-attack flood blacklist enable** command.
mDNS flood switch	Whether mDNS flood detection is enabled. ● enable ● disable To configure this parameter, run the **anti-attack flood disable** command.
mDNS flood STA rate threshold	Rate threshold for mDNS flood detection. To configure this parameter, run the **anti-attack flood sta-rate-threshold** command.
mDNS flood blacklist	Whether the mDNS flood blacklist function is enabled. ● enable ● disable To configure this parameter, run the **anti-attack flood blacklist enable** command.

Item	Description
Other broadcast flood switch	Whether the flood detection function is enabled for broadcast packets other than ARP, DHCP, DHCPv6, and ND packets. - enable - disable To configure this parameter, run the **anti-attack flood disable** command.
Other broadcast flood STA rate threshold	Rate threshold for flood detection of broadcast packets other than ARP, DHCP, DHCPv6, and ND packets. To configure this parameter, run the **anti-attack flood sta-rate-threshold** command.
Other broadcast flood blacklist	Whether the flood blacklist function is enabled for broadcast packets other than ARP, DHCP, DHCPv6, and ND packets. - enable - disable To configure this parameter, run the **anti-attack flood blacklist enable** command.
Other multicast flood switch	Whether the flood detection function is enabled for multicast packets other than IGMP and mDNS packets. - enable - disable To configure this parameter, run the **anti-attack flood disable** command.
Other multicast flood STA rate threshold	Rate threshold for flood detection of multicast packets other than IGMP and mDNS packets. To configure this parameter, run the **anti-attack flood sta-rate-threshold** command.

Item	Description
Other multicast flood blacklist	Whether the flood blacklist function is enabled for multicast packets other than IGMP and mDNS packets. - enable - disable To configure this parameter, run the **anti-attack flood blacklist enable** command.
SSID profile	Name of the SSID profile referenced by a VAP profile. To configure this parameter, run the **ssid-profile (VAP profile view)** command.
Security profile	Name of the security profile referenced by a VAP profile. To configure this parameter, run the **security-profile (VAP profile view)** command.
Traffic profile	Name of the traffic profile referenced by a VAP profile. To configure this parameter, run the **traffic-profile (VAP profile view)** command.
Authentication profile	Name of the authentication profile referenced by a VAP profile.
SAC profile	Name of the SAC profile referenced by a VAP profile. To configure this parameter, run the **sac-profile (VAP profile view)** command.
Hotspot2.0 profile	Name of the Hotspot2.0 profile referenced by a VAP profile. To configure this parameter, run the **hotspot2-profile (VAP profile view)** command.
SoftGRE profile	Name of the soft GRE profile referenced by a VAP profile. To configure this parameter, run the **forward-mode softgre** *profile-name* command.

Item	Description
Service experience analysis	Whether the SEA function is enabled. To configure this parameter, run the **service-experience-analysis enable** command.
SIP snooping port	SIP listening port number. To configure this parameter, run the **service-experience-analysis sip-snooping port** command.
mDNS Snooping switch	Whether the mDNS snooping function is enabled. To configure this parameter, run the **mdns-snooping enable** command.
MU BA Trigger mode	Mode in which STAs reply with Block Ack frames. To configure this parameter, run the **mu-ba-trigger mode** command.
Dynamic flow inspection switch	Whether the DFI function is enabled. To configure this parameter, run the **dynamic flow inspection enable** command.
iConnect	Whether the iConnect SSID is enabled. To configure this parameter, run the **iconnect enable** command.
User Flow syslog switch	Whether the function of sending network access flow logs of users to a log server is enabled.
Multi-link operation	Whether the MLO function is enabled. To configure this parameter, run the **mlo disable** command.
Service experience analysis application list	List of applications monitored based on SEA on the VAP. ● Application ID ● Application Name To configure this parameter, run the **service-experience-analysis monitor application** command.

Item	Description
S-IPFPM application list	List of applications on the VAP for which iPCA 2.0 measurement is performed. ● Application ID ● Application Name To configure this parameter, run the **s-ipfpm measure application** command.
S-IPFPM flow list	iPCA 2.0 flow measurement configuration on VAPs. ● Flow ID: indicates the ID of a measurement flow. ● Role point: indicates the role of a measurement point. ● Direction: indicates the measurement flow direction. ● Bidirecion: indicates whether a measurement flow is bidirectional. To configure this parameter, run the **s-ipfpm measure flow (VAP profile view)** command.
S-IPFPM clear color-flag ingress	Whether the function of clearing the color bit in the ingress direction on the edge node is enabled. ● enable ● disable To configure this parameter, run the **s-ipfpm clear color-flag ingress** command.

11.1.94 display vap-service-backup auth-server-down

Function

The **display vap-service-backup auth-server-down** command displays the status of an authentication-server-down backup service VAP.

Format

display vap-service-backup auth-server-down [**vap-profile** *profile-name*]

Parameters

Parameter	Description	Value
vap-profile *profile-name*	Specifies the name of a VAP profile.	The VAP profile name must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check the status of an authentication-server-down backup service VAP.

Example

Display the status of an authentication-server-down backup service VAP.

```
<HUAWEI> display vap-service-backup auth-server-down
----------------------------------------------------------------------------------------------------
Vap-profile     VapSwitch      Mode      Radius-template      RadiusState
----------------------------------------------------------------------------------------------------
vap-1           ON             Auto      Radius-1             Down
vap-2           ON             Manual    Radius-2             Down
vap-3           OFF            Manual    Radius-3             Up
----------------------------------------------------------------------------------------------------
Total:3
```

Table 11-63 Description of the **display vap-service-backup auth-server-down** command output

Item	Description
Vap-profile	Name of a VAP profile.
VapSwitch	Status of the authentication-server-down backup service VAP.
Mode	Trigger mode of the authentication-server-down backup service VAP.
Radius-template	Name of a RADIUS server template.
RadiusState	Status of the RADIUS server.

11.1.95 display wlan config-errors

Function

The **display wlan config-errors** command displays WLAN configuration errors.

Format

display wlan config-errors

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check WLAN configuration errors.

Example

Display WLAN configuration errors.

```
<HUAWEI> display wlan config-errors
--------------------------------------------------------------------------------
Profile                                   Error
--------------------------------------------------------------------------------
vap-profile 1                                The authentication type specifie
d in the authentication-profile 1 does not match that in the security-profile 1.
--------------------------------------------------------------------------------
Total: 1
```

Table 11-64 Description of the **display wlan config-errors** command output

Item	Description
Profile	Profile name.
Error	Cause of a configuration error.

11.1.96 dot11a basic-rate

Function

The **dot11a basic-rate** command configures a basic rate set of the 802.11a protocol in a 5G radio profile.

The **undo dot11a basic-rate** command restores the default basic rate set of the 802.11a protocol in a 5G radio profile.

By default, a basic rate set of the 802.11a protocol in a 5G radio profile includes rates 6 Mbit/s, 12 Mbit/s, and 24 Mbit/s.

Format

dot11a basic-rate { *dot11a-rate-value* &<1-8> | **all** }

undo dot11a basic-rate

Parameters

Parameter	Description	Value
dot11a-rate-value	Specifies a basic rate set.	The value is of the enumerated type: • 6: 6 Mbit/s • 9: 9 Mbit/s • 12: 12 Mbit/s • 18: 18 Mbit/s • 24: 24 Mbit/s • 36: 36 Mbit/s • 48: 48 Mbit/s • 54: 54 Mbit/s
all	Supports all basic rates.	-

Views

5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The basic rate set includes all rates supported by both the AP and STA. A STA can associate with an AP only when the AP and STA support all rates in the basic rate set. For example, if you configure the basic rate set to contain rates 6 Mbit/s and 9 Mbit/s and deliver the configuration to an AP, only STAs supporting the two rates can associate with the AP. The AP and STA select a rate from the basic rate set or the supported rate set to transmit packets.

After you run this command to configure a basic rate set in a radio profile, bind the radio profile to an AP or AP group. If a STA associates with the AP in 802.11a mode, the STA must support all rates specified by the basic rate set; otherwise, the STA cannot associate with the AP.

When the rate set configuration exists in both the SSID profile and radio profile, the configuration in the SSID profile takes effect for AirEngine series APs and that in the radio profile takes effect for other AP models.

Precautions

This configuration applies only to STAs associated with an AP in 802.11a mode but does not take effect on STAs associated with the AP in other modes.

Example

Configure the 802.11a basic rate set to contain rates 6 Mbit/s and 9 Mbit/s in the 5G radio profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-5g-profile name default
[HUAWEI-wlan-radio-5g-prof-default] dot11a basic-rate 6 9
```

11.1.97 dot11a basic-rate (SSID profile view)

Function

The **dot11a basic-rate** command configures a basic rate set of the 802.11a protocol in an SSID profile.

The **undo dot11a basic-rate** command restores the default basic rate set of the 802.11a protocol in an SSID profile.

By default, no basic rate set of the 802.11a protocol is configured in an SSID profile, and the configuration in the radio profile takes effect.

NOTE

Only the AirEngine series APs support this command.

Format

dot11a basic-rate { *dot11a-rate-value* &<1-12> | **all** }

undo dot11a basic-rate

Parameters

Parameter	Description	Value
dot11a-rate-value	Specifies a basic rate set.	The value is of the enumerated type: ● 6: 6 Mbit/s ● 9: 9 Mbit/s ● 12: 12 Mbit/s ● 18: 18 Mbit/s ● 24: 24 Mbit/s ● 36: 36 Mbit/s ● 48: 48 Mbit/s ● 54: 54 Mbit/s
all	Supports all basic rates.	-

Usage Guidelines

Usage Scenario

The supported rate set contains rates supported by the AP in addition to the basic rates. The AP and STA can transmit data at all rates specified in the supported rate set. The AP and STA select a rate from the basic rate set or the supported rate set to transmit packets.

When a STA supports rates specified in the basic rate set, the STA can associate with the AP regardless of whether the STA supports rates specified in the supported rate set. In this case, the AP and STA can only select a rate from the basic rate set to transmit packets. For example, assume that you configure the basic rate set to contain rates 6 Mbps and 9 Mbps and the supported rate set to contain rates 48 Mbps and 54 Mbps. After you deliver the configurations to an AP, the STA supporting 6 Mbps and 9 Mbps can associate with the AP, and select either of the two rates to transmit packets with the AP. However, if the STA supports 6 Mbps, 9 Mbps, and 54 Mbps, the STA and AP select any of the three rates to transmit packets after the STA associates with the AP.

After you run this command to configure a supported rate set in a radio profile, bind the radio profile to an AP or AP group. If a STA associates with the AP in 802.11a mode, the AP and STA select a rate from the basic rate set or supported rate set to transmit packets.

When the rate set configuration exists in both the SSID profile and radio profile, the configuration in the SSID profile takes effect for AirEngine series APs and that in the radio profile takes effect for other AP models.

Precautions

This configuration applies only to STAs associated with an AP in 802.11a mode but does not take effect on STAs associated with the AP in other modes.

Example

Configure the 802.11a supported rate set to contain rates 6 Mbit/s and 9 Mbit/s in the 5G radio profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-5g-profile name default
[HUAWEI-wlan-radio-5g-prof-default] dot11a supported-rate 6 9
```

11.1.99 dot11a supported-rate (SSID profile view)

Function

The **dot11a supported-rate** command configures a supported rate set of the 802.11a protocol in an SSID profile.

The **undo dot11a supported-rate** command restores the default supported rate set of the 802.11a protocol in an SSID profile.

By default, no supported rate set of the 802.11a protocol is configured in an SSID profile, and the configuration in the radio profile takes effect.

NOTE

Only the AirEngine series APs support this command.

Format

dot11a supported-rate { *dot11a-rate-value* &<1-12> | **all** }

undo dot11a supported-rate

Parameters

Parameter	Description	Value
dot11a-rate-value	Specifies a supported rate set.	The value is of the enumerated type: ● 6: 6 Mbit/s ● 9: 9 Mbit/s ● 12: 12 Mbit/s ● 18: 18 Mbit/s ● 24: 24 Mbit/s ● 36: 36 Mbit/s ● 48: 48 Mbit/s ● 54: 54 Mbit/s

For example, assume that you configure the basic rate set to contain rates 6 Mbps and 9 Mbps and the supported rate set to contain rates 48 Mbps and 54 Mbps. After you deliver the configurations to an AP, the STA supporting 6 Mbps and 9 Mbps can associate with the AP, and select either of the two rates to transmit packets with the AP. However, if the STA supports 6 Mbps, 9 Mbps, and 54 Mbps, the STA and AP select any of the three rates to transmit packets after the STA associates with the AP.

After you run this command in an SSID profile to configure a supported rate set, bind the SSID profile to a VAP profile. If a STA associates with an AP in 802.11b/g mode, the actual data transmission rate between the AP and STA is selected from the basic rate set and the rate set supported by the STA.

When the rate set configuration exists in both the SSID profile and radio profile, the configuration in the SSID profile takes effect for AirEngine series APs and that in the radio profile takes effect for other AP models.

Precautions

This configuration applies only to STAs associated with an AP in 802.11b/g mode but does not take effect on STAs associated with the AP in other modes.

When the radio mode is 802.11b, only rates 1, 2, 5, and 11 Mbit/s take effect in the rate set configured in an SSID profile. If no rate in this rate set is configured in the SSID profile, the rate set configured in the radio profile is used.

Example

Configure the 802.11b/g supported rate set to contain rates 6 Mbit/s and 9 Mbit/s in the SSID profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name default
[HUAWEI-wlan-ssid-prof-default] dot11bg supported-rate 6 9
```

11.1.104 dtim-interval

Function

The **dtim-interval** command sets the delivery traffic indication map (DTIM) interval in an SSID profile.

The **undo dtim-interval** command restores the default DTIM interval in an SSID profile.

By default, the DTIM interval is 1.

Format

dtim-interval *dtim-interval*

undo dtim-interval

Parameters

Parameter	Description	Value
dtim-interval	Specifies the DTIM interval.	The value is an integer that ranges from 1 to 255, in Beacons.

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

DTIM refers to delivery traffic indication map. After a STA enters the dormancy mode, the associated AP saves the broadcast and multicast frames for the STA. When a Beacon frame sent to the STA by the AP contains DTIM, the saved broadcast and multicast frames will be transmitted to the STA. The DTIM interval refers to the number of Beacon frames sent before the Beacon frame that contains the DTIM. To set the interval for sending Beacon frames in an SSID profile, run the **beacon-interval** command.

- When the STA is in the dormancy status, the AP saves data transmitted to the STA and notifies the STA with a bit in broadcast Beacon frames. The STA receives data according to this bit. You can run this command to set the DTIM interval in the specified SSID profile.
- The DTIM interval specifies how many Beacon frames are sent before the Beacon frame that contains the DTIM. A long DTIM interval lengthens the dormancy time of the STA and saves power, but degrades the transmission capability of the STA. A short interval helps transmitting data in a timely manner, but the STA is woken up frequently, causing high power consumption.

Precautions

Changing the DTIM interval will restart the VAP to make the configuration take effect. During the VAP restart, services on the VAP are interrupted and STAs are disconnected.

Example

Set the DTIM interval to 5 in the SSID profile **ssid1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] dtim-interval 5
```

11.1.105 eirp

Function

(AP group radio view) The **eirp** command configures the transmit power for all specified radios in an AP group.

(AP group radio view) The **undo eirp** command restores the default transmit power for all specified radios in an AP group.

(AP radio view) The **eirp** command configures the transmit power for an AP radio.

(AP radio view) The **undo eirp** command cancels the configuration of the transmit power on an AP radio. The transmit power on the AP radio is then determined by that configured in the AP group radio view.

By default, the transmit power of a radio is 127 dBm. The transmit power that takes effect on APs is related to the AP type, country code, channel, and channel bandwidth. The transmit power in effect is the maximum transmit power that the AP radio supports under the current configuration. To check this value, run the **display radio** { **ap-name** *ap-name* | **ap-id** *ap-id* } command.

Format

eirp *eirp*

undo eirp

Parameters

Parameter	Description	Value
eirp	Specifies the transmit power.	The value is an integer that ranges from 1 to 127, in dBm.

Views

AP radio view, AP group radio view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Effective isotropic radiated power (EIRP) signifies the strength of signals transmitted from an antenna, that is, the transmit power of a radio plus the antenna gain. The transmit power of a radio configured using the **eirp** command is the EIRP plus the antenna gain on the radio.

You can configure the transmit power for a radio based on actual network environments, enabling radios to provide the required signal strength and improving signal quality on WLANs.

Precautions

The value of *antenna-gain* in the **antenna-gain** *antenna-gain* command must be consistent with the gain of the antenna connected to an AP.

If automatic transmit power selection is enabled by running the **calibrate auto-txpower-select enable** command, the transmit power configured by running the

eirp command does not take effect. The automatically selected transmit power is used.

If automatic transmit power selection is disabled by running the **calibrate auto-txpower-select disable** command, the transmit power configured by running the **eirp** command takes effect as follows:

The actual transmit power of an AP radio is determined by the configured transmit power of the radio, requirements of local laws and regulations, as well as the transmit power range supported by the AP. The actual transmit power of a radio cannot exceed the maximum transmit power required by local laws and regulations.

- If the configured transmit power of a radio is in compliance with local laws and regulations and within the transmit power range supported by the AP, the configured transmit power is the actual transmit power of the radio.
- If the configured transmit power of a radio is smaller than the minimum transmit power supported by the AP, the smaller one between the minimum transmit power supported by the AP and maximum transmit power required by local laws and regulations is the actual transmit power of the radio.
- If the configured transmit power of a radio is larger than the maximum transmit power supported by the AP, the smaller one between the maximum transmit power supported by the AP and maximum transmit power required by local laws and regulations is the actual transmit power of the radio.

The configuration in the AP radio view has a higher priority than that in the AP group radio view.

Example

Set the transmit power of radio 0 on AP 1 to 30 dBm.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 1
[HUAWEI-wlan-ap-1] radio 0
[HUAWEI-wlan-radio-1/0] eirp 30
Info: The EIRP value takes effect only when automatic transmit power selection i
s disabled, and the value depends on the AP specifications and local laws and re
gulations.
```

11.1.106 er-su disable

Function

The **er-su disable** command disables the Extended Range Single User (ER-SU) function.

The **undo er-su disable** command enables the ER-SU function.

By default, the ER-SU function is enabled.

NOTE

This command is not supported by the following models.

- AirEngine x760 series APs.

Format

er-su disable

undo er-su disable

Parameters

None

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

The ER-SU function improves the signal quality at the cell edge and further improves the long-distance coverage capability.

Example

Disable the ER-SU function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan view] ssid-prof name test
[HUAWEI-wlan-ssid-prof-test] er-su disable
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.1.107 forward-mode

Function

The **forward-mode** command sets the data forwarding mode in a VAP profile.

The **undo forward-mode** command restores the default data forwarding mode in a VAP profile.

By default, the direct forwarding mode is used in a VAP profile.

Format

forward-mode { **direct-forward** | **tunnel** | **softgre** *profile-name* }

undo forward-mode

Parameters

Parameter	Description	Value
direct-forward	Indicates the direct forwarding mode.	-
tunnel	Indicates the tunnel forwarding mode.	-
softgre *profile-name*	Indicates the soft GRE forwarding mode and specifies the name of the soft GRE profile bound to a VAP profile.	The specified soft GRE profile must exist.

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to configure the forwarding mode in a VAP profile. The forwarding modes of each VAP profile can be different.

A soft GRE profile can be bound to a VAP profile only after the destination IP address of the soft GRE tunnel is configured in the soft GRE profile.

Example

Create the VAP profile **vap1** and set the forwarding mode to direct forwarding in the profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] forward-mode direct-forward
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.1.108 fragmentation-threshold

Function

The **fragmentation-threshold** command sets the fragmentation threshold in a radio profile.

The **undo fragmentation-threshold** command restores the default fragmentation threshold in a radio profile.

By default, the packet fragmentation threshold is 2346 bytes.

Format

fragmentation-threshold *fragmentation-threshold*

undo fragmentation-threshold

Parameters

Parameter	Description	Value
fragmentation-threshold	Specifies the fragment threshold. If the length of a frame to be sent by the MAC layer exceeds this threshold, the frame is fragmented before being sent.	The value is an integer that ranges from 256 to 2346, in bytes. It must be an integral multiple of 2.

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A proper packet fragmentation threshold can improve channel bandwidth usage. Set the fragmentation threshold as required. A large threshold is recommended.

Precautions

When the packet fragmentation threshold is too small, packets are fragmented into smaller frames. These frames are transmitted at a high extra cost, resulting in low channel efficiency.

When the packet fragmentation threshold is too large, long packets are usually not fragmented, which increases the transmission time and error probability. If an error occurs, packets are retransmitted, resulting in a waste of channel bandwidth.

Example

Set the fragmentation threshold to 1500 bytes in the 2G radio profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] fragmentation-threshold 1500
```

11.1.109 frequency

Function

(AP group radio view) The **frequency** command sets the working frequency band of radios for all APs in an AP group.

(AP group radio view) The **undo frequency** command restores the default working frequency band of radios for all APs in an AP group.

(AP radio view) The **frequency** command sets the working frequency band of radios for an AP.

(AP radio view) The **undo frequency** command restores the default working frequency band of the radio on an AP to that configured in the AP group radio view.

By default, radio 0 and radio 2 in the AP group radio view work on the 2.4 GHz and 6 GHz frequency bands, respectively. If radio 2 does not support the 6 GHz frequency band, it works on the frequency band by default. There is no default value in the AP radio view, and the configuration in the AP group radio view is used.

Format

frequency { **2.4g** | **5g** | **6g** }

undo frequency

Parameters

Parameter	Description	Value
2.4g	Specifies 2.4 GHz frequency band.	-
5g	Specifies 5 GHz frequency band.	-
6g	Specifies the 6 GHz frequency band.	-

Views

AP radio view, AP group radio view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Radios of some AP models support frequency band switching but can work on only one frequency band at a time. You can configure the working frequency band of AP radios based on the frequency bands supported by STAs.

Precautions

When working in dual-5G mode, some APs support only low-band channels (36 to 64) or high-band channels (100 to 165) on the 5 GHz band.

- AirEngine 5760-51: Radio 1 on high bands and radio 2 on low bands
- AirEngine 6760-X1: Radio 1 on high bands and radio 2 on low bands
- AirEngine 6760-X1E: Radio 1 on high bands and radio 2 on low bands
- AirEngine 8760R-X1E: Radio 1 and radio 2 on all bands
- AirEngine 8760-X1-PRO: Radio 1 on high bands and radio 2 on low bands
- AirEngine 6761-21T: Radio 1 on high bands and radio 2 on low band
- AirEngine 6761S-21T: Radio 1 on high bands and radio 2 on low band
- AirEngine 5761R-11E: Radio 0 and radio 1 on all bands
- AirEngine 8771-X1T: Radio 1 on low bands and radio 2 on high band

Changing the working frequency band of radio 0 and radio 2 will delete the channel, power, and antenna gain configurations on radio 0 and radio 2. If an AP uses an external antenna, run the **antenna-gain** *antenna-gain* command to reconfigure the antenna gain to be consistent with the gain of the external antenna connected to the AP.

If the working frequency band of the AP radio set using the preceding commands is the same as that of the AP's actual working frequency band, the AP will not restart. Otherwise, the AP restarts after the preceding commands are run.

The configuration in the AP radio view has a higher priority than that in the AP group radio view.

If two radios of an AP work on the 5 GHz frequency band, the operating channels of the two 5 GHz radios must be separated by at least one channel to avoid interference. If two radios of an AP work on the 5 GHz and 6 GHz frequency bands, respectively, pay attention to channel planning as follows:

- For the model AirEngine 6761-22T: Do not use a 5 GHz high-frequency channel (149–165) and a 6 GHz low-frequency channel (80 MHz channels 1–13, 160 MHz channels 1–29) at the same time.
- For the model AirEngine 8771-X1T: Do not use a 5 GHz high-frequency channel (20 MHz channels 153–165, 40 MHz channels 132–161, 80 MHz channels 132–161, 160 MHz channels 100–128, 320 MHz channels 100–144) and a 6 GHz channel (160 MHz channels 1–29, 320 MHz channels 1–61) at the same time.

For example, a country supports 40 MHz+ 5G channels 36, 44, 52, and 60. When deploying 5 GHz radio channels, if one radio is deployed to work on channel 36, it is recommended that channel 52 or 60 be configured for the other radio. Channel 44 is not recommended in this case.

Example

Set the working frequency band of radio 0 of AP to the 5 GHz band.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 0
[HUAWEI-wlan-ap-0] radio 0
[HUAWEI-wlan-radio-0/0] frequency 5g
Warning: Modifying the frequency band will delete the channel, power, and antenn
a gain configurations of the current radio on the AP and reboot the AP. Continue
?[Y/N]:Y
```

11.1.110 guard-interval-mode

Function

The **guard-interval-mode** command configures the guard interval (GI) mode.

The **undo guard-interval-mode** command restores the default GI mode.

By default, the GI mode in 802.11n/ac is **short**, and the GI mode in 802.11ax/be is 0.8 us.

Format

guard-interval-mode { **short** | **normal** }

undo guard-interval-mode

guard-interval-mode dot11ax { **dot8** | **1dot6** | **3dot2** }

undo guard-interval-mode dot11ax

Parameters

Parameter	Description	Value
short	Sets the GI mode in 802.11n/ac to short GI.	-
normal	Sets the GI mode in 802.11n/ac to normal GI.	-
dot11ax { **dot8** | **1dot6** | **3dot2** }	Specifies the GI mode in 802.11ax/be.	-

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

During data transmission, the receive and transmit ends do not receive and send data at all times. When data is received and transmitted or multiple transmissions occur, multi-path interference is generated in radio signal propagation. An interval between transmissions can reduce the impact of interference. This interval is called guard interval (GI).

A smaller GI indicates higher transmission efficiency. A larger GI indicates a higher anti-interference capability. A small GI is recommended for indoor areas with low interference, and a large GI is recommended for outdoor areas with high interference.

- In 802.11a/b/g, the GI is fixed at 800 ns.
- In 802.11n and 802.11ac, the GI can be set to 400 ns (short) or 800 ns (normal).
- In 802.11ax and 802.11be, the GI can be set to 0.8 us (800 ns), 1.6 us, or 3.2 us.

Example

Set the GI mode to short.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] guard-interval-mode short
```

11.1.111 he mcs-map (SSID Profile)

Function

The **he mcs-map** command configures the number of 802.11ax spatial streams and the Modulation and Coding Scheme (MCS) of the spatial streams in an SSID profile.

The **undo he mcs-map** command restores the default number of 802.11ax spatial streams and the default MCS of the spatial streams in an SSID profile.

By default, the number of spatial streams sent and received in 802.11ax is 8, and the MCS of the spatial streams is 11 in an SSID profile.

Format

he { **tx** | **rx** } **mcs-map nss** *nss-value* **map** *mcs-value*

undo he { **tx** | **rx** } **mcs-map**

Parameters

Parameter	Description	Value
tx	Indicates the sent data.	-
rx	Indicates the received data.	-
nss *nss-value*	Specifies the number of spatial streams.	The value is an integer that ranges from 1 to 8.

Parameter	Description	Value
map *mcs-value*	Specifies the MCS of the spatial streams.	The value can be 7, 9, or 11.

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The rate of an 802.11ax-capable AP depends on the index value of the MCS. A larger MCS indicates a higher transmission rate.

- When the value of *nss-value* is greater than or equal to the number of spatial streams actually supported by an AP, the MCS value corresponding to all the spatial streams of the AP is the value of *mcs-value*.
- When the value of *nss-value* is smaller than the number of spatial streams actually supported by an AP, only the MCS value corresponding to the spatial streams on the AP is the value of *mcs-value*, and the maximum MCS value corresponding to other spatial streams does not take effect.

  For example, if the value of *nss-value* is 2, and the AP supports three spatial streams, only the MCS value corresponding to spatial streams 1 and 2 is the value of *mcs-value*, and the MCS value corresponding to spatial stream 3 does not take effect.

Precautions

This configuration takes effect only when the AP communicates with STAs through 802.11ax.

Example

Set the MCS value corresponding to spatial stream 4 to 9 when data is received in an SSID profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] he rx mcs-map nss 4 map 9
```

11.1.112 a-mpdu disable

Function

The **a-mpdu disable** command disables the aggregate MAC protocol data unit (A-MPDU) function.

The **undo a-mpdu disable** command enables the A-MPDU function.

By default, the A-MPDU function is enabled.

Format

a-mpdu disable

undo a-mpdu disable

Parameters

None

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

To reduce costs, 802.11n uses A-MPDU technology that aggregates two or more MPDUs into one frame for transmission.

The 802.11ac and later protocols require that the A-MPDU mode be enabled. Therefore, this command takes effect only for 802.11n APs.

Example

Disable the A-MPDU function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] a-mpdu disable
```

11.1.113 ht a-mpdu max-length-exponent

Function

The **ht a-mpdu max-length-exponent** command sets the maximum length of an aggregated MPDU (A-MPDU) on the 802.11n radio. MPDU stands for MAC protocol data unit.

The **undo ht a-mpdu max-length-exponent** command restores the maximum length of an A-MPDU on the 802.11n radio to the default value.

By default, the index for the maximum length of an A-MPDU is 3. The maximum length of the A-MPDU is 65535 bytes.

The function is not supported by the following models.

- AirEngine series APs

Format

ht a-mpdu max-length-exponent *max-length-exponent-index*

undo ht a-mpdu max-length-exponent

Parameters

Parameter	Description	Value
max-length-exponent-index	Indicates the index for the maximum length of the A-MPDU.	The value is an integer that ranges from 0 to 3. ● 0: indicates that the maximum length of the A-MPDU is 8191 bytes. ● 1: indicates that the maximum length of the A-MPDU is 16383 bytes. ● 2: indicates that the maximum length of the A-MPDU is 32767 bytes. ● 3: indicates that the maximum length of the A-MPDU is 65535 bytes.

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

To reduce costs, 802.11n uses frame aggregation technology that aggregates two or more frames into an A-MPDU to transmit.

Example

Set the index of the maximum length of the A-MPDU to 2 in the 2G radio profile **default**. The index 2 corresponds to a maximum length of 32767 bytes.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] ht a-mpdu max-length-exponent 2
```

11.1.114 keepalive (soft GRE profile view)

Function

The **keepalive** command enables Keepalive detection for a soft GRE tunnel and sets Keepalive parameters.

The **undo keepalive** command disables Keepalive detection for a soft GRE tunnel and restores the default Keepalive parameters.

By default, Keepalive detection is disabled for a soft GRE tunnel, the interval for sending Keepalive packets is 5 seconds, and the maximum number of retransmission attempts is 3.

Format

keepalive [**period** *period* [**retry-times** *retry-times*]]

undo keepalive

Parameters

Parameter	Description	Value
period *period*	Specifies the interval for sending Keepalive packets.	The value is an integer that ranges from 1 to 32767, in seconds.
retry-times *retry-times*	Specifies the maximum number of Keepalive packet retransmission times.	The value is an integer that ranges from 1 to 255.

Views

Soft GRE profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a network fault occurs and the remote end of a soft GRE tunnel becomes unreachable, an AP cannot detect the network fault and therefore will continue to send packets to the remote end. These packets waste device resources and bandwidth of the intermediate network. After Keepalive detection for a soft GRE tunnel is enabled, the AP can detect the soft GRE tunnel status. When detecting that the peer end of the soft GRE tunnel is unreachable, the AP stops sending packets to the peer end. Otherwise, the AP continues sending packets to the peer end. This mechanism reserves device resources and bandwidth.

After the Keepalive detection function for the soft GRE tunnel is enabled, the local AP periodically sends Keepalive packets to the peer end at specified intervals to check connectivity of the soft GRE tunnel. The value of the unreachable counter is incremented by 1 each time a Keepalive packet is sent but no response is received within the detection period. If a response is received before the value of **retry-times** is reached, the counter is reset. If the AP does not receive any response from the peer end when the counter value reaches the preset value (**retry-times**), it considers the peer unreachable and terminates the tunnel. If the AP receives a response, it considers the peer reachable and continues sending packets to the peer end.

Precautions

If only the **keepalive** command is executed and the parameter **period** *period* [**retry-times** *retry-times*] is not specified, the Keepalive detection function is enabled and the default value of **period** *period* [**retry-times** *retry-times*] parameter is used.

If you run the **keepalive** command several times, the latest configuration overrides the previous configurations.

The Keepalive detection function for a soft GRE tunnel takes effect unidirectionally. If the Keepalive detection function is required on both ends of a soft GRE tunnel, enable this function on each end of the tunnel. The Keepalive detection function takes effect on one end even if the function is disabled on the other end. However, you are advised to enable the Keepalive detection function on both ends of a tunnel.

Example

Enable the Keepalive detection function for a soft GRE tunnel using default parameters.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] softgre-profile name soft1
[HUAWEI-wlan-softgre-prof-soft1] keepalive
```

11.1.115 keep-service enable (VAP profile view)

Function

The **keep-service enable** command enables service holding upon CAPWAP link disconnection.

The **undo keep-service enable** command disables service holding upon CAPWAP link disconnection.

By default, service holding upon CAPWAP link disconnection is disabled.

Format

keep-service enable [**allow new-access** [**no-auth**]]

undo keep-service enable

Parameters

Parameter	Description	Value
allow new-access	Enables offline APs to allow access of new STAs.	-
no-auth	Allows STAs using Portal or MAC address authentication to go online without authentication.	-

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In direct forwarding mode, you can enable service holding upon CAPWAP link disconnection. In this way, when the CAPWAP link between an AP and AC is disconnected, the AP can continue to provide WLAN services, preventing service interruption and improving forwarding reliability.

Service holding upon CAPWAP link disconnection controls whether new STAs are allowed to go online. For high-security authentication modes such as MAC address authentication and Portal authentication, **no-auth** must be configured to enable STAs to go online without authentication upon CAPWAP link disconnection. Therefore, this function can be enabled in scenarios with low security requirements.

Precautions

- Service holding upon CAPWAP link disconnection can be configured in the VAP profile view and AP system profile view. The configuration in the VAP profile view takes precedence over that in the AP system profile view.
- Service holding upon CAPWAP link disconnection is applicable only to scenarios where direct forwarding is used for data services.
- The function of enabling offline APs to allow access of STAs is applicable to scenarios where service data is forwarded in direct mode and the STA authentication mode is Portal, MAC address, WEP, WPA/WPA2-PSK, or open system.

- Service holding upon CAPWAP link disconnection cannot be configured together with the AP-offline backup service VAP (configured using the **type service-backup ap-offline** command) or containment function. Service holding upon CAPWAP link disconnection does not take effect when the containment function is also configured.
- Service holding upon CAPWAP link disconnection is unavailable on a WDS network.
- After service holding upon CAPWAP link disconnection is enabled, the **display access-user** command cannot display information about NAC STAs that are online before the CAPWAP link is disconnected. To display information about such STAs, run the **display station** command.

Example

Enable service holding upon CAPWAP link disconnection in the VAP profile **vap1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] keep-service enable
```

11.1.116 legacy-station disable

Function

The **legacy-station disable** command denies access of non-HT STAs.

The **undo legacy-station disable** command permits access of non-HT STAs.

By default, access of non-HT STAs is permitted.

Format

legacy-station [**only-dot11b**] **disable**

undo legacy-station disable

Parameters

Parameter	Description	Value
only-dot11b	Denies access of non-HT STAs that support only 802.11b.	-

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Non-HT STAs support only 802.11a/b/g and provide a data transmission rate far smaller than the rate of STAs in compliance with 802.11n or later standards. If the non-HT STAs access the WLAN, the data transmission rate of STAs in compliance with 802.11n or later standards will be reduced. To prevent the transmission rate of these STAs from being affected, you can run the **legacy-station** [**only-dot11b**] **disable** command to deny access of all or only 802.11b-compliant non-HT STAs.

Configuration Impact

After the **legacy-station disable** command is run, non-HT STAs supporting only 802.11a/b/g cannot access the wireless network.

After the **legacy-station only-dot11b disable** command is run, non-HT STAs supporting only 802.11b cannot access the wireless network.

After access of non-HT STAs is denied, services may be interrupted.

Precautions

After the **legacy-station disable** command is run, the access of non-HT STAs supporting only 802.11a/b/g fails to be denied if any of the following functions is configured on the non-HT STAs:

- WMM function in a 2G or 5G radio profile disabled using the **wmm disable** command
- Pre-shared key authentication and TKIP encryption for WPA/WPA2 configured using the **security** { **wpa** | **wpa2** | **wpa-wpa2** } **psk** { **pass-phrase** | **hex** } *key-value* **tkip** command when the security profile is used
- 802.1X authentication and TKIP encryption for WPA/WPA2 configured using the **security** { **wpa** | **wpa2** | **wpa-wpa2** } **dot1x tkip** command when the security profile is used
- WEP authentication configured using the **security wep** [**share-key** | **dynamic**] command when the security profile is used
- 802.11b/g radio type in the 2G radio profile configured using the **radio-type** { **dot11b** | **dot11g** } command
- 802.11a radio type in the 5G radio profile configured using **radio-type dot11a** command

After the **legacy-station only-dot11b disable** command is run, the access of non-HT STAs supporting only 802.11b is denied. If 802.11b radio type in the 2G radio profile has been configured using the **radio-type dot11b** command, the access of non-HT STAs supporting only 802.11b fails to be denied.

Example

Deny access of non-HT STAs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] legacy-station disable
Warning:  If the wmm disable command, TKIP, WEP, or radio type of 802.11a/b/g is configured, the function
of denying access of legac
y STAs cannot take effect.
```

11.1.117 max-sta-number (SSID profile view)

Function

The **max-sta-number** command sets the maximum number of STAs that can be associated with a single VAP.

The **undo max-sta-number** command restores the default maximum number of STAs that can be associated with a single VAP.

By default, a VAP allows for association of a maximum of 64 STAs.

Format

max-sta-number *max-sta-number*

undo max-sta-number

Parameters

Parameter	Description	Value
max-sta-number	Specifies the maximum number of STAs that can be associated with a single VAP.	The value is an integer that ranges from 1 to 512.

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

More access users on a VAP indicate fewer network resources that each user can occupy. To ensure Internet experience of users, you can run this command to properly set the maximum number of STAs that can be associated with a single VAP.

Configuration Impact

After this command is executed, online STAs are disconnected. When STAs reassociate with the VAP and the number of associated STAs on the VAP reaches the maximum, new STAs fail to associate with this VAP.

The **max-sta-number** *max-sta-number* command sets the maximum number of STAs that can be associated with a single VAP.

Precautions

The setting configured by this command refers to the maximum number of STAs that can be associated with a VAP of a single AP.

Example

Set the maximum number of STAs that can be associated with a single VAP to 50.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] max-sta-number 50
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.1.118 mlo enable

Function

The **mlo enable** command enables the multi-link operation (MLO) function.

The **mlo disable** command disables the MLO function.

The **undo mlo** command restores the default status of the MLO function.

By default, the MLO function is disabled.

Format

mlo { **enable** | **disable** }

undo mlo

Parameters

None

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a STA communicates with an AP, the STA selects only one radio to set up a connection, for example, on the 2.4 GHz or 5 GHz frequency band. The maximum air interface rate of the STA is the maximum capability supported by the current radio. To further improve the air interface rate and reduce latency, 802.11be introduces the MLO function that allows for link setup on multiple radios for communication. To improve the air interface rate, transmit different data on different radios at the same time. Radios can back up each other so when the channel is busy on a radio, data is quickly switched to another radio for transmission, reducing air interface latency.

Precautions

After the MLO function is enabled, some incompatible STAs may fail to detect Wi-Fi signals or fail to associate with the WLAN. Such issues can be resolved after you disable the MLO function.

Currently, an AP supports a maximum of two concurrent radios, for example, 2.4 GHz + 5 GHz radios or 5 GHz + 6 GHz radios.

Both the AP and the STA need to support the MLO function. If both the AP and STA support the MLO function on the 2.4 GHz, 5 GHz, and 6 GHz frequency bands, the high-speed 5 GHz + 6 GHz radios are used to set up a link between the AP and STA. If the STA supports the MLO function only on the 2.4 GHz and 5 GHz frequency bands, the link can be set up only using 2.4 GHz + 5 GHz radios.

After the MLO function is enabled, if the configuration of one radio is modified and the modification affects MLO link renegotiation, VAP services on the two radios are interrupted, causing STAs to go offline and online again. Services of other VAPs on the radios are not affected. The configurations that affect MLO link renegotiation include: whether MLO is enabled, radio type, whether the radio is enabled, binding relationship between the VAP profile and radio, security policy, and SSID name.

After an MLO link is set up, information about the STA connected to the device can be viewed only on one radio. However, traffic statistics about the STA are still collected on the two radios. To view information about the access radio of the STA, log in to the AP associated with the STA and run the **display umac station mac** *mac-address* command in the diagnostic view to display MLO link setup information about the STA.

The MLO function takes effect only when the following conditions are met:

- A VAP profile is bound to multiple radios of an AP, and the WLAN IDs of the radios are the same.
- The radios work in 802.11be mode.
- The security policy is open (only 2.4 GHz + 5 GHz radios supported), WPA2 (only 2.4 GHz + 5 GHz radios supported), WPA3, WPA2-WPA3 (only 2.4 GHz + 5 GHz radios supported), or OWE.

The MLO and 802.11r fast roaming functions are mutually exclusive. After the 802.11r fast roaming function is enabled, the MLO function does not take effect.

Example

Enable the MLO function in the VAP profile **vap1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] mlo enable
Warning: After the MLO function is enabled, some incompatible STAs may fail to detect Wi-Fi signals and
cannot associate with the WLAN. This issue can be resolved after you disable the MLO function.
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.1.119 mu-ba-trigger mode

Function

The **mu-ba-trigger mode** command sets the mode in which STAs reply with Block Ack frames.

The **undo mu-ba-trigger mode** command restores the default mode in which STAs reply with Block Ack frames.

By default, STAs reply with Block Ack frames in MU-BAR mode.

This command is supported on the following APs.

- AirEngine x761
- AirEngine x762
- AirEngine x771

Format

mu-ba-trigger mode { **basic-trigger** | **mu-bar** }

undo mu-ba-trigger mode

Parameters

Parameter	Description	Value
basic-trigger	A-MPDU with basic trigger	-
mu-bar	A-MPDU with MU-BAR	-

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

The **mu-ba-trigger mode** command sets the mode in which STAs reply with Block Ack frames.

Example

Set the mode in which STAs reply with Block Ack frames to basic-trigger.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name test
[HUAWEI-wlan-vap-prof-test] mu-ba-trigger mode basic-trigger
```

11.1.120 mu-mimo disable

Function

The **mu-mimo disable** command disables the downlink MU-MIMO scheduling function.

The **undo mu-mimo disable** command enables the downlink MU-MIMO scheduling function.

By default, the downlink MU-MIMO scheduling function is enabled.

Format

mu-mimo disable

undo mu-mimo disable

Parameters

None

Views

SSID profile view, WDS profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Carrier sense multiple access with collision avoidance (CSMA-CA) allows an air interface channel to be occupied only by one STA, and other STAs cannot communicate with the AP. After downlink MU-MIMO scheduling is enabled, STAs supporting MU-MIMO can form an MU group to simultaneously receive downlink data from the same air interface channel, improving channel efficiency and overall downlink throughput.

Prerequisites

Before enabling downlink MU-MIMO scheduling, run the **undo beamforming disable** command to enable beamforming.

Precautions

- In WDS scenarios, ensure that the number of spatial streams on STA VAPs is smaller than that on AP VAPs. Otherwise, MU-MIMO cannot take effect. For example, if STA VAPs and AP VAPs are both configured with three spatial streams, an AP VAP can communicate with only one STA VAP even if MU-MIMO has been enabled.
- downlink MU-MIMO scheduling is not supported in the Mesh networking.

In VR scenarios, disabling downlink MU-MIMO scheduling is recommended.

Example

Enable in the SSID profile **test**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name test
[HUAWEI-wlan-ssid-prof-test] undo mu-mimo disable
```

11.1.121 mu-mimo optimize enable

Function

The **mu-mimo optimize enable** command enables the MU-MIMO optimization function.

The **undo mu-mimo optimize enable** command disables the MU-MIMO optimization function.

By default, the MU-MIMO optimization function is disabled.

Format

mu-mimo optimize enable

undo mu-mimo optimize enable

Parameters

None

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In an environment with less interference, you can run the **mu-mimo optimize enable** command to enable the MU-MIMO optimization function to meet requirements for high downlink throughput of the AP. The expected effect may fail to be achieved in some scenarios.

Prerequisites

The MU-MIMO function has been enabled using the **undo mu-mimo disable** command.

NOTE

The MU-MIMO optimization function is not supported by the following models.

- AirEngine series APs

Example

Enable the MU-MIMO optimization function in the SSID profile **test**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name test
[HUAWEI-wlan-ssid-prof-test] undo mu-mimo disable
[HUAWEI-wlan-ssid-prof-test] mu-mimo optimize enable
```

11.1.122 ofdma downlink disable

Function

The **ofdma downlink disable** command disables the downlink (DL) OFDMA function.

The **undo ofdma downlink disable** command enables the DL OFDMA function.

By default, the DL OFDMA function is enabled.

Format

ofdma downlink disable

undo ofdma downlink disable

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

OFDMA is a multi-user technology introduced in 802.11ax. This function improves the utilization of wireless spectrum resources, supports more concurrent STAs, and improves user experience in wireless Internet access.

Example

Enable the DL OFDMA function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name test
[HUAWEI-wlan-ssid-prof-test] undo ofdma downlink disable
```

11.1.123 ofdma uplink disable

Function

The **ofdma uplink disable** command disables the uplink (UL) OFDMA function.

The **undo ofdma uplink disable** command enables the UL OFDMA function.

By default, the UL OFDMA function is enabled.

Format

ofdma uplink disable

undo ofdma uplink disable

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

OFDMA is a multi-user technology introduced in 802.11ax. This function improves the utilization of wireless spectrum resources, supports more concurrent STAs, and improves user experience in wireless Internet access.

Example

Enable the UL OFDMA function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name test
[HUAWEI-wlan-ssid-prof-test] undo ofdma uplink disable
```

11.1.124 probe-response-retry

Function

The **probe-response-retry** command sets the number of times Probe Response packets are retransmitted.

The **undo probe-response-retry** command restores the default number of times Probe Response packets are retransmitted.

By default, the number of Probe Response retransmissions is 1.

Format

probe-response-retry *retry-time*

undo probe-response-retry

Parameters

Parameter	Description	Value
retry-time	Specifies the number of times Probe Response packets are retransmitted.	The value is an integer that ranges from 0 to 3. When the value is set to 0, Probe Response packets are not retransmitted.

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In high-density wireless scenarios, too many Probe Response frames occupy a large number of wireless resources. To reduce wireless resource occupation of the frames, you can run the **probe-response-retry** command to set a small number of or forbid Probe Response packet retransmissions.

Precautions

A small number of Probe Response packet retransmissions may reduce the channel scan efficiency of some STAs while a large number of Probe Response packet retransmissions may lower the wireless network performance.

Example

Set the number of times Probe Response packets are retransmitted to 0.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] probe-response-retry 0
```

11.1.125 qbss-load enable

Function

The **qbss-load enable** command enables the function of notifying STAs of AP load information.

The **undo qbss-load enable** command disables the function of notifying STAs of AP load information.

By default, the function of notifying STAs of AP load information is disabled.

Format

qbss-load enable

undo qbss-load enable

Parameters

None

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

After the **qbss-load enable** command is executed, STAs are notified of the AP load status during the STA association. The notified information includes the number of STAs associated with AP radios and channel utilization. A STA selects the optimal AP based on the load of each AP to improve air interface performance.

NOTE

This command takes effect only when dynamic load balancing is disabled, because with dynamic load balancing enabled, APs will definitely notify STAs of their loads.

Modifying this configuration will cause STAs connected to the SSID to go offline and then online, interrupting STAs' services.

Example

Enable the function of notifying STAs of AP load information in the SSID profile **ssid1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] qbss-load enable
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.1.126 radio

Function

The **radio** command displays the radio view.

Format

radio *radio-id*

Parameters

Parameter	Description	Value
radio-id	Specifies the radio ID.	The radio ID must exist.

Views

AP group view, AP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The radio configuration in the AP group view or AP view takes effect on all radios at the same time. To configure only a specified radio, enter the view of the radio to configure its parameters.

Precautions

If you run this command in the AP group view, configurations on all specified radios in the AP group are allowed. If you run this command in the AP view, configurations only on the specified radio on the AP are allowed.

Example

Display the view of radio 0 on AP 0.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 0
[HUAWEI-wlan-ap-0] radio 0
[HUAWEI-wlan-radio-0/0]
```

11.1.127 radio disable

Function

(AP group radio view) The **radio disable** command disables specified radios on all APs in an AP group.

(AP group radio view) The **undo radio disable** command enables specified radios on all APs in an AP group.

(AP radio view) The **radio disable** command disables a specified radio on a single AP.

(AP radio view) The **undo radio disable** command restores the state of a specified radio on an AP to the radio state in the AP group radio view.

By default, radios on all AP are enabled.

Format

radio disable

undo radio disable

Parameters

None

Views

AP radio view, AP group radio view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to enable or disable a specified radio.

If radio calibration is enabled on an AP, radio calibration is triggered to fill coverage holes after the radio is disabled for 8 minutes.

Example

Disable radio 0 on AP 0 .

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 0
[HUAWEI-wlan-ap-0] radio 0
[HUAWEI-wlan-radio-0/0] radio disable
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.1.128 radio-2g-profile (WLAN view)

Function

The **radio-2g-profile** command creates a 2G radio profile and displays the 2G radio profile view, or displays the view of an existing 2G radio profile.

The **undo radio-2g-profile** command deletes a 2G radio profile.

By default, the system provides the 2G radio profile **default**.

Format

radio-2g-profile name *profile-name*

undo radio-2g-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a 2G radio profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all 2G radio profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A 2G radio profile is used to configure and optimize the 2.4 GHz radio of an AP, but does not take effect on the 5 GHz radio.

Follow-up Procedure

Run the **radio-2g-profile** command to apply the 2G radio profile in the AP view, AP group view, AP radio view, or AP group radio view so that the 2G radio profile can take effect.

Precautions

- The 2G radio profile **default** cannot be deleted.
- The 2G radio profile referenced cannot be deleted. To delete the 2G radio profile, unbind it first.

Example

Create the 2G radio profile **radio-profile1** and display the view of the profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name radio-profile1
[HUAWEI-wlan-radio-2g-prof-radio-profile1]
```

11.1.129 radio-2g-profile

Function

The **radio-2g-profile** command binds a 2G radio profile to a 2G radio.

The **undo radio-2g-profile** command unbinds a 2G radio profile from a 2G radio.

By default, no 2G radio profile is applied in the AP view or AP radio view, but the 2G radio profile **default** is applied in the AP group view and AP group radio view.

Format

radio-2g-profile *profile-name* **radio** { *radio-id* | **all** }

undo radio-2g-profile radio { *radio-id* | **all** }

The parameter **radio** { *radio-id* | **all** } is supported only in the AP group view and AP view.

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a 2G radio profile.	The 2G radio profile must exist.
radio *radio-id*	Specifies a radio ID.	The value can be 0 or 2.
radio all	Specifies all radios.	-

Views

AP group view, AP view, AP radio view, AP group radio view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you create a 2G radio profile using the **radio-2g-profile (WLAN view)** command, bind it to a 2.4 GHz radio so that the 2G radio profile can take effect.

Precautions

After a 2G radio profile is applied in the AP group view or AP view, the parameter settings in the profile take effect on all 2.4 GHz radios on APs in the AP group or on the AP.

The configuration in the AP view and AP radio view has a higher priority than that in the AP group view and AP group radio view.

Example

Create the 2G radio profile **radio-profile1** and bind it to the AP group **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name radio-profile1
[HUAWEI-wlan-radio-2g-prof-radio-profile1] quit
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] radio-2g-profile radio-profile1 radio 0
```

11.1.130 radio-5g-profile (WLAN view)

Function

The **radio-5g-profile** command creates a 5G radio profile and displays the 5G radio profile view, or displays the view of an existing 5G radio profile.

The **undo radio-5g-profile** command deletes a 5G radio profile.

By default, the system provides the 5G radio profile **default**.

Format

radio-5g-profile name *profile-name*

undo radio-5g-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a 5G radio profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all 5G radio profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A 5G radio profile is used to configure and optimize the 5 GHz/6 GHz radio of an AP, but does not take effect on the 2.4 GHz radio.

Follow-up Procedure

Run the **radio-5g-profile** command to apply the 5G radio profile in the AP view, AP group view, AP radio view, or AP group radio view so that the 5G radio profile can take effect.

Precautions

- The 5G radio profile **default** cannot be deleted.
- A 5G radio profile referenced cannot be deleted. To delete the 5G radio profile, unbind it first.

Example

Create the 5G radio profile **radio-profile2** and display the view of the profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-5g-profile name radio-profile2
[HUAWEI-wlan-radio-5g-prof-radio-profile2]
```

11.1.131 radio-5g-profile

Function

The **radio-5g-profile** command binds a 5G radio profile to a 5 GHz or 6 GHz radio.

The **undo radio-5g-profile** command unbinds a 5G radio profile from a 5 GHz or 6 GHz radio.

By default, no 5G radio profile is applied in the AP view or AP radio view, but the 5G radio profile **default** is applied in the AP group view and AP group radio view.

Format

radio-5g-profile *profile-name* **radio** { *id* | **all** }

undo radio-5g-profile radio { *id* | **all** }

The parameter **radio** { *id* | **all** } is supported only in the AP group view and AP view.

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a 5G radio profile.	The 5G radio profile must exist.
radio *id*	Specifies a radio ID.	The value is an integer that ranges from 0 to 2.
radio all	Specifies all radios.	-

Views

AP group view, AP view, AP radio view, AP group radio view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you create a 5G radio profile using the **radio-5g-profile (WLAN view)** command, bind it to a 5 GHz radio so that the 5G radio profile can take effect.

Precautions

After a 5G radio profile is applied in the AP group view or AP view, the parameter settings in the profile take effect on all 5 GHz radios on APs in the AP group or on the AP.

The configuration in the AP view and AP radio view has a higher priority than that in the AP group view and AP group radio view.

Example

Create the 5G radio profile **radio-profile2** and bind it to the AP group **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-5g-profile name radio-profile2
[HUAWEI-wlan-radio-2g-prof-radio-profile2] quit
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] radio-5g-profile radio-profile2 radio 1
```

11.1.132 radio-mode

Function

The **radio-mode** command sets the radio mode of an AP.

The **undo radio-mode** command restores the default radio mode for an AP.

By default, no radio mode is configured on an AP, and the default radio mode of the AP is used.

Format

radio-mode { **2radio-standard** | **2radio-2g-enhanced** | **2radio-5g-enhanced** | **2radio-independent-scan** | **3radio** }

undo radio-mode

Parameters

Parameter	Description	Value
2radio-standard	Specifies the standard dual-radio mode.	-
2radio-2g-enhanced	Specifies the 2G enhanced dual-radio mode. Compared with the standard dual-radio mode, the 2.4 GHz radio in this mode provides more spatial streams and higher throughput. For details, see the specifications of the corresponding AP model.	-
2radio-5g-enhanced	Specifies the 5G enhanced dual-radio mode. Compared with the standard dual-radio mode, the 5 GHz radio in this mode provides more spatial streams and higher throughput. For details, see the specifications of the corresponding AP model.	-
2radio-independent-scan	Specifies the dual-radio + independent scanning radio mode. With the independent scanning radio, functions such as air scan can be implemented without affecting service experience.	-
3radio	Specifies the three-radio mode. A third radio (radio 2) is available to allow access of more STAs.	-

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

The **radio-mode** command sets the radio mode of an AP. Radio modes supported by APs vary depending on AP models. You can check the field **Radio mode** in the **display ap-type id** *ap-type-id* command output for the radio modes supported by a specified AP model. If an AP does not support the configured radio mode, it works in the default radio mode.

- When air interface resources are sufficient, the three-radio mode is recommended to increase the capacity.
- When air interface resources are insufficient, interference is severe, or APs are densely deployed, the dual-radio mode is recommended to reduce interference.

If allowed by the AP capability:

- Dual-radio mode: recommended in large-bandwidth scenarios. In this mode, the AP can provide high throughput.
- Three-radio mode: recommended in high-concurrency scenarios. In this mode, the AP allows for access of more STAs, improving the WLAN capacity.
- Dual-radio + independent scanning radio mode: recommended in high-interference scenarios. In this mode, the AP can use an independent radio to scan air interfaces without affecting performance, thereby achieving real-time monitoring and optimization for WLAN network quality.

NOTE

- Switching the radio mode will cause an AP to restart.
- For an AirEngine 6760-X1 or AirEngine 6760-X1E, load the RTU license to switch to the triple-radio mode or dual-radio + independent scanning mode. For an AirEngine 5760-51, load the RTU license to switch to the dual-radio + independent scanning mode.
- The independent radio scanning function applies only to the 5 GHz radios of the AirEngine 8760-X1-PRO, AirEngine 8760R-X1, AirEngine 8760R-X1E, AirEngine 6760-X1, AirEngine 6760-X1E, and AirEngine 5760-51. The radio scanning function on the 2.4 GHz frequency band can be implemented only through a service radio. In V200R021C10 and later versions, the independent radio scanning function of the AirEngine 6761-21, AirEngine 6761-21E and AirEngine 6761S-21 is effective for both the 2.4 GHz and 5 GHz frequency bands. (In V200R021C00, this function applies only to the 5 GHz frequency band.)
- The AirEngine 6761-21, AirEngine 6761-21E, and AirEngine 6761S-21 have a dedicated radio for scanning and can perform radio scanning even in **2radio-standard** mode.
- After the radio mode of an AirEngine 6760-51EI is switched to the 2G enhanced dual-radio mode, the 2.4 GHz radio provides four streams and the 5 GHz radio becomes unavailable. After the radio mode is switched to the 5G enhanced dual-radio mode, the 5 GHz radio provides four streams and the 2.4 GHz radio becomes unavailable.

Example

Configure the standard dual-radio mode for the AP.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] ap-system-profile name default
[HUAWEI-wlan-ap-system-prof-default] radio-mode 2radio-standard
```

11.1.133 radio-type (2G radio profile view)

Function

The **radio-type** command sets the radio type in a 2G radio profile.

The **undo radio-type** command restores the default radio type in a 2G radio profile.

By default, the radio type in a 2G radio profile is **dot11be**.

Format

radio-type { **dot11b** | **dot11g** | **dot11n** | **dot11ax** | **dot11be** }

undo radio-type

Parameters

Parameter	Description	Value
dot11b	Specifies the 802.11b radio type.	-
dot11g	Specifies the 802.11g radio type, which is backward compatible.	-
dot11n	Specifies the 802.11n radio type, which is backward compatible.	-
dot11ax	Specifies the 802.11ax radio type, which is backward compatible.	-
dot11be	Specifies the 802.11be radio type, which is backward compatible.	-

Views

2G radio profile

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Usually, the default radio type is used and does not need to be modified. If the default radio mode cannot meet requirements or a fault needs to be located, configure the radio type as required.

Precautions

If the configured radio type is not supported by an AP, the actual radio type supported by the AP takes effect.

If a rate in the basic rate set or supported rate set, or the multicast rate is not supported by the 802.11b protocol, the radio type cannot be set to **dot11b**.

If you run the **radio-type dot11b** command in the 2G radio profile view to set the radio type to **dot11b**, and the 2G radio profile is applied to an AP, the rates of management frames and multicast packets that take effect on the 2.4 GHz radio of the AP are fixed as 1 Mbit/s, and the values configured using the **beacon-2g-rate** *beacon-2g-rate* and **multicast-rate** *multicast-rate* commands do not take effect on the AP.

When the L-SIG field length compatibility function of the 802.11n protocol is enabled, the radio type cannot be set to **dot11ax** or **dot11be**.

Example

Set the radio type to **dot11g** in a 2G radio profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] radio-type dot11g
```

11.1.134 radio-type (5G radio profile view)

Function

The **radio-type** command sets the radio type in a 5G radio profile.

The **undo radio-type** command restores the default radio type in a 5G radio profile.

By default, the radio type in a 5G radio profile is **dot11be**.

Format

radio-type { **dot11a** | **dot11n** | **dot11ac** | **dot11ax** | **dot11be** }

undo radio-type

Parameters

Parameter	Description	Value
dot11a	Specifies the 802.11a radio type.	-
dot11n	Specifies the 802.11n radio type, which is backward compatible.	-
dot11ac	Specifies the 802.11ac radio type, which is backward compatible.	-
dot11ax	Specifies the 802.11ax radio type, which is backward compatible.	-

Parameter	Description	Value
dot11be	Specifies the 802.11be radio type, which is backward compatible.	-

Views

5G radio profile

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Usually, the default radio type is used and does not need to be modified. If the default radio mode cannot meet requirements or a fault needs to be located, configure the radio type as required.

Precautions

If the configured radio type is not supported by an AP, the actual radio type supported by the AP takes effect.

When the L-SIG field length compatibility function of the 802.11n protocol is enabled, the radio type cannot be set to **dot11ax** or **dot11be**.

Example

Set the radio type to **dot11n** in a 5G radio profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-5g-profile name default
[HUAWEI-wlan-radio-5g-prof-default] radio-type dot11n
```

11.1.135 reach-max-sta

Function

The **reach-max-sta** command controls access of new STAs when the number of STAs of a VAP reaches the maximum value.

The **undo reach-max-sta** command cancels the configuration.

By default, when the number of access users reaches the maximum value, you can determine whether to enable SSID hiding or enable the VAP to replace low-priority STAs with high-priority STAs.

Format

reach-max-sta { **hide-ssid disable** | **priority-replace** }

undo reach-max-sta

Parameters

Parameter	Description	Value
hide-ssid disable	Disable SSID hiding.	-
priority-replace	Enable the VAP to replace low-priority STAs with high-priority STAs.	-

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

When the number of access users reaches the maximum value, you can enable SSID hiding or enable the VAP to replace low-priority STAs with high-priority STAs. The two functions cannot be configured simultaneously.

- SSID hiding: New STAs cannot search for the SSID of the VAP and need to access other VAPs.
- Replacing low-priority STAs with high-priority STAs: A new VIP user will replace a common user. This ensures access experience of VIP users.

Example

Disable automatic SSID hiding when the number of users reaches the maximum.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] reach-max-sta hide-ssid disable
```

11.1.136 regulatory-domain-profile (WLAN view)

Function

The **regulatory-domain-profile** command creates a regulatory domain profile and displays the regulatory domain profile view, or displays the view of an existing regulatory domain profile.

The **undo regulatory-domain-profile** command deletes a regulatory domain profile.

By default, the system provides the regulatory domain profile **default**.

Format

regulatory-domain-profile name *profile-name*

undo regulatory-domain-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a regulatory domain profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all regulatory domain profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A regulatory domain profile contains settings of the country code, calibration channel, and calibration bandwidth, which take effect on APs using the regulatory domain profile.

Follow-up Procedure

Run the **regulatory-domain-profile** command to bind the regulatory domain profile to an AP or AP group so that the regulatory domain profile can take effect.

Precautions

- The regulatory domain profile **default** cannot be deleted.
- The regulatory domain profile referenced by an AP or AP group cannot be deleted. To delete the regulatory domain profile, unbind it from the AP or AP group first.

Example

Create the regulatory domain profile **domain1** and display the regulatory domain profile view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] regulatory-domain-profile name domain1
[HUAWEI-wlan-regulate-domain-domain1]
```

11.1.137 regulatory-domain-profile

Function

The **regulatory-domain-profile** command binds a regulatory domain profile to an AP or AP group.

The **undo regulatory-domain-profile** command unbinds a regulatory domain profile from an AP or AP group.

By default, the regulatory domain profile **default** is bound to an AP group, but no regulatory domain profile is bound to an AP. In the default regulatory domain profile, the country code is China, 2.4G calibration channels include channels 1, 6, and 11, 5G calibration channels include channels 149, 153, 157, 161, and 165, the 5G calibration bandwidth is 20 MHz, and the wideband function is disabled.

Format

regulatory-domain-profile *profile-name*

undo regulatory-domain-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a regulatory domain profile.	The regulatory domain profile must exist.

Views

AP group view, AP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you create a regulatory domain profile using the **regulatory-domain-profile (WLAN view)** command, bind it to an AP or AP group so that the regulatory domain profile can take effect.

Precautions

After a regulatory domain profile is bound to an AP or AP group, parameter settings in the regulatory domain profile apply to all APs using the profile.

Example

Create the regulatory domain profile **domain1** and bind it to AP group **group1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] regulatory-domain-profile name domain1
[HUAWEI-wlan-regulate-domain-domain1] quit
[HUAWEI-wlan-view] ap-group name group1
[HUAWEI-wlan-ap-group-group1] regulatory-domain-profile domain1
Warning: This configuration change will clear the channel and power configurations of radios, and may
restart APs. Continue?[Y/N]:y
```

11.1.138 report-disassoc-request disable

Function

The **report-disassoc-request disable** command disables an AP from reporting disassociation request packets of STAs to the AC.

The **undo report-disassoc-request disable** command enables an AP to report disassociation request packets of STAs to the AC.

By default, an AP is enabled to report disassociation request packets of STAs to the AC.

Format

report-disassoc-request disable

undo report-disassoc-request disable

Parameters

None

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

If a large number of STAs disassociate from the network in a certain time, the APs need to report lots of disassociation request packets to the AC, impacting the AC performance. To alleviate the impact on the AC, you can disable APs from reporting disassociation request packets of STAs to the AC.

Example

Disable an AP from reporting disassociation request packets of STAs to the AC.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ab
[HUAWEI-wlan-ap-system-prof-ab] report-disassoc-request disable
```

11.1.139 report-sta-assoc enable

Function

The **report-sta-assoc enable** command enables the function of recording STA association information or STA login information in the log.

The **undo report-sta-assoc enable** command disables the function of recording STA association information or STA login information in the log.

By default, the function of recording STA association information or STA login information in the log is disabled.

Format

report-sta-assoc enable

undo report-sta-assoc enable

Parameters

None

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

If a STA is associated or goes online after this function is enabled, the device records the STA association or login information in the log.

NOTE

Enabling this function will generate a large number of logs. If there are a large number of STAs, log files may overwrite each other due to limited storage space, which affects fault locating. To enable this function, you are advised to configure a log server to report logs. For details, choose **Configuring Information Center** > **Configuring Log Output** in the *Configuration Guide*.

Example

Enable the function of recording STA association information or STA login information in the log.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] report-sta-assoc enable
Warning: This operation will generate a large number of logs, which may overwrite other logs.
Configuring a log server is recommended. Continue?[Y/N]:y
```

11.1.140 report-sta-info enable

Function

The **report-sta-info enable** command enables an AC to report information about STA traffic statistics and online duration on APs.

The **undo report-sta-info enable** command disables an AC from reporting information about STA traffic statistics and online duration on APs.

By default, an AC is disabled from reporting information about STA traffic statistics and online duration on APs.

Format

report-sta-info enable

undo report-sta-info enable

Parameters

None

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

You can run the **report-sta-info enable** command to enable an AC to report information about STA traffic statistics and online duration on APs to eSight. After this function is enabled, the AC collects and reports information about STA traffic statistics and online duration on APs to eSight through syslogs when STAs get offline or roam within the AC, which facilitates data query on eSight. The STA traffic statistics include the AC's MAC address, AC name, APs' MAC addresses, AP names, radio IDs, SSID, user names, and STAs' MAC addresses.

NOTE

Enabling this function will generate a large number of logs. If there are a large number of STAs, log files may overwrite each other due to limited storage space, which affects fault locating. To enable this function, you are advised to configure a log server to report logs. For details, choose **Configuring Information Center** > **Configuring Log Output** in the *Configuration Guide*.

Example

Enable an AC to report information about STA traffic statistics and online duration on APs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] report-sta-info enable
Warning: This operation will generate a large number of logs, which may overwrite other logs.
Configuring a log server is recommended. Continue?[Y/N]:y
```

11.1.141 reset ap offline-record

Function

The **reset ap offline-record** command clears AP going-offline records.

Format

reset ap offline-record { **all** | **mac** *mac-address* }

Parameters

Parameter	Description	Value
all	Clears going-offline records of all APs.	-
mac *mac-address*	Clears going-offline records of the AP with specified MAC address.	The AP's MAC address must exist.

3: Management level

Usage Guidelines

Usage Scenario

To re-collect records about AP online failures, run this command to clear existing records first.

Precautions

The cleared records cannot be restored.

Example

Clear online failure records of all APs.

```
<HUAWEI> reset ap online-fail-record all
```

11.1.143 reset ap unauthorized record

Function

The **reset ap unauthorized record** command clears information about unauthorized APs.

Format

reset ap unauthorized record

Parameters

None

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run this command to clear the unauthorized AP list so that removed APs or unauthenticated APs that are physically disconnected from the AC can be cleared. This helps users easily collect statistics and confirm unauthorized APs.

Precautions

If an AP physically connects to the AC but has not been authenticated, the AP is added to the unauthorized AP list after you run the **reset ap unauthorized record** command.

Example

Clear information about unauthorized APs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] reset ap unauthorized record
Warning: Clear unauthorized AP record, continue?[Y/N]:y
```

11.1.144 reset channel switch-record

Function

The **reset channel switch-record** command deletes channel switching records on a device.

Format

reset channel switch-record all

Parameters

Parameter	Description	Value
all	Deletes all channel switching records.	-

Views

All views

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can use this command to delete existing channel switching records so that the system can record new channel switching events.

Precautions

Deleted channel switching records cannot be restored.

Example

Delete all channel switching records.

```
<HUAWEI> reset channel switch-record all
```

11.1.145 reset station assoc-info ap-offline-record

Function

The **reset station assoc-info ap-offline-record** command deletes information about STAs that connect to the APs in fault state.

Format

reset station assoc-info ap-offline-record { **all** | { **ap-name** *ap-name* | **ap-id** *ap-id* } [**radio** *radio-id*] }

Parameters

Parameter	Description	Value
all	Deletes information about all STAs that connect to APs in fault state from the AC.	-
ap-name *ap-name*	Clears information about STAs that go online on the AP with a specified name in fault state.	The AP name must exist.
ap-id *ap-id*	Clears information about STAs that go online on the AP with a specified ID in fault state.	The AP ID must exist.
radio *radio-id*	Deletes information about STAs that connect to the specified radio of the AP in fault state.	The radio ID must exist.

Views

All views

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Before collecting statistics on the STAs that connect to the APs in fault state within a specific period, run the **reset station assoc-info ap-offline-record** command to delete the original STA information.

Prerequisites

The APs in fault state have been enabled to allow access of new STAs using the **keep-service enable allow new-access** command.

Function

The deleted STA information cannot be restored. Exercise caution when you run the **reset station assoc-info ap-offline-record** command.

Example

Delete information about all STAs that connect to APs in fault state from the AC.

```
<HUAWEI> reset station assoc-info ap-offline-record all
```

11.1.146 reset station offline-record

Function

The **reset station offline-record** command deletes STAs' going-offline records.

Format

reset station offline-record { **all** | **ap-name** *ap-name* | **ap-id** *ap-id* | **sta-mac** *sta-mac* }

Parameters

Parameter	Description	Value
all	Deletes going-offline records of all STAs.	-
ap-name *ap-name*	Deletes STAs' going-offline records on the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Deletes STAs' going-offline records on the AP with a specified ID.	The AP ID must exist.
sta-mac *sta-mac*	Deletes going-offline records of a specified STA.	The STA's MAC address must exist.

Usage Scenario

You can use this command to delete existing STAs' going-offline records so that the system can record new STAs' going-offline events.

Precautions

The deleted records cannot be restored.

Example

Delete going-offline records of all STAs.

```
<HUAWEI> reset station offline-record all
```

11.1.147 reset station online-fail-record

Function

The **reset station online-fail-record** command deletes records of STAs' failures to go online.

Format

reset station online-fail-record { **all** | **ap-name** *ap-name* | **ap-id** *ap-id* | **sta-mac** *sta-mac-address* }

Parameters

Parameter	Description	Value
all	Deletes records of all STAs' failures to go online.	-
ap-name *ap-name*	Deletes records of STAs' failures to go online on the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Deletes records of STAs' failures to go online on the AP with a specified ID.	The AP ID must exist.
sta-mac *sta-mac-address*	Deletes records of failures to go online of the STA with a specified MAC address.	The STA's MAC address must exist.

Usage Scenario

You can use this command to delete existing records of STAs' failures to go online so that the system can record new failures of STAs to go online.

Precautions

The deleted records cannot be restored.

Example

Delete records of all STAs' failures to go online.

```
<HUAWEI> reset station online-fail-record all
```

11.1.148 reset station statistics

Function

The **reset station statistics** command deletes statistics about online STAs.

Format

reset station statistics [**sta-mac** *sta-mac-address*]

Parameters

Parameter	Description	Value
sta-mac *sta-mac-address*	Specifies the MAC address of an online STA.	The STA's MAC address must exist.

Views

All views

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Before recollecting statistics about online STAs, run the command to clear the existing statistics.

Precautions

After the command is run, statistics about online STAs are cleared and cannot be restored.

Example

Delete statistics about the STA with MAC address 00e0-fc88-b74f.

```
<HUAWEI> reset station statistics sta-mac 00e0-fc88-b74f
```

11.1.149 rf-ping

Function

The **rf-ping** command enables an AP to proactively detect wireless link quality.

NOTE

The rf-ping function is not supported on the following APs.

- AirEngine x762

Format

rf-ping [**-m** *time* | **-c** *number* | **-p** { **be** | **bk** | **vi** | **vo** }] * *mac-address*

Parameters

Parameter	Description	Value
-m *time*	Specifies the interval for sending probe data packets.	The value is an integer that ranges from 100 to 10000, in milliseconds. The default value is 100.
-c *number*	Specifies the number of probe data packets sent by the AP.	The value is an integer that ranges from 1 to 1000. The default value is 10.
-p { **be** | **bk** | **vi** | **vo** }	Specifies the priority of probe data packets sent by the AP, which can be AC_BE, AC_BK, AC_VI, or AC_VO. If this parameter is not specified, the default priority is AC_BE.	-
mac-address	Specifies the MAC address of a STA.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command can be used to obtain parameters of wireless links between APs and STAs, including the signal strength, air interface rate, and packet transmission delay.

Prerequisites

STAs have been associated with the APs and gone online.

Example

Configure an AP to automatically detect the quality of the wireless link with the STA whose MAC address is 00e0-fc12-3456.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rf-ping 00e0-fc12-3456
 Tx rate=52.0 Mbps, Reply from 00e0-fc12-3456: RSSI=-58 dBm time < 1 ms
 1 packets transmitted, 1 received, 0% packet loss, time < 1 ms, RSSI -58 dBm
```

Table 11-65 Description of the **rf-ping** command output

Item	Description
Tx rate	Transmit rate.
Reply from	STA's MAC address.
RSSI	Received signal strength.
time	Delay.
x packets transmitted	*x* packets are transmitted.
x received	*x* packets are received.
x% packet loss	Packet loss rate.

11.1.150 rts-cts-mode

Function

The **rts-cts-mode** command sets the request to send (RTS)-clear to send (CTS) operation mode in a radio profile.

The **undo rts-cts-mode** command restores the default RTS-CTS operation mode in a radio profile.

By default, the RTS-CTS operation mode is **rts-cts**.

Format

rts-cts-mode { **cts-to-self** | **disable** | **rts-cts** }

undo rts-cts-mode

Parameters

Parameter	Description	Value
cts-to-self	Sets the RTS-CTS operation mode to **cts-to-self** (only supported in the 2G radio profile view).	-
disable	Disables RTS-CTS.	-
rts-cts	Sets the RTS-CTS operation mode to **rts-cts**.	-

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

- In **rts-cts** mode, an AP sends an RTS frame before sending data to a STA. After receiving the RTS frame, all the devices within the coverage of the AP do not send data within the specified time. Upon receiving the RTS frame, the target STA sends a CTS frame. This ensures that all the devices within the coverage of the STA do not send data within the specified time. This mode avoids conflicts but involves transmission of two frames (RTS and CTS frames), increasing the overhead.
- In **cts-to-self** mode, an AP sends a CTS frame with the AP's own address as the receiver address (RA) before sending data to a STA. This ensures that all the devices within the coverage of the AP do not send data within the specified time. In most scenarios, this mode allows an AP to only send one frame to avoid channel conflicts. However, if there is a device within the STA's coverage area but not within the AP's coverage area, a channel conflict may still occur.

Compared to the **rts-cts** mode, the **cts-to-self** mode reduces the number of control frames transmitted on the network. In some cases, however, a channel conflict may still occur when a hidden node exists and does not receive the CTS frame from the AP. Therefore, the **rts-cts** mode is more effective in avoiding channel conflicts than the **cts-to-self** mode.

To avoid the data transmission failure caused by a channel conflict, run this command to set the RTS-CTS operation mode in a radio profile as required.

Example

Set the RTS-CTS operation mode to **rts-cts** in a 2G radio profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] rts-cts-mode rts-cts
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.1.151 rts-cts-threshold

Function

The **rts-cts-threshold** command sets the RTS-CTS threshold in a radio profile.

The **undo rts-cts-threshold** command restores the default RTS-CTS threshold in a radio profile.

The default RTS-CTS alarm threshold is 1400 bytes.

Format

rts-cts-threshold *rts-cts-threshold*

undo rts-cts-threshold

Parameters

Parameter	Description	Value
rts-cts-threshold	Specifies the RTS-CTS threshold. If the length of a frame to be sent by the MAC Layer exceeds this threshold, an RTS frame needs to be sent before this frame.	The value is an integer that ranges from 64 to 2347, in bytes.

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

The IEEE 802.11 MAC protocol provides an RTS-CTS handshake protocol to prevent conflicts between channels and failure to transmit data. STA A sends an RTS frame before sending data to STA B. STA A can send data after receiving a CTS frame from STA B. If multiple STAs send RTS frames to the same STA, only the STA that receives a CTS frame can send data, and other STAs must wait for a certain period and then send RTS frames again.

If STAs implement RTS-CTS handshakes before sending data, the channel bandwidth is consumed by too much RTS frames. You can set an RTS threshold to specify the length of frames to be sent. When the length of frames to be sent by the STA is smaller than the RTS threshold, no RTS/CTS handshake is implemented.

Example

Set the RTS-CTS threshold to 2300 bytes in the 2G radio profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] rts-cts-threshold 2300
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.1.152 rx-stbc disable

Function

The **rx-stbc disable** command disables the space-time block coding (STBC) function in the receive direction.

The **undo rx-stbc disable** command enables the STBC function in the receive direction.

By default, the STBC function in the receive direction is enabled.

NOTE

The STBC function in the receive function is unconfigurable and always enabled for the following models:

- AirEngine x761
- AirEngine x762
- AirEngine x771

Format

rx-stbc disable

undo rx-stbc disable

Parameters

None

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

STBC is a coding technology used in Wi-Fi standards. It uses time and space diversity in a multi-antenna system to transmit the same data over multiple antennas to improve data transmission reliability.

If severe packet loss occurs on a STA that uses STBC to send packets, it is recommended that the STBC function be disabled in the receive direction of the AP.

Example

Disable the STBC function in the receive direction in the 2G radio profile view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] rx-stbc disable
```

11.1.153 service-mode disable

Function

The **service-mode disable** command disables the service mode of a VAP.

The **undo service-mode disable** command enables the service mode of a VAP.

By default, the service mode of a VAP is enabled.

Format

service-mode disable

undo service-mode disable

Parameters

None

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

You can run the **service-mode disable** command to disable the service mode of a VAP. After the service mode of a VAP is disabled, the VAP is disabled.

- After the service mode of a VAP is enabled, run the **auto-off service** command to enable the scheduled VAP auto-off function. In the scheduled time, the VAP is disabled. To enable the VAP, run the **undo auto-off service** command.
- After the service mode of a VAP is disabled, the scheduled VAP auto-off function does not take effect.

Example

Disable the service mode of VAP **vap1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] service-mode disable
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.1.154 service-vlan (VAP profile view)

Function

The **service-vlan** command configures a service VLAN for a VAP.

The **undo service-vlan** command restores the default service VLAN of a VAP.

By default, VLAN 1 is the service VLAN of a VAP.

Format

service-vlan { **vlan-id** *vlan-id* | **vlan-pool** *pool-name* }

undo service-vlan

Parameters

Parameter	Description	Value
vlan-id *vlan-id*	Specifies a service VLAN ID of a VAP.	The value is an integer that ranges from 1 to 4094.
vlan-pool *pool-name*	Sets the service VLANs of a VAP to all VLANs in a VLAN pool.	The VLAN pool must exist.

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can specify a specific VLAN as the service VLAN of a VAP or all VLANs in a VLAN pool as the service VLANs of a VAP. Layer 2 data packets delivered from the VAP to an AP carry the service VLAN IDs.

- When a specific VLAN is configured as the service VLAN of a VAP, STAs connected to the VAP join the same VLAN.

- When VLANs in a VLAN pool are configured as the service VLANs of a VAP, STAs connected to the VAP join different VLANs. The VLAN assignment algorithm can be configured using the **assignment** command.

Precautions

Modifying the service VLAN of a VAP will interrupt services of STAs connected to the VAP. Exercise caution when you run the command.

Example

Set the service VLAN to VLAN 2 in the VAP profile **vap1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] service-vlan vlan-id 2
```

11.1.155 short-preamble disable

Function

The **short-preamble disable** command configures a radio profile not to support the short preamble.

The **undo short-preamble disable** command configures a radio profile to support the short preamble.

By default, a radio profile supports the short preamble.

Format

short-preamble disable

undo short-preamble disable

Parameters

None

Views

2G radio profile view

Default Level

2: Configuration level

Usage Guidelines

The preamble is a section of bits in the header of a data frame. It synchronizes signals transmitted between the sender and receiver. The preamble is classified into the long preamble and short preamble. The short preamble ensures better synchronization performance and therefore is recommended. The long preamble is usually used for compatibility with earlier network adapters of clients.

Example

Configure the 2G radio profile **default** not to support the short preamble.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] short-preamble disable
```

11.1.156 single-txchain enable

Function

The **single-txchain enable** command enables the single-antenna transmission mode.

The **undo single-txchain enable** command disables the single-antenna transmission mode.

By default, the single-antenna transmission mode is disabled.

Format

single-txchain enable

undo single-txchain enable

Parameters

None

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Some non-HT STAs that support 802.11a/b/g cannot receive packets sent by APs using multiple antennas. As a result, network access failures, frequent STA roaming, or network instability is caused. After running the **single-txchain enable** command to enable the single-antenna transmission mode in an SSID profile, management packets on the corresponding VAP and data packets sent by the AP to non-HT STAs on the VAP will be sent in single-antenna transmission mode. For a radio that is bound to a VAP with the single-antenna transmission mode enabled, control packets of the radio are sent in single-antenna transmission mode as long as non-HT STAs is connected to the VAP. When no non-HT STA is connected to the VAP, the control packets are still sent in multi-antenna transmission mode.

Precautions

APs supporting MU-MIMO support the single-antenna transmission mode.

After the single-antenna transmission mode is enabled in an SSID profile, the RSSI of STAs may be affected.

Example

Enable the single-antenna transmission mode in SSID profile **ssid1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] single-txchain enable
```

11.1.157 softgre-profile (WLAN view)

Function

The **softgre-profile** command creates a soft GRE profile and displays its view, or displays the view of an existing soft GRE profile.

The **undo softgre-profile** command deletes a soft GRE profile.

By default, no soft GRE profile exists in the system.

Format

softgre-profile name *profile-name*

undo softgre-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a soft GRE profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all soft GRE profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the data forwarding mode is set to **soft-GRE**, create a soft GRE profile and bind it to a VAP profile for the soft GRE profile to take effect.

To configure parameters in a soft GRE profile, run this command to enter the soft GRE profile view. If a soft GRE profile is no longer needed, you can delete it.

Follow-up Procedure

Run the **forward-mode** command to bind the soft GRE profile to a VAP profile so that the soft GRE profile can take effect.

Precautions

The soft GRE profile referenced by a VAP profile cannot be deleted. To delete the soft GRE profile, unbind it from the VAP profile first.

Example

Create the soft GRE profile **soft1** and enter the soft GRE profile view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] softgre-profile name soft1
[HUAWEI-wlan-softgre-prof-soft1]
```

11.1.158 ssid

Function

The **ssid** command sets a service set identifier (SSID) for an SSID profile.

The **undo ssid** command deletes the SSID of an SSID profile.

By default, the SSID HUAWEI-WLAN is configured in an SSID profile.

Format

ssid *ssid*

undo ssid

Parameters

Parameter	Description	Value
ssid	Specifies the name of an SSID.	The value is a string of 1 to 32 case-sensitive characters. It supports Chinese characters or Chinese + English characters, without tab characters. To start an SSID with a space, you need to encompass the SSID with double quotation marks (" "), for example, **" hello"**. The double quotation marks occupy two characters. To start an SSID with a double quotation mark, you need to add a backslash (\) before the double quotation mark, for example, **\"hello**. The backslash occupies one character. **NOTE** You can only use a command editor of the UTF-8 encoding format to edit Chinese characters. SSIDs containing Chinese characters cannot be displayed on STAs that do not support the UTF-8 encoding format.

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An SSID specifies a wireless network. When you search for available wireless networks on your wireless terminal, SSIDs are displayed to identify the available wireless networks.

Precautions

When you configure an SSID containing Chinese characters, do not delete characters by pressing the **Delete** button if you want to modify the SSID that has been entered. Otherwise, the SSID will contain garbled characters after the configuration. In this case, run the **ssid** command to reconfigure the SSID.

Example

Set the SSID to **wlan-net** in the SSID profile **ssid1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] ssid wlan-net
```

11.1.159 ssid-hide enable

Function

The **ssid-hide enable** command enables SSID hiding in Beacon frames in an SSID profile.

The **undo ssid-hide enable** command disables SSID hiding in Beacon frames in an SSID profile.

By default, SSID hiding in Beacon frames is disabled in an SSID profile.

Format

ssid-hide enable

undo ssid-hide enable

Parameters

None

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A STA listens on the Beacon frames that an AP periodically sends in each channel to obtain AP information. The STA can obtain SSIDs from Beacon frames that contain the SSIDs.

The STA can actively send a probe frame with a specified SSID, only the AP with the same SSID will respond to the STA. If the STA broadcasts a probe frame without an SSID, only the APs on which SSID hiding in Beacon frames is disabled will respond to the STA.

- After the **ssid-hide enable** command is used, an AP periodically sends Beacon frames that contain empty SSID character strings and does not reply to the broadcast probe requests sent from STAs. The STAs can send probe frames with the AP's SSID to discover the SSID.
- After the **undo ssid-hide enable** command is used, an AP periodically sends Beacon frames that contain valid SSID character strings and replies to the broadcast probe requests sent from STAs. The STAs can send probe frames with the AP's SSID to discover the SSID.

Precautions

If the **ssid-hide enable** or **undo ssid-hide enable** command is run in the SSID profile after STAs are associated with an SSID, service interruptions may occur for all online STAs.

Example

Configure SSID hiding in Beacon frames in the SSID profile **ssid1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] ssid-hide enable
```

11.1.160 ssid-profile (WLAN view)

Function

The **ssid-profile** command creates an SSID profile and displays the SSID profile view, or displays the view of an existing SSID profile.

The **undo ssid-profile** command deletes an SSID profile.

By default, the system provides the SSID profile **default**.

Format

ssid-profile name *profile-name*

undo ssid-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of an SSID profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all SSID profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An SSID profile is used to configure STA association and access parameters based on SSIDs, including the SSID name, STA association timeout period, non-HT STA access, and QoS CAR.

Follow-up Procedure

Run the **ssid-profile (VAP profile view)** command in the VAP profile view to bind the SSID profile to the VAP profile, and then bind the VAP profile to an AP, so that the SSID profile can take effect.

Precautions

- The SSID profile **default** cannot be deleted.
- An SSID profile referenced by a VAP profile cannot be deleted. To delete the SSID profile, unbind it from the VAP profile first.
- If a VAP profile has been applied to an AP, modifying the SSID profile will interrupt services.

Example

Create an SSID profile named **ssid1** and enter the SSID profile view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1]
```

11.1.161 ssid-profile (VAP profile view)

Function

The **ssid-profile** command binds an SSID profile to a VAP profile.

The **undo ssid-profile** command unbinds an SSID profile from a VAP profile.

By default, the SSID profile **default** is bound to a VAP profile.

Format

ssid-profile *profile-name*

undo ssid-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of an SSID profile.	The SSID profile must exist.

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you create an SSID profile using the **ssid-profile (WLAN view)** command, bind it to a VAP profile to make the SSID profile take effect.

Precautions

After an SSID profile is bound to a VAP profile, parameter settings in the SSID profile take effect on all APs using the VAP profile.

Example

Create the SSID profile **ssid1** and bind it to the VAP profile **vap1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] quit
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] ssid-profile ssid1
```

11.1.162 sta-ipv6-service enable

Function

The **sta-ipv6-service enable** command enables the function of processing STA IPv6 services.

The **undo sta-ipv6-service enable** command disables the function of processing STA IPv6 services.

By default, the function of processing STA IPv6 services is disabled.

Format

sta-ipv6-service enable

undo sta-ipv6-service enable

Parameters

None

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Currently, IPv4 WLANs are widely deployed. If many IPv6 packets exist on an IPv4 WLAN, the performance of the WLAN is affected, and the CPU processing capability of devices will also be degraded. To improve performance of a pure IPv4 network, you can configure devices on the network to not process IPv6 packets of STAs.

Precautions

The function of processing STA IPv6 services takes effect only when the following conditions are met:

- In tunnel forwarding mode, the device does not function as an IPv6 gateway. This condition is not required in direct forwarding mode.
- The security policy is open authentication.

After the function of processing STA IPv6 services is disabled:

- The AC and APs do not process IPv6 packets of the wireless side.
- IPv6 functions cannot be configured on the wireless side.
- IPv6 functions of the wireless side are disabled even if they are enabled in default settings.

Running the **ipv6 enable** command in the interface view only enables the IPv6 function on the wired-side interface. The command cannot enable the WLAN module to process STA IPv6 services. To enable the WLAN module to process IPv6 services of STAs, you need to run the **sta-ipv6-service enable** command in the WLAN view.

Example

Enable the function of processing STA IPv6 services.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sta-ipv6-service enable
```

11.1.163 sta-network-detect disable

Function

The **sta-network-detect disable** command disables network detection upon STA reassociation.

The **undo sta-network-detect disable** command enables network detection upon STA reassociation.

By default, network detection upon STA reassociation is enabled.

Format

sta-network-detect disable

undo sta-network-detect disable

Parameters

None

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

When accessing a new Wi-Fi network, some STAs initiate reassociation requests but not association requests. For example, this may happen when a STA attempts to access a new Wi-Fi network with the same name as the network that the STA has accessed. In this case, the STA considers that the access to the new Wi-Fi network is normal, while it actually fails to access the network. As a result, the STA cannot access network resources. To enable STAs to access the network through the normal process, you can enable network detection upon STA reassociation. When a STA reassociates with the network, the AP forcibly disconnects the STA and enables it to reinitiate an association request to access the network if all of the following conditions are met:

- The STA does not send DHCP Request messages or receive ARP Reply packets within 5s after it reassociates with the AP and goes online.
- The STA has only uplink traffic but no downlink traffic.

Example

Enable network detection upon STA reassociation.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] undo sta-network-detect disable
```

11.1.164 sta-network-detect assoc enable

Function

The **sta-network-detect assoc enable** command enables network detection upon STA association.

The **undo sta-network-detect assoc enable** command disables network detection upon STA association.

By default, network detection upon STA association is disabled.

Format

sta-network-detect assoc enable

undo sta-network-detect assoc enable

Parameters

None

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Some STAs may fail to access the Internet after sending association requests. To enable STAs to access the network through the normal process, you can enable network detection upon STA association. When a STA associates with the network, the AP forcibly disconnects the STA and enables it to reinitiate an association request to access the network if both of the following conditions are met:

- The STA does not send DHCP Request messages or receive ARP Reply packets within 5s after it associates with the AP and goes online.
- The STA has only uplink traffic but no downlink traffic.

Example

Enable network detection upon STA association.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] sta-network-detect assoc enable
```

11.1.165 sta-offline-delay aging-time

Function

The **sta-offline-delay aging-time** command configures the aging time for STA offline delay.

The **undo sta-offline-delay aging-time** command restores the default aging time for STA offline delay.

The default aging time for STA offline delay is 180 seconds.

Format

sta-offline-delay aging-time *time*

undo sta-offline-delay aging-time

Parameters

Parameter	Description	Value
time	Specifies the aging time for STA offline delay.	The value is an integer that ranges from 1 to 604800, in seconds. The default value is 180.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the STA offline delay function is enabled, STAs can go offline and online again in the aging time without being authenticated, reducing the load on the authentication server. You can run the **sta-offline-delay aging-time** command to set the aging time.

Set the aging time for STA offline delay based on the network requirements and device performance. A long aging time causes the STA offline delay function to occupy many resources, affecting new STA access. A short aging time cannot achieve a noticeable effect in releasing the load on the authentication server.

If 802.1X authentication is used for STAs, it is recommended that set the aging time of the STA offline delay state a value ranging from 1s to 1800s. Within this range, you can set a longer delay to improve the roaming success rate of fast roaming using PMK caching and 802.11r fast roaming.

Prerequisites

The STA offline delay function has been enabled using the **sta-offline-delay enable** command.

Example

Set the aging time for STA offline delay to 300s.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sta-offline-delay enable
[HUAWEI-wlan-view] sta-offline-delay aging-time 300
```

11.1.166 sta-offline-delay enable

Function

The **sta-offline-delay enable** command enables the STA offline delay function.

The **undo sta-offline-delay enable** command disables the STA offline delay function.

By default, the STA offline delay function is disabled.

Format

sta-offline-delay enable

undo sta-offline-delay enable

Parameters

None

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a WLAN, some online STAs may go offline due to reasons such as screen lock. When these STAs go online again, they are reauthenticated, increasing the load on the authentication server. After the STA offline delay function is enabled, if a STA goes offline normally (for example, by sending a disassociation or deauthentication request or reaching the association aging time) and online again within the aging time, it does not need to be authenticated by an external or built-in authentication server. This reduces the load on the authentication server and avoids multiple authentication operations. This function takes effect for STAs only in Portal, MAC address, 802.1X, or MAC address-prioritized Portal authentication mode.

NOTE

After the STA offline delay function is enabled, if a STA goes offline normally and online again within the aging time, no authentication is needed. This may bring security risks. Exercise caution when configuring this function.

Precautions

The STA offline delay function is implemented for new access and Layer 2 roaming STAs. When a STA reassociates with a WLAN within the aging time, the STA offline delay function is implemented only in the following scenarios:

- Non-roaming scenarios. That is, the STA goes online again on the same VAP.
- Intra-AC Layer 2 roaming in direct forwarding mode, intra-AC Layer 3 roaming in direct forwarding mode (with the tunnel endpoint on the AC), or intra-AC Layer 2/3 roaming in tunnel forwarding mode.
- Inter-AC Layer 2 roaming in direct or tunnel forwarding mode.

The STA offline delay function and online STA detection on the external Portal server are mutually exclusive.

Example

Enable the STA offline delay function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sta-offline-delay enable
```

11.1.167 sta-offline-delay full-sta-reject enable

Function

The **sta-offline-delay full-sta-reject enable** command disables an AP to force STAs in offline delay state to go offline and allow new STAs to go online after the number of STAs reaches the maximum.

The **undo sta-offline-delay full-sta-reject enable** command enables an AP to force STAs in offline delay state to go offline and allow new STAs to go online after the number of STAs reaches the maximum.

By default, an AP is enabled to force STAs in offline delay state to go offline and allow new STAs to go online after the number of STAs reaches the maximum.

Format

sta-offline-delay full-sta-reject enable

undo sta-offline-delay full-sta-reject enable

Parameters

None

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the STA offline delay function is enabled on an AP, you can run this command to enable an AP to force STAs in offline delay state to go offline and allow new STAs to go online after the number of STAs reaches the maximum.

Prerequisites

Before this command is executed, the **sta-offline-delay enable** command has been executed to enable the STA offline delay function.

Example

Disable an AP to force STAs in offline delay state to go offline and allow new STAs to go online after the number of STAs reaches the maximum.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sta-offline-delay enable
[HUAWEI-wlan-view] sta-offline-delay full-sta-reject enable
```

11.1.168 sta-offline-delay max-number

Function

The **sta-offline-delay max-number** command sets the maximum number of STAs that are allowed to delay going offline.

The **undo sta-offline-delay max-number** command restores the default maximum number of STAs that are allowed to delay going offline.

The default maximum number of STAs that are allowed to delay going offline is one fifth of the maximum number of STAs supported by an AC.

Format

sta-offline-delay max-number *max-number*

undo sta-offline-delay max-number

Parameters

Parameter	Description	Value
max-number	Specifies the maximum number of STAs that are allowed to delay going offline.	The value is an integer that ranges from 1 to the maximum number of STAs supported by an AC. The default value is one fifth of the maximum value. If one fifth of the maximum value is a non-integer value, round down the value.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the STA offline delay function is enabled, you can run this command to set the maximum number of STAs that are allowed to delay going offline.

Set the maximum number of STAs that are allowed to delay going offline based on the network requirements and device performance. A large value causes the STA offline delay function to occupy many resources, affecting new STA access. A small value cannot achieve a noticeable effect in releasing the load on the authentication server.

Prerequisites

The STA offline delay function has been enabled using the **sta-offline-delay enable** command.

Example

Set the maximum number of STAs that are allowed to delay going offline to 800.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sta-offline-delay enable
[HUAWEI-wlan-view] sta-offline-delay max-number 800
```

11.1.169 station connectivity-detect disable

Function

The **station connectivity-detect disable** command disables STA connectivity check on the AP.

The **undo station connectivity-detect disable** command enables STA connectivity check on the AP.

By default, STA connectivity check is enabled on the AP.

Format

station connectivity-detect disable

undo station connectivity-detect disable

Parameters

None

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

The STA connectivity check function is enabled on an AP by default to help locate the Internet access failure issue of some STAs in certain scenarios. The AP periodically checks the uplink and downlink unicast traffic of STAs. If an exception is detected, the AP randomly selects a certain number of STAs, pings the gateway and STAs to check network connectivity, and logs the check result. After a STA is detected, the STA will not be detected repeatedly within a certain period of time.

Example

Disable STA connectivity check.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name default
[HUAWEI-wlan-ap-system-prof-default] station connectivity-detect disable
```

11.1.170 twt enable

Function

The **twt enable** command enables the target wake time (TWT) function.

The **undo twt enable** command disables the TWT function.

By default, the TWT function is disabled.

Format

twt enable

undo twt enable

Parameters

None

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

TWT is a scheduling algorithm introduced in 802.11ax. A TWT Requesting STA negotiates with a TWT Responding STA (AP) to determine TWT parameters and wake ups for some time called service period (SP). In this manner, STAs can doze always except during the SP intervals, which saves power consumption of the STA and allows an AP to manage activities in the BSS in order to minimize contention between STAs.

It is recommended that the TWT function be disabled if the STA and AP are incompatible with each other due to different protocol implementation modes.

Example

Enable the TWT function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] twt enable
```

11.1.171 type (VAP profile view)

Function

The **type** command sets the type for a VAP.

The **undo type** command restores the default VAP type.

By default, the type of a VAP is service.

Format

type { **ap-management** | **service** | **service-backup ap-offline** | **service-backup auth-server-down radius-server template** *template-name* | **service-backup distribute** }

undo type

Parameters

Parameter	Description	Value
ap-management	Sets the VAP type to AP management.	-
service	Sets the VAP type to service.	-
service-backup ap-offline	Sets the VAP type to AP-offline backup service.	-
service-backup auth-server-down	Sets the VAP type to authentication-server-down backup service.	-
radius-server template *template-name*	Specifies the name of a RADIUS server template.	The specified name of the RADIUS server template must exist.
service-backup distribute	Sets the VAP type to distributed-AP backup service. **NOTE** This parameter takes effect only for the backup AP in the zero-roaming distributed architecture.	-

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

- If the type of a VAP is set to **ap-management**, STAs connected to the VAP can only access APs but not network resources. AP management VAPs are used in STA access and AP management scenarios.
- If the type of a VAP is set to **service**, STAs connected to the VAP can only access network resources but not APs. Service VAPs are used in regular WLAN deployment scenarios.
- If the type of a VAP is set to **service-backup ap-offline**, STAs can access the network through the backup service VAP after the AP goes offline. For example, on a headquarters-branch network, when APs at branches connect to the AC at the headquarters through a WAN, APs may go offline due to the WAN instability. In this case, you can configure a backup service VAP to allow new STAs to access the network if the AP goes offline.

- If the type of a VAP is set to **service-backup auth-server-down**, the VAP is automatically enabled to allow network access of associated STAs when the authentication server is not accessible. When the authentication server recovers, this VAP is not automatically disabled. You can manually disable it if needed. If the authentication server is accessible but rejects user access, this VAP is not automatically enabled. You can manually enable it if needed. To enable or disable this VAP, run the **vap-service-backup auth-server-down** command.
- When the VAP type is distributed-AP backup service, the backup VAP continuously detects the signal output of the distributed VAP with the same SSID. If the signal from the distributed VAP with the same SSID is not detected within 25 Beacon intervals, the backup VAP considers the distributed AP faulty and automatically releases signals to ensure that STAs can access the network. After the distributed VAP recovers, the signal of the backup VAP is shut down, and STAs are switched back to the distributed VAP.

Precautions

- After the VAP type is configured in the VAP profile view, the VAPs generated by the VAP profile use the configured VAP type. The new VAP type will overwrite the old one.
- For an AP management VAP:
  - Portal, MAC address, and 802.1X authentication using an external server is not supported.
  - The VAP profile in which the VAP type is set to **ap-management** can be applied only to one radio of an AP or AP group.
  - If an AD9431DN-24X or AirEngine 9700D-M is used as the central AP, STAs log in to RUs through the offline management VAP. If a central AP other than the AD9431DN-24X or AirEngine 9700D-M is used, STAs log in to the central AP through the offline management VAP.
- For an AP-offline backup service VAP:
  - Only the WPA3 SAE, WPA2-WPA3 PSK-SAE, open, WEP, WPA+PSK, WPA2+PSK and WPA-WPA2+PSK authentication modes are supported.
  - Service data can be forwarded only in direct mode.
  - When the number of configured AP-offline backup service VAPs reaches the maximum on the AP, if the offline management VAP function is enabled, the offline management VAP does not take effect when the AP goes offline.
- For an authentication-server-down backup service VAP:
  - Only the WPA3 SAE, WPA2-WPA3 PSK-SAE, open, WEP, WPA+PSK, WPA2+PSK and WPA-WPA2+PSK authentication modes are supported.
  - This VAP type is exclusive with the AP management VAP and AP-offline backup service VAP.
- For a distributed-AP backup service VAP:
  - Before configuring distributed AP backup, run the **distribute-mode enable** command to enable DAP network collaboration.
  - When a STA switches between a distributed VAP and backup VAP, the process is similar to WLAN roaming, and a few packets may be lost.

Example

Create the VAP profile **vap1** and set the VAP type to AP management VAP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] type ap-management
```

Create the VAP profile **vap1** and set the VAP type to **authentication-server-down backup service**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] type service-backup auth-server-down radius-server template temp1
```

11.1.172 u-apsd enable

Function

The **u-apsd enable** command enables the Unscheduled Automatic Power Save Delivery (U-APSD) function.

The **undo u-apsd enable** command disables the U-APSD function.

By default, the U-APSD function is disabled.

Format

u-apsd enable

undo u-apsd enable

Parameters

None

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

U-APSD is a new energy saving mode defined for WMM, which can improve the energy-saving capability of STAs.

If some STAs on the network do not support the U-APSD function, disable the U-APSD function.

Precautions

The U-APSD function takes effect only when WMM is enabled.

After the U-APSD function is enabled, services may be interrupted.

Example

Enable the U-APSD function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] u-apsd enable
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.1.173 undo ap

Function

The **undo ap** command deletes an AP.

Format

undo ap { **ap-name** *ap-name* | **ap-id** *ap-list* | **ap-mac** *ap-mac* | **ap-group** *group-name* | **all** }

Parameters

Parameter	Description	Value
ap-name *ap-name*	Deletes the AP with a specified AP name.	The AP name must exist.
ap-id *ap-list*	Deletes APs with the specified IDs in a batch.	The value is a string of 1 to 255 characters. When multiple APs are selected, use commas (,) or hyphens (-) to separate AP IDs. For example, **5,8,10-13,20** indicates the list of APs with IDs 5, 8, 10, 11, 12, 13, and 20.
ap-mac *ap-mac*	Deletes the AP with a specified MAC address.	The AP's MAC address must exist.
ap-group *group-name*	Deletes the APs in a specified AP group.	The AP group must exist.
all	Deletes all APs.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If you do not want a specified Fit AP to go online on the AC, run this command to delete the Fit AP from the AC. After the Fit AP is deleted, it goes offline from the AC.

Configuration Impact

Deleting an AP will interrupt services of STAs connected to the AP.

Precautions

APs that are being upgraded, stay in standby or unauth state, or are executing the **ap-ping** command cannot be deleted.

In NETCONF mode, if any of the APs managed by the switch has been registered on the iMaster NCE-Campus, you cannot delete all APs using the **undo ap all** command. AP registration on the iMaster NCE-Campus indicates that an AP has been online on the iMaster NCE-Campus or the switch successfully synchronizes the configured AP information to the iMaster NCE-Campus.

Example

Delete the AP named **Area_1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] undo ap ap-name Area_1
Warning: Deleting the AP will interrupt user services. Continue?[Y/N]:y
```

11.1.174 untagged vlan (soft GRE profile view)

Function

The **untagged vlan** command configures soft GRE tunnel packets sent by APs not to carry VLAN tags.

The **undo untagged vlan** command restores the default status of whether soft GRE tunnel packets sent by APs carry VLAN tags.

By default, soft GRE tunnel packets sent by APs carry VLAN tags.

Format

untagged vlan *vlan-id*

undo untagged vlan

Parameters

Parameter	Description	Value
vlan-id	Specifies the ID of the VLAN tag to be removed.	The value is an integer that ranges from 1 to 4094.

Views

Soft GRE profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After receiving service data packets from STAs, an AP adds a service VLAN tag to the packets and performs soft GRE tunnel encapsulation. Then the soft GRE tunnel packets sent by the AP carry the VLAN tag. However, in some scenarios, the peer device of the soft GRE tunnel connected to the AP cannot process tagged packets. After this command is run, the soft GRE interface is added to the configured VLAN in untagged mode, and the PVID is also set to the configured VLAN. If the configured VLAN is a service VLAN, the service VLAN tag is removed after packets pass through the soft GRE interface. The soft GRE tunnel packets sent by the AP are transmitted in untagged mode.

Precautions

A soft GRE profile supports only one untagged VLAN.

Example

Configure APs to remove service VLAN 101 from soft GRE tunnel packets and transmit the packets in untagged mode.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] softgre-profile name soft1
[HUAWEI-wlan-softgre-prof-soft1] untagged vlan 101
```

11.1.175 utmost-power

Function

The **utmost-power disable** command disables radios from sending packets at the maximum power.

The **utmost-power enable** command enables radios to send packets at the maximum power.

The **undo utmost-power** command restores the adaptive mode for radios to send packets.

By default, a radio sends packets in adaptive mode.

Format

utmost-power { **disable** | **enable** }

undo utmost-power

Parameters

None

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command is valid for all country codes. You can run the **utmost-power enable** command to enable radios to send packets at the maximum power or run the **utmost-power disable** command to enable radios to send packets at the power specified by the country code. After you run the **undo utmost-power** command to restore the adaptive mode, radios send packets at the maximum power if the country code is CN or at the power specified by other country codes.

Precautions

This function may cause AP radios to exceed the laws and regulations of the local country or region. Therefore, ensure that you have obtained permission from the local administrative department before using this function.

For APs running R024C00 or later, this function takes effect only on the 2.4 GHz and 5 GHz radios, but not on 6 GHz radios.

Example

Disable radios from sending packets at the maximum power.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] utmost-power disable
```

11.1.176 vap-profile (WLAN view)

Function

The **vap-profile** command creates a VAP profile and displays the VAP profile view, or displays the view of an existing VAP profile.

The **undo vap-profile** command deletes a VAP profile.

By default, the system provides the VAP profile **default**.

Format

vap-profile name *profile-name*

undo vap-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a VAP profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all VAP profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a radio profile is bound to an AP, the AP can send and receive radio signals. After a VAP profile is bound to an AP, the VAP is generated to provide wireless access services for STAs. You can configure parameters in the VAP profile to enable APs to provide different wireless services.

Follow-up Procedure

Run the **vap-profile** command to apply the VAP profile in the AP group view, AP view, AP radio view, or AP group radio view so that the VAP profile can take effect.

Precautions

- The VAP profile **default** cannot be deleted.
- The VAP profile referenced in the AP group view, AP view, AP radio view, or AP group radio view cannot be deleted. To delete the VAP profile, unbind it from the AP group view, AP view, AP radio view, or AP group radio view first.
- By default, the SSID profile **default**, security profile **default**, and traffic profile **default** are bound to a VAP profile.

Example

Create the VAP profile **vap1** and enter the VAP profile view.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1]
```

11.1.177 vap-profile

Function

The **vap-profile** command binds a VAP profile to a radio.

The **undo vap-profile** command unbinds a VAP profile from a radio.

By default, no VAP profile is bound to a radio.

Format

vap-profile *profile-name* **wlan** *wlan-id* **radio** { *radio-id* | **all** } [**service-vlan** { **vlan-id** *vlan-id* | **vlan-pool** *pool-name* }]

undo vap-profile *profile-name* **wlan** *wlan-id* **radio** { *radio-id* | **all** }

The parameter **radio** { *radio-id* | **all** } is supported only in the AP group view and AP view.

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a VAP profile.	The VAP profile must exist.

Parameter	Description	Value
wlan *wlan-id*	Specifies the WLAN ID of a VAP.	The value is an integer that ranges from 1 to 16. **NOTE** ● The WLAN ID for the WDS service can be 13 or 14. ● The WLAN ID for the Mesh service is 16. ● The WLAN ID for the offline management VAP configuration is 15 or an integer that ranges from 1 to 12. ● For some AP models, the maximum number of VAPs supported by each radio is less than 16. If the value of *wlan-id* exceeds the AP specifications, the configuration cannot take effect and the AP cannot generate radio signals.
radio	Specifies a radio.	-
radio-id	Specifies a radio ID.	The value is an integer that ranges from 0 to 2.
all	Specifies all radios.	-
service-vlan	Specifies a service VLAN ID.	-
vlan-id *vlan-id*	Specifies a VLAN ID.	The VLAN ID must exist.
vlan-pool *pool-name*	Specifies the name of a VLAN pool.	The VLAN pool must exist.

Views

AP group view, AP view, AP radio view, AP group radio view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you create a VAP profile using the **vap-profile (WLAN view)** command, bind it to a radio so that the VAP profile can take effect.

In some scenarios, users want to configure one VAP for all APs. However, APs use different service VLANs. To simplify the configuration, you can specify a service VLAN using the parameter **service-vlan** when binding a VAP profile. The priority of the service VLAN specified in this command is higher than that of a service VLAN configured using the **service-vlan** command.

Precautions

After a VAP profile is bound to a radio, parameter settings in the VAP profile apply to the radio using the profile.

Example

Create the VAP profile **vap1** and bind **vap1** to the AP group **group1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] quit
[HUAWEI-wlan-view] ap-group name group1
[HUAWEI-wlan-ap-group-group1] vap-profile vap1 wlan 1 radio 0
```

11.1.178 vap-service-backup auth-server-down

Function

The **vap-service-backup auth-server-down** command manually enables or disables an authentication-server-down backup service VAP.

Format

vap-service-backup auth-server-down { **active** | **inactive** } [**vap-profile** *profile-name*]

Parameters

Parameter	Description	Value
active	Manually enables an authentication-server-down backup service VAP.	-
inactive	Manually disables an authentication-server-down backup service VAP.	-

Parameter	Description	Value
vap-profile *profile-name*	Specifies the name of a VAP profile. If this parameter is not specified, VAPs of this type on all referenced radios are enabled.	The VAP profile name must exist.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an authentication-server-down backup service VAP is not automatically disabled after the authentication server is restored, the administrator can manually disable this VAP. When the authentication server rejects access of STAs, the administrator can manually enable an authentication-server-down backup service VAP to enable the STAs to enter the survival state.

Precautions

After an authentication-server-down backup service VAP is manually disabled, STAs associated with this VAP go offline.

Example

Manually enable an authentication-server-down backup service VAP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-service-backup auth-server-down active vap-profile vap1
```

11.1.179 vht a-mpdu max-length-exponent

Function

The **vht a-mpdu max-length-exponent** command sets the maximum length of an aggregated MPDU (A-MPDU) on the 802.11ac radio. MPDU stands for MAC protocol data unit.

The **undo vht a-mpdu max-length-exponent** command restores the maximum length of an A-MPDU on the 802.11ac radio to the default value.

By default, the index for the maximum length of an A-MPDU is 7. The maximum length of the A-MPDU is 1048575 bytes.

The function is not supported by the following models.

- AirEngine series APs

Format

vht a-mpdu max-length-exponent *max-length-exponent-index*

undo vht a-mpdu max-length-exponent

Parameters

Parameter	Description	Value
max-length-exponent-index	Indicates the index for the maximum length of the A-MPDU.	The value is an integer that ranges from 0 to 7. - 0: indicates that the maximum length of the A-MPDU is 8191 bytes. - 1: indicates that the maximum length of the A-MPDU is 16383 bytes. - 2: indicates that the maximum length of the A-MPDU is 32767 bytes. - 3: indicates that the maximum length of the A-MPDU is 65535 bytes. - 4: indicates that the maximum length of the A-MPDU is 131071 bytes. - 5: indicates that the maximum length of the A-MPDU is 262143 bytes. - 6: indicates that the maximum length of the A-MPDU is 524287 bytes. - 7: indicates that the maximum length of the A-MPDU is 1048575 bytes.

Views

5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

To reduce costs, 802.11ac uses frame aggregation technology that aggregates two or more frames into an A-MPDU to transmit.

Example

Set the index of the maximum length of the A-MPDU to 2 in the 5G radio profile **default**. The index 2 corresponds to a maximum length of 32767 bytes.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-5g-profile name default
[HUAWEI-wlan-radio-5g-prof-default] vht a-mpdu max-length-exponent 2
```

11.1.180 a-msdu enable

Function

The **a-msdu enable** command enables the function of sending 802.11 frames in A-MSDU mode.

The **undo a-msdu** command restores the default configuration of sending 802.11 frames in A-MSDU mode.

By default, the function of sending 802.11 frames in A-MSDU mode is in self-adaptive state.

Format

a-msdu { **enable** | **disable** | **auto** }

undo a-msdu

Parameters

Parameter	Description	Value
enable	Enables the A-MSDU function.	-
disable	Disables the A-MSDU function.	-

Parameter	Description	Value
auto	Sets the A-MSDU function to the self-adaptive mode to enable or disable the A-MSDU function based on the AP capability. When this parameter is delivered to APs running a version earlier than V200R020C00, this function is disabled on the APs. When this parameter is delivered to APs running V200R020C00 or later, this function is enabled on the APs.	-

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Aggregated MAC Service Data Unit (A-MSDU) technology aggregates multiple MAC Service Data Units (MSDUs) into an MAC Protocol Data Unit (MPDU), which reduces MAC layer costs of the 802.11 packets and improves packet transmission efficiency especially when short MSDUs are aggregated.

Precautions

The function of sending 802.11 frames in A-MSDU mode can be enabled on radios in compliance with 802.11n and later standards.

For AirEngine series APs, it is recommended that this function be enabled to improve air interface performance.

Example

Enable the function of sending 802.11 frames in A-MSDU mode.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-5g-profile name default
[HUAWEI-wlan-radio-5g-prof-default] a-msdu enable
```

11.1.181 vht a-msdu max-frame-num

Function

The **vht a-msdu max-frame-num** command sets the maximum number of subframes that can be aggregated into an A-MSDU at one time.

The **undo vht a-msdu max-frame-num** command restores the default maximum number of subframes that can be aggregated into an A-MSDU at one time.

By default, a maximum of two subframes can be aggregated into an A-MSDU at one time.

The function is not supported by the following models.

- AirEngine series APs

Format

vht a-msdu max-frame-num *max-frame-number*

undo vht a-msdu max-frame-num

Parameters

Parameter	Description	Value
max-frame-number	Specifies the maximum number of subframes that can be aggregated into an A-MSDU at one time.	The value is an integer that ranges from 2 to 15.

Views

5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A-MSDU technology aggregates multiple MSDUs into an MPDU, which reduces MAC layer costs of the 802.11 packets.

- When the wireless network quality is satisfactory, increase the maximum number of subframes that can be aggregated into an A-MSDU at one time to improve the network usage efficiency and wireless service performance.
- When the wireless network quality is unsatisfactory or delay-sensitive services, such as voice services are transmitted, reduce the maximum number of subframes that can be aggregated into an A-MSDU at one time to minimize the impact of packet loss on services and reduce packet transmission delay. Some STAs have restrictions on the number of subframes aggregated into a received A-MSDU. If the number of subframes sent by the AP exceeds the threshold, the STAs cannot receive the frames properly.

Prerequisites

The function of sending 802.11 frames in A-MSDU mode has been enabled using the **a-msdu enable** command.

Example

Set the maximum number of subframes that can be aggregated into an A-MSDU at one time to 3.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-5g-profile name default
[HUAWEI-wlan-radio-5g-prof-default] vht a-msdu max-frame-num 3
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.1.182 vht mcs-map

Function

The **vht mcs-map** command configures the maximum number of spatial streams and the maximum MCS value supported by 802.11ac in the 5G radio profile.

The **undo vht mcs-map** command restores the default configuration.

By default, the maximum number of spatial streams and the maximum MCS value are not specified in the 5G radio profile.

Format

vht mcs-map nss *nss-value* **max-mcs** *max-mcs-value*

undo vht mcs-map

Parameters

Parameter	Description	Value
nss *nss-value*	Specifies the maximum number of available spatial streams.	The value is an integer ranging from 1 to 8.
max-mcs *max-mcs-value*	Specified the maximum MCS value that can be negotiated for spatial streams.	The value is an integer ranging from 7 to 9.

Views

5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Rates of 802.11ac APs depend on the index value of MCS. A larger MCS value indicates a higher transmission rate.

- When *nss-value* is greater than or equal to the maximum number of spatial streams supported by an AP, the number of available spatial streams is the same as the maximum number of spatial streams supported by the AP.
- When *nss-value* is smaller than the maximum number of spatial streams supported by an AP, the number of available spatial streams is the same as *nss-value* and remaining spatial streams do not take effect.

  For example, if *nss-value* is set to 2 and the AP supports a maximum of 3 spatial streams, the maximum number of available spatial streams on the AP is 2.

Precautions

The following configurations take effect in descending order of priority: Reliability-first service guarantee mode configured using the **service-guarantee reliability-first** command in the SSID profile > Number of spatial streams and MCS value configured using the **vht mcs-map (SSID Profile)** command in the SSID profile > Number of spatial streams and MCS value configured using the **vht mcs-map** command in the 5G radio profile.

This configuration takes effect only when the AP communicates with STAs through 802.11ac.

Example

In the 5G radio profile, set the maximum number of available spatial streams to 2 and the maximum MCS value to 8.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-5g-profile name default
[HUAWEI-wlan-radio-5g-prof-default] vht mcs-map nss 2 max-mcs 8
```

11.1.183 vht mcs-map (SSID profile)

Function

The **vht mcs-map** command configures the maximum number of spatial streams and the maximum MCS value supported by 802.11ac in the SSID profile.

The **undo vht mcs-map** command restores the default configuration.

By default, the maximum number of spatial streams and the maximum MCS value are not specified in the SSID profile.

Format

vht { **tx** | **rx** } **mcs-map nss** *nss-value* **map** *mcs-value*

undo vht { **tx** | **rx** } **mcs-map**

Parameters

Parameter	Description	Value
tx	Indicates the sent data.	-
rx	Indicates the received data.	-
nss *nss-value*	Specifies the maximum number of available spatial streams.	The value is an integer that ranges from 1 to 8.
map *mcs-value*	Specified the maximum MCS value that can be negotiated for spatial streams.	The value is an integer that ranges from 7 to 9.

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Rates of 802.11ac APs depend on the index value of MCS. A larger MCS value indicates a higher transmission rate.

- When *nss-value* is greater than or equal to the maximum number of spatial streams supported by an AP, the number of available spatial streams is the same as the maximum number of spatial streams supported by the AP.
- When *nss-value* is smaller than the maximum number of spatial streams supported by an AP, the number of available spatial streams is the same as *nss-value* and remaining spatial streams do not take effect.

  For example, if *nss-value* is set to 2 and the AP supports a maximum of 3 spatial streams, the maximum number of available spatial streams on the AP is 2.

Precautions

The following configurations take effect in descending order of priority: Reliability-first service guarantee mode configured using the **service-guarantee reliability-first** command in the SSID profile > Number of spatial streams and MCS value configured using the **vht mcs-map (SSID Profile)** command in the SSID profile > Number of spatial streams and MCS value configured using the **vht mcs-map** command in the 5G radio profile.

This configuration takes effect only when the AP communicates with STAs through 802.11ac.

Example

In the SSID profile, set the maximum number of available spatial streams to 2 and the maximum MCS value to 8.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] vht rx mcs-map nss 2 map 8
```

11.1.184 vip-user bandwidth reservation-ratio

Function

The **vip-user bandwidth reservation-ratio** command configures the percentage of bandwidth reserved for VIP users.

The **undo vip-user bandwidth reservation-ratio** command restores the default percentage of bandwidth reserved for VIP users.

The default percentage of bandwidth reserved for VIP users is 20%.

Format

vip-user bandwidth reservation-ratio *reservation-ratio*

undo vip-user bandwidth reservation-ratio

Parameters

Parameter	Description	Value
reservation-ratio	Specifies the percentage of bandwidth reserved for VIP users.	The value is an integer that ranges from 0 to 100, in percentage. The default value is 20.

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

Bandwidth reservation for VIP users enables VIP users to preferentially enjoy experience improvement brought by resource reservation in the case of air interface congestion. You can run this command to adjust the percentage of bandwidth reserved for VIP users based on radios. The reserved bandwidth is shared by all VIP users.

The specific improvement effect depends on factors such as the number of VIP users and service types. It is recommended that you set *reservation-ratio* to 75%

when the **proportion of the number of VIP users to the total number of users** is 50% or set the value to 50% when the proportion is 20%. You can adjust the value based on the site requirements.

Example

In the 2G radio profile **default**, set the percentage of bandwidth reserved for VIP users to 30%.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] vip-user bandwidth reservation-ratio 30
```

11.1.185 wlan

Function

The **wlan** command displays the WLAN view.

Format

wlan

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Before performing WLAN configurations, run the **wlan** command to enter the WLAN view. All WLAN configuration commands need to be used in the WLAN view or WLAN sub-view.

Example

Enter the WLAN view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view]
```

11.2 AP Management Configuration Commands

11.2.1 Command Support

WLAN-AC commands are supported only by the following models: S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.

11.2.2 access-user syslog-restrain enable

Function

The **access-user syslog-restrain enable** command enables system log suppression.

The **undo access-user syslog-restrain enable** command disables system log suppression.

By default, system log suppression is enabled.

Format

access-user syslog-restrain enable

undo access-user syslog-restrain enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

After a STA passes authentication or successfully associates with the AP, the AP sends system logs to the NMS server. A system log contains MAC addresses of the STA, AC, and AP, AP and AC name and current time, and authentication result.

If a STA fails to associate with an AP or fails authentication, the STA attempts to go online continuously. The AP sends a large number of duplicate logs to the AC in a short period, which wastes resources and deteriorates system performance. To prevent this problem, enable system log suppression.

Example

Enable system log suppression.

```
<HUAWEI> system-view
[HUAWEI] access-user syslog-restrain enable
```

11.2.3 access-user syslog-restrain period

Function

The **access-user syslog-restrain period** command sets the period of system log suppression.

The **undo access-user syslog-restrain period** command restores the default period of system log suppression.

By default, the period of system log suppression is 300s.

Format

access-user syslog-restrain period *period*

undo access-user syslog-restrain period

Parameters

Parameter	Description	Value
period	Specifies the period of system log suppression.	The value is an integer that ranges from 60 to 604800, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

When a STA is authenticated or successfully associates with an AP, the AP sends system logs to the NMS server. A system log contains the MAC addresses of the STA, AP, and AC, AP name, AC name, current time, and authentication result.

A STA retries continuously after it fails to associate with an AP or pass the authentication. When this occurs, the AC sends a large number of logs in a short time. This results in a high statistics failure rate and degrades the NMS performance. The system log suppression function reduces impact of such logs on the NMS. After the period of system log suppression is set, the AC will send only one system log to the NMS server during the suppression period, reducing the load on the server.

Example

Set the period of system log suppression to 600s.

```
<HUAWEI> system-view
[HUAWEI] access-user syslog-restrain period 600
```

11.2.4 ac-list (AP view)

Function

The **ac-list** command configures an AC IPv4 address list for APs.

The **undo ac-list** command restores the AC IPv4 address list to the default value.

By default, no AC IPv4 address list is configured.

Format

ac-list *ipv4-address* &<1-4>

undo ac-list

Parameters

Parameter	Description	Value
ipv4-address	Specifies the IPv4 address of an AC.	The value is in dotted decimal notation.

Views

AP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to statically configure an AC IPv4 address list for APs.

In addition to the static configuration, APs can dynamically obtain an AC IP address list through DHCP or DNS. When an AP goes online, it sends Discovery Request unicast packets to all ACs' IP addresses that are statically or dynamically obtained. After receiving the Discovery Request packets, the ACs respond to the AP with a Discovery Response packet. Based on AC information such as the AP management capability, maximum number of access STAs, and IP address, the AP selects one AC to establish a CAPWAP tunnel. If the AP does not have the AC IP address list or receives no response to the Discovery Request packet, the AP broadcasts Discovery Request packets to discover ACs on the same network segment.

Precautions

After the configuration is delivered, restart the APs to make the configuration take effect.

Example

Set the AC's IPv4 address to 192.168.10.1 in the AP view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 0
[HUAWEI-wlan-ap-0] ac-list 192.168.10.1
Warning: The incorrect configuration will cause the AP to go out of management. This operation will
deliver parameter setting and ma
y cause reboot of AP(s). Continue?[Y/N]:y
```

11.2.5 ac-list (AP provisioning view)

Function

The **ac-list** command configures an AC IPv4 address list for APs.

The **undo ac-list** command disables the AC from delivering this parameter setting to APs after the configuration is delivered using the **commit** command.

By default, no AC IPv4 address list is configured.

Format

ac-list *ipv4-address* &<1-4>

undo ac-list

Parameters

Parameter	Description	Value
ipv4-address	Specifies the IPv4 address of an AC.	The value is in dotted decimal notation.

Views

AP provisioning view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to statically configure an AC IPv4 address list for APs.

In addition to the static configuration, APs can dynamically obtain an AC IP address list through DHCP or DNS. When an AP goes online, it sends Discovery

Request unicast packets to all ACs' IP addresses that are statically or dynamically obtained. After receiving the Discovery Request packets, the ACs respond to the AP with a Discovery Response packet. Based on AC information such as the AP management capability, maximum number of access STAs, and IP address, the AP selects one AC to establish a CAPWAP tunnel. If the AP does not have the AC IP address list or receives no response to the Discovery Request packet, the AP broadcasts Discovery Request packets to discover ACs on the same network segment.

Follow-up Procedure

Run the **commit** command to deliver configuration to APs and restart the APs to make the configuration take effect.

Example

Set the AC's IPv4 address to 192.168.10.1 in the AP provisioning view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] provision-ap
[HUAWEI-wlan-provision-ap] ac-list 192.168.10.1
```

11.2.6 address-mode (AP view)

Function

The **address-mode** command sets the mode in which an AP obtains an IP address.

The **undo address-mode** command restores the default mode in which an AP obtains an IP address.

By default, the mode in which an AP obtains an IP address is not configured.

Format

address-mode { **dhcp** | **static** }

undo address-mode

Parameters

Parameter	Description	Value
dhcp	Indicates that an IP address is obtained in DHCP mode. The AP functions as a DHCP client and is assigned an IP address by the DHCP server.	-
static	Indicates that a static IP address is obtained. The AP must be configured with a static IP address.	-

Views

AP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **address-mode** command to configure an AP to obtain an IP address in DHCP or static mode.

Precautions

After the configuration is delivered, restart the APs to make the configuration take effect.

Example

Configure an AP to obtain an IP address in DHCP mode.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 0
[HUAWEI-wlan-ap-0] address-mode dhcp
Warning: The incorrect configuration will cause the AP to go out of management. This operation will
deliver parameter setting and ma
y cause reboot of AP(s). Continue?[Y/N]:y
```

11.2.7 address-mode (AP provisioning view)

Function

The **address-mode** command sets the mode in which an AP obtains an IP address.

The **undo address-mode** command disables the AC from delivering this parameter setting to APs after the configuration is delivered using the **commit** command.

By default, the mode in which an AP obtains an IP address is not configured.

Format

address-mode { **dhcp** | **static** }

undo address-mode

Parameters

Parameter	Description	Value
dhcp	Indicates that an IP address is obtained in DHCP mode. The AP functions as a DHCP client and is assigned an IP address by the DHCP server.	-

Parameter	Description	Value
static	Indicates that a static IP address is obtained. The AP must be configured with a static IP address.	-

Views

AP provisioning view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **address-mode** command to configure an AP to obtain an IP address in DHCP or static mode.

Follow-up Procedure

Run the **commit** command to deliver configuration to APs and restart the APs to make the configuration take effect.

Example

Configure an AP to obtain an IP address in DHCP mode.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] provision-ap
[HUAWEI-wlan-provision-ap] address-mode dhcp
```

11.2.8 alarm-restriction disable

Function

The **alarm-restriction disable** command disables alarm suppression for an AP.

The **undo alarm-restriction disable** command enables alarm suppression for an AP.

By default, alarm suppression is enabled for an AP.

Format

alarm-restriction disable

undo alarm-restriction disable

Parameters

None

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

If a STA cannot go online due to security type mismatch, UAC, or access user upper limit exceeding, the STA will automatically re-connect to the AP. During this period, the AP sends a large number of the same STA association failure alarms to the AC, which degrades the system performance.

To solve this problem, enable alarm suppression for the AP. The AP then does not report alarms repeatedly in the alarm suppression period, preventing alarm storms.

Example

Disable alarm suppression for an AP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] alarm-restriction disable
```

11.2.9 alarm-restriction period

Function

The **alarm-restriction period** command configures the period of alarm suppression on an AP.

The **undo alarm-restriction period** command restores the default period of alarm suppression for an AP.

The default alarm suppression period is 60 seconds on an AP.

Format

alarm-restriction period *period*

undo alarm-restriction period

Parameters

Parameter	Description	Value
period	Specifies the period of alarm suppression for an AP.	The value is an integer that ranges from 10 to 300, in seconds.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

You can run the **ap alarm-restriction period** command to configure the period of alarm suppression for an AP. The AP reports an alarm only one time in the specified period if the alarm is repeatedly generated.

Example

Set the period of alarm suppression to 200 seconds for an AP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] alarm-restriction period 200
```

11.2.10 ap lldp enable

Function

The **ap lldp enable** command enables the Link Layer Discovery Protocol (LLDP) in the WLAN view.

The **undo ap lldp enable** command disables LLDP in the WLAN view.

By default, LLDP is enabled in the WLAN view.

Format

ap lldp enable

undo ap lldp enable

Parameters

None

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

LLDP is a Layer 2 discovery protocol defined in the IEEE 802.1ab standard. Using LLDP, the AC or NMS can obtain Layer 2 information about the connected APs, including APs' interfaces and connections with other devices. Additionally, the AC or NMS can obtain details about network topology and interface changes. To view the Layer 2 link status between APs, and between APs and switch or analyze the network topology, enable WLAN LLDP.

Precautions

WLAN LLDP can be enabled in the system view and the AP wired port link profile view.

- An AP can send and receive LLDP packets only after LLDP is enabled in both the WLAN view and the AP wired port link profile view.
- After LLDP is disabled in the WLAN view, the commands for enabling and disabling LLDP on the AP wired port link profile view do not take effect.

Example

Enable LLDP in the WLAN view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap lldp enable
```

11.2.11 ap manufacturer-config

Function

The **ap manufacturer-config** command restores the factory settings of APs.

Format

ap manufacturer-config { **ap-name** *ap-name* | **ap-mac** *ap-mac* | **ap-id** *ap-id* }

Parameters

Parameter	Description	Value
ap-name *ap-name*	Specifies the name of the AP whose factory settings need to be restored.	The AP name must already exist.
ap-mac *ap-mac*	Specifies the MAC address of the AP whose factory settings need to be restored.	The AP's MAC address must already exist.
ap-id *ap-id*	Specifies the ID of the AP whose factory settings need to be restored.	The AP ID must already exist.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

When a configuration error occurs on an AP, you can run this command to clear AP configurations.

NOTICE

Restoring the factory defaults of an AP will reset the AP and restore all the default AP configurations.

Example

Restore the factory settings of AP **N1-2**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap manufacturer-config ap-name N1-2
Warning: Reset AP to the manufacturing default configuration, continue?[Y/N]:y
```

11.2.12 ap update ftp-server

Function

The **ap update ftp-server** command configures basic FTP information, including the IP address, user name, and password of the FTP server.

The **undo ap update ftp-server** command restores default FTP settings.

By default, no basic FTP information is configured.

Format

ap update ftp-server ip-address *server-ip-address* [**port** *port*] **ftp-username** *ftp-username* **ftp-password cipher** *ftp-password*

undo ap update ftp-server ip-address

Parameters

Parameter	Description	Value
ip-address *server-ip-address*	Specifies an IPv4 address for the FTP server.	The value is in dotted decimal notation.

Parameter	Description	Value
port *port*	Specifies a port number for the FTP server. If no port number is specified, the default port 21 is used.	The value is an integer that ranges from 1 to 65535.
ftp-username *ftp-username*	Specifies the user name for logging in to the FTP server.	The value is a string of 1 to 31 characters. It cannot contain question marks (?), and cannot start or end with double quotation marks (") or spaces.
ftp-password	Specifies the password for logging in to the FTP server.	-
cipher	Specifies the password in ciphertext.	-
ftp-password	Specifies the FTP server password.	The value is a string of characters without question marks (?), and cannot start or end with double quotation marks (") or spaces. *ftp-password* can be a string of 1 to 188 characters in ciphertext, such as **%^%#A<g;&zQR7P3TF+,[MxQ1X%4[2~Gb]Vp#(e<y:~)/%^%#**, or a string of 1 to 128 characters in plaintext, such as **YsHsjx_202206**.

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

- The FTP configuration is used when the automatic upgrade and online upgrade modes are FTP. In the automatic upgrade or online upgrade, the AC sends basic FTP information to the AP, and the AP requests the FTP server for upgrade based on FTP information.
- After running the **ap update ftp-server** command, you can perform the following operations:
  a. Run the **ap update mode** command to set the upgrade mode to ftp-mode.
  b. Run the **ap update multi-load** command to upgrade APs in batches.

Precautions

- It is recommended that you use an external FTP server to upgrade APs. If the AC functions as the FTP server, a maximum of five APs can be upgraded simultaneously. If there are *n* login VTY users, the maximum number of APs that can be upgraded simultaneously is subtracted by *n* - 1.
- APs do not support the double quotation marks ("). Ensure that the FTP server user name and unencrypted password configured on the AC do not contain the preceding characters. Otherwise, the FTP upgrade fails.
- When the FTP port number is specified, the upgrade is applicable only to APs in V200R020C10 and later. If the source version of APs is earlier than V200R020C10, the FTP upgrade fails.
- The FTP server must support the REST field. Otherwise, the upgrade will fail. If the following information is displayed, the upgrade fails because the server does not support the REST field. In this case, replace the server.

```
Error: Upgrade failed because the FTP server does not support the REST command.
```

Example

Configure the IP address, user name, and password of the FTP server.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap update ftp-server ip-address 192.168.1.100 ftp-username admin ftp-password
cipher YsHsjx_202206
```

11.2.13 ap update ftp-server max-connect-number

Function

The **ap update ftp-server** command configures the maximum number of APs that can be upgraded simultaneously in FTP mode.

The **undo ap update ftp-server** command restores the default maximum number of APs that can be upgraded simultaneously in FTP mode.

By default, a maximum of 50 APs can be upgraded simultaneously in FTP mode.

Format

ap update ftp-server max-connect-number *max-connect-number*

undo ap update ftp-server max-connect-number

Parameters

Parameter	Description	Value
max-connect-number	Specifies the maximum number of APs that can be upgraded simultaneously.	The value is an integer that ranges from 1 to 64.

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When APs are upgraded in FTP mode, you can configure the value of *max-connect-number* to change the maximum number of APs that can be upgraded simultaneously.

- If the number of APs to be upgraded is equal to or smaller than *max-connect-number*, all APs can be upgraded simultaneously.
- If the number of APs to be upgraded is larger than *max-connect-number*, only the specified number of APs can be upgraded simultaneously. After the specified number of APs are upgraded, the remaining APs are upgraded automatically until all APs are upgraded. The number of APs that are upgraded at a time cannot exceed the value of *max-connect-number*.

Precautions

An external FTP server can be used, which is recommended. The AC can also function as the FTP server.

- When an external FTP server is used, the maximum number of APs that can be upgraded simultaneously is the configured *max-connect-number*.
- If an AC is used as the FTP server, a maximum of five APs can be upgraded simultaneously even if the specified number is larger than five.

  When the AC functions as the FTP server, run the **ap update ftp-server max-connect-number** *max-connect-number* command to set the maximum number of APs that can be upgraded simultaneously. The value of *max-connect-number* is an integer ranging from 1 to 5. During the upgrade, a maximum of 1 to 5 APs can be upgraded at a time until all APs are upgraded.

  If the configured number of APs to be upgraded simultaneously is larger than five, an error message will be displayed after the first five APs are upgraded. The remaining APs cannot be automatically upgraded. You have to repeat the command until all APs are upgraded.

If there are *n* login VTY users, the maximum number of APs that can be upgraded simultaneously is subtracted by *n* - 1.

Example

Set the maximum number of APs that can be upgraded simultaneously in FTP mode to 10.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap update ftp-server max-connect-number 10
```

11.2.14 ap update load

Function

The **ap update load** command upgrades a specified AP.

The **undo ap update load** command cancels AP upgrade.

Format

ap update load { **ap-name** *ap-name* | **ap-mac** *ap-mac* | **ap-id** *ap-id* } **update-filename** *update-file-name*

undo ap update load { **ap-name** *ap-name* | **ap-mac** *ap-mac* | **ap-id** *ap-id* }

Parameters

Parameter	Description	Value
ap-name *ap-name*	Specifies the name of the AP to be upgraded.	The AP name must already exist.
ap-mac *ap-mac*	Specifies the MAC address of the AP to be upgraded.	The AP's MAC address must already exist.
ap-id *ap-id*	Specifies the ID of the AP to be upgraded.	The AP ID must already exist.
update-filename *update-file-name*	Specifies the AP upgrade file.	The upgrade file name must already exist.

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When APs are upgraded in batches based on AP types, if the new version fails, the version rollback takes a long period. Therefore, you can upgrade a single AP to check whether faults occur on the version, ensuring successful upgrades in batches.

Prerequisites

When the AC mode is used, the AP upgrade file has been uploaded to the AC. If the FTP or SFTP mode is used, the AP upgrade file has been uploaded to the FTP server or SFTP server.

The AP is in normal or vmiss state.

Follow-up Procedure

Run the **ap update reset** { **ap-name** *ap-name* | **ap-mac** *ap-mac* | **ap-id** *ap-id* } command to restart the AP to make the upgrade take effect.

Precautions

The **undo ap update load** { **ap-name** *ap-name* | **ap-mac** *ap-mac* | **ap-id** *ap-id* } command cancels AP upgrade. However, if the AP system software has been written to the flash memory during the upgrade, the command does not take effect. You can run the **display ap update status** { **ap-name** *ap-name* | **ap-id** *ap-id* } command to check AP upgrade progress.

Example

Upgrade the AP **N1-2** using the upgrade file **AirEngineX760-V200R021C10.cc**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap update load ap-name N1-2 update-filename AirEngineX760-V200R021C10.cc
Info: The current upgrade mode is AC mode, which may affect performance and take a long time. The FTP
or SFTP upgrade mode is recommended. Continue? [Y/N]:y
```

11.2.15 ap update mode

Function

The **ap update mode** command configures the AP upgrade mode.

The **undo ap update mode** command restores the default AP upgrade mode.

The default upgrade mode is **ac-mode**.

Format

ap update mode { **ftp-mode** | **ac-mode** | **sftp-mode** }

undo ap update mode

Parameters

Parameter	Description	Value
ac-mode	Indicates the AP upgrade mode in which APs download the upgrade version file from the AC.	-
ftp-mode	Indicates the FTP mode. The AC delivers the FTP configuration to APs using the **ap update ftp-server** command, and APs download the upgrade version file from the FTP server.	-
sftp-mode	Indicates the SFTP mode. The AC delivers the SFTP configuration to APs using the **ap update sftp-server** command, and APs download the upgrade version file from the SFTP server.	-

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

- The AC, FTP, or SFTP upgrade mode must be preset on the AP for automatic upgrade and online upgrade.
- Subsequently, you can run the **ap update multi-load** command to upgrade APs in batches.

NOTE

SFTP is recommended because it is more secure than FTP.

Example

Set the AP upgrade mode to **sftp-mode**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap update mode sftp-mode
```

11.2.16 ap update multi-load

Function

The **ap update multi-load** command upgrades APs in batches.

The **undo ap update multi-load** command cancels batch upgrade of APs.

Format

ap update multi-load ap-type *type-id* [**ap-group** *group-name* | { **ap-name** *ap-name* | **ap-id** *ap-id* } &<1-10>]

ap update multi-load ap-group *group-name* [{ **ap-name** *ap-name* } &<1-10> | { **ap-id** *ap-id* } &<1-10>]

undo ap update multi-load ap-type *type-id* [**ap-group** *group-name* | { **ap-name** *ap-name* | **ap-id** *ap-id* } &<1-10>]

undo ap update multi-load ap-group *group-name* [{ **ap-name** *ap-name* } &<1-10> | { **ap-id** *ap-id* } &<1-10>]

Parameters

Parameter	Description	Value
ap-type *type-id*	Specifies the AP type ID.	The value is an integer that ranges from 0 to .
ap-group *group-name*	Specifies an AP group.	The AP group must exist.
ap-name *ap-name*	Specifies an AP name.	The AP name must exist.
ap-id *ap-id*	Specifies an AP ID.	The AP ID must exist.

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **ap update multi-load ap-type** *type-id* [**ap-group** *group-name* | { **ap-name** *ap-name* | **ap-id** *ap-id* } &<1-10>] command to upgrade APs of the same type in batches in the online upgrade mode.

- If **ap-group** *group-name* is specified, only APs of the same type and in the specified AP group are upgraded.
- If **ap-name** *ap-name* or **ap-id** *ap-id* is specified, only APs of the specified type and with the specified AP name or AP ID are upgraded
- If none of the **ap-group** *group-name*, **ap-name** *ap-name*, and **ap-id** *ap-id* parameters are specified, all APs of the specified type are upgraded.

- If the type of APs specified by **ap-group** *group-name*, **ap-name** *ap-name*, or **ap-id** *ap-id* is different from **ap-type** *type-id*, the APs cannot be upgraded.

You can run the **ap update multi-load ap-group** *group-name* [{ **ap-name** *ap-name* } &<1-10> | { **ap-id** *ap-id* } &<1-10>] command to batch upgrade APs in the specified AP group online.

- If **ap-name** *ap-name* or **ap-id** *ap-id* is specified, only APs with the specified name or ID in the specified AP group are upgraded.
- If neither **ap-name** *ap-name* nor **ap-id** *ap-id* is specified, all APs in the specified AP group are upgraded.
- If APs specified by **ap-name** *ap-name* and **ap-id** *ap-id* are in different AP groups, the APs cannot be upgraded.

Prerequisites

AP upgrade files have been configured in batches using the **ap update update-filename** command.

Follow-up Procedure

Run the **ap update multi-reset** command to reset APs in batches to make AP upgrade take effect.

Precautions

The **undo ap update multi-load** command cancels batch upgrade of APs. However, if the AP system software has been written to the flash memory during the upgrade, the command does not take effect. You can run the **display ap update status all** command to check AP upgrade progress.

Example

Upgrade APs with **type-id** 56 in batches online.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap update multi-load ap-type 56
Info: The current upgrade mode is AC mode, which may affect performance and take a long time. The FTP
or SFTP upgrade mode is recommended. Continue? [Y/N]:y
```

Upgrade all APs in the AP group **group1** in batches online.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap update multi-load ap-group group1
Info: The current upgrade mode is AC mode, which may affect performance and take a long time. The FTP
or SFTP upgrade mode is recommended. Continue? [Y/N]:y
```

11.2.17 ap update multi-reset

Function

The **ap update multi-reset** command resets APs in batches.

The **undo ap update multi-reset partition** command cancels the AP reset by channel-based partition.

Format

ap update multi-reset ap-type *type-id* [**ap-group** *group-name* | { **ap-name** *ap-name* | **ap-id** *ap-id* } &<1-10>]

ap update multi-reset ap-group *group-name* [{ **ap-name** *ap-name* } &<1-10> | { **ap-id** *ap-id* } &<1-10>]

ap update multi-reset { **partition** { **all** | **partition-id** *partition-id* } | **ap-id** *ap-id* } [**primary-access** { **ipv4** *ipv4-address* | **ipv6** *ipv6-address* }]

undo ap update multi-reset partition

Parameters

Parameter	Description	Value
ap-type *type-id*	Resets APs of the specified type ID.	The AP type ID must exist.
ap-group *group-name*	Resets APs in the specified AP group.	The AP group must exist.
ap-name *ap-name*	Resets the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Resets the AP with a specified ID.	The AP ID must exist.
partition all	Resets APs in all channel-based partitions.	-
partition partition-id *partition-id*	Resets APs in the specified channel-based partition.	The value is an integer that ranges from 0 to 255.
primary-access ipv4 *ipv4-address*	Specifies the IPv4 address of the AC with which APs re-establish links after the APs are reset.	The value is in dotted decimal notation.
primary-access ipv6 *ipv6-address*	Specifies the IPv6 address of the AC with which APs re-establish links after the APs are reset.	The value is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

This command resets APs in batches and can be used only after APs are upgraded in batches.

Run the **ap update multi-reset ap-type** *type-id* [**ap-group** *group-name* | { **ap-name** *ap-name* | **ap-id** *ap-id* } &<1-10>] command to batch reset APs of the specified type online.

- If **ap-group** *group-name* is specified, only APs of the specified type and in the specified AP group are reset.
- If **ap-name** *ap-name* or **ap-id** *ap-id* is specified, only APs of the specified type and with the specified AP name or ID are reset.
- If none of the **ap-group** *group-name*, **ap-name** *ap-name*, and **ap-id** *ap-id* parameters are specified, all APs of the specified type are reset.
- If the type of APs specified by **ap-group** *group-name*, **ap-name** *ap-name*, or **ap-id** *ap-id* is different from **ap-type** *type-id*, the APs cannot be reset.

You can run the **ap update multi-reset ap-group** *group-name* [{ **ap-name** *ap-name* } &<1-10> | { **ap-id** *ap-id* } &<1-10>] command to batch reset APs in the specified AP group online.

- If **ap-name** *ap-name* or **ap-id** *ap-id* is specified, only APs with the specified name or ID in the specified AP group are reset.
- If neither **ap-name** *ap-name* nor **ap-id** *ap-id* is specified, all APs in the specified AP group are reset.
- If APs specified by **ap-name** *ap-name* or **ap-id** *ap-id* are not in the AP group specified by **ap-group** *group-name*, the APs cannot be reset.

The **ap update multi-reset** { **partition** { **all** | **partition-id** *partition-id* } | **ap-id** *ap-id* } [**primary-access** { **ipv4** *ipv4-address* | **ipv6** *ipv6-address* }] command is used to reset APs in a specified channel-based partition in batches. To perform an in-service upgrade for all APs on the entire network, you can divide APs into different partitions based on channels and reset the APs by partition in sequence after loading the target version files to all APs. This prevents network service interruption caused by resetting a large number of APs. When APs are reset by partition, surrounding APs automatically fill coverage holes to ensure service continuity. For service continuity, ensure that at least two APs are deployed in one place.

In dual-AC scenarios, when APs are upgraded by channel-based partition, you can specify the IP address of the AC with which APs re-establish links after the APs are reset.

If an upgrade exception occurs when the **ap update multi-reset partition all** command is used to reset all RUs by channel-based partition, you can run the **undo ap update multi-reset partition** command to cancel the subsequent RU reset by channel-based partition.

Example

Reset APs with **type-id** 56 in batches.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap update multi-reset ap-type 56
Warning: Reset the APs in batches to make the upgrade take effect. Continue? [Y/N]:y
```

11.2.18 ap update reset

Function

The **ap update reset** command restarts a specified AP after it is upgraded.

Format

ap update reset { **ap-name** *ap-name* | **ap-mac** *ap-mac* | **ap-id** *ap-id* }

Parameters

Parameter	Description	Value
ap-name *ap-name*	Specifies the name of the AP to be restarted.	The AP name must already exist.
ap-mac *ap-mac*	Specifies the MAC address of the AP to be restarted.	The AP's MAC address must already exist.
ap-id *ap-id*	Specifies the ID of the AP to be restarted.	The AP ID must already exist.

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After an AP has been upgraded, run the **ap update reset** command to restart it to make the AP upgrade take effect.

Prerequisites

The AP is in normal or vmiss state.

The **ap update load** { **ap-name** *ap-name* | **ap-mac** *ap-mac* | **ap-id** *ap-id* } **update-filename** *update-file-name* command has been executed to upgrade a specified AP, and the **display ap update status** command has been executed to verify that **Update Status** of the specified AP is **succeed(need reset)**.

Example

Restart AP **N1-2** after the upgrade.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] ap update load ap-name N1-2 update-filename AirEngineX760-V200R021C10.cc
[HUAWEI-wlan-view] ap update reset ap-name N1-2
```

11.2.19 ap update sftp-server

Function

The **ap update sftp-server** command configures basic SFTP information, including the IP address, user name, and password of the SFTP server.

The **undo ap update sftp-server** command restores default SFTP settings.

By default, no basic SFTP information is configured.

Format

ap update sftp-server ip-address *server-ip-address* [**port** *port*] **sftp-username** *sftp-username* **sftp-password cipher** *sftp-password*

undo ap update sftp-server ip-address

Parameters

Parameter	Description	Value
ip-address *server-ip-address*	Specifies an IPv4 address for the SFTP server.	The value is in dotted decimal notation.
port *port*	Specifies a port number for the SFTP server. If no port number is specified, the default port 22 is used.	The value is an integer that ranges from 1 to 65535.
sftp-username *sftp-username*	Specifies the user name for logging in to the SFTP server.	The value is a string of 1 to 31 characters. It cannot contain question marks (?), and cannot start or end with double quotation marks (") or spaces.
sftp-password	Specifies the password for logging in to the SFTP server.	-
cipher	Specifies the password in ciphertext.	-

Parameter	Description	Value
sftp-password	Specifies the SFTP server password.	The value is a string of characters. It cannot contain question marks (?), and cannot start or end with double quotation marks (") or spaces. *sftp-password* can be a string of 1 to 188 characters in ciphertext, such as **%^%#A<g;&zQR7P3TF+,[MxQ1X%4[2~Gb]Vp#(e<y:~)/%^%#**, or a string of 1 to 128 characters in plaintext, such as **YsHsjx_202206**.

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

- The SFTP configuration is used when the automatic upgrade and online upgrade modes are SFTP. In the automatic upgrade or online upgrade, the AC sends basic SFTP information to the AP, and the AP requests the SFTP server for upgrade based on SFTP information.
- After running the **ap update sftp-server** command, you can perform the following operations:
  a. Run the **ap update mode** command to set the upgrade mode to sftp-mode.
  b. Run the **ap update multi-load** command to upgrade APs in batches.

Precautions

- It is recommended that you use an external SFTP server to upgrade APs. If the AC functions as the SFTP server, a maximum of five APs can be upgraded simultaneously. If there are *n* login VTY users, the maximum number of APs that can be upgraded simultaneously is subtracted by *n* - 1.

- APs do not support the double quotation marks ("). Ensure that the SFTP server user name and unencrypted password configured on the AC do not contain the preceding characters. Otherwise, the SFTP upgrade fails.
- When the SFTP port number is specified, the upgrade is applicable only to APs in V200R020C10 and later. If the source version of APs is earlier than V200R020C10, the SFTP upgrade fails.

Example

Configure the IP address, user name, and password of the SFTP server.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap update sftp-server ip-address 192.168.1.100 sftp-username admin sftp-password cipher YsHsjx_202206
```

11.2.20 ap update sftp-server max-connect-number

Function

The **ap update sftp-server** command configures the maximum number of APs that can be upgraded simultaneously in SFTP mode.

The **undo ap update sftp-server** command restores the default maximum number of APs that can be upgraded simultaneously in SFTP mode.

By default, a maximum of 50 APs can be upgraded simultaneously in SFTP mode.

Format

ap update sftp-server max-connect-number *max-connect-number*

undo ap update sftp-server max-connect-number

Parameters

Parameter	Description	Value
max-connect-number	Specifies the maximum number of APs that can be upgraded simultaneously.	The value is an integer that ranges from 1 to 64.

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When APs are upgraded in SFTP mode, you can configure the value of *max-connect-number* to change the maximum number of APs that can be upgraded simultaneously.

- If the number of APs to be upgraded is equal to or smaller than *max-connect-number*, all APs can be upgraded simultaneously.
- If the number of APs to be upgraded is larger than *max-connect-number*, only the specified number of APs can be upgraded simultaneously. After the specified number of APs are upgraded, the remaining APs are upgraded automatically until all APs are upgraded. The number of APs that are upgraded at a time cannot exceed the value of *max-connect-number*.

Precautions

An external SFTP server can be used, which is recommended. The AC can also function as the SFTP server.

- When an external SFTP server is used, the maximum number of APs that can be upgraded simultaneously is the configured *max-connect-number*.
- When an AC is used as the SFTP server, a maximum of five APs can be upgraded simultaneously even if the specified number of APs to be upgraded is larger than five.

  When the AC functions as the SFTP server, run the **ap update sftp-server max-connect-number** *max-connect-number* command to set the maximum number of APs that can be upgraded simultaneously. The value of *max-connect-number* is an integer ranging from 1 to 5. During the upgrade, a maximum of 1 to 5 APs can be upgraded at a time until all APs are upgraded.

  If *max-connect-number* is set larger than 5, an error message will be displayed after the first five APs are upgraded. The remaining APs cannot be automatically upgraded. You have to repeat the command until all APs are upgraded.

  If there are *n* login VTY users, the maximum number of APs that can be upgraded simultaneously is subtracted by *n* - 1.

Example

Set the maximum number of APs that can be upgraded simultaneously in SFTP mode to 10.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap update sftp-server max-connect-number 10
```

11.2.21 ap update update-filename

Function

The **ap update update-filename** command configures the upgrade file name for APs of a specified type.

The **undo ap update update-filename** command deletes the upgrade file name for APs of a specified type.

Format

ap update update-filename *filename* **ap-type** *type-id* [**ap-group** *ap-group-name*]

undo ap update update-filename ap-type *type-id* [**ap-group** *ap-group-name*]

Parameters

Parameter	Description	Value
ap-type *type-id*	Specifies the AP type ID.	The value is an integer that ranges from 0 to .
filename	Specifies the AP upgrade file name.	The value is a string of 1 to 255 case-sensitive characters. Ensure that the file name is the same as the actual upgrade file name and has an extension.
ap-group *ap-group-name*	Specifies an AP group.	The AP group must already exist.

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

If you specify **ap-group** *ap-group-name*, the command configures the upgrade file name only for APs of the specified type and in the specified group. The upgrade file name configured for an AP group takes precedence over that configured without an AP group specified if they are different. To cancel the upgrade file name configuration of the AP group, specify the AP group name using the parameter **ap-group** *ap-group-name* when running the **undo** command.

Run the **ap update multi-load ap-type** command to upgrade APs of the same type in batches.

Example

Set the upgrade file name for APs with the type ID 127 to **AirEngineX760-V200R021C10.cc**.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] ap update update-filename AirEngineX760-V200R021C10.cc ap-type 127
Warning: If an AP is performing the automatic upgrade, the AP will be upgraded to the latest version.
Continue?[Y/N]:y
Warning: If AP update mode is AC-mode, update-file's default path is flash:/. Continue?[Y/N]:y
```

11.2.22 ap update schedule-task

Function

The **ap update schedule-task** command configures a scheduled AP upgrade task.

The **undo ap update schedule-task** command deletes a scheduled AP upgrade task.

By default, no scheduled AP upgrade task is configured.

Format

ap update schedule-task task-id *task-id* **start-time** *start-time start-date* **stop-time** *stop-time stop-date* **ap-type** *type-id* [**ap-group** *group-name* | { { **ap-name** *ap-name* } &<1-10> } | { { **ap-id** *ap-id* } &<1-10> }]

ap update schedule-task task-id *task-id* **start-time** *start-time start-date* **stop-time** *stop-time stop-date* **ap-group** *group-name*

undo ap update schedule-task { **all** | **task-id** *task-id* }

Parameters

Parameter	Description	Value
task-id *task-id*	Specifies the ID of a scheduled AP upgrade task.	The value is an integer that ranges from 0 to 31.
start-time *start-time*	Specifies the start time of the scheduled AP upgrade task.	The value is in HH:MM format, ranging from 00:00 to 23:59.
start-date	Specifies the start date of the scheduled AP upgrade task.	The value is in YYYY/MM/DD format, ranging from 2000-01-01 to 2050-12-31.
stop-time *stop-time*	Specifies the end time of the scheduled AP upgrade task.	The value is in HH:MM format, ranging from 00:00 to 23:59.

Parameter	Description	Value
stop-date	Specifies the end date of the scheduled AP upgrade task.	The value is in YYYY/MM/DD format, ranging from 2000-01-01 to 2050-12-31. *stop-time stop-date* must be later than *start-time start-date*.
ap-type *type-id*	Specifies an AP type ID.	The value is an integer. To view all AP types, run the **display ap-type all** command.
ap-group *group-name*	Specifies an AP group name.	The value is a string of 1 to 35 characters, which can be Chinese characters or Chinese + English characters. It cannot contain question marks (?) or slashes (/), and cannot start or end with spaces or double quotation marks (" "). If the AP group name contains spaces, the input name must start and end with a quotation mark ("), for example, **"hello name1"**. The quotation marks at the beginning and end of the AP group name occupy two characters in total. **NOTE** You can only use a command editor of the UTF-8 encoding format to edit Chinese characters.

Parameter	Description	Value
ap-name *ap-name*	Specifies an AP name.	The value is a string of 1 to 63 case-sensitive characters, which can be Chinese characters or Chinese + English characters. It cannot contain question marks (?), and cannot start or end with spaces or double quotation marks (" "). If the AP name contains spaces, the input name must start and end with a quotation mark ("), for example, "hello name1". The quotation marks at the beginning and end of the AP name occupy two characters in total. **NOTE** You can only use a command editor of the UTF-8 encoding format to edit Chinese characters.
ap-id *ap-id*	Specifies an AP ID.	The value is an integer. The value range depends on the actual device.

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can configure a scheduled AP upgrade task to upgrade APs in a specified time period, such as off-peak hours.

If you specify **ap-group** *group-name* in the command, the configured task will upgrade only APs in the specified AP group. Similarly, if you specify **ap-type** *type-id*, **ap-name** *ap-name*, or **ap-id** *ap-id*, the configured task will upgrade only the specified APs.

The scheduled task configuration will not be automatically deleted after a scheduled upgrade task is completed. To delete the task, run the **undo ap update schedule-task** { **all** | **task-id** *task-id* } command.

Prerequisites

The AP upgrade file has been specified using the **ap update update-filename** command.

Configuration Impact

After scheduled upgrade tasks are configured, automatic upgrade cannot be performed if not all tasks are in the DONE, OVERTIME, or DEAD state. To perform automatic upgrade, you need to delete the scheduled upgrade tasks not in DONE, OVERTIME, or DEAD state. To check the status of scheduled AP upgrade tasks, run the **display ap update schedule-task** command.

Precautions

- For scheduled AP upgrade tasks with the same start time, the task with a smaller **task-id** *task-id* is executed preferentially.
- During the scheduled AP upgrade, if the time for task B is reached before task A is completed, task B waits until task A is completed. Subsequent scheduled AP upgrade tasks wait in sequence until the previous task is completed.
- When the time specified by **stop-time** *stop-time stop-date* is reached, ongoing upgrade tasks continue until the upgrade is completed and those tasks waiting in queues stop.
- After APs in a scheduled upgrade task are all upgraded, the APs automatically restart. The APs that fail the upgrade do not restart.
- After a scheduled AP upgrade task is configured, if the AP group or all APs are deleted, the task fails to be executed, which is not recorded as upgrade failure information.
- If an AP is performing the automatic upgrade when you configure a scheduled AP upgrade task, the upgrade continues until the upgrade is completed. APs that have not started the automatic upgrade will not execute the automatic upgrade.
- If the system time is changed after you configure a scheduled AP upgrade task, the following impacts may be caused:
  - If the system time is changed **before** the scheduled AP upgrade task starts, the start time and end time of the scheduled AP upgrade task are subject to the system time **after** the change. For example, the current system time is 1:00, and the start time and end time of the scheduled AP upgrade task are 3:00 and 4:00 respectively. When the system time is changed to 2:00 at 1:05, the start time and end time of the scheduled AP upgrade task are still 3:00 and 4:00 respectively.
  - If the system time is changed **after** the scheduled AP upgrade task starts, the start time and end time of the scheduled AP upgrade task are subject to the system time **before** the change.

Example

Configure APs with **ap-type** as **54** to perform the scheduled upgrade from 01:00 to 04:00 on May 20, 2018.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap update schedule-task task-id 1 start-time 1:00 2018/5/20 stop-time 4:00
2018/5/20 ap-type 54
```

11.2.23 ap username

Function

The **ap username** command sets the user name and password for AP login.

By default, no user name or password is configured for AP login.

Format

ap username *username* **password cipher**

Parameters

Parameter	Description	Value
username	Specifies the user name for AP login.	The value is a string of 4 to 31 characters. It can contain letters, underscores, and digits, and must start with a letter.
password	Specifies the password for AP login.	-

Parameter	Description	Value
cipher	Indicates the ciphertext password.	The password can be entered in plaintext or ciphertext: ● In plaintext, the password is a string of 8 to 128 case-sensitive characters. It must contain at least three of the following types: uppercase letters, lowercase letters, digits, and special characters, without question marks (?). ● In ciphertext, the password is a string of 48 to 188 characters. It must contain at least the following types: uppercase letters, lowercase letters, digits, and special characters.

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

You can run this command to change the user name and password for logging in to an AP. If the user name and password of the AP have not been configured, you must configure them first in order to log in to the AP.

Running this command will disconnect the administrator who is logging in to the AP.

NOTE

It is recommended that you change the user name and password in a timely manner to ensure device security.

The password cannot be the same as the user name or the mirror user name.

Example

Set the user name to **example** and password to **Zz123456**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap username example password cipher
Warning: This operation will disconnect administrator users logging in to the AP, Continue? [Y/N]:y
Enter the password (plain-text password of 8-128 characters or cipher-text password of 48-188 characters
that must be a combination
of at least three of the following: lowercase letters a to z, uppercase letters A to Z, digits, and special
characters):
Confirm password:
```

11.2.24 ap-group

Function

The **ap-group** command creates an AP group and displays the AP group view, or displays the view of an existing AP group.

The **undo ap-group** command deletes an AP group.

By default, the system provides the AP group **default**.

Format

ap-group name *group-name*

undo ap-group { **name** *group-name* | **all** }

Parameters

Parameter	Description	Value
name *group-name*	Specifies the name of an AP group.	The value is a string of 1 to 35 characters, which can be Chinese characters or Chinese + English characters. It cannot contain question marks (?) or slashes (/), and cannot start or end with spaces or double quotation marks (" "). If the AP group name contains spaces, the input name must start and end with a quotation mark ("), for example, **"hello name1"**. The quotation marks at the beginning and end of the AP group name occupy two characters in total. **NOTE** You can only use a command editor of the UTF-8 encoding format to edit Chinese characters.
all	Deletes all AP groups. **NOTE** This configuration does not delete the AP group **default** or any AP group that has APs in it.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If you need to perform the same configuration on multiple APs, add the APs to an AP group and perform the configuration in the AP group. The configuration takes effect on all APs of the group. This prevents repetitive configuration.

Follow-up Procedure

Run the **ap-group (AP view)** or **ap-regroup** command to add APs to an AP group.

Precautions

- If the configuration of an AP in the AP view is different from that in the AP group view, the configuration in the AP view is preferentially used.
- The device supports a maximum of 256 AP groups.
- The AP group that has APs cannot be deleted. The AP group **default** cannot be deleted either.
- By default, an AP group has the following profiles bound: AP system profile **default**, 2G radio profile **default**, 5G radio profile **default**, regulatory domain profile **default**, WIDS profile **default**, and AP wired port profile **default**.

Example

Create the AP group **group1** and display the AP group view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name group1
[HUAWEI-wlan-ap-group-group1]
```

11.2.25 ap-group (AP view)

Function

The **ap-group** command configures an AP group.

The **undo ap-group** command restores the default AP group.

By default, no AP group is configured.

Format

ap-group *ap-group*

undo ap-group

Parameters

Parameter	Description	Value
ap-group	Specifies an AP group.	The AP group must exist.

Views

AP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If you need to perform the same configuration on multiple APs, add the APs to an AP group and perform the configuration in the AP group. The configuration takes effect on all APs of the group. This prevents you from configuring each AP one by one.

Each AP must be added to an AP group. If no AP group is configured for an AP, the AP automatically joins the AP group **default**.

Example

Configure the AP group **ap-new-group** for an AP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 0
[HUAWEI-wlan-ap-0] ap-group ap-new-group
Warning: This operation may cause AP reset. If the country code changes, it will clear channel, power and
antenna gain configurations of the radio, Whether to continue? [Y/N]:y
```

11.2.26 ap-group all vap-profile

Function

The **ap-group all vap-profile** command binds a VAP profile to all AP groups.

The **undo ap-group all vap-profile** command unbinds a VAP profile from all AP groups.

By default, no VAP profile is bound to radios of an AP group.

Format

ap-group all vap-profile *profile-name* **wlan** *wlan-id* **radio** { *radio-id* | **all** }

undo ap-group all vap-profile wlan *wlan-id* **radio** { *radio-id* | **all** }

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a VAP profile.	The value must be the name of an existing VAP profile.

Parameter	Description	Value
wlan *wlan-id*	Specifies a VAP ID.	The value is an integer that ranges from 1 to 16. **NOTE** - The WLAN ID for the WDS service can be 13 or 14. - The WLAN ID for the Mesh service is 16. - The WLAN ID for the offline management VAP configuration is 15 or an integer that ranges from 1 to 12. - For some AP models, the maximum number of VAPs supported by each radio is less than 16. If the value of *wlan-id* exceeds the AP specifications, the configuration cannot take effect and the AP cannot generate radio signals.
radio *radio-id*	Specifies a radio ID.	The value is an integer that ranges from 0 to 2. Three radios are available only on the following models: - AirEngine 8760-X1-PRO, AirEngine 8760R-X1E, AirEngine 6760-X1, AirEngine 6760-X1E, AirEngine 5760-51 - AirEngine 6761-21T, AirEngine 6761S-21T, AirEngine 6761-22T - AirEngine 8771-X1T
radio all	Specifies all radios.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

You can run the **ap-group all vap-profile** command to bind a VAP profile to all AP groups.

Example

Bind the VAP profile **office01** to all AP groups.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group all vap-profile office01 wlan 1 radio 0
Info: This operation may take a few seconds, please wait.......done.
Warning: This operation is to bind the profile to 4 AP groups. Success count: 3. Failure count: 1. The failure
```

```
causes are as follows:
--------------------------------------------------------------------------------------------------------------------------
AP group                          Config fail reason
--------------------------------------------------------------------------------------------------------------------------
default                          The WLAN ID on the radio is in use. Please use an unassigned WLAN ID.
--------------------------------------------------------------------------------------------------------------------------
```

Table 11-66 Description of the **ap-group all vap-profile** command output

Item	Description
AP group	AP group to which the VAP profile fails to be bound.
Config fail reason	Binding failure cause.

11.2.27 ap-group all wids-profile

Function

The **ap-group all wids-profile** command binds a WIDS profile to all AP groups.

The **undo ap-group all wids-profile** command unbinds a WIDS profile from all AP groups.

By default, the WIDS profile **default** is bound to an AP group.

Format

ap-group all wids-profile *profile-name*

undo ap-group all wids-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a WIDS profile.	The value must be the name of an existing WIDS profile.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

You can run the **ap-group all wids-profile** command to bind a WIDS profile to all AP groups.

Example

Bind the WIDS profile **office01** to all AP groups.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group all wids-profile office01
```

11.2.28 ap-group all wired-port-profile

Function

The **ap-group all wired-port-profile** command binds an AP wired port profile to all AP groups.

The **undo ap-group all wired-port-profile** command unbinds an AP wired port profile from all AP groups.

By default, the AP wired port profile **default** is bound to an AP group.

Format

ap-group all wired-port-profile *profile-name interface-type interface-number*

undo ap-group all wired-port-profile *interface-type interface-number*

Parameters

Parameter	Description	Value
profile-name	Specifies the name of an AP wired port profile.	The value must be the name of an existing AP wired port profile.
interface-type interface-number	Specifies the type and number of an AP's wired interface.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

You can run the **ap-group all wired-port-profile** command to bind an AP wired port profile to all AP groups.

Example

Bind the AP wired port profile **office01** to all AP groups.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group all wired-port-profile office01 gigabitethernet 0
```

11.2.29 ap-mode

Function

The **ap-mode** command sets the working mode of an AP.

The **undo ap-mode** command disables the AC from delivering this parameter setting to APs after the configuration is delivered using the **commit** command.

By default, the working mode of an AP is not specified in the AP provisioning view.

Format

ap-mode { **fat** | **cloud** | **fit** }

undo ap-mode

Parameters

Parameter	Description	Value
fat	Specifies the Fat mode.	-
cloud	Specifies the cloud mode.	-
fit	Specifies the Fit mode.	-

Views

AP provisioning view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The working mode of an AP is configured on the AC and delivered to the AP. After a restart, the AP will switch the working mode accordingly.

Prerequisites

- The AP has gone online on the AC in Fit mode.
- Corresponding system files have been uploaded to the AC, FTP server, or SFTP server.

Follow-up Procedure

Run the **commit** command to commit the configuration.

In V200R023C00 or a later version: To switch the working mode of a Fit AP, run the **undo ap** (WLAN view) command on the to delete the Fit AP from the before the restart is complete. If the Fit AP is not deleted, the AP may switch back to the Fit mode in accordance with the foolproof mechanism after the restart is complete.

Configuration Impact

After the working mode of the AP is switched to Fat or cloud, the AP will be out of control by the AC.

NOTICE

This command is supported only by the following models:

- AirEngine series APs (excluding RUs) (The AirEngine 8771-X1T supports only the Fit and cloud modes.)
- AirEngine series central APs

Example

Set the working mode of an AP to Fat.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] provision-ap
[HUAWEI-wlan-provision-ap] ap-mode fat
Warning: When the configuration is committed, the AP mode will be switched if supported and the AP will
be out of control by the AC.Continue?[Y/N]: y
```

11.2.30 ap-name

Function

The **ap-name** command displays the AP view.

Format

ap-name *ap-name*

Parameters

Parameter	Description	Value
ap-name	Specifies the AP name.	The AP name must exist.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

After entering the AP view, you can perform personalized configuration on an AP.

Example

Display the view of the AP named **area_1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-name area_1
[HUAWEI-wlan-ap-2]
```

11.2.31 ap-name (AP provisioning view)

Function

The **ap-name** command sets the name of an AP.

The **undo ap-name** command disables the AC from delivering this parameter setting to APs after the configuration is delivered using the **commit** command.

By default, no AP name is configured.

Format

ap-name *ap-new-name*

undo ap-name

Parameters

Parameter	Description	Value
ap-new-name	Specifies an AP name.	The value is a string of 1 to 63 case-sensitive characters, which can be Chinese characters or Chinese + English characters. It cannot contain question marks (?), and cannot start or end with spaces or double quotation marks (" "). If the AP name contains spaces, the input name must start and end with a quotation mark ("), for example, "hello name1". The quotation marks at the beginning and end of the AP name occupy two characters in total. **NOTE** You can only use a command editor of the UTF-8 encoding format to edit Chinese characters.

Views

AP provisioning view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the name of an AP is changed and the change is delivered to the AP, the AP goes online using the new name.

Precautions

The new AP name cannot be the same as the existing AP name.

If the AP name is not configured, the default name of an AP is the AP's MAC address after the AP goes online.

Follow-up Procedure

Run the **commit** command to deliver the configuration to the AP.

Example

Change the AP name to **AP-N1-2**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] provision-ap
[HUAWEI-wlan-provision-ap] ap-name AP-N1-2
```

11.2.32 ap-name (AP view)

Function

The **ap-name** command configures an AP name.

The **undo ap-name** command restores the default AP name.

By default, no AP name is configured for an AP.

Format

ap-name *ap-name*

undo ap-name

Parameters

Parameter	Description	Value
ap-name	Specifies an AP name.	The value is a string of 1 to 63 case-sensitive characters, which can be Chinese characters or Chinese + English characters. It cannot contain question marks (?), and cannot start or end with spaces or double quotation marks (" "). If the AP name contains spaces, the input name must start and end with a quotation mark ("), for example, "hello name1". The quotation marks at the beginning and end of the AP name occupy two characters in total. **NOTE** You can only use a command editor of the UTF-8 encoding format to edit Chinese characters.

Views

AP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To facilitate AP maintenance, management, and differentiation, you can name the AP according to actual situations.

Precautions

The new AP name cannot be the same as the existing AP name.

The new AP name cannot be the same as the MAC address of an existing AP. Otherwise, the AP name will be lost after the device saves the configuration and restarts.

If a new AP name is the same as an existing AP name, the new AP is restarted after its name is changed.

If the AP name is not configured, the default name of an AP is the AP's MAC address after the AP goes online.

Example

Change the AP name to **AP-N1-2**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 0
[HUAWEI-wlan-ap-0] ap-name AP-N1-2
```

```
Warning: The AP name of more than 31 characters does not take effect for APs in versions earlier than
V200R009C00.
Warning: This operation may cause AP reset. Continue? [Y/N]:y
```

11.2.33 ap password policy

Function

The **ap password policy** command enables the AP login password policy function and displays the AP password policy view.

The **undo ap password policy** command disables the AP login password policy function.

By default, the AP login password policy function is disabled.

Format

ap password policy

undo ap password policy

Parameters

None

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After a password is configured using the **ap username** command, the minimum length and complexity of the password are limited. If you want to improve password security, you can run the following commands to configure a password policy for the local administrator:

- Run the **password expire** command to set the password expiration time.
- Run the **password alert before-expire** command to set the password expiration prompt days.
- Run the **password alert original** command to enable the device to prompt users to change initial passwords.
- Run the **password history record number** command to set the maximum number of historical passwords recorded for each user.

Precautions

Running the **undo ap password policy** command invalidates the password policy, posing security risks.

Example

Enable the AP login password policy function and display the AP password policy view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap password policy
[HUAWEI-wlan-ap-pwd-policy]
```

11.2.34 ap-patch update load

Function

The **ap-patch update load** command loads a patch for a specified AP.

The **undo ap-patch update load** command cancels a patch upgrade from a specified AP.

Format

ap-patch update load { **ap-name** *ap-name* | **ap-mac** *ap-mac* | **ap-id** *ap-id* } **update-filename** *update-file-name* [**next-startup**]

undo ap-patch update load { **ap-name** *ap-name* | **ap-mac** *ap-mac* | **ap-id** *ap-id* }

Parameters

Parameter	Description	Value
ap-name *ap-name*	Specifies an AP name.	The AP name must exist.
ap-mac *ap-mac*	Specifies the AP's MAC address.	The specified AP's MAC address must exist.
ap-id *ap-id*	Specifies an AP ID.	The AP ID must exist.
update-filename *update-file-name*	Specifies the name of an AP patch file.	The value is a string of 1 to 255 case-sensitive characters. Ensure that the file name is the same as the actual patch file name, with a file name extension of .pat.
next-startup	Specifies the patch for next startup.	-

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When you load the patch for multiple APs of a specified type, a version exception will lead to a long-time patch uninstallation. In this case, before loading the patch in a batch, you can load the patch for a single AP for testing, helping detect any exception in advance and ensuring the success of subsequent batch patch loading.

If the parameter **next-startup** is specified, the patch is loaded upon next startup. If this parameter is not specified, the patch is loaded immediately and is also used for next startup.

Precautions

If the AC or AP version is earlier than V200R021C10, the patch is uninstalled when you run the **undo ap-patch update load** command to cancel the AP patch upgrade. Running this command cancels the AP patch upgrade but does not uninstall the patch only when both the AC and AP versions are V200R021C10 or later. In this case, to uninstall the patch, run the **ap-patch delete** command.

Prerequisites

In AC upgrade mode, the AP's patch file has been uploaded to the AC. In FTP or SFTP upgrade mode, the AP's patch file has been uploaded to an FTP or SFTP server.

Follow-up Procedure

Run the **display ap update status** command to check the patch loading progress.

Example

Load the patch **AirEngineX760_V200R019C10.pat** for the AP named **N1-2**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-patch update load ap-name N1-2 update-filename
AirEngineX760_V200R019C10.pat
Info: The current upgrade mode is AC mode, which may affect performance and take a long time. The FTP
or SFTP upgrade mode is recommended. Continue? [Y/N]: y
```

11.2.35 ap-patch update multi-load

Function

The **ap-patch update multi-load** command batch loads the patch for APs.

The **undo ap-patch update multi-load** command cancels AP patch upgrades in batches.

Format

ap-patch update multi-load ap-type *type-id* [**ap-group** *group-name* | { **ap-name** *ap-name* | **ap-id** *ap-id* } &<1-10>] [**next-startup**]

ap-patch update multi-load ap-group *group-name* [{ **ap-name** *ap-name* } &<1-10> | { **ap-id** *ap-id* } &<1-10>] [**next-startup**]

undo ap-patch update multi-load ap-group *group-name* [{ **ap-name** *ap-name* } &<1-10> | { **ap-id** *ap-id* } &<1-10>]

undo ap-patch update multi-load ap-type *type-id* [**ap-group** *group-name* | { **ap-name** *ap-name* | **ap-id** *ap-id* } &<1-10>]

Parameters

Parameter	Description	Value
ap-type *type-id*	Specifies an AP type ID.	The AP type ID must exist.
ap-group *group-name*	Specifies an AP group.	The AP group must exist.
ap-name *ap-name*	Specifies an AP name.	The AP name must exist.
ap-id *ap-id*	Specifies an AP ID.	The AP ID must exist.
next-startup	Specifies the patch for next startup.	-

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **ap-patch update multi-load ap-type** *type-id* [**ap-group** *group-name* | { **ap-name** *ap-name* | **ap-id** *ap-id* } &<1-10>] [**next-startup**] command to batch load the patch for APs by type.

- When the parameter **ap-group** *group-name* is specified, the patch is loaded only for APs of a specified type in a specified AP group.
- When the parameter **ap-name** *ap-name* or **ap-id** *ap-id* is specified, the patch is loaded only for APs of a specified type that have specified names or IDs.
- When the parameters **ap-group** *group-name*, **ap-name** *ap-name*, and **ap-id** *ap-id* are not specified, the patch is loaded for all APs of a specified type.

- When the parameter **ap-group** *group-name*, **ap-name** *ap-name*, or **ap-id** *ap-id* is different from the specified **ap-type** *type-id*, the patch is not loaded.
- If the parameter **next-startup** is specified, the patch is loaded upon next startup. If this parameter is not specified, the patch is loaded immediately and is also used for next startup.

You can run the **ap-patch update multi-load ap-group** *group-name* [{ **ap-name** *ap-name* } &<1-10> | { **ap-id** *ap-id* } &<1-10>] [**next-startup**] command to batch load the patch for APs by AP group.

- When the parameter **ap-name** *ap-name* or **ap-id** *ap-id* is specified, the patch is loaded only for APs in a specified group that have specified names or IDs.
- When the parameters **ap-name** *ap-name* and **ap-id** *ap-id* are not specified, the patch is loaded for all APs in a specified group.
- When the AP group to which an AP specified by **ap-name** *ap-name* or **ap-id** *ap-id* is different from the specified AP group, the patch is not loaded for the AP.
- If the parameter **next-startup** is specified, the patch is loaded upon next startup. If this parameter is not specified, the patch is loaded immediately and is also used for next startup.

Precautions

If the AC or AP version is earlier than V200R021C10, the patch is uninstalled when you run the **undo ap-patch update multi-load** command to cancel the AP patch upgrade. Running this command cancels the AP patch upgrade but does not uninstall the patch only when both the AC and AP versions are V200R021C10 or later. In this case, to uninstall the patch, run the **ap-patch delete** command.

Prerequisites

The patch file for batch loading has been configured using the **ap-patch update update-filename** command.

Follow-up Procedure

Run the **display ap update status** command to check the patch loading progress.

Example

Load the patch for all APs with the **type-id** of 56.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-patch update multi-load ap-type 56
Info: The current upgrade mode is AC mode, which may affect performance and take a long time. The FTP
or SFTP upgrade mode is recommended. Continue? [Y/N]: y
```

Load the patch for all APs in the AP group **group1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-patch update multi-load ap-group group1
Info: The current upgrade mode is AC mode, which may affect performance and take a long time. The FTP
or SFTP upgrade mode is recommended. Continue? [Y/N]: y
```

11.2.36 ap-patch update update-filename

Function

The **ap-patch update update-filename** command specifies the patch file name for APs of a specified type.

The **undo ap-patch update update-filename** command cancels the patch file name configured for APs of a specified type.

Format

ap-patch update update-filename *filename* **ap-type** *type-id* [**ap-group** *ap-group-name*]

undo ap-patch update update-filename ap-type *type-id* [**ap-group** *ap-group-name*]

Parameters

Parameter	Description	Value
ap-type *type-id*	Specifies an AP type ID.	The AP type ID must exist.
filename	Specifies the name of a patch file.	The value is a string of 1 to 255 case-sensitive characters. Ensure that the file name is the same as the actual patch file name, with a file name extension of .pat.
ap-group *ap-group-name*	Specifies an AP group.	The AP group must exist.

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

After **ap-group** *ap-group-name* is specified, the patch file name is configured only for APs of a specified type in this AP group.

After configuring the AP patch file name, you can batch load the patch for APs of the same type using the **ap–patch update multi-load ap-type** command.

Example

Set the patch file name of APs with the type ID of 56 to **AirEngineX760_V200R019C10.pat**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-patch update update-filename AirEngineX760_V200R019C10.pat ap-type 56
Warning: If an AP is performing the automatic upgrade, the AP will be upgraded to the latest version. Continue?[Y/N]:y
```

11.2.37 ap-ping

Function

The **ap-ping** command uses a specified AP to ping a network device and displays the returned result.

Format

ap-ping { **ap-name** *ap-name* | **ap-id** *ap-id* } [**-c** *count* | **-s** *packetsize* | **-m** *time* | **-t** *timeout*] * *host*

Parameters

Parameter	Description	Value
ap-name *ap-name*	Specifies the name of an AP used to ping other network devices.	The AP name must already exist.
ap-id *ap-id*	Specifies the ID of an AP used to ping other network devices.	The AP ID must already exist.
-c *count*	Specifies the number of ICMP Echo Request packets to be sent.	The value is an integer that ranges from 1 to 10. The default value is 4.
-s *packetsize*	Specifies the length of an Echo Request packet excluding the IP header and ICMP header.	The value is an integer that ranges from 20 to 8100, in bytes. The default value is 56 bytes.
-m *time*	Specifies the time to wait before sending the next ICMP Request packet.	The value is an integer that ranges from 1 to 5000, in milliseconds. The default value is 2000 ms.

Parameter	Description	Value
-t *timeout*	Specifies the timeout period for an ICMP Echo Response packet.	The value is an integer that ranges from 0 to 10000, in milliseconds. The default value is 2000 ms.
host	Specifies the domain name or IP address of the destination host.	The value is a string of 1 to 20 characters.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

- You can run this command to check the connectivity between an AP and network device by pinging a network device from an AP.
- The prerequisite is that the AP is online and has been configured with an IP address.

Precautions

- This command may cost much time because the parameters such as waiting time affects the command running.
- Only one AP can perform the ping operation at a time.

Example

Use the AP **N1-2** to perform a ping operation.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-ping ap-name N1-2 10.1.1.1
Warning: This operation maybe takes several minutes, continue?[Y/N]:y
[HUAWEI-wlan-view]
  AP ping result
    Success count         : 4
    Failure count         : 0
    Average response time: 1 ms
    Minimum response time: 1 ms
    Maximum response time: 1 ms
```

11.2.38 ap-pki-profile (WLAN view)

Function

The **ap-pki-profile** command creates an AP PKI realm profile and enters the AP PKI realm profile view, or enters the view of an existing AP PKI realm profile.

The **undo ap-pki-profile** command deletes an AP PKI realm profile.

By default, no AP PKI realm profile is created on the device.

Format

ap-pki-profile name *profile-name*

undo ap-pki-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Indicates the name of an AP PKI realm profile.	The value is a string of 1 to 35 case-sensitive characters. It cannot contain question marks (?) or spaces, and cannot start or end with double quotation marks (").
all	Specifies all AP PKI realm profiles to be deleted.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to create an AP PKI realm profile on the AC or enter the view of an existing AP PKI realm profile to configure the AP PKI realm, facilitating unified management and maintenance of AP certificates.

Follow-up Procedure

1. Run the **pki realm (AP PKI realm profile view)** command to configure an AP PKI realm and the CA certificate, local certificate, CRL file, and private key file to be bound to the realm.
2. Run the **ap-pki-profile (AP group view and AP view)** command to bind the AP PKI realm profile to an AP or AP group.
3. Run the **load-file (WLAN view)** command to manually load a certificate file in the AP PKI realm to an AP.

Example

Create an AP PKI realm profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-pki-profile name default
[HUAWEI-wlan-ap-pki-prof-default]
```

11.2.39 ap-pki-profile (AP group view and AP view)

Function

The **ap-pki-profile** command binds an AP PKI realm profile to an AP or AP group.

The **undo ap-pki-profile** command unbinds an AP PKI realm profile from an AP or AP group.

By default, no AP PKI realm profile is bound to an AP group or AP.

Format

ap-pki-profile *profile-name*

undo ap-pki-profile

Parameters

Parameter	Description	Value
profile-name	Indicates the name of an AP PKI realm profile.	The value is a string of 1 to 35 case-sensitive characters. It cannot contain question marks (?) or spaces, and cannot start or end with double quotation marks (").

Views

AP group view, AP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After an AP PKI realm profile is created and an AP PKI realm is configured, you can run this command to bind the AP PKI realm profile to an AP or AP group.

Prerequisites

1. An AP PKI realm profile has been created using the **ap-pki-profile (WLAN view)** command.
2. An AP PKI realm and the CA certificate, local certificate, CRL file, and private key file to be bound to the realm have been configured using the **pki realm (AP PKI realm profile view)** command.

Follow-up Procedure

Run the **load-file (WLAN view)** command to manually load a certificate file in the AP PKI realm to an AP.

Example

Create an AP PKI realm profile **default** and bind it to the AP group **group1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-pki-profile name default
[HUAWEI-wlan-ap-pki-prof-default] quit
[HUAWEI-wlan-ap-group-group1] ap-pki-profile default
```

11.2.40 ap-regroup

Function

The **ap-regroup** command changes the group that an AP joins.

Format

ap-regroup { **ap-name** *ap-name* | **ap-id** *ap-id* } **new-group** *new-group-name*

Parameters

Parameter	Description	Value
ap-name *ap-name*	Specifies an AP name.	The AP name must exist.

Parameter	Description	Value
ap-id *ap-id*	Specifies an AP ID.	The AP ID must exist. The value is a string of 1 to 255 characters. When multiple APs are selected, use commas (,) to separate AP IDs or use hyphens (-) to indicate continuous AP IDs. For example, **5,8,10-13,20** indicates the list of APs with IDs 5, 8, 10, 11, 12, 13, and 20.
new-group *new-group-name*	Specifies the name of the new group to which the AP is added.	The AP group must exist.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the current AP group is not applicable to an AP or the AP is added to an incorrect group, you can run this command to delete the AP from the current AP group and add the AP to a new AP group.

Prerequisites

The AP group has been created using the **ap-group** command.

Configuration Impact

Adding an AP to a new AP group will cause the AP to restart, interrupting services. Therefore, exercise caution when performing this operation.

Example

Change the group that an AP joins to the AP group **group1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] ap-group name group1
[HUAWEI-wlan-ap-group-group1] quit
[HUAWEI-wlan-view] ap-regroup ap-name 00e0-fc76-e360 new-group group1
Warning: This operation may cause AP reset. If the country code changes, it will clear channel, power and
antenna gain configurations of the radio, Whether to continue? [Y/N]:y
```

11.2.41 ap-rename

Function

The **ap-rename** command changes the name of an AP.

Format

ap-rename { **ap-name** *name* | **ap-mac** *ap-mac-address* | **ap-id** *ap-id* } **new-name** *ap-new-name*

Parameters

Parameter	Description	Value
ap-name *name*	Specifies the old name of an AP.	The AP name must exist.
ap-mac *ap-mac-address*	Specifies the MAC address of an AP.	The AP's MAC address must exist.
ap-id *ap-id*	Specifies the ID of an AP.	The AP ID must exist.

Parameter	Description	Value
new-name *ap-new-name*	Specifies the new name of an AP.	The value is a string of 1 to 63 case-sensitive characters, which can be Chinese characters or Chinese + English characters. It cannot contain question marks (?), and cannot start or end with spaces or double quotation marks (" "). If the AP name contains spaces, the input name must start and end with a quotation mark ("), for example, "hello name1". The quotation marks at the beginning and end of the AP name occupy two characters in total. **NOTE** You can only use a command editor of the UTF-8 encoding format to edit Chinese characters.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

If the name of an AP conflicts with that of another or an AP requires a more proper name, you can run this command to change the name of the AP.

If a new AP name is the same as an existing AP name, the new AP is restarted after its name is changed.

Example

Change the AP name from **N1-2** to **N2-2**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-rename ap-name N1-2 new-name N2-2
Warning: The AP name of more than 31 characters does not take effect for APs in versions earlier than
V200R009C00.
Warning: This operation may cause AP reset. Continue? [Y/N]:y
```

11.2.42 ap-reset

Function

The **ap-reset** command resets an AP.

Format

ap-reset { **all** | **ap-name** *ap-name* | **ap-mac** *ap-mac* | **ap-id** *ap-id* | **ap-group** *ap-group* | **ap-type** { **type** *type-name* | **type-id** *type-id* } }

ap-reset wait-rtu-validate

Parameters

Parameter	Description	Value
all	Resets all APs.	-
ap-name *ap-name*	Resets the AP with the specified AP name.	The AP name must exist.
ap-mac *ap-mac*	Resets the AP with the specified MAC address.	The AP's MAC address must exist.
ap-id *ap-id*	Resets the AP with the specified AP ID.	The AP ID must exist. The value is a string of 1 to 255 characters. When multiple APs are selected, use commas (,) to separate AP IDs or use hyphens (-) to indicate continuous AP IDs. For example, **5,8,10-13,20** indicates the list of APs with IDs 5, 8, 10, 11, 12, 13, and 20.

Parameter	Description	Value
ap-group *ap-group*	Resets APs in the specified AP group.	The AP group must exist.
ap-type	Resets APs of the specified AP type.	-
type *type-name*	Resets APs of the specified type name.	The AP type name must exist.
type-id *type-id*	Resets APs of the specified type ID.	The AP type ID must exist.
wait-rtu-validate	Resets APs on which RTU licenses have been loaded but have not taken effect.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After in-service upgrade of APs is complete, you can run the **ap-reset** command to reset the APs. After the command is run, the APs restart with the upgraded software version. You can also use the command to restart APs for other reasons.

Prerequisites

An AP exists on the AC.

Example

Reset the AP **N1-2**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-reset ap-name N1-2
Warning: Reset AP(s), continue?[Y/N]:y
```

11.2.43 ap-system-profile (WLAN view)

Function

The **ap-system-profile** command creates an AP system profile and displays the AP system profile view, or displays the view of an existing AP system profile.

The **undo ap-system-profile** command deletes an AP system profile.

By default, the system provides the AP system profile **default**.

Format

ap-system-profile name *profile-name*

undo ap-system-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of an AP system profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all AP system profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To manage and maintain multiple APs in a centralized manner, add the APs in an AP group, configure parameters in an AP system profile, and apply the AP system profile to the AP group.

To manage and maintain an AP independently, configure parameters in an AP system profile and apply the AP system profile to the AP specific profile.

Follow-up Procedure

Run the **ap-system-profile (AP group view and AP view)** command to bind the AP system profile to an AP or AP group so that the AP system profile can take effect.

Precautions

- The AP system profile **default** cannot be deleted.
- The AP system profile referenced by an AP or AP group cannot be deleted. To delete the AP system profile, unbind it from the AP or AP group first.

Example

Create the AP system profile **ap-system1** and display the AP system profile view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1]
```

11.2.44 ap-system-profile (AP group view and AP view)

Function

The **ap-system-profile** command binds an AP system profile to an AP or AP group.

The **undo ap-system-profile** command unbinds an AP system profile from an AP or AP group.

By default, the AP system profile **default** is bound to an AP group, but no AP system profile is bound to an AP.

Format

ap-system-profile *profile-name*

undo ap-system-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of an AP system profile.	The AP system profile must exist.

Views

AP group view, AP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you create an AP system profile using the **ap-system-profile (WLAN view)** command, bind it to an AP or AP group so that the AP system profile can take effect.

Precautions

After an AP system profile is bound to an AP or AP group, parameter settings in the AP system profile apply to all APs using the profile.

Example

Create the AP system profile **ap-system1** and bind it to AP group **group1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] quit
[HUAWEI-wlan-view] ap-group name group1
[HUAWEI-wlan-ap-group-group1] ap-system-profile ap-system1
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.2.45 ap-type

Function

The **ap-type** command creates an AP type for a new AP model.

The **undo ap-type** command deletes a specified AP type.

Format

ap-type *type-description* **type-id** *type-id*

undo ap-type *type-description*

Parameters

Parameter	Description	Value
type-description	Describes an AP type.	The value is a string of 1 to 31 case-insensitive characters. It cannot contain question marks (?), and cannot start or end with double quotation marks (" ").
type-id *type-id*	Specifies the ID of an AP type.	The value is an integer that ranges from 0 to .

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To allow a new AP model to connect to an AC, you can run the **ap-type** command on the AC to create an AP type for this model. If you do not need the new AP model, you can run the **undo ap-type** command to delete the AP type of this model.

Precautions

In the **ap-type** command, ensure that the value of the *type-description* or *type-id* parameter does not conflict with the description or ID of an existing AP type. You can run the **display ap-type all** command to check existing AP types, including the default AP types that have been added during initialization and AP types that are created using commands.

Note the following points when using the **undo ap-type** command:

- The default AP types that are registered during initialization cannot be deleted.
- If configurations (for example, upgrade configurations) related to an AP type exist on the AC, this AP type cannot be deleted.

After the **ap-type** command is run to create an AP type for a new AP model, the new AP model is authorized to connect to an AC of an earlier version. However, if the connection process between the new AP model and AC is changed, the new AP model cannot connect to the AC.

Generally, you are not advised to run the **ap-type** command to create an AP type for a new model. If you want to create an AP type using this command, ensure that the mapping between *type-id* and *type-description* is configured correctly. Otherwise, the new AP model fails to connect to the AC. For the mapping between *type-id* and *type-description*, see the **AP Type Names and IDs** sheet in **Quick Reference for WLAN AP Version Mapping and Models**.

The AC does not support the type of a central AP and matching RUs running a later version.

Example

Create AP type **AP9530DN** with the ID **254** for a new AP model.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-type AP9530DN type-id 254
```

11.2.46 auto create ap-type

Function

The **auto create ap-type** command automatically imports AP types.

Format

auto create ap-type { **type-id** *type-id* | **type** *type-description* | **all** }

Parameters

Parameter	Description	Value
type-id *type-id*	Automatically imports the AP type with a specified ID.	The value is an integer that ranges from 0 to .
type *type-description*	Automatically imports the AP type with a specified description.	The value is a string of 1 to 31 characters. It cannot contain question marks (?), and cannot start or end with double quotation marks (" ").
all	Automatically imports the types of all APs.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

If a new AP model cannot connect to the AC, you can check whether the AP type has been created. To list the undefined AP types, run the **display ap-type undefined record** command. Then run the **auto create ap-type** command to automatically import the AP types of these APs.

The AC does not support the type of a central AP and matching RUs running a later version.

Example

Automatically import the types of all APs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] auto create ap-type all
Info: 1 succeeded, 3 failed.
List of AP types that failed to be added:
------------------------------------------------------------------------------
AP type           Type ID     Reason
------------------------------------------------------------------------------
AP5010DN          29          This AP type already exists
AP6010DN          21          This type ID already exists
AP9910DN          133          Reached the maximum specifications of the AP type
------------------------------------------------------------------------------
Total : 3
```

Table 11-67 Description of the **ap-type auto create ap-type** command output

Item	Description
AP type	AP type.
Type ID	ID of an AP type.
Reason	Cause of the failure to automatically import an AP type, which can be: ● This AP type already exists ● This type ID already exists ● Reached the maximum specifications of the AP type

11.2.47 broadcast-suppression auto-detect (AP system profile view)

Function

The **broadcast-suppression auto-detect** command configures the rate limit for broadcast packets during intelligent flow control.

The **undo broadcast-suppression auto-detect** command restores the default rate limit for broadcast packets during intelligent flow control.

By default, the rate limit for broadcast packets is 256 pps.

NOTE

This function is not supported by the following models:

- AirEngine X760 series APs (excluding the AirEngine 5760-10)
- AirEngine 9700D-S (including matching ORUs)

Format

broadcast-suppression auto-detect packets *packets*

undo broadcast-suppression auto-detect

Parameters

Parameter	Description	Value
packets *packets*	Specifies the rate limit for broadcast packets.	The value is an integer that ranges from 64 to 1024, in pps.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

When there are a large number of broadcast, multicast, and unknown unicast packets, the CPU becomes busy processing these packets and the buffer of the packet for receiving incoming packets is occupied. When the buffer decreases to the specified threshold, the device automatically rate-limits the broadcast, multicast, and unknown unicast packets. You can run this command to specify the rate limit for intelligent flow control as required. Rate limiting takes effect only for incoming traffic.

Example

Set the rate limit for broadcast packets during intelligent flow control to 300 pps.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name system1
[HUAWEI-wlan-ap-system-prof-system1] broadcast-suppression auto-detect packets 300
```

11.2.48 capwap dtls server-auth (AP provisioning view)

Function

The **capwap dtls server-auth** { **enable** | **disable** } command enables or disables the AC authentication function for APs.

The **undo capwap dtls server-auth** command disables the device from modifying this parameter setting for APs after the configuration is delivered using the **commit** command.

By default, the AC authentication function for APs is disabled.

Format

capwap dtls server-auth { **enable** | **disable** }

undo capwap dtls server-auth

Parameters

Parameter	Description	Value
enable	Enables the AC authentication function for APs.	-

Parameter	Description	Value
disable	Disables the AC authentication function for APs.	-

Views

AP provisioning view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an AP attempts to go online, it receives Discovery Response packets from ACs and discover an available AC. A bogus AC may maliciously send a Discovery Response packet to the AP, causing the AP to go online on the bogus AC.

After the AC authentication function for APs is enabled, an AP initiates DTLS authentication to the AC before establishing a CAPWAP tunnel with it. The AP then uses the DTLS PSK or initial certificate to authenticate the AC. The CAPWAP tunnel can be established only after the authentication succeeds.

Follow-up Procedure

Run the **commit** command to deliver the configuration to APs and restart the APs to make the configuration take effect.

Precautions

This function is available only for APs running V200R022C00 or later, but does not take effect for APs running versions earlier than V200R022C00.

Example

Enable the AC authentication function for APs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] provision-ap
[HUAWEI-wlan-provision-ap] capwap dtls server-auth enable
```

11.2.49 capwap dtls server-auth cn (AP provisioning view)

Function

The **capwap dtls server-auth cn** command specifies the CN field used by APs to verify an AC's certificate.

The **undo capwap dtls server-auth cn** *cn-string* command clears the CN field used by APs to verify an AC's certificate.

The **undo capwap dtls server-auth cn** command disables the device from modifying this parameter setting for APs after the configuration is delivered using the **commit** command.

By default, no CN field is specified for APs to verify an AC's certificate.

Format

capwap dtls server-auth cn *cn-string*

undo capwap dtls server-auth cn *cn-string*

undo capwap dtls server-auth cn

Parameters

Parameter	Description	Value
cn-string	Verifies the CN field in certificates based on the specified character string.	The value is a string of 1 to 64 case-sensitive characters without spaces.

Views

AP provisioning view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the AC authentication function for APs is enabled, an AP authenticates the AC based on the initial certificate if DTLS PSK authentication is unavailable or fails for three consecutive times. In this case, you can run this command to specify the CN field used by APs to verify an AC's certificate.

After this command is run, when an AP authenticates the AC based on the initial certificate, the AP verifies the CN field of the certificate based on the specified character string. This ensures that the AP can go online only on the specified AC, thereby enhancing network security.

Prerequisites

The AC authentication function for APs has been enabled using the **capwap dtls server-auth enable** command in the AP provisioning view.

By default, the AC authentication function for APs is disabled.

Follow-up Procedure

Run the **commit** command to deliver the configuration to APs and restart the APs to make the configuration take effect.

Precautions

This configuration applies only to the scenario the AC device replacement scenarios. Note the following when configuring CN fields:

- Ensure that the configured CN field is the same as that in the initial certificate of the AC in the **default** realm, and run this command with assistance from technical support personnel. Otherwise, the AP may fail to go online. To query the CN field in the initial certificate in the **default** realm, run the **display pki certificate local realm** *default* command.
- You can run this command multiple times, and a maximum of five CN fields are supported.
- Ensure that at least two CN fields are configured and the CN field list covers all possible ACs on which APs will go online. The APs cannot go online on the AC out of the CN field list.
- If only one CN field is configured, this function does not take effect.

Example

Configure the CN fields **123.example.com** and **456.example.com** used by APs to verify an AC's.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] provision-ap
[HUAWEI-wlan-provision-ap] capwap dtls server-auth cn 123.example.com
Warning: This operation will enable the AP to verify the CN field in AC certificates using DTLS. Ensure that
this field be set to the same as that in the AC certificates under the guidance of technical personnel.
Otherwise, the AP cannot go online. Continue? [Y/N]:y
Warning: Ensure that at least two CNs are configured for the AP to authenticate the AC. If a multi-AC
backup networking is used or the AC needs to be replaced, ensure that the CN fields in the certificates of all
ACs are configured on the AP. Otherwise, the AP cannot go online. Continue? [Y/N]:y
[HUAWEI-wlan-provision-ap] capwap dtls server-auth cn 456.example.com
Warning: This operation will enable the AP to verify the CN field in AC certificates using DTLS. Ensure that
this field be set to the same as that in the AC certificates under the guidance of technical personnel.
Otherwise, the AP cannot go online. Continue? [Y/N]:y
Warning: Ensure that at least two CNs are configured for the AP to authenticate the AC. If a multi-AC
backup networking is used or the AC needs to be replaced, ensure that the CN fields in the certificates of all
ACs are configured on the AP. Otherwise, the AP cannot go online. Continue? [Y/N]:y
```

11.2.50 channel-load-mode indoor

Function

The **channel-load-mode indoor** command sets the AP channel mode to indoor mode.

The **undo channel-load-mode indoor** command restores the default channel mode of APs.

The default channel mode of an AP is outdoor mode.

Format

channel-load-mode indoor

undo channel-load-mode indoor

Parameters

None

Views

Regulatory domain profile view

Default Level

2: Configuration level

Usage Guidelines

In scenarios where indoor and outdoor boundaries are unclear, such as subway and train platforms, it is recommended that outdoor APs be deployed. When a large volume of data is transmitted, outdoor APs in outdoor channel mode have no sufficient channels to meet data transmission requirements. In this case, you can run the **channel-load-mode indoor** command to set the channel mode of the APs to indoor mode, so that data can be transmitted on more channels.

Precautions

This command will cause an AP running V200R019C10 or earlier to automatically restart. Therefore, exercise caution when running this command.

This function is supported only by outdoor AP models.

Example

Set the AP channel mode to indoor mode.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan] regulatory-domain-profile name default
[HUAWEI-wlan-regulate-domain-default] channel-load-mode indoor
Warning: This operation may change the operating channels of APs and restart the APs that run
V200R019C00 or earlier. Continue? [Y/N]:y
```

11.2.51 clear configuration this

Function

The **clear configuration this** command clears all configurations in the AP provisioning view.

Format

clear configuration this

Parameters

None

Views

AP provisioning view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To configure new AP provisioning parameters, run the **clear configuration this** command in the AP provisioning view to clear existing configurations.

Configuration Impact

Configurations in the AP provisioning view cannot be restored after they are cleared. Therefore, exercise caution when running the **clear configuration this** command.

Example

Clear all configurations in the AP provisioning view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] provision-ap
[HUAWEI-wlan-provision-ap] clear configuration this
```

11.2.52 commit (AP provisioning view)

Function

The **commit** command commits configuration to an AP, a group of APs, or all the online APs.

Format

commit { **ap-name** *ap-name* | **ap-mac** *ap-mac-address* | **ap-id** *ap-id* | **ap-group** *ap-group-name* | **all** }

Parameters

Parameter	Description	Value
ap-name *ap-name*	Commits configuration to the AP with the specified AP name.	The AP name must already exist.
ap-mac *ap-mac-address*	Commits configuration to the AP with the specified MAC address.	The AP's MAC address must already exist.
ap-id *ap-id*	Commits configuration to the AP with the specified AP ID.	The AP ID must already exist.

Parameter	Description	Value
ap-group *ap-group-name*	Commits configuration to the AP in the specified AP group.	The AP group must already exist.
all	Commits configuration to all the online APs.	-

Views

AP provisioning view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can configure AP provisioning parameters on the AC, such as the AP's management VLAN, static IP address, gateway, and AC list. After the configuration is complete, run the **commit** command, and the configuration will be delivered to the AP.

Prerequisites

APs have gone online on the AC.

Precautions

- After the configuration is committed, the AP receives the configuration and compares the configuration with its local configuration.
  - If they are consistent, the AP does not process the received configuration.
  - If they are different, the AP saves the committed configuration and automatically restarts, and the received configuration takes effect.
- If the name or static IP address of an AP is specified in the AP provisioning view, the configuration is delivered only to the AP by specifying the AP name or MAC address, but cannot be delivered to APs in the specified AP group.
- If you commit configurations to a large number of APs simultaneously, some of the APs may fail to receive the configurations. In this case, you are advised to commit the configurations again.

Example

Commit the configuration to the AP with the MAC address 00e0-fc76-e360.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] provision-ap
[HUAWEI-wlan-provision-ap] commit ap-mac 00e0-fc76-e360
Warning: The incorrect configuration will cause the AP to go out of management. This operation will
deliver parameter setting and may cause reboot of AP(s). Continue?[Y/N]:y
```

11.2.53 console ble-mode (AP system profile view)

Function

The **console ble-mode** command configures the mode of the Bluetooth serial port.

The **undo console ble-mode** command restores the default mode of the Bluetooth serial port.

The default mode of the Bluetooth serial port is dynamic.

NOTE

The following models do not support the Bluetooth serial port function:

- AirEngine 5761-10W, AirEngine 5761S-10W, and AirEngine 5761-10WD
- AirEngine 5762-10 and AirEngine 5762-10SW
- AirEngine 9700D-M and AirEngine 9700D-M1

Format

console ble-mode { **dynamic** | **persistent** | **disable** }

undo console ble-mode

Parameters

Parameter	Description	Value
dynamic	Sets the mode of the Bluetooth serial port to **dynamic**. In this mode, when a Fit AP is disconnected from an AC, the Bluetooth serial port is automatically enabled; when the link between the AP and AC is normal, the Bluetooth serial port is disabled.	-
persistent	Sets the mode of the Bluetooth serial port to persistent. The Bluetooth serial port remains enabled in this mode.	-
disable	Disables the Bluetooth serial port.	-

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the Bluetooth serial port is enabled on an AP, STAs can be connected to the AP through Bluetooth and use the CloudCampus APP to log in to the AP through the Bluetooth serial port, facilitating fault diagnosis and debugging of the AP.

Precautions

Console port login has been enabled on the AP using the **undo console disable** command.

Upon an AP restart, the Bluetooth function is automatically enabled before the AP starts up, facilitating AP fault diagnosis and debugging. If the Bluetooth serial port has been disabled using the **console ble-mode disable** command before the AP restarts, this function will be automatically disabled after the AP starts up.

Example

Set the mode of the Bluetooth serial port to **persistent** in the AP system profile **system1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name system1
[HUAWEI-wlan-ap-system-prof-system1] console ble-mode persistent
Warning: Bluetooth-based console port login cannot be used together with Bluetooth-based monitoring,
Bluetooth-based tag locating, and Bluetooth-based transparent data transmission, Whether to continue?
[Y/N]:y
```

11.2.54 console disable

Function

The **console disable** command disables a user from logging in to the AP through a console port.

The **undo console disable** command enables a user from logging in to the AP through a console port.

By default, a user can log in to the AP through a console port.

Format

console disable

undo console disable

Parameters

None

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

When a user cannot telnet or stelnet to the AP, the user can log in to the AP through a console port to manage and configure the AP.

After the **console disable** command is run, unauthorized users cannot log in to the AP through the console port to perform operations.

Example

Disable a user to log in to the AP through a console port.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] console disable
```

11.2.55 coordinate

Function

The **coordinate** command sets the latitude and longitude of an AP.

The **undo coordinate** command restores the latitude and longitude of an AP to empty.

By default, no latitude or longitude is configured for an AP.

NOTE

This command is not available for the following APs:

- AirEngine 5761-10W and AirEngine 5761S-10W

Format

coordinate longitude { **e** | **w** } *longitude-value* **latitude** { **s** | **n** } *latitude-value*

undo coordinate

Parameters

Parameter	Description	Value
longitude e *longitude-value*	Specifies the east longitude value of an AP.	The value supports two formats: degrees, minutes, and seconds (DMS) and decimal degrees (DD). ● The DMS format is XXX-XX-XX. XXX ranges from 0 to 180, and XX ranges from 0 to 59. ● The DD format is XXX.XXXXXXXXX. XXX ranges from 0 to 180, and XXXXXXXXX is a decimal supporting a maximum of 9 digits.

Parameter	Description	Value
longitude w *longitude-value*	Specifies the west longitude value of an AP.	The value supports two formats: DMS and DD. ● The DMS format is XXX-XX-XX. XXX ranges from 0 to 180, and XX ranges from 0 to 59. ● The DD format is XXX.XXXXXXXXX. XXX ranges from 0 to 180, and XXXXXXXXX is a decimal supporting a maximum of 9 digits.
latitude s *latitude-value*	Specifies the south latitude value of an AP.	The value supports two formats: DMS and DD. ● The DMS format is XX-XX-XX. The first XX ranges from 0 to 90, and the other XXs range from 0 to 59. ● The DD format is XX.XXXXXXXXX. XX ranges from 0 to 90, and XXXXXXXXX is a decimal supporting a maximum of 9 digits.
latitude n *latitude-value*	Specifies the north latitude value of an AP.	The value supports two formats: DMS and DD. ● The DMS format is XX-XX-XX. The first XX ranges from 0 to 90, and the other XXs range from 0 to 59. ● The DD format is XX.XXXXXXXXX. XX ranges from 0 to 90, and XXXXXXXXX is a decimal supporting a maximum of 9 digits.

Views

AP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to set the longitude and latitude of an AP for easily locating it.

Example

Set the longitude and latitude of an AP to 114.3435°E and 14.3435°S, respectively.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 0
[HUAWEI-wlan-ap-0] coordinate longitude e 114.3435 latitude s 14.3435
```

11.2.56 cpu-usage threshold

Function

The **cpu-usage threshold** command configures a CPU usage alarm threshold for APs.

The **undo cpu-usage threshold** command restores the default CPU usage alarm threshold.

By default, the CPU usage alarm threshold of APs is 90.

Format

cpu-usage threshold *threshold*

undo cpu-usage threshold

Parameters

Parameter	Description	Value
threshold	Specifies the CPU usage alarm threshold of APs.	The value is an integer that ranges from 50 to 100.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

You can run the **cpu-usage threshold** command to configure the CPU usage alarm threshold in the AP system profile view. The configuration is delivered to all APs using the profile.

- When the CPU usage of an AP exceeds the alarm threshold, .
- When the CPU usage of an AP falls below the alarm threshold,

Example

Set the CPU usage alarm threshold to 60.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] cpu-usage threshold 60
```

11.2.57 cpu-defend packet-type

Function

The **cpu-defend packet-type** command configures a rate limit for packets sent by an AP to the CPU.

The **undo cpu-defend packet-type** command restores the default rate limit for packets sent by an AP to the CPU.

By default, an AP does not limit the rates of packets sent to the CPU.

Format

cpu-defend packet-type *packet-type* **rate-limit** *rate-value* { **wired** | **wireless** }

undo cpu-defend packet-type *packet-type* **rate-limit** { **wired** | **wireless** }

Parameters

Parameter	Description	Value
packet-type	Specifies the protocol type of packets.	The value depends on the protocol types supported by the device.
rate-limit *rate-value*	Specifies the rate limit. The value of *rate-value* indicates the rate limit for protocol packets.	The value is an integer that ranges from 1 to 4294967295, in pps.
wired	Indicates wired packets.	-
wireless	Indicates wireless packets.	-

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an AP receives attack packets of a certain protocol type or a large number of normal packets destined for the CPU, you can limit the rates of these packets within a small range in the AP system profile to reduce the impact on CPU processing of normal services.

Precautions

If you run the **cpu-defend packet-type** command with the same *packet-type* value multiple times, only the latest configuration takes effect.

Example

Set the protocol type to wired ARP reply packet, and set the rate limit to 1260 pps.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] cpu-defend packet-type arp-reply rate-limit 1260 wired
```

11.2.58 crc-alarm enable

Function

The **crc-alarm enable** command enables the alarm function for CRC errors on the AP's wired interface and specifies the alarm threshold and clear alarm threshold.

The **undo crc-alarm enable** command disables the alarm function for CRC errors on the AP's wired interface and restores the alarm threshold and clear alarm threshold to the default values.

By default, the alarm function for CRC errors is disabled on the AP's wired interface. The alarm threshold for CRC errors is 50 and the clear alarm threshold is 20.

Format

crc-alarm enable [**high-threshold** *high-threshold-value* | **low-threshold** *low-threshold-value*]*

undo crc-alarm enable

Parameters

Parameter	Description	Value
high-threshold *high-threshold-value*	Specifies the alarm threshold for CRC errors on the AP's wired interface.	The value is an integer that ranges from 1 to 100. The unit is 1/10000. The value of *high-threshold-value* must be larger than the value of *low-threshold-value*.
low-threshold *low-threshold-value*	Specifies the clear alarm threshold for CRC errors on the AP's wired interface.	The value is an integer that ranges from 1 to 100.

Views

AP wired port link profile view

Default Level

2: Configuration level

Usage Guidelines

When the AP detects that the number of CRC errors exceeds the configured upper alarm threshold in a specified period (the time period can be configured using the **sample-time** command, and is 30s by default), it sends an alarm message to the AC. To prevent the AP from frequently sending alarm messages or alarm clearance messages to the AC, you need to configure the lower threshold for clearing the alarm. The AP sends an alarm clearance message to the AC only when the AP detects that the number of CRC errors is lower than the configured lower threshold.

Example

Enable the alarm function for CRC errors on the AP's wired interface.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] port-link-profile name port-link1
[HUAWEI-wlan-port-link-prof-port-link1] crc-alarm enable
```

11.2.59 dai enable (AP wired port profile view)

Function

The **dai enable** command enables dynamic ARP inspection (DAI) on an AP's wired interface.

The **undo dai enable** command disables DAI on an AP's wired interface.

By default, DAI is disabled on an AP's wired interface.

Format

dai enable

undo dai enable

Parameters

None

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can enable DAI using this command to prevent Man in The Middle (MITM) attacks and theft on authorized user information. When a device receives an ARP packet, it compares the source IP address, source MAC address, interface number, and VLAN ID of the ARP packet with DHCP snooping binding entries. If the ARP packet matches a binding entry, the device allows the packet to pass through. If the ARP packet does not match any binding entry, the device discards the packet.

Prerequisites

Terminal address learning has been enabled on the AP's wired interface using the **learn-client-address enable** command.

Follow-up Procedure

Bind the AP wired port profile to an AP group or AP.

Precautions

This command takes effect only on ARP packets transmitted on an AP's wired interface.

An AP's wired interface added to an Eth-Trunk does not support this function.

Example

Enable DAI on an AP's wired interface.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wired-port-profile name wire1
[HUAWEI-wlan-wired-port-wire1] dai enable
```

11.2.60 description (AP wired port profile view)

Function

The **description** command configures the description of the AP's wired interface.

The **undo description** command restores the default description of the AP's wired interface.

By default, the AP's wired interface has no description.

Format

description *description*

undo description

Parameters

Parameter	Description	Value
description	Specifies the description of the AP's wired interface.	The value is a string of 1 to 242 case-sensitive characters with spaces.

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

To manage AP interfaces conveniently, run this command to set AP interface descriptions. The description of an AP interface helps you identify the AP interface and know its functions.

Example

Change the description of the AP's wired interface to **poe-power**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wired-port-profile name wired-port1
[HUAWEI-wlan-wired-port-wired-port1] description poe-power
```

11.2.61 display ap around-ssid-list

Function

The **display ap around-ssid-list** command displays SSIDs of neighbors of a specified AP.

Format

display ap around-ssid-list { **ap-name** *ap-name* | **ap-id** *ap-id* }

Parameters

Parameter	Description	Value
ap-name *ap-name*	Specifies an AP name.	The AP name must exist.
ap-id *ap-id*	Specifies an AP ID.	The AP ID must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view SSIDs of neighbors of a specified AP. Neighbors of an AP include authorized and unauthorized neighbors. Authorized neighbors are other APs managed by the same AC. APs that are managed by other ACs are unauthorized neighbors.

Example

Display SSIDs of neighbors of AP **example**.

```
<HUAWEI> display ap around-ssid-list ap-name example
In control AP(2.4G):
--------------------------------------------------
SSID
--------------------------------------------------
test1
--------------------------------------------------
Total: 1
Uncontrol AP(2.4G):
--------------------------------------------------
SSID
--------------------------------------------------
test2
--------------------------------------------------
Total: 1
In control AP(5G):
--------------------------------------------------
SSID
--------------------------------------------------
test3
--------------------------------------------------
Total: 1
Uncontrol AP(5G):
--------------------------------------------------
SSID
--------------------------------------------------
test4
--------------------------------------------------
Total: 1
```

Table 11-68 Description of the **display ap around-ssid-list** command output

Item	Description
In control AP	SSIDs of authorized neighbors.
Uncontrol AP	SSIDs of unauthorized neighbors.

11.2.62 display ap asyn-message err-info

Function

The **display ap asyn-message err-info** command displays records about AP restart failures.

Format

display ap asyn-message err-info { **all** | **ap-name** *ap-name* | **ap-id** *ap-id* }

Parameters

Parameter	Description	Value
all	Displays records about restart failures of all APs.	-
ap-name *ap-name*	Displays records about restart failures of the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Displays records about restart failures of the AP with a specified ID.	The AP ID must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When you use commands on the AC to restart an AP manually, during an upgrade, or to restore its factory settings, the restart message delivered by the AC may get lost due to transmission failures. Therefore, APs are not restarted. If an AP does not receive the restart message, the AP is still connected to the AC, which makes the AC incorrectly consider that the AP is restarted successfully. This command displays records about AP restart failures, helping you check whether the AP is restarted successfully. If the AP restart fails, restart the AP.

Example

Display records about restart failures of all APs.

```
<HUAWEI> display ap asyn-message err-info all
------------------------------------------------------------------------------
AP Name MAC            Time                  Reason
------------------------------------------------------------------------------
area_1  00e0-fc76-e360 2015-1-19 14:41:59      update
area_2  00e0-fc74-9640 2015-1-19 14:45:56      clear config
------------------------------------------------------------------------------
Total: 2
```

Table 11-69 Description of the **display ap asyn-message err-info** command output

Item	Description
AP Name	Name of an AP.
MAC	MAC address of an AP.
Time	Time when AP restart fails.
Reason	Type of AP restart failures. ● update: The AP fails to be restarted during an upgrade. ● clear config: The AP fails to be restarted when restoring factory settings. ● other: The AP fails to be restarted manually. ● reset timeout: The AP fails to be restarted because the restart command execution times out.

11.2.63 display ap coordinate

Function

The **display ap coordinate** command displays information about longitudes and latitudes of APs.

Format

display ap coordinate { **all** | **ap-group** *ap-group-name* }

Parameters

Parameter	Description	Value
all	Displays information about longitudes and latitudes of all APs.	-
ap-group *ap-group-name*	Displays information about longitudes and latitudes of APs in the specified AP group.	The AP group must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view longitudes and latitudes of APs.

Example

Display information about longitudes and latitudes of all APs.

```
<HUAWEI> display ap coordinate all
--------------------------------------------------------------------------------------------------------
ID   Name            Group      Longitude           Latitude
--------------------------------------------------------------------------------------------------------
0    area_1          default    30.1111111°E        40.2222222°N
1    area_2          default    110°59’59"W         77°25'53"N
2    area_3          default    -                   -
-------------------------------------------------------------------------------------------------------
Total: 3
```

Table 11-70 Description of the **display ap coordinate all** command output

Item	Description
ID	AP ID.
Name	AP name.
Group	AP group.
Longitude	Longitude of an AP. Its display varies depending on the format: - Example: 114°3’14’’E in the format of degree/minute/second - Example: 114.3435°E in the format of decimal degree - Hyphen (-) if it is not configured
Latitude	Latitude of an AP. - Example: 114°3’14’’S in the format of degree/minute/second - Example: 114.3435°S in the format of decimal degree - Hyphen (-) if it is not configured

11.2.64 display ap elabel

Function

The **display ap elabel** command displays electronic label information about a specified AP.

Format

display ap elabel { **ap-name** *ap-name* | **ap-id** *ap-id* | **all** }

Parameters

Parameter	Description	Value
ap-name *ap-name*	Displays electronic label information about the AP with the specified name.	The AP name must exist.
ap-id *ap-id*	Displays electronic label information about the AP with the specified ID.	The AP ID must exist.
all	Displays electronic label information of all APs.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view electronic label information about an AP. An electronic label is also called permanent configuration data or information and is written in the storage device during AP testing or commissioning. An electronic label includes the AP name, serial number, manufacture date and manufacturer information.

Example

Display electronic label information about the AP named **example**.

```
<HUAWEI> display ap elabel ap-name example
/$[ArchivesInfo Version]
/$ArchivesInfoVersion=3.0

 [Board Properties]
 BoardType=AirEnginexxxx

11.2.65 display ap fan

Function

The **display ap fan** command displays fan information about an AP.

Format

display ap fan { **ap-name** *ap-name* | **ap-id** *ap-id* }

Parameters

Parameter	Description	Value
ap-name *ap-name*	Displays fan information about the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Displays fan information about the AP with a specified ID.	The AP ID must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check fan information about an AP, including the fan speed, operating mode, and airflow direction.

Fan information query is supported only by the AirEngine 9700D-M, AirEngine 9700D-S, and AirEngine 9700D-M1.

Example

Display fan information about AP **0**.

```
<HUAWEI> display ap fan ap-id 0
--------------------------------------------------------------------------------
Fan   State    Speed rate   Mode   Airflow direction
--------------------------------------------------------------------------------
0     Running  40%          AUTO   Front-to-Back
1     Running  40%          AUTO   Front-to-Back
--------------------------------------------------------------------------------
```

Table 11-73 Description of the **display ap fan** command output

Item	Description
Fan	Fan ID.

Item	Description
State	Status of a fan. - Absent: The fan is not in position. - Abnormal: The fan is working abnormally. - Running: The fan is running. - Stop: The fan stops.
Speed rate	Ratio of the current fan speed to the full speed.
Mode	Operating mode of a fan. - AUTO: automatic mode - MANUAL: manual mode
Airflow direction	Airflow direction of a fan. - Front-to-Back: Air flows from the front to the rear.

11.2.66 display ap lldp neighbor

Function

The **display ap lldp neighbor** command displays LLDP neighbor information on a specified AP.

Format

display ap lldp neighbor { { **ap-name** *ap-name* | **ap-id** *ap-id* } [**interface** *interface-type interface-number*] | **brief** }

Parameters

Parameter	Description	Value
ap-name *ap-name*	Displays LLDP neighbor information about the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Displays LLDP neighbor information about the AP with a specified ID.	The AP ID must exist.

Parameter	Description	Value
interface *interface-type* *interface-number*	Displays LLDP neighbor information about a specified AP interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
brief	Displays brief LLDP neighbor information about APs.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run this command to view LLDP neighbor information on a specified AP, including the number of LLDP neighbors, device ID, interface ID, system name system description, and management address of each neighbor. The LLDP neighbor information is reported by an AP to the connected AC.

If no parameter is specified, LLDP neighbor information about all AP interfaces is displayed.

Prerequisites

The AP has been enabled to report LLDP neighbor information by using the **lldp report enable** command in the AP system profile view.

Example

Display LLDP neighbor information on all APs.

```
<HUAWEI> display ap lldp neighbor brief
------------------------------------------------------------------------------------------
Hostname  Neighbor device  Management address  Local intf  Neighbor intf          TTL
------------------------------------------------------------------------------------------
hello     HUAWEI         10.10.10.3          GE0        GigabitEthernet0/0/16  119
------------------------------------------------------------------------------------------
Total: 1
```

Table 11-74 Description of the **display ap lldp neighbor** command output

Item	Description
Hostname	AP name.
Neighbor device	System name of an AP neighbor.
Management address	Management address of an AP neighbor.
Local intf	Local interface of the AP.
Neighbor intf	Interface of an AP neighbor.
TTL	Time to live (TTL) of the AP neighbor information stored on the local AP.

Display LLDP neighbor information about GE0 of the AP named **hello**.

```
<HUAWEI> display ap lldp neighbor ap-name hello interface gigabitethernet 0
-------------------------------------------------------------------------------
AP 1 Port 0 has 1 neighbor(s):

Table 11-75 Description of the **display ap lldp neighbor ap-name** *ap-name* **interface** *interface-type interface-number* command output

Item	Description
Neighbor index	Index of a neighbor.
Host Name	AP name.
Chassis ID type	ID subtype of a neighbor device. ● chassisComponent: chassis alias ● interfaceAlias: interface alias ● portComponent: interface or backplane alias ● macAddress: MAC address ● networkAddress: network address ● interfaceName: name of the interface ● local: name of the local device
Chassis ID	ID of a neighbor device. ● A MAC address is displayed when the neighbor device ID subtype is **macAddress**. ● An IP address is displayed when the neighbor device ID subtype is **networkAddress**. ● A character string is displayed when the neighbor device ID subtype is neither **macAddress** nor **networkAddress**.

Item	Description
Port ID type	ID subtype of the neighbor interface. - interfaceAlias: interface alias - portComponent: interface or backplane alias - macAddress: MAC address - networkAddress: network address - interfaceName: name of the interface - agentCircuitID: loopback interface ID of the DHCP relay - local: name of the local device
Port ID	ID of the neighbor interface. - A MAC address is displayed when the neighbor interface ID subtype is **macAddress**. - An IP address is displayed when the neighbor interface ID subtype is **networkAddress**. - A character string is displayed when the neighbor interface ID subtype is neither **macAddress** nor **networkAddress**.
Time to live	Time to live (TTL) of the AP neighbor information stored on the local AP.
Port description	Description of the neighbor interface.
System name	System name.
System description	System description of the neighbor.
System capabilities supported	Capabilities of the neighbor device. - other: other capabilities - repeater: repeater - bridge: bridge device - wlanAccessPoint: wireless access point - router: router - telephone: wireless device - docsisCableDevice: management station - stationOnly: base station

Item	Description
System capabilities enabled	Capabilities enabled on the neighbor device. - other: other capabilities - repeater: repeater - bridge: bridge device - wlanAccessPoint: wireless access point - router: router - telephone: wireless device - docsisCableDevice: management station - stationOnly: base station
Management address type	Management address type of the neighbor.
Management address	Management address of the neighbor.
OperMau	Speed and duplex status of a neighbor interface. - The value of **speed** can be 10, 100, 1000, 2500, 5000, 10000, 40000, or **Unknown**. **Unknown** indicates that the neighbor device does not carry the interface speed. - The value of **duplex** can be **Half**, **Full**, or **Unknown**. **Unknown** indicates that the neighbor device does not carry the duplex mode.
Power port class	PoE type: - PSE: power-sourcing equipment. - PD: powered device. - Unknown: unknown PoE type.
PSE power supported	Whether the PSE power is supported. - Yes: PSE power is supported. - No: PSE power is not supported.
PSE power enabled	Whether the PSE power is enabled. - Yes: enabled. - No: disabled.
PSE pairs control ability	Whether the PSE control is supported. - Yes: PSE control is supported. - No: PSE control is not supported.

Item	Description
Power pairs	PoE remote power supply mode: - Signal: power supply mode of signal lines. - Spare: power supply mode of spare signal lines. - Unknown: an unknown remote power supply mode.
Port power classification	PD power control level on the interface: - Class0: indicates level 1. - Class1: indicates level 2. - Class2: indicates level 3. - Class3: indicates level 4. - Class4: indicates level 5. - Class5: indicates level 6. - Class6 indicates level 7. - Class7 indicates level 8. - Unknown: indicates an unknown control level.
Power type	PoE device type:
Power source	Power supply source. Type of the PSE: **Primary power source**, **Backup source**, **Reserved**, and **Unknown** Type of the PD: **PSE**, **Reserved**, **PSE and local**, and **Unknown**
Power priority	Power priority: - Critical: the highest priority. - High: the second highest priority. - Low: the lowest priority. - Unknown: unknown priority.
PD requested power value	Power requested by the PD.
PSE allocated power value	Power allocated by the PSE.
PD requested power value Mode A	Power requested by the PD in mode A.
PD requested power value Mode B	Power requested by the PD in mode B.
PSE allocated power value Alternative A	Power allocated by the PSE for a PD in mode A.

Item	Description
PSE allocated power value Alternative B	Power allocated by the PSE for a PD in mode B.
Power Class	Power class requested by the PD or allocated by the PSE.
PSE power pairsx	Mode in which the PSE supplies power to a PD.
Power typex	Working type of the device.
PD 4PID	Whether the PD supports all power receive types. - No: The PD does not support all power receive modes. - Yes: The PD supports all power receive types.
PD Load	Whether isolation between modes A and B is required for the PD. - No: Isolation between modes A and B is not required for the PD. - Yes: Isolation between modes A and B is required for the PD.
PSE maximum available power	Maximum output power of the PSE.
PSE Autoclass support	Whether the PSE supports Autoclass. - No: The PSE does not support Autoclass. - Yes: The PSE supports Autoclass.
Autoclass completed	Whether Autoclass is completed.
Autoclass request	Whether Autoclass is required for the PD.
Power down	Whether the PD requires power supply from the PSE.
4-pair PoE Supported	Whether the interface supports UPoE.
Spare pair Detection/Classification required	Whether the standby device supports the requirement for detection and classification.
PD Spare Pair Desired State	Requirement state of the standby PD.
PSE Spare Pair Operational State	Operation state of the standby PSE.

11.2.67 display ap led

Function

The **display ap led** command displays the indicator blinking status of an AP.

Format

display ap led { **ap-mac** *ap-mac* | **ap-name** *ap-name* | **ap-id** *ap-id* }

Parameters

Parameter	Description	Value
ap-mac *ap-mac*	Specifies the MAC address of an AP.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.
ap-name *ap-name*	Specifies the AP name.	The AP name must exist.
ap-id *ap-id*	Specifies the AP ID.	The AP ID must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view the indicator blinking status of an AP.

This function is not available for central APs.

Example

Display the indicator blinking status of the AP with the MAC address of 00e0-fc12-3456.

```
<HUAWEI> display ap led ap-mac 00e0-fc12-3456
Led status          : blink
Blink left time(s)  : 100
```

Table 11-76 Description of the **display ap led** command output

Item	Description
Led status	Blinking status of the indicator. - off: The indicator is off. - blink: The indicator is blinking. To configure the parameter, run the **led blink-time** command. - normal: The indicator is running properly. The running status of the AP is displayed according to the indicator description.
Blink left time(s)	Remaining time of the indicator blinking status.

11.2.68 display ap neighbor

Function

The **display ap neighbor** command displays information about neighbors of a radio, including authorized and unauthorized neighbors.

Format

display ap neighbor { **ap-name** *ap-name* | **ap-id** *ap-id* } [**radio** *radio*]

Parameters

Parameter	Description	Value
ap-name *ap-name*	Specifies an AP name.	The AP name must exist.
ap-id *ap-id*	Specifies an AP ID.	The AP ID must exist.
radio *radio*	Specifies radio ID of an AP.	The radio ID must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

APs' neighbor information reflects the APs' locations and neighbor relationships, helping you plan the network.

If a neighboring AP is an authorized one, the system displays the RSSI of signals received from the neighboring AP as well as the path loss.

If a neighboring AP is an unauthorized one, the system displays only the RSSI of signals received from the neighboring AP.

Prerequisites

The radio calibration function has been enabled using the **calibrate enable { auto | manual | schedule time }** command.

Precautions

In auto radio calibration mode, APs continuously report and update neighboring information so that the AC can query the latest AP neighbor information. In manual or scheduled radio calibration mode, APs report neighbor information during radio calibration. Information about unauthorized neighbors ages 1 hour later, and that about authorized neighbor information ages 32 hours later. Neighbor information can be queried only before the aging time expires.

Example

Display information about neighbors of radio 0 on the AP named **hello**.

```
<HUAWEI> display ap neighbor ap-name hello radio 0
Info: This operation may take a few seconds. Please wait for a moment.done.
Radio: Radio ID of AP
CH/BW: Channel/Bandwidth
SC RSSI: Single-chain RSSI
In control AP:
------------------------------------------------------------------------------------------------------------------------

0      00e0-fcf2-d1e0 6        -78        2022-09-13/19:27:39     hw_manage_d1e0
----------------------------------------------------------------------------------------------------
Total: 1
```

Table 11-77 Description of the **display ap neighbor** command output

Item	Description
In control AP	Authorized neighboring AP.

Item	Description
AP ID	ID of a neighboring AP.
AP name	Name of a neighboring AP.
Radio	Radio ID of a neighboring AP.
CH/BW	Working channel and bandwidth of a neighboring AP. **NOTE** The device displays only information about neighboring APs detected on the current channel.
RSSI(dBm)	Received signal strength indicator (RSSI) of a neighboring AP.
SC RSSI(dBm)	Single-chain RSSI.
RSSI pathloss(dB)	RSSI path loss.
RSRP(dBm)	Reference signal received power (RSRP) of a neighboring AP. The RSRP indicates the strength of the received reference signals.
RSRP pathloss(dB)	RSRP path loss.
Last Update Time	Last update time.
Uncontrol AP	Unauthorized neighboring AP.
Radio	Neighboring AP detected on an AP radio.
BSSID	BSSID of an unauthorized neighbor.
Channel	Channel that the unauthorized neighboring AP uses.
RSRP(dBm)	Strength of signals received from the neighboring AP.
Last Update Time	Latest time when the AP is detected.
SSID	SSID of an unauthorized neighbor.

11.2.69 display ap optical-info

Function

The **display ap optical-info** command displays optical module information.

Format

display ap optical-info { **ap-name** *ap-name* | **ap-id** *ap-id* }

Parameters

Parameter	Description	Value
ap-name *ap-name*	Displays optical module information of the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Displays optical module information of the AP with a specified ID.	The AP ID must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run this command to view optical module information, including the optical module type, transmit optical power, and receive optical power.

Prerequisites

The AP has been online. You can run the **display ap** command to check the AP status.

The AP supports optical modules. You can run the **display ap-type** command to view the AP model.

NOTE

Optical module query is supported only by the following models:

- AirEngine X760 series APs (excluding the AirEngine 6760-51EI)
- AirEngine 6761-21, AirEngine 6761-21E, AirEngine 6761S-21, AirEngine 5761R-11, AirEngine 5761R-11E, AirEngine 5761RS-11, AirEngine 5761-11EI
- AirEngine 5762-15HW
- AirEngine 8771-X1T
- AirEngine 9700D-S (including matching ORUs)
- AirEngine series central APs

Precautions

If a copper module is inserted into an optical interface, diagnostic information is not supported.

Example

Display optical module information about the AP named **example**.

```
<HUAWEI> display ap optical-info ap-name example

Table 11-78 Description of the **display ap optical-info** command output

Item	Description
Interface name	Name of the optical module.
Transceiver Type	Type of the optical module.
Connector	Interface type.
Wavelength(nm)	Optical wavelength, in nm.
Transfer Distance(m)	Transmission distance, in meters.
Copper link length(m)	Length of the copper cable, in meters.
Digital Diagnostic Monitoring	Whether diagnostic information about the optical module is monitored.
Vendor name	Name of the vendor.
Vendor part number	Product code provided by the vendor.
Vendor IEEE company ID	Version number provided by the vendor.
Vendor revision level	Product serial number provided by the vendor.
Nominal bit rate(MBits/sec)	Bit rate of the optical module, in Mbit/s.
Vendor serial number	Vendor sequence number of the optical module.
Manufacturing Date	Manufacturing date of the optical module.
Temperature(degree C)	Current temperature of the optical module, in °C.
Temp High Threshold(degree C)	The upper threshold for the temperature of the optical module, in °C.

Item	Description
Temp Low Threshold(degree C)	The lower threshold for the temperature of the optical module, in °C.
Supply voltage(0.1mV)	Current voltage of the optical module, in 0.1 mV.
Volt High Threshold(0.1mV)	The upper threshold for the voltage of the optical module, in 0.1 mV.
Volt Low Threshold(0.1mV)	The lower threshold for the voltage of the optical module, in 0.1 mV.
TX bias current(mA)	Bias current of the optical module, in mA.
Bias High Threshold(mA)	Upper threshold for the bias current of the optical module, in mA.
Bias Low Threshold(mA)	Lower threshold for the bias current of the optical module, in mA.
RX power(0.1uw)	Receive power of the optical module, in 0.1 uW.
RX Power High Threshold(0.1uw)	Upper receive power threshold for the optical module, in 0.1 uW.
RX Power Low Threshold(0.1uw)	Lower receive power threshold for the optical module, in 0.1 uW.
TX power(0.1uw)	Transmit power of the optical module, in 0.1 uW.
TX Power High Threshold(0.1uw)	Upper transmit power threshold for the optical module, in 0.1 uW.
TX Power Low Threshold(0.1uw)	Lower transmit power threshold for the optical module, in 0.1 uW.

11.2.70 display ap performance statistics

Function

The **display ap performance statistics** command displays performance statistics about an AP.

Format

display ap performance statistics { **ap-name** *ap-name* | **ap-id** *ap-id* }

Parameters

Parameter	Description	Value
ap-name *ap-name*	Displays performance statistics about the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Displays performance statistics about the AP with a specified ID.	The AP ID must exist.

Views

All views

Default Level

```

Table 11-79 Description of the **display ap performance statistics** command output

Item	Description
Memory usage(%)	Memory usage (%).
Memory average usage(%)	Average memory usage (%).
CPU usage(%)	CPU usage (%).
CPU average usage(%)	Average CPU usage (%).
Available space size(KB)	Available space, in KB.
Device Temperature(degree C)	AP's device temperature (°C). The temperature is displayed as a hyphen (-) for APs that do not support the temperature display.
Environment Temperature(degree C)	AP's ambient temperature (°C). The temperature is displayed as a hyphen (-) for APs that do not support the temperature display.
CPU Temperature(degree C)	AP's CPU temperature (°C). The temperature is displayed as a hyphen (-) for APs that do not support the temperature display.
NP Temperature(degree C)	AP's NP module temperature (°C). The temperature is displayed as a hyphen (-) for APs that do not support the temperature display.
IRF*n* Temperature(degree C)	Temperature of IRF *n* (°C). The temperature is displayed as a hyphen (-) for APs that do not support the temperature display.
Online user number	Number of online users.
Upstream traffic(wireless)(KB)	Traffic volume on the wireless upstream interface in a specified period, in KB.

Item	Description
Wireless port drop frames(RX)	Number of discarded data frames received by the wireless interface.
Wireless port drop frames(TX)	Number of discarded data frames sent by the wireless interface.
Wireless port total bytes(RX)	Total number of bytes received by the wireless interface.
Wireless port total bytes(TX)	Total number of bytes sent by the wireless interface.
Wireless port unicast frames(RX)	Number of unicast data frames received by the wireless interface.
GigabitEthernet port x	ID of a wired interface.
port drop frames(RX)	Number of discarded data frames received by the wired interface.
port drop frames(TX)	Number of discarded data frames sent by the wired interface.
port total Bytes(RX)	Number of bytes received by the wired interface.
port total Bytes(TX)	Number of bytes sent by the wired interface.
port unknown frames(RX)	Number of unknown protocol packets received by the wired interface.
port error frames(TX)	Number of error data frames sent by the wired interface.
port updown counts	Number of times the wired interface alternates between Up and Down.
port output rate(Kbps)	Wired-side sending rate (kbps).
port input rate(Kbps)	Wired-side receiving rate (kbps).

NOTE

If the AP does not support this parameter, a hyphen (-) is displayed.

To clear wired-side statistics on an AP, run the **reset statistics** { **ap-name** *ap-name* | **ap-id** *ap-id* } [**ssid** *ssid*] command. Alternatively, you can run **reset statistics all** the command to clear statistics on all APs.

11.2.71 display ap provision

Function

The **display ap provision** command displays the configurations for an AP to go online.

Format

display ap provision ap-id *ap-id*

Parameters

Parameter	Description	Value
ap-id *ap-id*	Specifies an AP ID.	The AP ID must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After you set parameters for an AP to go online in the AP view, you can run this command to view the detailed configuration.

Example

Display configurations in the AP view.

```
<HUAWEI> display ap provision ap-id 0
--------------------------------------------------------------------------------
AP name                  : area_1
AP group                 : default
AP address mode          : static
IPv4 address             : -
IPv4 mask address        : -
IPv4 gateway address     : -
IPv4 AC list             : -
Management Vlan          : 2
DTLS server-auth         : enable
DTLS server-auth cn list : -
--------------------------------------------------------------------------------
```

Table 11-80 Description of the **display ap provision ap-id** *ap-id* command output

Item	Description
AP name	AP name. To configure this parameter, run the **ap-name (AP view)** command.
AP group	AP group to which an AP belongs. To configure this parameter, run the **ap-group (AP view)** command.
AP address mode	Mode in which an AP obtains an IP address. To configure this parameter, run the **address-mode (AP view)** command.
IPv4 address	Static IPv4 address of an AP. To configure this parameter, run the **ip-address (AP view)** command.
IPv4 mask address	Static IPv4 mask of an AP. To configure this parameter, run the **ip-address (AP view)** command.
IPv4 gateway address	IPv4 gateway address of an AP. To configure this parameter, run the **ip-address (AP view)** command.
IPv4 AC list	AC IPv4 address list for APs. To configure this parameter, run the **ac-list (AP view)** command.
Management Vlan	Management VLAN tag carried in CAPWAP packets sent from the AP's wired interface. To configure this parameter, run the **management-vlan** command.
DTLS server-auth	Whether the AC authentication function is enabled for the AP. To restore the default value, run the **undo capwap dtls server-auth (AP view)** command. To enable or disable this function, run the **capwap dtls server-auth (AP provisioning view)** command and run the **commit** command to deliver the configuration.

Item	Description
DTLS server-auth cn list	CN field used by APs to verify an AC's certificate. To restore the default value, run the **undo capwap dtls server-auth cn (AP view)** command. To configure the CN field, run the **capwap dtls server-auth cn (AP provisioning view)** command and run the **commit** command to deliver the configuration.

11.2.72 display ap pki certificate

Function

The **display ap pki certificate** command displays AP certification information.

Format

display ap pki certificate ap-id *ap-id* { **ca** | **local** } **realm** *realm-name*

Parameters

Parameter	Description	Value
ap-id *ap-id*	Displays certificate information about the AP with a specified ID.	The AP ID must exist.
ca	Displays information about the CA certificate.	-
local	Displays information about the local certificate.	-
realm *realm-name*	Specifies the PKI realm name of a certificate.	The value must be an existing PKI realm name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ap pki certificate** command to view information about the CA or local certificate of a specified AP.

Example

Display information about the CA certificate of AP 1 in the PKI realm **abc**.

```
<HUAWEI> display ap pki certificate ap-id 1 ca realm abc
Info: This operation may take a few seconds. Please wait for a moment...done.
------------------------------------------------------------------------------
Serial Number: 0c:f0:1a:f3:67:21:44:9a:4a:eb:ec:63:75:5d:d7:5f
Issuer: CN=ca_root
Validity
    Not Before: Jun  4 14:58:17 2015 GMT
    Not After : Jun  4 15:07:10 2020 GMT
Subject: CN=ca_root
------------------------------------------------------------------------------
Total: 1
```

Table 11-81 Description of the **display ap pki certificate** command output

Item	Description
Serial Number	Serial number of a certificate.
Issuer	Issuer of a certificate.
Validity	Validity period of a certificate.
Subject	Subject of a certificate. The subject includes the following attributes: C: country code of a PKI entity. ST: name of the state or province to which a PKI entity belongs. L: geographic area where a PKI entity is located. O: organization to which a PKI entity belongs. OU: department to which a PKI entity belongs. CN: common name of a PKI entity.

11.2.73 display ap pki status

Function

The **display ap pki status** command displays an AP PKI realm and the certificate file status in the PKI realm.

Format

display ap pki status [**ap-id** *ap-id*]

Parameters

Parameter	Description	Value
ap-id *ap-id*	Displays the AP PKI realm by specifying an AP ID and the certificate file status in the PKI realm.	The AP ID must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ap pki status** command to view the AP PKI realm and the certificate file status in the PKI realm.

Example

Display all AP PKI realms and the certificate file status in the PKI realms.

```
<HUAWEI> display ap pki status
------------------------------------------------------------
AP-ID REALM1      REALM2   REALM3    REALM4   REALM5
------------------------------------------------------------
0     default/ok test/nok  -/-       -/-       -/-
1     default/ok test/ok  web/nok   -/-       -/-
2     default/ok test/ok  -/-       -/-       -/-
3     default/ok test/ok  web/ok    8021x/ok -/-
4     -/-        -/-      -/-       -/-       -/-
```

Display a specified AP PKI realm and the detailed certificate file status in the PKI realm.

```
<HUAWEI> display ap pki status ap-id 1
apid                                        : 1
realm1                                      : default
ca file           : 1.txt            status   : exist
local file        : 2.txt            status   : exist
private key file  : 3.txt            status   : exist
CRL file          : 4.txt            status   : exist
realm2                                      : test
ca file           : 1.txt            status   : exist
local file        : 2.txt            status   : exist
private key file  : 3.txt            status   : exist
CRL file          : 4.txt            status   : exist
realm3                                      : web
ca file           : 1.txt            status   : exist
local file        :                  status   :
private key file  : 3.txt            status   : exist
CRL file          : 4.txt            status   : exist
realm4                                      :
ca file           :                  status   :
local file        :                  status   :
private key file  :                  status   :
CRL file          :                  status   :
```

```
realm5                                        :
ca file              :                  status   :
local file           :                  status   :

CRL file             :                  status   :
```

Table 11-82 Description of the **display ap pki status** command output

Item	Description
AP-ID	AP ID.
REALMX	Name of a PKI realm. The value can be **ok** or **nok**. **ok** indicates that the file is loaded, and **nok** indicates that the file is not loaded.
apid	AP ID.
realmx	Name of a PKI realm.
ca file	CA certificate file.
local file	Local certificate file.
private key file	Private key file.
CRL file	CRL file.
status	Certificate loading status.

11.2.74 display ap port

Function

The **display ap port** command displays the AP port status and traffic information.

Format

display ap port { **all** | **ap-name** *ap-name* | **ap-id** *ap-id* | **ap-mac** *ap-mac* }

Parameters

Parameter	Description	Value
all	Displays port status and traffic information of all APs.	-
ap-name *ap-name*	Displays port status and traffic information of the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Displays port status and traffic information of the AP with a specified ID.	The AP ID must exist.

Parameter	Description	Value
ap-mac *ap-mac*	Displays port status and traffic information of the AP with a specified MAC address.	The AP's MAC address must exist.

Views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ap port** command to check the port status and traffic information of online APs, which facilitates AP port maintenance and management.

Example

Display the port status and traffic information of all APs.

```
<HUAWEI> display ap port all
Info: Waiting for AP response.
------------------------------------------------------------------------------------------------------------------------------
-----
AP-ID Port   Trunk ID    State Mode Speed Duplex TX-Packets       Tx-ErrorPackets  TX-Rate(Kbps) RX-
Packets       RX-DropPackets   RX-Rate(Kbps)
------------------------------------------------------------------------------------------------------------------------------
-----
0     GE0    0(active)   up    root 1000  full   9178           0            0          12857          0             1
......
------------------------------------------------------------------------------------------------------------------------------
-----
Printed: 1
```

Table 11-83 Description of the **display ap port** command output

Item	Description
AP-ID	AP ID.
Port	AP port.

Item	Description

Trunk ID	Whether the Eth-Trunk function is configured on the AC and whether the AP port is added to an Eth-Trunk.
	- The field outside parentheses indicates the configuration on the AC.
	  – 0: The AC is configured to add AP ports to Eth-Trunk 0.
	  – -: The AC is not configured to add AP ports to an Eth-Trunk.
	- The field in parentheses indicates the effective configuration on the AP.
	  – -: The AP port does not support the Eth-Trunk function.
	  – active: The AP port has been added to an Eth-Trunk.
	  – inactive: The AP port is not added to an Eth-Trunk.
	The entire field is described as follows:
	- 0(active): The AP port is added to Eth-Trunk 0, and this configuration is in effect.
	- 0(inactive): The AC is configured to add AP ports to Eth-Trunk 0, but this configuration takes effect only after a restart. The current AP port is not in an Eth-Trunk.
	- 0(-): The AC is configured to add AP ports to Eth-Trunk 0, but the current AP port does not support the Eth-Trunk function.
	- -(-): The current AP port does not support the Eth-Trunk function, and the AC is not configured to add AP ports to an Eth-Trunk.
	- -(active): The AC is configured to remove AP ports from an Eth-Trunk, but this configuration takes effect only after a restart. The current AP port is still in an Eth-Trunk.
	- -(inactive): The AP port is configured to leave an Eth-Trunk, and this configuration is in effect.

State	Status of the AP port. - down: The AP port is Down. - up: The AP port is Up.
Mode	Working mode of the AP port. - root - middle - endpoint
Speed	Speed of the AP port, in Mbit/s.

Item	Description
Duplex	Duplex mode of the AP port, which includes the half-duplex and full-duplex modes.
TX-Packets	Number of data frames sent by the AP port.
Tx-ErrorPackets	Number of error data frames sent by the AP port.
TX-Rate(Kbps)	Uplink rate of the AP port.
RX-Packets	Number of data frames received by the AP port.
RX-DropPackets	Number of discarded data frames that are received by the AP port.
RX-Rate(Kbps)	Downlink rate of the AP port.

11.2.75 display ap power-workmode

Function

The **display ap power-workmode** command displays the current power mode of APs.

Format

display ap power-workmode { **all** | **ap-name** *ap-name* | **ap-id** *ap-id* | **ap-mac** *ap-mac* | **ap-group** *ap-group* }

Parameters

Parameter	Description	Value
all	Displays the current power mode of all APs.	-
ap-name *ap-name*	Displays the current power mode of the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Displays the current power mode of the AP with a specified ID.	The AP ID must exist.
ap-mac *ap-mac*	Displays the current power mode of the AP with a specified MAC address.	The AP's MAC address must exist.
ap-group *ap-group*	Displays the current power mode of APs in a specified AP group.	The AP group must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When an AP is supplied with DC or PoE power, the AP may work in low-power mode if the power fails to meet requirements. You can run this command to view the current power mode of the AP and verify that the current power mode can enable the AP to work with all functions.

Example

Display the current power mode of all APs.

```
<HUAWEI> display ap power-workmode all
--------------------------------------------------------------------------------------------------------------------------------------
-----
ID    MAC            Name   Group    Power-workmode     Decided by
--------------------------------------------------------------------------------------------------------------------------------------
-----
0     00e0-fc76-e360   ap_1    default   AT(Limited)       LLDP
--------------------------------------------------------------------------------------------------------------------------------------
-----
Total: 1
```

Table 11-84 Description of the **display ap power-workmode** command output

Item	Description
ID	AP ID.
MAC	AP's MAC address.
Name	AP name.
Group	AP group to which an AP belongs.

Item	Description
Power-workmode	Current power mode of an AP. - The power mode of an AP can be AF, AT, BT60, or BT90, which presents 802.3af, 802.3at, 802.3bt Class 6, and 802.3bt Class 8, respectively. - The working mode of an AP can be Normal, Limited, or Insufficient. In Normal mode, functions of the AP are unrestricted. In Limited mode, functions of the AP are partially restricted. In Insufficient mode, the AP restarts due to insufficient power supply, and you are not advised to use the AP in this mode. Limited: For impact on AP services by insufficient power supply. Visit **Info-Finder**, select a product series, and view hardware specifications in the hardware center. You can check the power supply downgrade limits at different power supply levels. Insufficient: Check the power supply capability of the PSE or contact technical support personnel. If the value of **Power-workmode** is **AF(Insufficient)** and the AP restarts for 10 consecutive times within a short period, the possible cause is that the power supply of the AP is insufficient. After the AP restarts for the eleventh time, it enters the AF power mode. One hour later, the AP automatically restarts and restores the original power mode. During the waiting period, you can check whether the PSE power supply is stable and replace the PSE power supply if it is unstable.
Decided by	The current power mode of an AP is determined by: - LLDP: LLDP negotiation result - Hardware detect: hardware detection result - AP capability: its own highest capability - Configuration: **power force work-mode** command configuration

11.2.76 display ap power

Function

The **display ap power** command displays power supply information about an AP.

Format

display ap power { **ap-name** *ap-name* | **ap-id** *ap-id* }

Parameters

Parameter	Description	Value
ap-name *ap-name*	Displays power supply information about the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Displays power supply information about the AP with a specified ID.	The AP ID must exist.

Views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check power supply information about an AP, including the power supply mode, rated voltage, and rated power.

Power supply information query is supported only by the AirEngine 9700D-M and AirEngine 9700D-S.

Example

Display power supply information about AP **0**.

```
<HUAWEI> display ap power ap-id 0
--------------------------------------------------------------------------------
PowerNo   Present  Mode  State   Voltage(V)  Power(W)
--------------------------------------------------------------------------------
PWRI      YES      AC    Normal  56          1000
--------------------------------------------------------------------------------
```

Table 11-85 Description of the **display ap power** command output

Item	Description
PowerNo	Number of a power module.
Present	Whether a power module is in position. ● YES: The power module is in position. ● NO: The power module is not in position.
Mode	Power supply mode of a power module. ● DC: DC power supply ● AC: AC power supply
State	Power supply status of a power module. ● Normal: The power module has current output. ● Abnormal: The power module has no current output.
Voltage(V)	Rated voltage of a power module (V).
Power(W)	Rated power of a power module (W).

11.2.77 display ap resource

Function

The **display ap resource** command displays the number of CAPWAP tunnel resources used by APs on a device.

Format

display ap resource slot *slot-id*

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies the slot ID of a device.	The value must be set according to the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check the number of CAPWAP tunnel resources used by APs on a device.

Example

Display the number of CAPWAP tunnel resources used by APs on a device.

```
<HUAWEI> display ap resource slot 0
  Slot  0
------------------------------------------------------------------------
  Number Used :0
  Number Free : 1024
  Number Total: 1024
------------------------------------------------------------------------
```

Table 11-86 Description of the **display ap resource slot** *slot-id* command output

Item	Description
Number Used	Number of CAPWAP tunnel resources used by APs.
Number Free	Number of available CAPWAP tunnel resources.
Number Total	Total number of CAPWAP tunnel resources on the device.

11.2.78 display ap run-info

Function

The **display ap run-info** command displays the running status of an AP.

Format

display ap run-info { **ap-name** *ap-name* | **ap-id** *ap-id* }

Parameters

Parameter	Description	Value
ap-name *ap-name*	Displays the running status of the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Displays the running status of the AP with a specified ID.	The AP ID must exist.

Table 11-87 Description of the **display ap run-info** command output

Item	Description
AP type	AP type.
Country code	Country code.
Software version	Software version of an AP.
Hardware version	Hardware version of an AP.
BIOS version	BIOS version of an AP.
BOM version	BOM version of an AP.
Memory size(MB)	Memory size of an AP, in MB.
Flash size(MB)	Flash memory size of an AP, in MB.
SD Card size(MB)	SD card size of an AP, in MB.
Manufacture	Manufacturer of an AP.
Software vendor	AP software manufacturer.
Online time(ddd:hh:mm:ss)	AP online duration.
Run time(ddd:hh:mm:ss)	Running duration of an AP.
NAT IP address	This item is displayed only when the AP is on the private network and the AC is on the public network in NAT scenarios. The value of this parameter is the translated public IP address of the AP.
IP address	AP IPv4 address.
IP mask	IP address mask of an AP.
Gateway	Gateway IP address of an AP.
DNS server	IP address of the DNS server.

Item	Description
AP mode	AP mode. campus: The AP is not added to a branch group.
USB	Whether USB is enabled. ● disable: This function is disabled. ● enable(2.5w): USB is enabled and works at the 2.5 W power. ● enable(5w): USB is enabled and works at the 5 W power. ● -: USB is not supported.
PoE	Status of the PoE function on the interface. ● disable: This function is disabled. ● enable: This function is enabled. ● -: PoE is not supported.
XGigabitEthernet port *number*	ID of the AP's XGigabitEthernet port. This item is displayed only for an AP with an XGigabitEthernet port.
MultiGE port *number*	ID of the AP's MultiGE port. This item is displayed only for an AP with a MultiGE port.
GigabitEthernet port *number*	ID of the AP's Ethernet interface.
Ethernet port *number*	Number of the AP's Ethernet port. This item is displayed only for an AP with an Ethernet port.
Port speed(Mbps)	Rate on the upstream Ethernet interface, in Mbit/s.
Port speed mode	Rate mode of the upstream Ethernet interface, including automatic and non-automatic negotiation modes.
Port duplex	Duplex type of the upstream Ethernet interface, including full duplex and half duplex.
Port duplex mode	Duplex mode of the upstream Ethernet interface, including automatic and non-automatic negotiation modes.

Item	Description
Port state	AP interface status. - down: indicates that the interface is disabled. - up: indicates that the interface is enabled. - admin shutdown: indicates that the interface is shut down. - stp shutdown: indicates that STP on the interface is disabled.
STP down recovery time(ddd:hh:mm:ss)	Remaining recovery time of the STP.
Card status	IoT card status. - -: indicates that the IoT card is not in position. - present: indicates that the IoT card is in position.

11.2.79 display ap service-config acl

Function

The **display ap service-config acl** command displays the ACL configuration on a specified AP.

Format

display ap service-config acl { **ap-name** *ap-name* | **ap-id** *ap-id* }

Parameters

Parameter	Description	Value
ap-name *ap-name*	Displays the ACL configuration on the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Displays the ACL configuration on the AP with a specified ID.	The AP ID must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can determine which ACLs have been delivered to the AP based on the command output, which helps locate and troubleshoot faults about user rights.

Example

Display the ACL configuration on AP **hello**.

```
<HUAWEI> display ap service-config acl ap-name hello
--------------------------------------------------------------------------------
Index          ACL number
--------------------------------------------------------------------------------
1             3000
2             3002
3             3015
4             3022
5             3030
--------------------------------------------------------------------------------
Total: 5
```

Table 11-88 Description of the **display ap service-config acl** command output

Item	Description
Index	Index.
ACL number	ACL number configured on an AP.
IPv6 ACL number	ACL6 number configured on an AP.

11.2.80 display ap traffic statistics wireless

Function

The **display ap traffic statistics wireless** command displays statistics about packets with the specified SSID on the radio of an AP.

Format

display ap traffic statistics wireless { **ap-name** *ap-name* | **ap-id** *ap-id* } **radio** *radio-id* [**ssid** *ssid*]

Parameters

Parameter	Description	Value
ap-name *ap-name*	Specifies an AP name.	The AP name must exist.

Parameter	Description	Value
ap-id *ap-id*	Specifies an AP ID.	The AP ID must exist.
radio *radio-id*	Specifies the radio ID.	The radio ID must exist.
ssid *ssid*	Specifies the SSID that STAs associate with.	The value must be an existing SSID.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ap traffic statistics wireless** command to view statistics about packets with the specified SSID on the radio of an AP.

After an AP performs self-healing, packet statistics on the AP radios are cleared.

The values of some command output items are displayed as 0 due to different function support specifications.

Example

Display statistics about packets with the SSID **cmcc** on radio 0 of the AP 0.

```
<HUAWEI> display ap traffic statistics wireless ap-id 0 radio 0 ssid cmcc
------------------------------------------------------------------
Wireless bytes(RX)           : 14583149
Wireless error frames(RX)    : 10
Wireless frames(RX)          : 97419
Wireless unicast frames(RX)  : 16
Wireless dropped frames(RX)  : 0
Wireless bytes(TX)           : 1725974
Wireless error frames(TX)    : 6
Wireless frames(TX)          : 9704
Wireless unicast frames(TX)  : 9680

Wireless retransmitted frames: 32674
Current accessed STA number  : 0
------------------------------------------------------------------
```

Table 11-89 Description of the **display ap traffic statistics wireless** { **ap-name** *ap-name* | **ap-id** *ap-id* } **radio** *radio-id* **ssid** *ssid* command output

Item	Description
Wireless bytes(RX)	Total number of bytes of data frames received by the radio.
Wireless error frames(RX)	Total number of received error frames.

Item	Description
Wireless frames(RX)	Total number of received frames.
Wireless unicast frames(RX)	Total number of received unicast frames.
Wireless dropped frames(RX)	Total number of received frames that are discarded.
Wireless bytes(TX)	Total number of bytes of data frames sent by the radio.
Wireless error frames(TX)	Total number of transmitted error frames.
Wireless frames(TX)	Total number of transmitted frames.
Wireless unicast frames(TX)	Total number of transmitted unicast frames.
Wireless dropped frames(TX)	Total number of transmitted frames that are discarded.
Wireless retransmitted frames	Total number of retransmitted frames.
Current accessed STA number	Number of STAs that connect to the AP normally.

Display packet statistics on radio 0 of the AP 0.

```

```

Table 11-90 Description of the **display ap traffic statistics wireless** { **ap-name** *ap-name* | **ap-id** *ap-id* } **radio** *radio-id* command output

Item	Description
Wireless frames(RX)	Total number of data frames and management frames received by the radio.
Wireless bytes(RX)	Total number of bytes of data frames received by the radio.
Wireless error frames(RX)	Total number of error frames received by the radio.
Wireless physical layer error frames(RX)	Number of error frames received at the physical layer of the radio.
Wireless MIC error frames(RX)	Number of frames with message integrity code (MIC) received by the radio.
Wireless private key and decrypt fail frames(RX)	Number of frames with incorrect keys received by the radio.
Wireless unicast frames(RX)	Total number of received unicast frames.
Wireless management frames(RX)	Number of management frames received by the radio.
Wireless data frames(RX)	Number of data frames received by the radio.
Wireless frames(TX)	Total number of transmitted frames.
Wireless bytes(TX)	Total number of bytes of data frames sent by the radio.
Wireless RTS successes(TX)	Number of Request to Send (RTS) frames that are successfully sent by the radio.

Item	Description
Wireless unicast frames(TX)	Total number of transmitted unicast frames.
Wireless broadcast frames(TX)	Number of broadcast frames sent by the radio.
Wireless failure frames(TX)	Number of frames that the radio fails to send.
Wireless management frames(TX)	Number of management frames sent from the radio.
Wireless data frames(TX)	Number of data frames sent from the radio.
Wireless noise(dBm)	Radio noise level, in dBm.
Wireless port up rate(Kbps)	Upstream rate of the radio, in kbit/s.
Wireless port down rate(Kbps)	Downstream rate of the radio, in kbit/s.
Wireless port PS-Poll Frames	Number of data frames sent by the STA working in power saving mode.
Wireless port Association Request	Number of Association Request frames.
Wireless port Association Response	Number of Association Response frames.
Wireless port ReAssociation Request	Number of Reassociation Request frames.
Wireless port ReAssociation Response	Number of Reassociation Response frames.
Wireless port Disassociation Frames	Number of Disassociation frames.
Wireless port Deauthentication Frames	Number of Deauthentication frames.
Wireless retry frames	Number of frames that are retransmitted by the radio.
Wireless PER(%)	Packet error rate of the radio.
Wireless PER of the last 5min(%)	Packet error rate of the radio in the previous statistical period (5 minutes).
Wireless port PLR(%)	Packet loss ratio of the radio.
Wireless port PLR of the last 5min(%)	Packet loss rate of the radio in the previous statistical period (5 minutes).
Wireless retransmitted rate(%)	Retransmission rate of the radio.

Item	Description
Wireless retransmitted rate of the last 5min(%)	Retransmission rate of the radio in the previous statistical period (5 minutes).
Wireless channel utilization(%)	Channel utilization of the radio. **NOTE** When an AP radio works in monitor mode, this parameter is displayed as **-**.
WMM AC_BE retry ratio(%)	Retransmission ratio of AC_BE packets in the WMM queue.
WMM AC_BK retry ratio(%)	Retransmission rate of AC_BK packets in the WMM queue.
WMM AC_VI retry ratio(%)	Retransmission ratio of AC_VI packets in the WMM queue.
WMM AC_VO retry ratio(%)	Retransmission ratio of AC_VO packets in the WMM queue.
WMM AC_BE PLR(%)	Packet loss rate of AC_BE packets in the WMM queue.
WMM AC_BK PLR(%)	Packet loss rate of AC_BK packets in the WMM queue.
WMM AC_VI PLR(%)	Packet loss rate of AC_VI packets in the WMM queue.
WMM AC_VO PLR(%)	Packet loss rate of AC_VO packets in the WMM queue.

11.2.81 display ap uncontrol all

Function

The **display ap uncontrol all** command displays information about all uncontrolled APs that are not managed by the local AC.

Format

display ap uncontrol all

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view information about all uncontrolled APs. The command output includes channel of the controlled AP closest to the uncontrolled AP and the strength of signals that the controlled AP received from the uncontrolled AP.

Example

View information about all uncontrolled APs.

```
<HUAWEI> display ap uncontrol all
---------------------------------------------------------
BSSID          NEAREST-AP      CHANNEL  RSSI(dBm)   SSID
---------------------------------------------------------
00e0-fc76-e360 ap-13           149      -68         test
---------------------------------------------------------
Total: 1
```

Table 11-91 Description of the **display ap uncontrol all** command output

Item	Description
BSSID	BSSID of an uncontrolled AP.
NEAREST-AP	Name of the controlled AP that is closest to the uncontrolled AP.
CHANNEL	Channel on which the uncontrolled AP is detected. If a rogue AP is detected on multiple channels, the channel with the strongest signal strength is displayed.
RSSI(dBm)	Strength of signals that the closest controlled AP receives from the uncontrolled AP, in dBm.
SSID	SSID of an uncontrolled AP.

11.2.82 display ap update configuration

Function

The **display ap update configuration** command displays AP upgrade configuration.

Format

display ap update configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view the AP upgrade configuration, including the upgrade mode, FTP server configuration, and SFTP server configuration.

Example

Display the AP upgrade configuration.

```
<HUAWEI> display ap update configuration
------------------------------------------------------------------------------
AP update mode         : AC-mode
FTP configuration
 FTP IPv4 address      : -
 FTP IPv4 port         : 21
 FTP IPv4 username     :
 FTP IPv4 password     :
 FTP IPv4 max number   : 50
SFTP configuration
 SFTP IPV4 address     : -
 SFTP IPv4 port        : 22
 SFTP IPV4 username    :
 SFTP IPV4 password    :
 SFTP IPV4 max number  : 50
AP update schedule-task
 ap update schedule-task task-id 1 start-time 11:11 2017/1/1 stop-time 11:12 201 7/1/1 ap-type 54
AP type/AP-group update filename/patch filename
 AirEngine6760R-51     : AirEngineX760-V200R019C10.cc/-
------------------------------------------------------------------------------
```

Table 11-92 Description of the **display ap update configuration** command output

Item	Description
AP update mode	AP upgrade mode. ● AC-mode: indicates the AC mode. ● FTP-mode: indicates the FTP mode. ● SFTP-mode: indicates the SFTP mode. To configure this parameter, run the **ap update mode** command.
FTP configuration	FTP server configuration.

Item	Description
FTP IPv4 address	IPv4 address of the FTP server. To configure this parameter, run the **ap update ftp-server** command.
FTP IPv4 port	IPv4 port number of the FTP server. To configure this parameter, run the **ap update ftp-server** command.
FTP IPv4 username	IPv4 user name for logging in to the FTP server. To configure this parameter, run the **ap update ftp-server** command.
FTP IPv4 password	IPv4 password for logging in to the FTP server. To configure this parameter, run the **ap update ftp-server** command.
FTP IPv4 max number	Maximum number of APs that can be upgraded simultaneously when an IPv4 address is used to access the FTP server. To configure this parameter, run the **ap update ftp-server** command.
SFTP configuration	SFTP server configuration.
SFTP IPv4 address	IPv4 address of the SFTP server. To configure this parameter, run the **ap update sftp-server** command.
SFTP IPv4 port	IPv4 port number of the SFTP server. To configure this parameter, run the **ap update sftp-server** command.
SFTP IPv4 username	IPv4 user name for logging in to the SFTP server. To configure this parameter, run the **ap update sftp-server** command.
SFTP IPv4 password	IPv4 password for logging in to the SFTP server. To configure this parameter, run the **ap update sftp-server** command.

Item	Description
SFTP IPv4 max number	Maximum number of APs that can be upgraded simultaneously when an IPv4 address is used to access the SFTP server. To configure this parameter, run the **ap update sftp-server** command.
AP update schedule-task	ID of a scheduled AP upgrade task. To configure this parameter, run the **ap update schedule-task** command.
AP type/AP-group update filename/ patch filename	Name of the upgrade file/name of the patch file for a specified AP type or group. To configure this parameter, run the **ap update update-filename** and **ap-patch update update-filename** commands.

11.2.83 display ap update schedule-task

Function

The **display ap update schedule-task** command displays information about scheduled AP upgrade tasks.

Format

display ap update schedule-task

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use this command to view information about scheduled AP upgrade tasks, and run the **undo ap update schedule-task** { **all** | **task-id** *task-id* } command to delete the scheduled tasks that have been completed or are not needed.

Example

Display information about scheduled AP upgrade tasks.

```
<HUAWEI> display ap update schedule-task
--------------------------------------------------------------------------------
 Task-ID  Task-State  Start-Time        Stop-Time         AP-Type  AP-Group
--------------------------------------------------------------------------------
 1        IDLE        2020/01/01 11:11  2020/01/02 11:12  125      -
--------------------------------------------------------------------------------
```

Table 11-93 Description of the **display ap update schedule-task** command output

Item	Description
Task-ID	ID of a scheduled AP upgrade task.
Task-State	Status of the scheduled AP upgrade task. ● DEAD: The start time of the task is earlier than the system time, or the task stops unexpectedly. ● DONE: The task is executed. ● IDLE: The task has not been activated. ● OVERTIME: The task times out. ● RUNNING: The task is running. ● WAITING: The task is in waiting state because the start time of the task has reached but a task is running.
Start-Time	Start time of the scheduled AP upgrade task.
Stop-Time	End time of the scheduled AP upgrade task.
AP-Type	Type of the APs to be upgraded.
AP-Group	AP group to which the APs to be upgraded belong.

11.2.84 display ap update status

Function

The **display ap update status** command displays the progress of upgrading Fit APs through the current AC.

Format

display ap update status { **all** | **downloading** | **failed** | **succeed** | **ap-name** *ap-name* | **ap-id** *ap-id* | **ap-type** *ap-type* | **ap-group** *ap-group* | **waiting** }

Parameters

Parameter	Description	Value
all	Displays upgrade progress of all APs.	-
downloading	Displays APs that are upgrading.	-
failed	Displays APs that failed to be upgraded.	-
succeed	Displays APs that have been successfully upgraded.	-
ap-name *ap-name*	Displays upgrade progress of the AP with a specified name.	The value is a string of 1 to 63 case-sensitive characters, which can be Chinese characters or Chinese + English characters. It cannot contain question marks (?), and cannot start or end with spaces or double quotation marks (" "). If the AP name contains spaces, the input name must start and end with a quotation mark ("), for example, "hello name1". The quotation marks at the beginning and end of the AP name occupy two characters in total. **NOTE** You can only use a command editor of the UTF-8 encoding format to edit Chinese characters.
ap-id *ap-id*	Displays upgrade progress of the AP with a specified ID.	The AP ID must exist.

Parameter	Description	Value
ap-type *ap-type*	Displays upgrade progress of APs of a specified type.	The value is an integer. To view all AP types, run the **display ap-type all** command.
ap-group *ap-group*	Displays upgrade progress of APs in a specified AP group.	The value is a string of 1 to 35 characters, which can be Chinese characters or Chinese + English characters. It cannot contain question marks (?) or slashes (/), and cannot start or end with spaces or double quotation marks (" "). If the AP group name contains spaces, the input name must start and end with a quotation mark ("), for example, **"hello name1"**. The quotation marks at the beginning and end of the AP group name occupy two characters in total. **NOTE** You can only use a command editor of the UTF-8 encoding format to edit Chinese characters.
waiting	Displays APs waiting for an upgrade.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After APs are upgraded on the AC, you can run this command to view the AP upgrade progress or AP information by upgrade status.

Example

Display upgrade progress of all APs.

```
<HUAWEI> display ap update status all
FT  : File Type
N : Next startup
---------------------------------------------------------------------------------------------------------------------------
------
ID    Name      AP Type           AP Group AP MAC        FT       Update Version        Last Update Time

```

Table 11-94 Description of the **display ap update status all** command output

Item	Description
ID	AP ID.
Name	AP name.
AP Type	AP type.
AP Group	AP group.
AP MAC	MAC address of an AP.
FT	Type of the AP upgrade file. **PATCH(N)** indicates that the patch is specified for next startup.
Update Version	Target version to which an AP is upgraded.
Last Update Time	Last end time when an AP is upgraded.
Update Status	AP upgrade status. For details about the upgrade status and its corresponding handling suggestions, see **Table 11-95**.

Table 11-95 AP upgrade status and handling suggestions

AP Upgrade Status	Description	Handling Suggestion
Waiting download	The AP is waiting for an upgrade.	No action is required.
downloading(progress: *x* %/*y*%)	*x*% indicates the download progress of the system software package, and *y*% indicates the progress of writing the system software package to the flash memory.	No action is required.
failed(AC global caching)	The upgrade failed. ● When an AP is downloading system software package during an in-service upgrade, the system displays this message if the AP starts automatic upgrade which triggers a new process for downloading the software package. ● When multiple RUs automatically upgrade at the same time, this message may also be displayed. **NOTE** In this situation, the actual RU upgrade result depends on that displayed in the **display ap update status all** command output.	Wait until the online upgrade is completed.
failed(alloc memory for file)	The upgrade failed because the AP failed to apply for memory resources.	Clear the memory of the AC, and ensure that the memory is sufficient for the AP upgrade.
failed(AP is updating now. Please wait.)	The AC delivers an upgrade instruction again when the AP is running an upgrade task.	The AP is upgrading. Wait until the upgrade is complete. If the status persists after 5 minutes, run the upgrade command again.

AP Upgrade Status	Description	Handling Suggestion
failed(AP type in the EFS mismatch)	The upgrade failed because the AP type in the EFS file trailer of the current AP version does not match the AP.	The upgrade file is incorrect. Replace the upgrade file.
failed(AP type mismatch with batch upgrade AP type)	The upgrade failed because the AP type is different from the batch upgrade AP type.	Upgrade the AC version. If the problem persists, contact technical support personnel.
failed(AP wait for fragmentation timeout)	The upgrade failed because the time that the AP waits for fragment data expired.	Check the network connection.
failed(block full)	The upgrade failed because the number of APs simultaneously upgraded in AC mode reaches the maximum.	The number of concurrent upgrades exceeds the maximum. Wait until the upgrade of other APs is complete.
failed(change to standby)	The upgrade failed due a revertive switchover failure.	Wait until the active/ standby switchover is complete.
failed(fail to download the file)	The upgrade failed because the system software failed to be downloaded.	Check whether the network connection is normal or the system software package exists.
failed(file content error)	The upgrade failed due to incorrect system software file contents.	The upgrade file is incorrect. Replace the upgrade file.
failed(file version inconsistent)	The upgrade failed because the AP type in the EFS file trailer does not match the AP type contained in the system software package name.	The upgrade file is incorrect. Replace the upgrade file or upgrade the AC to the latest version.
failed(invalid file name)	The upgrade failed because the name of the AP version file is incorrect.	Ensure that the file name of the software package meets the specified requirement.
failed(link down)	The upgrade failed because the AP failed to communicate with the AC.	Check the network connection.

AP Upgrade Status	Description	Handling Suggestion
failed(mode changed)	The upgrade failed because the AP upgrade mode is changed during the AP automatic upgrade.	This is a normal process. Perform the upgrade again.
failed(nospace in AP memory)	The upgrade failed because the AP memory resources were insufficient.	Ensure that the AP memory can support the upgrade.
failed(not receive update result)	The upgrade failed because the AC receives no AP upgrade result.	Check the network connection. If the network connection is normal, contact technical support personnel.
failed(over max upgrade time)	The upgrade failed because the upgrade duration exceeds the maximum upgrade time allowed.	Check the network connection. If the network connection is normal, contact technical support personnel.
failed(server password is too long)	The upgrade failed because the FTP/SFTP server password is too long.	Change the password of the FTP/SFTP server to a value with a length less than the maximum.
failed(read file)	The upgrade failed because no upgrade file is available in the flash memory.	Check the upgrade file.
failed(receive file failed)	The upgrade failed because fragments failed to be received.	Check the network connection. If the network connection is normal, contact technical support personnel.
failed(retransfer over times)	The upgrade failed because the number of fragment retransmissions exceeds the threshold.	Check the network connection. If the network connection is normal, contact technical support personnel.
failed(send first file failed)	The upgrade failed because the first fragment failed to be sent.	Check the network connection. If the network connection is normal, contact technical support personnel.
failed(other reason)	The upgrade failed due to an unknown error.	Contact technical support personnel.

AP Upgrade Status	Description	Handling Suggestion
failed(upgrade timeout)	The upgrade timed out and failed.	Check the network connection. If the network connection is normal, contact technical support personnel.
failed(user canceled)	The upgrade failed because the user canceled the upgrade.	No action is required.
failed(waited for next batch)	The upgrade failed. The AP has to wait for the next upgrade.	No action is required.
failed(write flash error)	The upgrade failed because the system software package failed to be written to the flash memory.	Contact technical support personnel.
failed(file changed)	The upgrade failed because the upgrade file was modified during the automatic upgrade.	This is a normal process. Wait for the next upgrade.
failed(age time out)	The upgrade failed because the state machine aged out.	Check the network connection. If the network connection is normal, contact technical support personnel.
succeed	The upgrade succeeded.	No action is required.
succeed(auto resetting)	The upgrade succeeded and the AP is being automatically restarted.	No action is required.
succeed(need reset)	The upgrade succeeded. The AP must be restarted.	No action is required.
succeed(resetting)	The upgrade succeeded and the AP is being manually restarted.	No action is required.
succeed(no need to update)	The upgrade succeeded. There is no need to upgrade the AP.	No action is required.
succeed(need mode switch)	The upgrade succeeded. The AP mode needs to be switched.	No action is required.

AP Upgrade Status	Description	Handling Suggestion
failed(send upgrade configuration)	The upgrade failed because the upgrade configuration failed to be sent.	Check the network connection. If the network connection is normal, contact technical support personnel.
failed(send upgrade request)	The upgrade failed because the upgrade request failed to be sent.	Check the network connection. If the network connection is normal, contact technical support personnel.
failed(upgrade configuration response error)	The upgrade failed because there was an error in the AP's upgrade response.	Contact technical support personnel.
failed(process upgrade filename)	The upgrade failed because the AC failed to process the upgrade file name.	Contact technical support personnel.
failed(cannot get AP type)	The upgrade failed because the AC failed to obtain the AP type.	Contact technical support personnel.
failed(analyze the version by upgrade filename)	The upgrade failed because the device failed to analyze the version number in the file name.	Contact technical support personnel.
failed(state transition check failed for the update module)	The upgrade failed because the AC failed to check the status transition of the upgrade module.	Contact technical support personnel.
failed(flash component change)	The upgrade failed because the flash model is not supported.	Replace the device with one that supports the new flash memory model or contact technical support personnel.
failed(Backing up the system software)	The upgrade failed because the system software is being synchronized from the main area to the standby area.	Wait until the synchronization between the active and standby areas is complete.

AP Upgrade Status	Description	Handling Suggestion
failed (incompatible hardware BOM version)	The upgrade failed because the AP hardware of the target version is incompatible with the BOM version.	The AP does not support downgrade. No action is required.
failed(patch checksum error)	The upgrade failed because of a patch checksum error.	Check the integrity of the patch file.
failed(patch file error)	The upgrade failed because of a patch file error.	Check the integrity of the patch file.
failed (patch active failed)	The upgrade failed because of a failure to activate the patch.	Check whether the patch and the software package match with each other.
failed(vrp patch process active failed)	The upgrade failed because of a failure to activate the patch on the control plane.	Contact technical support personnel.
failed(vfp patch active failed)	The upgrade failed because of a failure to activate the patch on the forwarding plane.	Contact technical support personnel.
failed(kernel patch actived)	The upgrade failed because of a failure to activate the kernel patch.	Contact technical support personnel.
failed(patch inner proc error)	The upgrade failed because of an internal patch processing failure.	Contact technical support personnel.
failed(wifi target chip patch active failed)	The upgrade failed because of a failure to activate the Wi-Fi chip patch.	Contact technical support personnel.
failed(the current AP version does not support patch updates)	The upgrade failed because the AP version does not support the patch upgrade.	No action is required.
failed(insufficient space on the AP flash memory)	The upgrade failed due to insufficient space on the AP's flash memory.	Delete unnecessary files from the flash memory.

AP Upgrade Status	Description	Handling Suggestion
failed(nospace in AC memory)	The upgrade failed because the AC memory resources were insufficient.	Upgrade or restart the AP during off-peak hours.
failed(patch version mismatch)	The upgrade failed because the patch version does not match the AP version.	Check the patch version.
failed(The current AP version does not support the change of the FTP/SFTP server port.)	The upgrade failed because the FTP/SFTP port number of the AP cannot be changed.	Use the default FTP/SFTP port for the upgrade.
failed(The AP or AP version does not support the HOUP-based upgrade)	The upgrade failed because the current AP or AP version does not support the HOUP upgrade mode.	Use FTP or SFTP to perform the upgrade.
failed(The FTP server does not support the REST command)	The upgrade failed because the FTP server does not support REST commands.	Replace the FTP server.
failed(The AP version does not support the configuration for specifying the patch to take effect upon the next startup)	The upgrade failed because the current AP version does not support the configuration for specifying the patch for next startup.	When installing the patch, do not specify the parameter **next-startup** in the command.
failed(AP type not config)	The AP type is different from the AP type specified for the batch upgrade.	Perform the upgrade again or contact technical support personnel.
failed(The rate of the optical module does not match)	The upgrade failed because the rate of the optical module does not match.	The AP does not support downgrade. No action is required.
-	The AP requires no upgrade.	No action is required.

11.2.85 display ap update status partition

Function

The **display ap update status partition** command displays information about channel-based partitions.

Format

display ap update status partition { **all** | **partition-id** *partition-id* }

Parameters

Parameter	Description	Value
all	Displays information about all channel-based partitions.	-
partition-id *partition-id*	Displays information about the channel-based partition with a specified ID.	The value is an integer that ranges from 0 to 255.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display ap update status partition** { **all** | **partition-id** *partition-id* } command displays information about the only that APs that need to be upgraded. The APs that need to be upgraded refer to those whose target version files have been loaded to the standby area and are waiting for reset.

Example

Display information about channel-based partition **1**.

```
<HUAWEI> display ap update status partition partition-id 1
PID : Partition ID
CH : Channel
----------------------------------------------------------------------------------------------------------------------------
----------------
PID  CH  AP ID  Name   AP Type          AP Group   AP MAC         Update Version     Last Update Time
Update Status
----------------------------------------------------------------------------------------------------------------------------
----------------
1    36  0      hw0    AirEngine6760R-51  default    00e0-fc76-e320  V200R019C10B035    2019/08/22 18:51
succeed(need reset)
2    100 1      hw1    AirEngine6760R-51  default    00e0-fc76-e340  V200R019C10B035    2019/08/22
18:51   succeed(need reset)
2    100 2      hw2    AirEngine6760R-51  default    00e0-fc76-e360  V200R019C10B035    2019/08/22
```

```
18:51   succeed(need reset)
255  -   4      hw4    AirEngine6760R-51  default    00e0-fc76-e3a0  V200R019C10B035    2019/08/22 18:51
succeed(need reset)
255  -   5      hw5    AirEngine6760R-51  default    00e0-fc76-e3c0  V200R019C10B035    2019/08/22 18:51
succeed(need reset)
------------------------------------------------------------------------------------------------------------------------
----------------
Total: 5
```

Table 11-96 Description of the **display ap update status partition** command output

Item	Description
PID	Channel-based partition ID. The value **255** indicates that a channel-based partition that does not work properly.
CH	Channel.
AP ID	AP ID.
Name	AP name.
AP Type	AP type.
AP Group	AP group.
AP MAC	AP's MAC address.
Update Version	Target version to which an AP is upgraded.
Last Update Time	Last end time when an AP is upgraded.
Update Status	AP upgrade status. For details about the upgrade status and its corresponding handling suggestions, see **Table 11-95**.

11.2.86 display ap username

Function

The **display ap username** command displays information about users logged in to the AP.

Format

display ap username

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ap username** command to view information about users logged in to the AP.

Example

Display information about users logged in to the AP.

```
<HUAWEI> display ap username
----------------------------------------------------------------------------
AP username: admin
AP password: ******
Password control                  : Disable
Is original password              : YES
Password set time                  : 1970-01-01 00:00:00
  Password expiration              : Disable (90 days)
  Password history                : Disable  (5)
  Password alert before expiration : 30 days
  Password alert original          : Enable
  Password expired                : NO
----------------------------------------------------------------------------
```

Table 11-97 Description of the **display ap username** command output

Item	Description
AP username	User name for logging in to the AP. To configure this parameter, run the **ap username** command.
AP password	Password for logging in to the AP. To configure this parameter, run the **ap username** command.
Password control	Whether to enable the password policy function.
Is original password	Whether a password is the initial password.
Password set time	Password setting time
Password expiration	Password validity period.
Password history	Number of historical passwords recorded for each user.
Password alert before expiration	Number of password expiration prompt days.

Item	Description
Password alert original	Whether to enable the initial password change prompt function.
Password expired	Whether a password expires.

11.2.87 display ap version

Function

The **display ap version** command displays version information about APs.

Format

display ap version { **all** | { **ap-group** *ap-group-name* | **version-name** *version-name* } * }

Parameters

Parameter	Description	Value
all	Displays version information about all APs.	-
ap-group *ap-group-name*	Displays version information about all APs of a specified AP group.	The AP group must exist.
version-name *version-name*	Displays version information about a specified AP.	The value is string of 11 to 17 characters, in the format of **VxxxRxxxCxxx** or **VxxxRxxxCxxxSPCxxx**, for example, V200R006C00 or V200R005C10SPC200.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ap version** command to check version information about APs.

Example

Display version information about all APs.

```
<HUAWEI> display ap version all
Backward compatible versions : V200R020 V200R021 V200R022
The forward compatible versions depend on the AP. For the specific versions, log in to the AP and run the
"display system-information" command.
--------------------------------------------------------------------------------------------
ID   Name           Group  Type                 Version          PatchVersion    state
--------------------------------------------------------------------------------------------
0    00e0-fc76-e360 default AirEngine8760-X1-PRO   V200R023C00      -              normal
--------------------------------------------------------------------------------------------
Total: 1
```

Table 11-98 Description of the **display ap version** command output

Item	Description
Backward compatible versions	Backward compatible version.
The forward compatible versions depend on the AP. For the specific versions, log in to the AP and run the "display system-information" command.	The forward compatible versions depend on the AP. You can log in to the AP and run the **display system-information** command to query the forward compatible versions.
ID	ID.
Name	AP name.
Group	AP group name.
Type	AP type.
Version	AP version name.
PatchVersion	AP patch version.
state	AP state. For details, see **Table 11-5**.

Table 11-99 AP state list

AP State	Description	Possible Cause	Handling Suggestion
commit-failed (cmtfa)	WLAN service configurations fail to be delivered to an AP after the AP goes online on an AC.	After an AP goes online on the AC, WLAN service configurations are performed for the AP. If the link between the AP and AC is disconnected or the peer end has no response, the AP enters the commit-failed state.	Check the network connection.
committing (cmt)	WLAN service configurations are being delivered to an AP after the AP goes online on an AC.	After an AP goes online on the AC, WLAN service configurations are being delivered to the AP. During this process, the AP is in committing state.	This is a normal state, and no action is required.
config (cfg)	WLAN service configurations are being delivered to an AP when the AP is going online on an AC.	After an AP establishes a link with the AC, WLAN service configurations are delivered to the AP. During this process, the AP is in config state.	This is a normal state, and no action is required.
config-failed (cfgfa)	WLAN service configurations fail to be delivered to an AP when the AP is going online on an AC.	After an AP establishes a link with the AC, WLAN service configurations are delivered to the AP. If the configuration delivery fails due to various reasons (such as link disconnection), the AP enters the config-failed state.	Check the network connection.
download (dload)	An AP is in upgrade state.	When an AP is performing an upgrade, it enters the download state.	When the AP upgrade is complete, check the AP state.

AP State	Description	Possible Cause	Handling Suggestion
fault	An AP fails to go online.	An AP fails to go online, which is usually caused by the following: ● The AP fails to obtain an IP address or obtains an incorrect IP address. ● The network between the AP and AC is faulty. ● The AP fails to be authenticated. ● The number of APs on an AC has reached the maximum value. ● The AP is faulty. ● In dual-link cold backup or N+1 backup scenario, if the link between the active and standby ACs is established properly, an AP that goes online on the active AC is in fault state on the standby AC.	Handle the AP online failure. For details, see **An AP Fails to Go Online on the AC** in the *Troubleshooting Guide*.

AP State	Description	Possible Cause	Handling Suggestion
idle	It is the initialization state of an AP before it establishes a link with the AC for the first time.	When an AP has not established a CAPWAP link with the AC, the MAC address and SN of an AP that is added offline are different from the actual MAC address and SN of the AP, or the AC cannot manage an AP due to license resource insufficiency, the AP enters the idle state.	Perform the following operations. Check whether the AP is connected to the network. If the AP connection is normal, go to next step. Check the MAC address and SN of the AP that is added offline are different from the actual MAC address and SN of the AP. If not, perform the following operations: 1. Run the **display ap all** command to check AP information. 2. Run the **undo ap** { **ap-name** *ap-name* | **ap-id** *ap-id* | **ap-mac** *ap-mac* | **ap-group** *group-name* | **all** } command to delete the AP. 3. Run the **ap-id** *ap-id* [[**type-id** *type-id* | **ap-type** *ap-type*] { **ap-mac** *ap-mac* | **ap-sn** *ap-sn* | **ap-mac** *ap-mac* **ap-sn** *ap-sn* }] or **ap-mac** *ap-mac* [**type-id** *type-id* | **ap-type** *ap-type*] [**ap-id** *ap-id*] [**ap-sn** *ap-sn*] command to add correct AP information. If the fault persists, expand the license capacity. Note that RUs managed by the AC do not occupy

AP State	Description	Possible Cause	Handling Suggestion
			license resources of the AC.
name-conflicted (namec)	The name of an AP conflicts with that of an existing AP.	The name of an AP conflicts with the name of another AP that has been online on the same AC.	Run the **ap-rename ap-id** *ap-id* **new-name** *ap-new-name* command to change the AP name.
normal (nor)	An AP is working properly.	An AP successfully goes online on an AC.	This is a normal state, and no action is required.
standby (stdby)	An AP is in normal state on the standby AC.	In the HSB scenario, if the link between the master and backup ACs is established properly, an AP is in standby state on the backup AC and in normal state on the master AC.	This is a normal state, and no action is required.
ver-mismatch (vmiss)	The version of an AP does not match that of an AC on which the AP is about to go online.	The versions of the AP and AC do not match.	Log in to Huawei technical support website and download the release notes. Based on the version mapping, upgrade the AP or AC to the matching version. - Enterprise technical support website: **https://support.huawei.com/enterprise** - Carrier technical support website: **https://support.huawei.com**

AP State	Description	Possible Cause	Handling Suggestion
countryCode-mismatch (cmiss)	The country codes of the AP and AC do not match.	The AP's current version does not support the country code configured on the AC. The country code of the AP is locked, and the country code configured on the AC is not supported.	The AP does not support the country code. Upgrade the AP or modify the country code configuration on the AC. The country code of the AP is locked. Replace the AP or change the country code on the AC to be the same as that of the AP.
type-mismatch (tmiss)	The AP type does not match that configured on the AC.	The AP type configured on the AC did not match the actual AP type.	Change the AP type configured on the AC.
unauth	An AP is not authenticated.	The AP fails to be authenticated.	Run the **display ap unauthorized record** command to query authenticated APs. Run the **ap-confirm** command to confirm unauthenticated APs and allow them to go online.

11.2.88 display ap wired-port

Function

The **display ap wired-port** command displays AP wired interface configuration.

Format

display ap wired-port *interface-type interface-number* { **ap-name** *ap-name* | **ap-id** *ap-id* }

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an AP's wired interface.	The interface type and number need to be selected according to the actual device.
ap-name *ap-name*	Specifies an AP name.	The AP name must exist.
ap-id *ap-id*	Specifies an AP ID.	The AP ID must exist.

------------------------------------------------------------------------------------------
-------------------------------------------------------------------------------
```

Table 11-100 Description about the **display ap wired-port gigabitethernet 0 ap-name** command output

Item	Description
Wired port number	Number of the wired interface.
Wired port type	Type of the wired interface.
Wired port description	Description of the wired interface.
Wired port workmode	Mode of the wired interface.
Wired port STP	Whether STP is enabled on the wired interface.
Wired port user isolate	Whether user isolation is enabled on the wired interface.
Wired port PVID VLAN	PVID of the wired interface.
Wired port VLAN tagged	VLAN to which the interface is added in tagged mode.
Wired port VLAN untagged	VLAN to which the interface is added in untagged mode.
Wired port Eth-trunk	Trunk ID to which the wired interface is bound.
Wired port LLDP	Whether LLDP is enabled on the wired interface.
Wired port LLDP basic TLV management address	TLV of the management IP address of the wired interface.
Wired port LLDP basic TLV port description	TLV of wired interface description.
Wired port LLDP basic TLV system capability	TLV of the wired interface capability set.
Wired port LLDP basic TLV system description	TLV of wired interface system description.
Wired port LLDP basic TLV system name	TLV of the wired interface system name.
Wired port CRC warn switch	Whether to enable the alarm function for CRC errors on the wired interface.
Wired port CRC warn high threshold	Upper alarm threshold for CRC errors on the wired interface.

Item	Description
Wired port CRC warn low threshold	Lower alarm threshold for CRC errors on the wired interface.
Traffic Type	ACL-based packet filtering and re-marking implemented by the AP wired port. ● traffic-filter ● traffic-remark
Direction	Incoming or outgoing packets.
AppliedRecord	IPv4/IPv6/L2 packet filtering and re-marking based on ACLs.
RemarkType	Protocol type. ● dscp ● dot1p
RemarkValue	Protocol type value. ● dscp: 0-63 ● dot1p: 0-7

Display the Eth-Trunk interface configuration of the AP named **example**.

```
<HUAWEI> display ap wired-port eth-trunk 0 ap-name example
------------------------------------------------------------------------------
Eth-trunk ID                 : 0
Eth-trunk description        : -

RemarkValue	Protocol type value. ● dscp: 0-63 ● dot1p: 0-7

11.2.89 display ap-pki-profile

Function

The **display ap-pki-profile** command displays information about an AP PKI realm profile.

Format

display ap-pki-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays information about all AP PKI realm profiles.	-
name *profile-name*	Displays information about a specified AP PKI realm profile.	The AP PKI realm profile must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command displays information about an AP PKI realm profile, including the number of times the profile is referenced, PKI realms in the profile, and certificate files in the PKI realms.

Example

Display information about all AP PKI realm profiles.

```
<HUAWEI> display ap-pki-profile all
Total: 2
------------------------------------------------------------------------
Profile name                    Reference
------------------------------------------------------------------------
default                         5
mytest                          2
------------------------------------------------------------------------
```

Display detailed information about a specified AP PKI realm profile.

Table 11-102 Description of the **display ap-pki-profile** command output

Item	Description
Profile name	Name of an AP PKI realm profile.
Reference	Number of times an AP PKI realm profile is referenced.
PKI realmx name	Name of a PKI realm.
ca file format	CA certificate format.
ca file name	Name of a CA certificate file.
local file format	Format of a local certificate file.

Item	Description
local file name	Name of a local certificate file.
private key file format	Format of a private key file.
private key file name	Name of a private key file.
private key file password	Decryption password of a private key file.
CRL file	Name of a CRL file.

11.2.90 display ap-system-profile

Function

The **display ap-system-profile** command displays reference and configuration information about an AP system profile.

Format

display ap-system-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays information about all AP system profiles.	-
name *profile-name*	Displays information about a specified AP system profile.	The AP system profile must exist.

Views

Table 11-104 Description of the **display ap-system-profile name** *profile-name* command output

Item	Description
AC priority	AC priority. To configure this parameter, run the **priority** command.
Protect AC IP address	IP address of the standby AC. To configure this parameter, run the **protect-ac** command.
Primary AC	IP address of the primary AC. To configure this parameter, run the **primary-access** command.
Backup AC	IP address of the backup AC. To configure this parameter, run the **backup-access** command.
AP management VLAN	Management VLAN for APs To configure this parameter, run the **management-vlan** command.

Item	Description
Keep service	Whether service holding upon CAPWAP link disconnection is enabled. ● enable: This function is enabled. ● disable: This function is disabled. To configure this parameter, run the **keep-service enable** command.
Keep service allow new access	Whether new STAs using the open, WEP, or WPA/WPA2-PSK security policy are allowed to go online when an AP is offline. ● enable: This function is enabled. ● disable: This function is disabled. To configure this parameter, run the **keep-service enable allow new-access** command.
Keep service allow new access no auth	Whether the offline AP allows access of new STAs using Portal or MAC address authentication. ● enable: This function is enabled. ● disable: This function is disabled. To configure this parameter, run the **keep-service enable allow new-access no-auth** command.
Temporary management switch	Whether the offline management VAP and antenna alignment VAP are enabled for APs. ● enable: The functions are enabled. ● disable: The functions are disabled. To configure this parameter, run the **temporary-management disable (AP system profile view)** command.
Card connect type	Communication connection type between IoT cards and APs. To configure this parameter, run the **card connect-type** command.
Temporary management psk	PSK of offline management VAP and antenna alignment VAP on APs. To configure this parameter, run the **temporary-management psk** command.

Item	Description
Mesh role	Mesh role. To configure this parameter, run the **mesh-role** command.
Mesh route aging time(s)	Aging time of a Mesh route. To configure the parameter, run the **mesh-route aging-time** command.
STA access mode	STA access mode. To configure this parameter, run the **sta-access-mode** command.
STA whitelist profile	Name of a STA whitelist profile referenced by an AP system profile. To configure this parameter, run the **sta-access-mode** command.
STA blacklist profile	Name of a STA blacklist profile referenced by an AP system profile. To configure this parameter, run the **sta-access-mode** command.
EAPOL start mode	EAPoL-Start packet encapsulation mode. To configure this parameter, run the **eapol-start dest-address transform-to** command.
EAPOL start transform	EAPoL-Start packet conversion mode. To configure this parameter, run the **eapol-start dest-address transform-condition** command.
EAPOL response mode	EAPoL-Response packet encapsulation mode. To configure this parameter, run the **eapol-response dest-address transform-to** command.
EAPOL response transform	EAPoL-Response packet conversion mode. To configure this parameter, run the **eapol-response dest-address transform-condition** command.
AP LLDP message transmission delay time(s)	Delay for an AP to send LLDP packets to neighbors. To configure this parameter, run the **lldp message-transmission delay (AP system profile view)** command.

Item	Description
AP LLDP message transmission hold multiplier	Hold time multiplier of AP information on neighbors. To configure this parameter, run the **lldp message-transmission hold-multiplier (AP system profile view)** command.
AP LLDP message transmission interval time(s)	Interval at which an AP sends LLDP packets to neighbors. To configure this parameter, run the **lldp message-transmission interval (AP system profile view)** command.
AP LLDP restart delay time(s)	Delay in re-enabling LLDP. To configure this parameter, run the **lldp restart-delay** command.
AP LLDP admin status	LLDP mode on an AP. ● tx: The AP sends but does not receive LLDP packets. ● rx: The AP receives but does not send LLDP packets. ● txrx: The AP sends and receives LLDP packets. To configure this parameter, run the **lldp admin-status** command.
AP LLDP report interval time(s)	Interval at which an AP reports LLDP neighbor information to an AC. To configure this parameter, run the **lldp report-interval** command.
AP LLDP report enable	Whether an AP is enabled to report information about its LLDP neighbors. To configure this parameter, run the **lldp report enable** command.
AP device high temperature threshold (degree C)	Upper device temperature alarm threshold of an AP. To configure this parameter, run the **high-temperature threshold** command.
AP environment high temperature threshold (degree C)	Upper ambient temperature alarm threshold of an AP. To configure this parameter, run the **high-temperature threshold** command.

Item	Description
AP CPU high temperature threshold (degree C)	Upper CPU temperature alarm threshold of an AP. To configure this parameter, run the **high-temperature threshold** command.
AP NP high temperature threshold (degree C)	Upper NP module temperature alarm threshold of an AP. To configure this parameter, run the **high-temperature threshold** command.
AP device low temperature threshold (degree C)	Lower device temperature alarm threshold of an AP. To configure this parameter, run the **low-temperature threshold** command.
AP environment low temperature threshold (degree C)	Lower ambient temperature alarm threshold of an AP. To configure this parameter, run the **low-temperature threshold** command.
AP CPU low temperature threshold (degree C)	Lower CPU temperature alarm threshold of an AP. To configure this parameter, run the **low-temperature threshold** command.
AP NP low temperature threshold (degree C)	Lower NP module temperature alarm threshold of an AP. To configure this parameter, run the **low-temperature threshold** command.
AP CPU usage threshold(%)	CPU usage alarm threshold of an AP. To configure this parameter, run the **cpu-usage threshold** command.
AP memory usage threshold(%)	Memory usage alarm threshold of an AP. To configure this parameter, run the **memory-usage threshold** command.
AP disk usage threshold(%)	Disk usage alarm threshold of an AP. To configure this parameter, run the **disk-usage threshold** command.

Item	Description
Alarm restriction	Alarm suppression status of an AP. To configure this parameter, run the **alarm-restriction disable** command.
Alarm restriction period(s)	Alarm suppression period of an AP. To configure this parameter, run the **alarm-restriction period** command.
Log server IP address	IP address of the log server. To configure this parameter, run the **log-server** command.
Log server Port	Port number of the log server. To configure this parameter, run the **log-server** command.
Log record level	Level of AP logs to be backed up. To configure this parameter, run the **log-record-level** command.
Ethernet port MTU(byte)	MTU of Ethernet interfaces. To configure this parameter, run the **mtu** command.
Telnet	Whether AP Telnet login is enabled. To configure this parameter, run the **telnet enable** command.
STelnet server	Whether the STelnet server function of an AP is enabled. To configure this parameter, run the **stelnet server disable** command.
SFTP server	SFTP server status of an AP. To configure this parameter, run the **sftp server disable** command.
Console	Whether AP console port login is enabled. To configure this parameter, run the **console disable** command.
STA ARP-ND Proxy before-assoc	Whether an AP is enabled to send ARP/ND proxy packets for a STA before the STA is successfully associated. To configure this parameter, run the **sta arp-nd-proxy before-assoc** command.

Item	Description
Antenna output mode	Output mode of the AP's 2.4 GHz or 5 GHz antenna. To configure this parameter, run the **antenna-output** command.
Led	Whether AP indicators are allowed to turn on. - on: The AP indicators are allowed to turn on. - off: The AP indicators are forbidden to turn on. To configure this parameter, run the **led off** command.
Led off time range	Time range within which the AP indicators are forbidden to turn on. To configure this parameter, run the **led off** command.
DHCP client option12	AP information contained in Option 12 carried in DHCP messages reported by an AP. - ap-name: AP name contained in Option 12 carried in DHCP messages reported by an AP. - ap-type ap-mac: AP type and MAC address contained in Option 12 carried in DHCP messages reported by an AP. - disable: The Option 12 is not carried in DHCP messages reported by an AP. To configure this parameter, run the **dhcp client option12** command.
Console ble-mode	Bluetooth-based serial port login mode. - dynamic - persistent - disable: The Bluetooth-based serial port login function is disabled. To configure this parameter, run the **console ble-mode (AP system profile view)** command.

Item	Description
Report disassoc request	Whether an AP is enabled to report disassociation request packets of STAs to the AC. To configure this parameter, run the **report-disassoc-request disable** command.
Sample time(s)	AP's sampling interval. To configure this parameter, run the **sample-time** command.
Dynamic blacklist aging time(s)	Aging time of a dynamic blacklist entry. To configure this parameter, run the **dynamic-blacklist aging-time** command.
MPP active reselection	Active MPP reselection. To configure this parameter, run the **mpp-active-reselection enable** command.
AP report to	Mode in which an AP reports spectrum data. ● server: The AP reports spectrum data to a spectrum server directly. ● AC: The AP reports spectrum data to a spectrum server via the AC. To configure this parameter, run the **spectrum-analysis server** command.
Server IP	IP address of the spectrum server. To configure this parameter, run the **spectrum-analysis server** command.
Server port	Port number (UDP) of the spectrum server. To configure this parameter, run the **spectrum-analysis server** command.
AC port	Port number used by the AC to receive spectrum data (in UDP packets) from the AP. To configure this parameter, run the **spectrum-analysis server** command.

Item	Description
Device aging-time(minute)	Aging time of non-Wi-Fi device data on an AC. To set the aging time, run the **spectrum-analysis non-wifi-device aging-time** command.
PoE max power(mW)	Maximum output power of the central AP. To configure this parameter, run the **poe max-power (AP system profile view)** command.
PoE power reserved(%)	Percentage of reserved PoE power to the available PoE power on the central AP. To configure this parameter, run the **poe power-reserved (AP system profile view)** command.
PoE power threshold(%)	Alarm threshold of PoE power consumption percentage on the central AP. To configure this parameter, run the **poe power-threshold (AP system profile view)** command.
PoE af inrush	PoE standard of the central AP. To configure this parameter, run the **poe af-inrush enable (AP system profile view)** command.
PoE high inrush	Whether the central AP is enabled to allow high inrush current during power-on. To configure this parameter, run the **poe high-inrush enable (AP system profile view)** command.
Group address start	Start multicast group address. To configure this parameter, run the **igmp-snooping group-bandwidth (AP system profile view)** command.
Group address end	End multicast group address. To configure this parameter, run the **igmp-snooping group-bandwidth (AP system profile view)** command.

Item	Description
Bandwidth(kbps)	Bandwidth of global multicast groups on an AP. To configure this parameter, run the **igmp-snooping group-bandwidth (AP system profile view)** command.
USB	Whether USB is enabled. To configure this parameter, run the **usb enable (AP system profile view)** command.
SSH config	SSH configurations.
Client first time	Whether initial authentication is enabled on the SSH client. To configure this parameter, run the **ssh client first-time enable (AP system profile view)** command.
User interface vty X	VTY user interface *X*. The value of *X* is an integer that ranges from 0 to 4.
Idle timeout	Timeout period of user connections. To configure this parameter, run the **user-interface vty idle-timeout** command.
Screen length	Number of lines on each terminal screen. To configure this parameter, run the **user-interface vty screen-length** command.
ACL inbound	ACL that restricts STAs with a specified IPv4 address or within a specified IPv4 address segment from logging in to the device. To configure this parameter, run the **user-interface vty acl** command.
ACL outbound	ACL that restricts IPv4 STAs who have logged in to the device from logging in to other devices. To configure this parameter, run the **user-interface vty acl** command.

Item	Description
ACL ipv6 inbound	ACL that restricts STAs with a specified IPv6 address or within a specified IPv6 address segment from logging in to the device. To configure this parameter, run the **user-interface vty acl** command.
ACL ipv6 outbound	ACL that restricts IPv6 STAs who have logged in to the device from logging in to other devices. To configure this parameter, run the **user-interface vty acl** command.
AC protect link switch mode	Active/standby link switchover mode. To configure this parameter, run the **ac protect link-switch mode** command.
AC protect link switch packet loss echo probe time	Number of Echo probe packets sent within a statistics collection interval. To configure this parameter, run the **ac protect link-switch packet-loss echo-probe-time** command.
AC protect link switch packet loss start threshold(%)	Packet loss rate start threshold for an active/standby link switchover. To configure this parameter, run the **ac protect link-switch packet-loss** command.
AC protect link switch packet loss gap threshold(%)	Packet loss rate difference threshold for an active/standby link switchover. To configure this parameter, run the **ac protect link-switch packet-loss** command.
Traffic optimize broadcast suppression ARP	Whether the suppression function is enabled for ARP packets. To configure this parameter, run the **traffic-optimize broadcast-suppression disable (AP system profile view)** command.
Traffic optimize broadcast suppression IGMP	Whether the suppression function is enabled for IGMP packets. To configure this parameter, run the **traffic-optimize broadcast-suppression disable (AP system profile view)** command.

Item	Description
Traffic optimize broadcast suppression ND	Whether the suppression function is enabled for ND packets. To configure this parameter, run the **traffic-optimize broadcast-suppression disable (AP system profile view)** command.
Traffic optimize broadcast suppression DHCP	Whether the suppression function is enabled for DHCP packets. To configure this parameter, run the **traffic-optimize broadcast-suppression disable (AP system profile view)** command.
Traffic optimize broadcast suppression DHCPv6	Whether the suppression function is enabled for DHCPv6 packets. To configure this parameter, run the **traffic-optimize broadcast-suppression disable (AP system profile view)** command.
Traffic optimize broadcast suppression MDNS	Whether the suppression function is enabled for mDNS packets. To configure this parameter, run the **traffic-optimize broadcast-suppression disable (AP system profile view)** command.
Traffic optimize broadcast suppression other broadcast	Whether the suppression function is enabled for broadcast packets other than ARP, DHCP, DHCPv6, and ND packets. To configure this parameter, run the **traffic-optimize broadcast-suppression disable (AP system profile view)** command.
Traffic optimize broadcast suppression other multicast	Whether the suppression function is enabled for multicast packets other than IGMP and mDNS packets. To configure this parameter, run the **traffic-optimize broadcast-suppression disable (AP system profile view)** command.
Traffic optimize broadcast suppression ARP rate limit(pps)	Rate limit threshold for ARP packets. To configure this parameter, run the **traffic-optimize broadcast-suppression rate-threshold (AP system profile view)** command.

Item	Description
Traffic optimize broadcast suppression IGMP rate limit(pps)	Rate limit threshold for IGMP packets. To configure this parameter, run the **traffic-optimize broadcast-suppression rate-threshold (AP system profile view)** command.
Traffic optimize broadcast suppression ND rate limit(pps)	Rate limit threshold for ND packets. To configure this parameter, run the **traffic-optimize broadcast-suppression rate-threshold (AP system profile view)** command.
Traffic optimize broadcast suppression DHCP rate limit(pps)	Rate limit threshold for DHCP packets. To configure this parameter, run the **traffic-optimize broadcast-suppression rate-threshold (AP system profile view)** command.
Traffic optimize broadcast suppression DHCPv6 rate limit(pps)	Rate limit threshold for DHCPv6 packets. To configure this parameter, run the **traffic-optimize broadcast-suppression rate-threshold (AP system profile view)** command.
Traffic optimize broadcast suppression MDNS rate limit(pps)	Rate limit threshold for mDNS packets. To configure this parameter, run the **traffic-optimize broadcast-suppression rate-threshold (AP system profile view)** command.
Traffic optimize broadcast suppression other broadcast rate limit(pps)	Rate limit threshold for broadcast packets other than ARP, DHCP, DHCPv6, and ND packets. To configure this parameter, run the **traffic-optimize broadcast-suppression rate-threshold (AP system profile view)** command.
Traffic optimize broadcast suppression other multicast rate limit(pps)	Rate limit threshold for multicast packets other than IGMP and mDNS packets. To configure this parameter, run the **traffic-optimize broadcast-suppression rate-threshold (AP system profile view)** command.

Item	Description
Service-experience-analysis monitor interval(s)	Sampling interval for SEA-based application monitoring. To configure this parameter, run the **service-experience-analysis monitor interval** command.
Wmi server profile	WMI profile bound to the AP system profile. ● Index 1: WMI profile with index 1 ● Index 2: WMI profile with index 2 To configure this parameter, run the **wmi-server (AP system profile view)** command.
Broadcast suppression auto-detect packets(pps)	Rate limit threshold of broadcast packets. To configure this parameter, run the **broadcast-suppression auto-detect (AP system profile view)** command.
Multicast suppression auto-detect packets(pps)	Rate limit threshold of multicast packets. To configure this parameter, run the **multicast-suppression auto-detect (AP system profile view)** command.
Unicast suppression auto-detect packets(pps)	Rate limit threshold of unknown unicast packets. To configure this parameter, run the **unicast-suppression auto-detect (AP system profile view)** command.
Station connectivity-detect switch	Whether STA connectivity check is enabled. To configure this parameter, run the **station connectivity-detect disable** command.
Power force work-mode	Power supply mode of an AP. To configure this parameter, run the **power force work-mode** command.
NP fast-forwarding switch	Whether the NP fast forwarding function is enabled. To configure this parameter, run the **np fast-forwarding disable (AP system profile view)** command.

Item	Description
NP CAPWAP reassembly switch	Whether the NP CAPWAP reassembly function is enabled. To configure this parameter, run the **np capwap-reassembly (AP system profile view)** command.
Radio mode	Radio mode of an AP. To configure this parameter, run the **radio-mode** command.
CPU defend Packet type Rate limit Type	Rate limit for packets sent by an AP to the CPU. To configure these parameters, run the **cpu-defend packet-type** command. If this command is not configured, these parameters are not displayed in the command output. ● Packet type: indicates the protocol type of packets. ● Rate limit: indicates the rate limit. ● Type: indicates the packet type (wired or wireless).
Terminal identify	Whether the terminal identification 2.0 function is enabled. To configure this parameter, run the **terminal-identify disable** command. ● enable: This function is enabled. ● disable
S-IPFPM max user flow	Maximum number of iPCA 2.0 measurement flows for each user. To configure this parameter, run the **s-ipfpm measure max-user-flow** command.
Local management switch	Whether the AP local management function is enabled. To configure this parameter, run the **local-management** command.
Local management IPv4 address	AP local management address. To configure this parameter, run the **local-management ip-address** command.
Service-tunnel-profile	Name of the bound service tunnel profile.

Item	Description
Distribute mode switch	Whether the distributed AP network collaboration function is enabled. To configure this parameter, run the **distribute-mode enable** command.
Self-healing-reset timeout(h)	Time threshold for an AP to restart for self-healing. To configure this parameter, run the **ap-keep-online self-healing-reset** command.
AP keep online switch	Whether the AP always-online function is enabled. To configure this parameter, run the **ap-keep-online disable** command.

11.2.91 display ap-type

Function

The **display ap-type** command displays AP type information.

Format

display ap-type { **all** | **id** *type-id* | **type** *ap-type* }

Parameters

Parameter	Description	Value
all	Displays all the built-in AP types on the device.	-
id *type-id*	Specifies an AP type ID.	The AP type ID must exist.
type *ap-type*	Specifies an AP type name.	The AP type name must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view all the built-in AP types on the device and information about APs of the specified type.

Example

Display all the built-in AP types on the device.

```
<HUAWEI> display ap-type all
--------------------------------------------------------------------------------
ID     Type                          Configuration method
--------------------------------------------------------------------------------
......
```

Table 11-105 Description of the **display ap-type all** command output

Item	Description
ID	AP ID.
Type	AP type. The support for AP types depends on device models. For the mapping between AP types and IDs, see the tab page "AP Type Names and IDs" in **Quick Reference for WLAN AP Version Mapping and Models**.
Configuration method	AP type configuration method. • default: The AP type is registered during initialization. • configure(init): The AP type is added using a command, and no APs of such type have been online. • configure(normal): The AP type is added using a command, and the AC has synchronized AP type information from the AP.

Display the AP type with a specified AP type ID.

```
<HUAWEI> display ap-type id 125
------------------------------------------------------------------------------------
Type                                  : AirEnginexxxx

Table 11-106 Description of the **display ap-type id** command output

Item	Description
Type	AP type.
AP wired port number	Number of wired interfaces.
AP wired port 0 type	Type of wired interfaces.
AP Eth-Trunk number	Number of Eth-Trunk interfaces.
Radio number	Number of radios.
Radio 0 type	Type of the radio. The value 0 indicates the radio ID.
Maximal spatial streams	Maximum number of spatial streams on the radio.
Maximal antenna number	Maximum number of antennas on the radio.

Item	Description
Maximal VAP number	Maximum number of VAPs on the radio.
Antenna gain	Antenna gain of the radio, in dB. When the antenna gain of an AP is not an integer, the AC rounds the value off and delivers the integer antenna gain. For example, if the 2.4 GHz antenna gain of an AP is 2.5 dB, the 2.4 GHz antenna gain of 3 dB is displayed on the AC.
Frequency switching	Whether the radio can be switched.
Supported frequency	Supported frequency band.
Dual-5G high/low band support	Working frequency band of the 5 GHz radio. ● Low band (36-64): The 5 GHz radio works at a low frequency band. ● High band (100-165): The 5 GHz radio works at a high frequency band. ● All band (36-165): The 5 GHz radio works at any frequency band.
Maximum station number	Maximum number of supported STAs.
AP device high temperature threshold (degree C)	Upper device temperature alarm threshold of an AP. **NOTICE** This parameter is not displayed for the following models: AirEngine 8760-X1-PRO, AirEngine 6760-X1, AirEngine 6760-X1E, AirEngine 5760-51, AirEngine 5760-22W, AirEngine 5760-22WD, AirEngine 8760R-X1, AirEngine 8760R-X1E, AirEngine 6760R-51, AirEngine 6760R-51E.
AP environment high temperature threshold (degree C)	Upper ambient temperature alarm threshold of an AP. **NOTICE** This parameter is displayed only for the following models: AirEngine 8760-X1-PRO, AirEngine 6760-X1, AirEngine 6760-X1E, AirEngine 5760-51, AirEngine 5760-22W, AirEngine 5760-22WD, AirEngine 8760R-X1, AirEngine 8760R-X1E, AirEngine 6760R-51, AirEngine 6760R-51E, AirEngine central APs.

Item	Description
AP CPU high temperature threshold (degree C)	Upper CPU temperature alarm threshold of an AP. **NOTICE** This parameter is displayed only for the following models: AirEngine 8760-X1-PRO, AirEngine 6760-X1, AirEngine 6760-X1E, AirEngine 5760-51, AirEngine 5760-22W, AirEngine 5760-22WD, AirEngine 8760R-X1, AirEngine 8760R-X1E, AirEngine 6760R-51, AirEngine 6760R-51E, AirEngine 9700D-M.
AP NP high temperature threshold (degree C)	Upper NP module temperature alarm threshold of an AP. **NOTICE** This parameter is displayed only for the AirEngine 9700D-M.
AP IRF high temperature threshold (degree C)	Upper IRF temperature alarm threshold of an AP. **NOTICE** This parameter is displayed only for the following models: AirEngine 8760-X1-PRO, AirEngine 6760-X1, AirEngine 6760-X1E, AirEngine 5760-51, AirEngine 5760-22W, AirEngine 5760-22WD, AirEngine 8760R-X1, AirEngine 8760R-X1E, AirEngine 6760R-51, AirEngine 6760R-51E.
AP device low temperature threshold (degree C)	Lower device temperature alarm threshold of an AP. **NOTICE** This parameter is not displayed for the following models: AirEngine 8760-X1-PRO, AirEngine 6760-X1, AirEngine 6760-X1E, AirEngine 5760-51, AirEngine 5760-22W, AirEngine 5760-22WD, AirEngine 8760R-X1, AirEngine 8760R-X1E, AirEngine 6760R-51, AirEngine 6760R-51E.
AP environment low temperature threshold (degree C)	Lower ambient temperature alarm threshold of an AP. **NOTICE** This parameter is displayed only for the following models: AirEngine 8760-X1-PRO, AirEngine 6760-X1, AirEngine 6760-X1E, AirEngine 5760-51, AirEngine 5760-22W, AirEngine 5760-22WD, AirEngine 8760R-X1, AirEngine 8760R-X1E, AirEngine 6760R-51, AirEngine 6760R-51E, AirEngine central APs.

Item	Description
AP CPU low temperature threshold (degree C)	Lower CPU temperature alarm threshold of an AP. **NOTICE** This parameter is displayed only for the following models: AirEngine 8760-X1-PRO, AirEngine 6760-X1, AirEngine 6760-X1E, AirEngine 5760-51, AirEngine 5760-22W, AirEngine 5760-22WD, AirEngine 8760R-X1, AirEngine 8760R-X1E, AirEngine 6760R-51, AirEngine 6760R-51E, AirEngine 9700D-M.
AP NP low temperature threshold (degree C)	Lower NP module temperature alarm threshold of an AP. **NOTICE** This parameter is displayed only for the AirEngine 9700D-M.
AP IRF low temperature threshold (degree C)	Lower IRF temperature alarm threshold of an AP. **NOTICE** This parameter is displayed only for the following models: AirEngine 8760-X1-PRO, AirEngine 6760-X1, AirEngine 6760-X1E, AirEngine 5760-51, AirEngine 5760-22W, AirEngine 5760-22WD, AirEngine 8760R-X1, AirEngine 8760R-X1E, AirEngine 6760R-51, AirEngine 6760R-51E.
Outdoor	Whether the AP is an outdoor AP.
BLE	Whether Bluetooth is supported.
Number of IoT cards	Number of IoT cards.
PMF	Whether PMF is supported.
Optical module	Whether the optical module is supported.
Optical module information query	Whether optical module information can be queried.
Mesh	Whether the Mesh function is supported.
WDS	Whether the WDS function is supported.
Eth-Trunk	Whether the Eth-Trunk is supported.
External antenna	Whether external antennas are supported.
Frequency fast switching	Whether fast radio switching without the need of a restart is supported.

Item	Description
Radio mode	Radio mode supported by an AP. If multiple radio modes are supported, the default radio mode of the AP model is marked as **default**.

11.2.92 display ap-type undefined record

Function

The **display ap-type undefined record** command displays the types of the APs that fail to connect to an AC because the AC does not support these AP types.

Format

display ap-type undefined record

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If a new AP model cannot connect to the AC, you can check whether the AP type has been created. To list the undefined AP types, run the **display ap-type undefined record** command. Then run the **auto create ap-type** command to automatically import the AP types of these APs.

Example

Display the AP types of the APs that fail to connect to an AC because the AC does not support these AP types.

```
<HUAWEI> display ap-type undefined record
------------------------------------------------------------------------------------------
AP type      Type ID     Report AP MAC     Report Time
------------------------------------------------------------------------------------------
AP5010DN     29          00e0-fc76-e360   2019-04-28/23:39:00
------------------------------------------------------------------------------------------
Total : 1
```

Table 11-107 Description of the **display ap-type undefined record** command output

Item	Description
AP type	AP type.
Type ID	ID of an AP type.
Report AP MAC	MAC address of an AP that fails to connect to the AC the last time because the AC does not support the AP type.
Report Time	Last time when an AP fails to connect to the AC because the AC does not support the AP type.

11.2.93 display ap-type attributes abnormal-check-record

Function

The **display ap-type attributes abnormal-check-record** command displays records of AP attribute check exceptions after an AP type is created.

Format

display ap-type attributes abnormal-check-record

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When an AP of a new version is connected to an AC, the AC verifies the attributes of the AP to prevent the following problems:

- If the AP attributes defined in the earlier version are modified, for example, a value range is modified, an incompatibility issue may be caused.
- Some attributes of the AP are missing. As a result, the AP fails to connect to the AC.

Example

Display the records of AP attribute check exceptions after an AP type is created.

```
<HUAWEI> display ap-type attributes abnormal-check-record
------------------------------------------------------------------
AP type           Type ID   Result      Reason
------------------------------------------------------------------
AP5010DN          29        risky       range conflict
AP6010DN          21        failed      lost-attributes
------------------------------------------------------------------
Total : 2
```

Table 11-108 Description of the **display ap-type attributes abnormal-check-record** command output

Item	Description
AP type	AP type.
Type ID	ID of an AP type.
Result	AP attribute check result.
Reason	Cause for the check result.

11.2.94 display channel switch-record

Function

The **display channel switch-record** command displays channel switching records on the device.

Format

display channel switch-record { **all** | **calibrate** | **ap-name** *ap-name* **radio** *radio-id* | **ap-id** *ap-id* **radio** *radio-id* }

Parameters

Parameter	Description	Value
all	Displays all channel switching records.	-
calibrate	Displays channel switching records for radio calibration.	-
ap-name *ap-name*	Displays channel switching records of the AP with a specified name.	The AP name must exist.
radio *radio-id*	Displays channel switching records of a specified AP radio.	The radio ID must exist.

Parameter	Description	Value
ap-id *ap-id*	Displays channel switching records of the AP with a specified ID.	The AP ID must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check channel switching records on a device.

Run the **display channel switch-record calibrate** command to query channel or power switching records caused by radio calibration to check the calibration results.

Example

Display all channel switching records.

```
<HUAWEI> display channel switch-record all
OldCh/NewCh: Old channel/New channel
OldBw/NewBw: Old bandwidth/New bandwidth
RfID   : Radio ID
------------------------------------------------------------------------------------------------------------------------
AP ID AP name                  RfID    OldCh/NewCh      OldBw/NewBw      Switch reason        Switch time
------------------------------------------------------------------------------------------------------------------------
15    AirEngine6760R-51_324033A6 1       -/149            20M/20M          configuration
2020-07-13/14:43:46
------------------------------------------------------------------------------------------------------------------------
Total : 1, printed : 1
```

Table 11-109 Description of the **display channel switch-record all** command output

Item	Description
AP ID	AP ID.
AP name	AP name.
RfID	Radio ID.
OldCh/NewCh	Channels used before and after switching.
OldBw/NewBw	Bandwidths before and after channel switching.

Item	Description
Switch reason	Reason for channel switching. - calibration: channel switching caused by radio calibration - configuration: channel switching caused by configuration - dfs: channel switching performed to avoid radar channels - dfs (In AC): channel switching caused by channel delivery by the AC to avoid radar channels - dfs recover: channel switching caused by DFS channel switchback - mesh: channel switching caused by channel negotiation on a Mesh network - unsupported: channel switching performed because the AP does not support the channel delivered from the AC - wds: channel switching caused by channel negotiation on a WDS network - iot-notification: channel switching notified by an IoT card - AP sync: channel switching caused by configuration synchronization (through AC-Fit AP channel synchronization) - Poor quality: channel switching caused by radio calibration triggered when the analyzer identifies poor-QoE APs
Switch time	Time when channel switching occurred.

Display channel calibration records.

```
<HUAWEI> display channel switch-record calibrate
PCH : Pre channel
CCH : Current channel
PBW : Pre bandwidth
CBW : Current bandwidth
PE  : Pre EIRP (dBm)
CE  : Current EIRP (dBm)
PRS : Pre RX sensitivity(dBm)
CRS : Current RX sensitivity(dBm)
PR  : Pre RSSI (dBm)
CR  : Current RSSI (dBm)
```

```
RfID: Radio ID

----
Total : 2
```

Table 11-110 Description of the **display channel switch-record calibrate** command output

Item	Description
AP ID	AP ID.
AP name	AP name.
RfID	Radio ID.
PCH/CCH	Channels before and after calibration. **NOTE** PCH/CCH changes may be discontinuous for a radio.
PBW/CBW	Bandwidth before and after calibration.
PE/CE	Power before and after calibration. **NOTE** PE/CE changes may be discontinuous for a radio.
PRS/CRS	Receiver sensitivity values before and after calibration.
PR/CR	Interference values before and after calibration.

Item	Description
Reason	Reason for triggering calibration. ● Period recheck: periodic calibration ● Bad env: environment deterioration ● Non-Wi-Fi report: non-Wi-Fi report ● Rogue AP report: rogue AP report ● Noise interfere: noise interference ● Global plan: network-wide plan ● AP online: The AP radio is on, the radio is switched (between 2.4 GHz and 5 GHz bands), the radio working mode changes, or the AP goes online. ● AP offline: The AP radio is off, the radio is switched (between 2.4 GHz and 5 GHz bands), the radio working mode changes, or the AP goes offline. ● Bad Channel: The channel deteriorates, causing a loss of Beacon frames. ● iot-notification: An IoT card notifies calibration. ● DFS(In AC): The AC delivers a channel to avoid radar channels. ● High interference: Severe interference occurs. ● Unknown: unknown reason
Time	Time when calibration is triggered.
Trigger ID(Radio)	ID of the AP (radio) that triggers partial radio calibration. **NOTE** If global radio calibration is triggered, this field displays -.

11.2.95 display distribute-ap

Function

The **display distribute-ap** command displays information about RUs.

Format

display distribute-ap { **all** | **ap-id** *ap-id* | **ap-mac** *ap-mac* | **ap-name** *ap-name* | **central-ap-id** *central-ap-id* | **central-ap-mac** *central-ap-mac* | **central-ap-name** *central-ap-name* }

Parameters

Parameter	Description	Value
all	Displays information about all RUs.	-
ap-id *ap-id*	Displays information about the RU of a specified ID.	The RU ID must exist.
ap-mac *ap-mac*	Displays information about the RU of a specified MAC address.	The MAC address must exist.
ap-name *ap-name*	Displays information about the RU of a specified name.	The RU name must exist.
central-ap-id *central-ap-id*	Displays information about the RUs connected to the central AP of a specified ID.	The central AP ID must exist.
central-ap-mac *central-ap-mac*	Displays information about the RUs connected to the central AP of a specified MAC address.	The MAC address of the central AP must exist.
central-ap-name *central-ap-name*	Displays information about the RUs connected to the central AP of a specified name.	The central AP name must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check RU information.

Example

Display information about all RUs.

Total: 3
```

Table 11-111 Description of the **display distribute-ap all** command output

Item	Description
ID	RU ID.
MAC	MAC address of the RU.
Name	Name of the RU.
Group	AP group to which an RU belongs.
IP	IP address of the RU.
Type	RU type.
State	RU state, which is the same as a common AP. For details, see **Table 11-5**.
Central-AP ID	ID of the central AP.
Central-AP MAC	MAC address of the central AP.
Central-AP name	Name of the central AP.

Table 11-112 AP state list

AP State	Description	Possible Cause	Handling Suggestion
commit-failed (cmtfa)	WLAN service configurations fail to be delivered to an AP after the AP goes online on an AC.	After an AP goes online on the AC, WLAN service configurations are performed for the AP. If the link between the AP and AC is disconnected or the peer end has no response, the AP enters the commit-failed state.	Check the network connection.

AP State	Description	Possible Cause	Handling Suggestion
committing (cmt)	WLAN service configurations are being delivered to an AP after the AP goes online on an AC.	After an AP goes online on the AC, WLAN service configurations are being delivered to the AP. During this process, the AP is in committing state.	This is a normal state, and no action is required.
config (cfg)	WLAN service configurations are being delivered to an AP when the AP is going online on an AC.	After an AP establishes a link with the AC, WLAN service configurations are delivered to the AP. During this process, the AP is in config state.	This is a normal state, and no action is required.
config-failed (cfgfa)	WLAN service configurations fail to be delivered to an AP when the AP is going online on an AC.	After an AP establishes a link with the AC, WLAN service configurations are delivered to the AP. If the configuration delivery fails due to various reasons (such as link disconnection), the AP enters the config-failed state.	Check the network connection.
download (dload)	An AP is in upgrade state.	When an AP is performing an upgrade, it enters the download state.	When the AP upgrade is complete, check the AP state.

AP State	Description	Possible Cause	Handling Suggestion
fault	An AP fails to go online.	An AP fails to go online, which is usually caused by the following: • The AP fails to obtain an IP address or obtains an incorrect IP address. • The network between the AP and AC is faulty. • The AP fails to be authenticated. • The number of APs on an AC has reached the maximum value. • The AP is faulty. • In dual-link cold backup or N+1 backup scenario, if the link between the active and standby ACs is established properly, an AP that goes online on the active AC is in fault state on the standby AC.	Handle the AP online failure. For details, see **An AP Fails to Go Online on the AC** in the *Troubleshooting Guide*.

AP State	Description	Possible Cause	Handling Suggestion
idle	It is the initialization state of an AP before it establishes a link with the AC for the first time.	When an AP has not established a CAPWAP link with the AC, the MAC address and SN of an AP that is added offline are different from the actual MAC address and SN of the AP, or the AC cannot manage an AP due to license resource insufficiency, the AP enters the idle state.	Perform the following operations. Check whether the AP is connected to the network. If the AP connection is normal, go to next step. Check the MAC address and SN of the AP that is added offline are different from the actual MAC address and SN of the AP. If not, perform the following operations: 1. Run the **display ap all** command to check AP information. 2. Run the **undo ap** { **ap-name** *ap-name* | **ap-id** *ap-id* | **ap-mac** *ap-mac* | **ap-group** *group-name* | **all** } command to delete the AP. 3. Run the **ap-id** *ap-id* [[**type-id** *type-id* | **ap-type** *ap-type*] { **ap-mac** *ap-mac* | **ap-sn** *ap-sn* | **ap-mac** *ap-mac* **ap-sn** *ap-sn* }] or **ap-mac** *ap-mac* [**type-id** *type-id* | **ap-type** *ap-type*] [**ap-id** *ap-id*] [**ap-sn** *ap-sn*] command to add correct AP information. If the fault persists, expand the license capacity. Note that RUs managed by the AC do not occupy

AP State	Description	Possible Cause	Handling Suggestion
			license resources of the AC.
name-conflicted (namec)	The name of an AP conflicts with that of an existing AP.	The name of an AP conflicts with the name of another AP that has been online on the same AC.	Run the **ap-rename ap-id** *ap-id* **new-name** *ap-new-name* command to change the AP name.
normal (nor)	An AP is working properly.	An AP successfully goes online on an AC.	This is a normal state, and no action is required.
standby (stdby)	An AP is in normal state on the standby AC.	In the HSB scenario, if the link between the master and backup ACs is established properly, an AP is in standby state on the backup AC and in normal state on the master AC.	This is a normal state, and no action is required.
ver-mismatch (vmiss)	The version of an AP does not match that of an AC on which the AP is about to go online.	The versions of the AP and AC do not match.	Log in to Huawei technical support website and download the release notes. Based on the version mapping, upgrade the AP or AC to the matching version. ● Enterprise technical support website: **https://support.huawei.com/enterprise** ● Carrier technical support website: **https://support.huawei.com**

AP State	Description	Possible Cause	Handling Suggestion
countryCode-mismatch (cmiss)	The country codes of the AP and AC do not match.	The AP's current version does not support the country code configured on the AC. The country code of the AP is locked, and the country code configured on the AC is not supported.	The AP does not support the country code. Upgrade the AP or modify the country code configuration on the AC. The country code of the AP is locked. Replace the AP or change the country code on the AC to be the same as that of the AP.
type-mismatch (tmiss)	The AP type does not match that configured on the AC.	The AP type configured on the AC did not match the actual AP type.	Change the AP type configured on the AC.
unauth	An AP is not authenticated.	The AP fails to be authenticated.	Run the **display ap unauthorized record** command to query authenticated APs. Run the **ap-confirm** command to confirm unauthenticated APs and allow them to go online.

11.2.96 display mac-address ap-all

Function

The **display mac-address ap-all** command displays MAC address entries on all APs.

Format

display mac-address *mac-address* [**verbose**] **ap-all**

Parameters

Parameter	Description	Value
mac-address	Displays MAC address entries on all APs.	The value is in H-H-H format. An H contains four hexadecimal numbers.
verbose	Displays detailed information of the dynamic entries. If *verbose* is not specified, brief information about MAC address entries is displayed.	-

1: Monitoring level

Usage Guidelines

When errors or attacks occur on the network, you can run the **display mac-address ap-all** command to locate the attack sources based on the displayed MAC addresses.

Example

Display dynamic MAC address entries of all APs.

```
<HUAWEI> display mac-address 00e0-fc09-bcf9 ap-all
Info: Waiting for AP response...done.
-------------------------------------------------------------------------------
MAC Address     VLAN/VSI        Learned-From              Type        AP ID
-------------------------------------------------------------------------------
00e0-fc09-bcf9    1/-         GigabitEthernet0/0/0      dynamic     1
00e0-fc09-bcf9    1/-         GigabitEthernet0/0/0      dynamic     0
-------------------------------------------------------------------------------
Total: 2
```

Table 11-113 Description of the **display mac-address** *mac-address* **ap-all** command output

Item	Description
MAC Address	MAC address.
VLAN/VSI	ID of the VLAN or name of the VSI that a MAC address belongs to.

Item	Description
Learned-From	Interface on which the MAC address is learned.
Type	Type of a MAC address entry.
AP ID	AP ID.

11.2.97 display mac-address { ap-id | ap-name }

Function

The **display mac-address** { **ap-id** | **ap-name**} command displays all dynamic, dynamic secure, and sticky MAC address entries on an AP's wired interface.

Format

display mac-address { **ap-id** *ap-id* | **ap-name** *ap-name* } *interface-type interface-number*

Parameters

Parameter	Description	Value
ap-id *ap-id*	Displays all dynamic, dynamic secure, and sticky MAC address entries on wired interfaces of the AP with the specified ID.	The AP ID must exist.
ap-name *ap-name*	Displays all dynamic, dynamic secure, and sticky MAC address entries on wired interfaces of the AP with the specified name.	The AP name must exist.
interface-type interface-number	Displays all dynamic, dynamic secure, and sticky MAC address entries on a specified interface. • *interface-type* specifies the interface type. • *interface-number* specifies the number of the outbound interface.	The following types of outbound interfaces are supported: • Eth-Trunk • Ethernet • Gigabitethernet • MultiGE • XGigabitethernet

Usage Guidelines

You can run the **display mac-address** { **ap-id** | **ap-name**} command to check all dynamic, dynamic secure, and sticky MAC address entries on an AP's wired interface, including the MAC addresses and VLANs that the AP learns on specified interfaces.

Example

Display all dynamic, dynamic secure, and sticky MAC address entries on wired interfaces of the AP with ID 1.

```
<HUAWEI> display mac-address ap-id 1 ethernet 0
-----------------------------------------------------------
MAC Address     VLAN/VSI    Learned-From        Type
-----------------------------------------------------------
00e0-fc54-5a80 1/-        Ethernet0/0/0       dynamic
-----------------------------------------------------------
Total: 1
```

Table 11-114 Description of the **display mac-address ap-id** *ap-id interface-type interface-number* command output

Item	Description
MAC Address	MAC address.
VLAN/VSI	VLAN or VSI to which the device belongs.
Learned-From	Interface on which the MAC address is learned.
Type	Type of a MAC address entry.

11.2.98 display port-link-profile

Function

The **display port-link-profile** command displays reference and configuration information about an AP wired port link profile.

Format

display port-link-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays information about all AP wired port link profiles.	-
name *profile-name*	Displays information about a specified AP wired port link profile.	The AP wired port link profile must exist.

```

Table 11-116 Description of the **display port-link-profile name** *profile-name* command output

Item	Description
LLDP enable	Whether LLDP is enabled on an AP's wired interface. To configure the parameter, run the **lldp enable** command.
Management address	Whether an AP's wired interface is allowed to advertise the Management-address TLV. To configure the parameter, run the **lldp tlv-enable (AP wired port link profile view)** command.
Port description	Whether an AP's wired interface is allowed to advertise the Port-description TLV. To configure the parameter, run the **lldp tlv-enable (AP wired port link profile view)** command.
System capability	Whether an AP's wired interface is allowed to advertise the System-capability TLV. To configure the parameter, run the **lldp tlv-enable (AP wired port link profile view)** command.
System description	Whether an AP's wired interface is allowed to advertise the System-description TLV. To configure the parameter, run the **lldp tlv-enable (AP wired port link profile view)** command.

Item	Description
System name	Whether an AP's wired interface is allowed to advertise the System-name TLV. To configure the parameter, run the **lldp tlv-enable (AP wired port link profile view)** command.
802.3 TLV power	Whether an AP's wired interface is allowed to advertise the Power via MDI TLV. To configure the parameter, run the **lldp tlv-enable (AP wired port link profile view)** command.
802.3 TLV power format	802.3 Power via MDI TLV advertised by an AP's wired interface. ● 802.1ab: The 802.3 Power via MDI TLV sent by the interface conforms to 802.1ab. ● 802.3at: The 802.3 Power via MDI TLV sent by the interface conforms to 802.3at. ● 802.3bt: The 802.3 Power via MDI TLV sent by the interface conforms to 802.3bt. ● -: Default value. To configure the parameter, run the **lldp dot3-tlv power (AP wired port link profile view)** command.
Legacy TLV four pair power	Whether an AP's wired interface is allowed to advertise Cisco's customized TLVs. To configure the parameter, run the **lldp tlv-enable legacy-tlv four-pair-power (AP wired port link profile view)** command.
Legacy TLV power capability	Whether the supported power capability is carried in LLDP packets sent by an AP. To configure the parameter, run the **lldp tlv-enable legacy-tlv power-capability (AP wired port link profile view)** command.

Item	Description
CRC error alarm	Whether the alarm function for CRC errors is enabled on an AP's wired interface. To configure the parameter, run the **crc-alarm enable** command.
CRC error high threshold(1/10000)	Alarm threshold for CRC errors on an AP's wired interface. To configure the parameter, run the **crc-alarm enable** command.
CRC error Low threshold(1/10000)	Clear alarm threshold for CRC errors on an AP's wired interface. To configure the parameter, run the **crc-alarm enable** command.
PoE enable	Whether the PoE function is enabled on the AP's interfaces. To configure the parameter, run the **poe disable (AP wired port link profile view)** command.
PoE legacy	Whether PD compatibility check is enabled on the AP. To configure the parameter, run the **poe legacy enable (AP wired port link profile view)** command.
PoE priority	Power priority of PoE interfaces on the AP. To configure the parameter, run the **poe priority (AP wired port link profile view)** command.
PoE force power	Whether forcible PoE power supply is enabled on the AP's interfaces. To configure the parameter, run the **poe force-power (AP wired port link profile view)** command.
Shutdown switch	Whether the AP's wired interface function is disabled. To configure the parameter, run the **shutdown (AP wired port link profile view)** command.

Item	Description
Speed(Mbit/s)	Rate of the AP's wired interface in non-auto negotiation mode. To configure the parameter, run the **speed (AP wired port link profile view)** command.

11.2.99 display provision-ap parameter-list

Function

The **display provision-ap parameter-list** command displays AP provisioning parameters in the AP provisioning view.

Format

display provision-ap parameter-list

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Before running the **commit** command to deliver the AP provisioning parameters configured in the AP provisioning view, you can run the **display provision-ap parameter-list** command to check whether the parameters are correct and complete.

If a parameter is displayed as **-** in the command output, the parameter of the APs is not changed after the configuration is committed.

Example

Display AP provisioning parameters in the AP provisioning view.

```
<HUAWEI> display provision-ap parameter-list
--------------------------------------------------------------------------------
AP mode                 : -
AP name                 : -
AP address mode           : -
IPv4 address            : -
IPv4 mask address         : -
```

```
IPv4 gateway address     : -
IPv4 AC list             : -
Management Vlan          : 2
DTLS server-auth         : enable
DTLS server-auth cn list : -
------------------------------------------------------------------------------
```

Table 11-117 Description of the **display provision-ap parameter-list** command output

Item	Description
AP mode	AP mode. To set this parameter, run the **ap-mode** command.
AP name	AP name. To configure this parameter, run the **ap-name (AP provisioning view)** command.
AP address mode	Mode in which an AP obtains an IP address. To configure this parameter, run the **address-mode (AP provisioning view)** command.
IPv4 address	Static IPv4 address of an AP. To configure this parameter, run the **ip-address (AP provisioning view)** command.
IPv4 mask address	Static IPv4 address mask of an AP. To configure this parameter, run the **ip-address (AP provisioning view)** command.
IPv4 gateway address	IPv4 address gateway of the AP. To configure this parameter, run the **ip-address (AP provisioning view)** command.
IPv4 AC list	AC IPv4 address list of an AP. To configure this parameter, run the **ac-list (AP provisioning view)** command.
Management Vlan	Management VLAN tag carried in CAPWAP packets sent from the AP's wired interface. To configure this parameter, run the **management-vlan** command.

Item	Description
DTLS server-auth	Whether the AC authentication function is enabled for the AP. To configure this parameter, run the **capwap dtls server-auth (AP provisioning view)** command.
DTLS server-auth cn list	CN field in the AC certificate to be authenticated by the AP. To configure this parameter, run the **capwap dtls server-auth cn (AP provisioning view)** command.

11.2.100 display references ap-pki-profile

Function

The **display references ap-pki-profile** command displays reference information about an AP PKI realm profile.

Format

display references ap-pki-profile name *profile-name*

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the profile name.	The profile name must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view reference information about an AP PKI realm profile.

Example

Display reference information about an AP PKI realm profile.

```
<HUAWEI> display references ap-pki-profile name default
Total: 5
------------------------------------------------------------
Reference type          Reference name
------------------------------------------------------------
ap-group                 default
ap-group                 mytest
ap-id                  69
ap-id                  70
ap-id                  72
------------------------------------------------------------
```

Table 11-118 Description of the **display references ap-pki-profile** command output

Item	Description
Reference type	Profile binding type. The options are as follows: ● **ap-group**: bound to an AP group ● **ap-id**: bound to an AP The **ap-group** and **ap-id** types are available.
Reference name	Name of an AP group or ID of an AP to which the profile is bound.

11.2.101 display references ap-system-profile

Function

The **display references ap-system-profile** command displays reference information about an AP system profile.

Format

display references ap-system-profile name *profile-name*

Parameters

Parameter	Description	Value
name *profile-name*	Displays reference information about a specified AP system profile.	The AP system profile must exist.

Table 11-123 Description of the **display wired-port-profile name** *profile-name* command output

Item	Description
Port link profile	Name of the AP wired port link profile referenced by an AP wired port profile. To configure the parameter, run the **port-link-profile (AP wired port profile view)** command.
Description	Interface description. To configure the parameter, run the **description (AP wired port profile view)** command.
STP	STP status on a wired interface. To configure the parameter, run the **stp enable (AP wired port profile view)** command.
Port work mode	Working mode of a wired interface. ● root: indicates the root mode. ● endpoint: indicates the endpoint mode. ● middle: indicates the middle mode. ● -: indicates that the working mode of wired interfaces is not changed. To configure the parameter, run the **mode (AP wired port profile view)** command.
Port Tagged VLAN	VLAN to which a wired interface is added in tagged mode. To configure the parameter, run the **vlan (AP wired port profile view)** command.

Item	Description
Port untagged VLAN	VLAN to which a wired interface is added in untagged mode. To configure the parameter, run the **vlan (AP wired port profile view)** command.
Port PVID VLAN	PVID of a wired interface. To configure the parameter, run the **vlan pvid (AP wired port profile view)** command.
User isolate mode	User isolation status on a wired interface. To configure the parameter, run the **user-isolate (AP wired port profile view)** command.
DHCP trust port	Status of the DHCP trusted interface function. To configure the parameter, run the **dhcp trust port** command.
ND trust port	Status of the ND trusted interface function. To configure the parameter, run the **nd trust port** command.
Ethernet trunk ID	ID of the Eth-Trunk interface.
IPSG switch	Whether IP source guard (IPSG) is enabled on an AP's wired interface. To configure the parameter, run the **ipsg enable (AP wired port profile view)** command.
DAI switch	Whether DAI is enabled on an AP's wired interface. To configure the parameter, run the **dai enable (AP wired port profile view)** command.
STP auto shutdown switch	Whether STP-triggered port shutdown is enabled on an AP's wired interface. To configure the parameter, run the **stp auto-shutdown enable (AP wired port profile view)** command.

Item	Description
Auto shutdown recovery time	Recovery time of the shutdown port triggered by STP. To configure the parameter, run the **stp auto-shutdown recovery-time (AP wired port profile view)** command.
Learn client IPv4 address switch	Whether terminal IPv4 address learning is enabled on an AP's wired interface. To configure the parameter, run the **learn-client-address enable (AP wired port profile view)** command.
Learn client IPv6 address switch	Whether terminal IPv6 address learning is enabled on an AP's wired interface. To configure the parameter, run the **learn-client-address enable (AP wired port profile view)** command.
IGMP-Snooping switch	Whether IGMP snooping is enabled on an AP's wired interface. To configure the parameter, run the **igmp-snooping enable (AP wired port profile view)** command.
MLD-Snooping switch	Whether MLD snooping is enabled on an AP's wired interface. To configure the parameter, run the **mld-snooping enable (AP wired port profile view)** command.
Port security switch	Whether port security is enabled on an AP's wired interface. To configure the parameter, run the **port-security enable (AP wired port profile view)** command.
Port security sticky MAC	Whether the port security and sticky MAC functions are enabled on an AP's wired interface. To configure the parameter, run the **port-security mac-address sticky (AP wired port profile view)** command.

Item	Description
Port security maximum MAC	Maximum number of secure MAC addresses that can be learned by an interface. To configure the parameter, run the **port-security max-mac-num (AP wired port profile view)** command.
Port security protect action	Protection action to be taken when the number of secure MAC addresses learned by an interface exceeds the limit. ● protect: The interface discards packets with source MAC addresses that are not in the MAC address table. ● restrict: The interface discards packets with source MAC addresses that are not in the MAC address table and sends a trap message. To configure the parameter, run the **port-security protect-action (AP wired port profile view)** command.
Traffic optimize TCP adjust MSS(bytes)	Maximum segment size (MSS) of TCP packets on an AP's wired interface. To configure the parameter, run the **traffic-optimize tcp adjust-mss** command.
Traffic optimize broadcast suppression(pps)	Maximum broadcast traffic volume that can be received on an AP's wired interface. To configure the parameter, run the **traffic-optimize (AP wired port profile view)** command.
Traffic optimize unicast suppression(pps)	Maximum unknown unicast traffic volume that can be received on an AP's wired interface. To configure the parameter, run the **traffic-optimize (AP wired port profile view)** command.
Traffic optimize multicast suppression(pps)	Maximum multicast traffic volume that can be received on an AP's wired interface. To configure the parameter, run the **traffic-optimize (AP wired port profile view)** command.

Item	Description
Traffic Type	ACL-based packet filtering and re-marking implemented by the AP wired port. ● traffic-filter ● traffic-remark
Direction	Incoming or outgoing packets.
AppliedRecord	IPv4/IPv6/L2 packet filtering and re-marking based on ACLs.
RemarkType	Protocol type. ● dscp ● dot1p
RemarkValue	Protocol type value. ● dscp: 0-63 ● dot1p: 0-7

11.2.105 display wlan ble-link-info

Function

The **display wlan ble-link-info** command displays connection information about the Bluetooth-based air interface on an AP.

NOTE

The following models do not support the Bluetooth serial port function:

- AirEngine 5761-10W, AirEngine 5761S-10W, and AirEngine 5761-10WD
- AirEngine 5762-10 and AirEngine 5762-10SW
- AirEngine 9700D-M and AirEngine 9700D-M1

Format

display wlan ble-link-info { **ap-id** *ap-id* | **ap-name** *ap-name* }

Parameters

Parameter	Description	Value
ap-id *ap-id*	Specifies the AP ID.	The AP ID must exist.
ap-name *ap-name*	Specifies the AP name.	The AP name must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check connection information about the Bluetooth-based air interface on an AP.

Example

Display connection information about the Bluetooth-based air interface on the AP named **ap1**.

```
<HUAWEI> display wlan ble-link-info ap1
Info: This operation may take a few seconds. Please wait for a moment.done.
-------------------------------------------------------------------------------------
BLE access MAC                        : xxxx-xxxx-xxxx
Status                          : paired
Link status changed time              : 2019-04-11  09:12:46
-------------------------------------------------------------------------------------
```

Table 11-124 Description of the **display wlan ble-link-info** command output

Item	Description
BLE access MAC	MAC address of a STA accessed through Bluetooth. This address is randomly generated when the STA establishes a Bluetooth connection with the AP.
Status	Bluetooth connection status between a STA and the AP. ● link established: The link is established between the STA and AP. ● paired: The STA and AP are successfully paired.
Link status changed time	Time when the connection status is updated.

11.2.106 display wlan console ble statistics

Function

The **display wlan console ble statistics** command displays statistics about Bluetooth-based console port login on an AP.

NOTE

The following models do not support the Bluetooth serial port function:

- AirEngine 5761-10W, AirEngine 5761S-10W, and AirEngine 5761-10WD
- AirEngine 5762-10 and AirEngine 5762-10SW
- AirEngine 9700D-M and AirEngine 9700D-M1

Format

display wlan console ble statistics { **ap-id** *ap-id* | **ap-name** *ap-name* }

Parameters

Parameter	Description	Value
ap-id *ap-id*	Specifies the AP ID.	The AP ID must exist.
ap-name *ap-name*	Specifies the AP name.	The AP name must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check statistics about Bluetooth-based console port login on an AP.

Example

Display statistics about Bluetooth-based console port login on the AP named **huawei**.

```
<HUAWEI> display wlan console ble statistics ap-name huawei
Info: This operation may take a few seconds. Please wait for a moment.done.
------------------------------------------------------------------------------------
AP ID                                  : 0
AP Name                                : huawei
Air Frame Received (Packets)           : 11
Air Traffic Received (Bytes)           : 11
Air Frame Send (Packets)               : 8
Air Traffic Send (Bytes)               : 55
------------------------------------------------------------------------------------
```

Table 11-125 Description of the **display wlan console ble statistics** command output

Item	Description
AP ID	AP ID.
AP Name	AP name.
Air Frame Received (Packets)	Number of received air interface frames.
Air Traffic Received (Bytes)	Amount of received air interface traffic.
Air Frame Send (Packets)	Number of sent air interface frames.
Air Traffic Send (Bytes)	Amount of sent air interface traffic.

11.2.107 disk-usage threshold

Function

The **disk-usage threshold** command sets the disk usage alarm threshold of APs.

The **undo disk-usage threshold** command restores the default disk usage alarm threshold of APs.

The default disk usage alarm threshold of APs is 95.

Format

disk-usage threshold *threshold*

undo disk-usage threshold

Parameters

Parameter	Description	Value
threshold	Specifies a disk usage alarm threshold of APs.	The value is an integer that ranges from 6 to 100.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

You can run the **disk-usage threshold** command to set the disk usage alarm threshold of APs. The corresponding alarm clear threshold equals the specified alarm threshold minus 5. This configuration is delivered to APs using this AP system profile view.

- When the disk usage of APs exceeds the current alarm threshold, the APs report an alarm to the AC, which displays alarm information.
- When the disk usage of APs falls below the current alarm threshold, the APs report a clear alarm to the AC, which displays clear alarm information.

Example

Set the disk usage alarm threshold of APs to 60.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] disk-usage threshold 60
```

11.2.108 eapol-response dest-address transform-condition

Function

The **eapol-response dest-address transform-condition** command specifies the EAPOL-response packets to be encapsulated by an AP.

The **undo eapol-response dest-address transform-condition** command restores the default settings.

By default, an AP encapsulates only the EAPOL-response packets with the destination MAC addresses being the AP's BSSID.

Format

eapol-response dest-address transform-condition { **always** | **equal-bssid** }

undo eapol-response dest-address transform-condition

Parameters

Parameter	Description	Value
always	Configures the AP to encapsulate all EAPOL-response packets.	-
equal-bssid	Configures the AP to encapsulate only the EAPOL-response packets with the destination MAC address being the AP's BSSID.	-

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

During 802.1X authentication, the destination MAC addresses of the EAPOL-response packets sent by some STAs are APs' BSSIDs, but the destination MAC addresses of the EAPOL-response packets sent by other STAs are not APs' BSSIDs. You need to run this command to specify the EAPOL-response packets to be encapsulated.

Example

Configure the AP to encapsulate all EAPOL-response packets.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] eapol-response dest-address transform-condition always
```

11.2.109 eapol-response dest-address transform-to

Function

The **eapol-response dest-address transform-to** command configures an AP to encapsulate EAPOL-response packets into broadcast, multicast, or unicast packets.

The **undo eapol-response dest-address transform-to** command restores the default settings.

By default, an AP encapsulates EAPOL-response packets into unicast packets and actively learns the destination MAC address.

Format

eapol-response dest-address transform-to { **broadcast** | **multicast** | **mac** *mac-address* | **learning** }

undo eapol-response dest-address transform-to

Parameters

Parameter	Description	Value
broadcast	Configures an AP to encapsulate EAPOL-response packets into broadcast packets.	-

Parameter	Description	Value
multicast	Configures an AP to encapsulate EAPOL-response packets into multicast packets.	-
mac *mac-address*	Configures an AP to encapsulate EAPOL-response packets into unicast packets with a specified destination MAC address.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.
learning	Configures an AP to encapsulate EAPOL-response packets into unicast packets and actively learn the destination MAC address.	-

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

- If the authentication server can only process EAP multicast packets, configure the AP to encapsulate EAPOL-response packets into multicast packets.
- If the authentication server can only process EAP broadcast packets, configure the AP to encapsulate EAPOL-response packets into broadcast packets.
- If the authentication server can only process EAP unicast packets, configure the AP to encapsulate EAPOL-response packets into unicast packets. When the AP is configured to encapsulate EAPOL-response packets into unicast packets, a unicast MAC address must be configured.

Example

Configure an AP to encapsulate EAPOL-response packets into broadcast packets.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] eapol-response dest-address transform-to broadcast
```

11.2.110 eapol-start dest-address transform-condition

Function

The **eapol-start dest-address transform-condition** command specifies the EAPOL-start packets to be encapsulated by an AP.

The **undo eapol-start dest-address transform-condition** command restores the default settings.

By default, an AP encapsulates only the EAPOL-start packets with the destination MAC addresses being the AP's BSSID.

Format

eapol-start dest-address transform-condition { **always** | **equal-bssid** }

undo eapol-start dest-address transform-condition

Parameters

Parameter	Description	Value
always	Configures the AP to encapsulate all EAPOL-start packets.	-
equal-bssid	Configures the AP to encapsulate only the EAPOL-start packets with the destination MAC address being the AP's BSSID.	-

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During 802.1X authentication, the destination MAC addresses of the EAPOL-start packets sent by some STAs are APs' BSSIDs, but the destination MAC addresses of the EAPOL-start packets sent by other STAs are not APs' BSSIDs. You need to run this command to specify the EAPOL-start packets to be encapsulated.

Precautions

The packet types specified by the **eapol-start dest-address transform-condition** and **eapol-start dest-address transform-to** commands must be the same.

Example

Configure the AP to encapsulate all EAPOL-start packets.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] eapol-start dest-address transform-condition always
```

11.2.111 eapol-start dest-address transform-to

Function

The **eapol-start dest-address transform-to** command configures an AP to encapsulate EAPOL-start packets into broadcast, multicast, or unicast packets.

The **undo eapol-start dest-address transform-to** command restores the default settings.

By default, an AP encapsulates EAPOL-start packets into multicast packets.

Format

eapol-start dest-address transform-to { **broadcast** | **multicast** | **mac** *mac-address* }

undo eapol-start dest-address transform-to

Parameters

Parameter	Description	Value
broadcast	Configures an AP to encapsulate EAPOL-start packets into broadcast packets.	-
multicast	Configures an AP to encapsulate EAPOL-start packets into multicast packets.	-
mac *mac-address*	Configures an AP to encapsulate EAPOL-start packets into unicast packets.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

- If the authentication server can only process EAP multicast packets, configure the AP to encapsulate EAPOL-start packets into multicast packets.
- If the authentication server can only process EAP broadcast packets, configure the AP to encapsulate EAPOL-start packets into broadcast packets.
- If the authentication server can only process EAP unicast packets, configure the AP to encapsulate EAPOL-start packets into unicast packets. When the AP is configured to encapsulate EAPOL-start packets into unicast packets, a unicast MAC address must be configured.

Example

Configure an AP to encapsulate EAPOL-start packets into broadcast packets.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] eapol-start dest-address transform-to broadcast
```

11.2.112 eth-trunk (AP wired port profile view)

Function

The **eth-trunk** command adds an AP interface to an Eth-Trunk.

The **undo eth-trunk** command removes an AP interface from an Eth-Trunk.

By default, an AP interface is not added to any Eth-Trunk.

Format

eth-trunk *trunk-id*

undo eth-trunk

Parameters

Parameter	Description	Value
trunk-id	Specifies the ID of an Eth-Trunk.	The value is 0 or 1.

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To improve the connection reliability and increase the bandwidth, you can run this command to bind multiple interfaces into an Eth-Trunk.

Prerequisites

The physical interface to be added to an Eth-Trunk cannot have other configurations. Before adding a physical interface to an Eth-Trunk, clear all configurations on it except the interface status, descriptions, LLDP function, and alarm function for CRC errors.

Precautions

- After the configuration, you need to restart the AP to make the configured Eth-Trunk on the AP's wired interfaces take effect.
- APs that have only one physical uplink network interface do not support this command.
- Downlink interfaces on an AP do not support the Eth-Trunk function.
- Member interfaces in an Eth-Trunk do not support the PVID or user isolation configuration.
- For an AP that supports only one Eth-Trunk, the configuration takes effect only when the Eth-Trunk ID is set to 0.
- If a member interface of an Eth-Trunk is connected to a peer end, the peer interface directly connected to the local interface must also be a member interface of an Eth-Trunk.
- An Eth-Trunk cannot be added to another Eth-Trunk.
- Do not configure any member interface of an Eth-Trunk as an observing port. If this cannot be avoided, ensure that the bandwidth of service traffic on the member interface and the bandwidth of the mirrored traffic do not exceed the bandwidth limit of the interface.
- An Ethernet interface can be added to only one Eth-Trunk. To add the Ethernet interface in an Eth-Trunk to another Eth-Trunk, delete it from the original Eth-Trunk first.
- After an interface is added to an Eth-Trunk, MAC address entries and ARP entries are learned based on the Eth-Trunk but not based on member interfaces.

NOTE

The Eth-Trunk function is supported only by the following models:

- AirEngine X760 series APs
- AirEngine X761 series APs (except AirEngine 5761S-12, AirEngine 5761-12, and AirEngine 5761S-13)
- AirEngine 8771-X1T
- AirEngine 9700D-S (including matching ORUs)
- AirEngine series central APs

Example

Add the AP interface to Eth-Trunk 0.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wired-port-profile name wired-port1
[HUAWEI-wlan-wired-port-wired-port1] eth-trunk 0
```

11.2.113 high-temperature threshold

Function

The **high-temperature threshold** command sets an upper device, ambient, CPU, or NP module temperature alarm threshold for APs.

The **undo high-temperature threshold** command restores the default upper device, ambient, CPU, or NP module temperature alarm threshold of APs.

Table 11-126 Default upper temperature alarm threshold for APs

AP Model	Default Value (°C)
AirEngine 9700D-M1 (AP device/ ambient)	63/54

NOTE

This command is not supported by the following models:

- AirEngine series APs

Format

high-temperature [**ap-environment** | **cpu** | **np**] **threshold** *threshold*

undo high-temperature [**ap-environment** | **cpu** | **np**] **threshold**

Parameters

Parameter	Description	Value
ap-environment	Indicates the ambient temperature.	-
cpu	Indicates the CPU temperature.	-
np	Indicates the NP module temperature.	-

Parameter	Description	Value
threshold	Specifies the upper temperature alarm threshold.	The value is an integer that ranges from 20 to 110, in °C.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to set the upper temperature alarm threshold for an AP. When an AP's temperature exceeds the upper threshold, the AP generates an alarm and a log, and notifies the AC of the high temperature alarm.

The parameter **ap-environment** is supported only by the AirEngine 9700D-M and AirEngine 9700D-M1. The parameters **cpu** and **np** are supported only by the AirEngine 9700D-M.

If **ap-environment** | **cpu** | **np** is not specified, this command sets an upper temperature alarm threshold for APs.

Example

Set the upper temperature alarm threshold for APs to 65°C.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] high-temperature threshold 65
```

11.2.114 ipsg enable (AP wired port profile view)

Function

The **ipsg enable** command enables IP source guard (IPSG) on an AP's wired interface.

The **undo ipsg enable** command disables IPSG on an AP's wired interface.

By default, IPSG is disabled on an AP's wired interface.

Format

ipsg enable

undo ipsg enable

Parameters

None

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Attackers often use packets with the source IP addresses or MAC addresses of authorized users to access or attack networks. As a result, authorized users cannot obtain stable and secure network services. You can enable the IPSG function to prevent the situation.

Prerequisites

Terminal address learning has been enabled on the AP's wired interface using the **learn-client-address enable** command.

Follow-up Procedure

Bind the AP wired port profile to an AP group or AP.

Precautions

This command takes effect only on IP packets transmitted on an AP's wired interface.

An AP's wired interface added to an Eth-Trunk does not support this function.

Example

Enable IPSG on an AP's wired interface.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wired-port-profile name wire1
[HUAWEI-wlan-wired-port-wire1] ipsg enable
```

11.2.115 ip-address (AP view)

Function

The **ip-address** command configures a static IPv4 address and gateway for an AP.

The **undo ip-address** command restores the default static IPv4 address and gateway for an AP.

By default, no static IPv4 address and gateway are configured for an AP.

Format

ip-address *ip-address* { *mask-length* | *mask* } [**gateway** *gateway*]

undo ip-address

Parameters

Parameter	Description	Value
ip-address	Specifies the static IPv4 address for an AP.	The value is in dotted decimal notation.
mask	Specifies the IPv4 address mask for an AP.	The value is in dotted decimal notation.
mask-length	Specifies the IPv4 address mask length for an AP.	The value is an integer that ranges from 0 to 32.
gateway *gateway*	Specifies the egress gateway for AP routes.	The value is in dotted decimal notation.

Views

AP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure an AP to go online using a specified IPv4 address, run the command to configure a static IPv4 address for the AP.

Prerequisites

The AP has been configured to obtain an IP address in static mode using the **address-mode (AP provisioning view)** command.

Precautions

Ensure that there are reachable routes between the configured IPv4 address and the AC source address for an AP to go online. Otherwise, the AP may fail to go online.

CAPWAP packets between the central AP and RUs in versions earlier than V200R019C10 are forwarded at Layer 2 and are independent of IP addresses on an agile distributed WLAN. Therefore, the configuration of an IP address does not affect the RU going online. Ensure that a route is reachable between the IP address of the RU and the central AP source address. Otherwise, services involving IP addresses may be affected, for example, STelnet.

If the AP and AC are connected through a Layer 3 network, the egress gateway for AP routes must be configured.

Example

Set the static IPv4 address of the AP to 10.1.1.1/24.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 0
[HUAWEI-wlan-ap-0] address-mode static
Warning: The incorrect configuration will cause the AP to go out of management. This operation will
deliver parameter setting and ma
y cause reboot of AP(s). Continue?[Y/N]:y
[HUAWEI-wlan-ap-0] ip-address 10.1.1.1 24
Warning: The incorrect configuration will cause the AP to go out of management. This operation will
deliver parameter setting and ma
y cause reboot of AP(s). Continue?[Y/N]:y
```

11.2.116 ip-address (AP provisioning view)

Function

The **ip-address** command configures a static IPv4 address and gateway for an AP.

The **undo ip-address** command disables the AC from delivering this parameter setting to APs after the configuration is delivered using the **commit** command.

By default, no static IPv4 address and gateway are configured for an AP.

Format

ip-address *ip-address* { *mask-length* | *mask* } [**gateway** *gateway*]

undo ip-address

Parameters

Parameter	Description	Value
ip-address	Specifies the static IPv4 address for an AP.	The value is in dotted decimal notation.
mask	Specifies the IPv4 address mask for an AP.	The value is in dotted decimal notation.
mask-length	Specifies the IPv4 address mask length for an AP.	The value is an integer that ranges from 0 to 32.
gateway *gateway*	Specifies the egress gateway for AP routes.	The value is in dotted decimal notation.

Views

AP provisioning view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure an AP to go online using a specified IPv4 address, run the **ip-address** command to configure a static IPv4 address for the AP.

Prerequisites

The AP has been configured to obtain an IP address in static mode using the **address-mode (AP provisioning view)** command.

Follow-up Procedure

Run the **commit** command to deliver configuration to APs and restart the APs to make the configuration take effect.

Precautions

Ensure that there are reachable routes between the configured IPv4 address and the AC source address for an AP to go online. Otherwise, the AP may fail to go online.

CAPWAP packets between the central AP and RUs are forwarded at Layer 2 and are independent of IP addresses on an agile distributed WLAN. Therefore, the configuration of an IP address does not affect the RU going online. Ensure that a route is reachable between the IP address of the RU and the central AP source address. Otherwise, services involving IP addresses, for example, Telnet, may be affected.

If the AP and AC are connected through a Layer 3 network, the egress gateway for AP routes must be configured.

Example

Set the static IPv4 address of the AP to 10.1.1.1/24.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] provision-ap
[HUAWEI-wlan-provision-ap] address-mode static
[HUAWEI-wlan-provision-ap] ip-address 10.1.1.1 24
```

11.2.117 ip domain-name

Function

The **ip domain-name** command sets the default domain name suffix.

The **undo ip domain-name** command deletes the default domain name suffix.

By default, no default domain name suffix is provided.

Format

ip domain-name *domain-name*

undo ip domain-name

Parameters

Parameter	Description	Value
domain-name	Specifies the domain name suffix.	The value is a string of 1 to 255 characters.

Views

AP view, AP group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Devices with the same system name may exist in different domains. In this case, you can configure a fully qualified domain name (FQDN) for a device to uniquely identify it. The FQDN of a device consists of the default domain name suffix and device name. You can run the **ip domain-name** command to set the default domain name suffix and the **sysname** command to set the device name.

Precautions

If you run this command multiple times, the latest configuration overrides the previous ones.

Example

Set the domain name suffix to **com.cn**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 1
[HUAWEI-wlan-ap-1] ip domain-name com.cn
```

11.2.118 igmp-snooping enable (AP wired port profile view)

Function

The **igmp-snooping enable** command enables IGMP snooping on an AP's wired interface.

The **undo igmp-snooping enable** command disables IGMP snooping on an AP's wired interface.

By default, IGMP snooping is disabled on an AP's wired interface.

Format

igmp-snooping enable

undo igmp-snooping enable

Parameters

None

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IGMP snooping is a basic Layer 2 multicast function that forwards and controls multicast traffic at the data link layer. IGMP snooping runs on a Layer 2 device and analyzes IGMP messages exchanged between a Layer 3 device and hosts to set up and maintain a Layer 2 multicast forwarding table. The Layer 2 device forwards multicast packets based on the Layer 2 multicast forwarding table.

Prerequisites

An AP wired port profile has been created.

Precautions

The AP wired interfaces added to an Eth-trunk interface do not support this function.

The **igmp-snooping enable** command is used to enable Layer 2 multicast services. To ensure multicast service experience, you are advised to disable the multicast packet rate limiting function by using the **traffic-optimize broadcast-suppression other-multicast disable** command in the AP system profile view.

When multicast services are enabled, the multicast services may be affected if rate limiting for multicast packets is enabled on an AP. In this case, you are advised to run the **traffic-optimize broadcast-suppression rate-threshold (AP system profile view)** command to adjust the rate limit threshold for multicast packets.

Example

Enable IGMP snooping on AP wired port profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] wired-port-profile name p1
[HUAWEI-wlan-wired-port-p1] igmp-snooping enable
```

11.2.119 keep-service enable

Function

The **keep-service enable** command enables service holding upon CAPWAP link disconnection.

The **undo keep-service enable** command disables service holding upon CAPWAP link disconnection.

By default, service holding upon CAPWAP link disconnection is disabled.

Format

keep-service enable

undo keep-service enable

Parameters

None

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In direct forwarding mode, you can enable service holding upon CAPWAP link disconnection. In this way, when the CAPWAP link between an AP and AC is disconnected, the AP can continue to provide WLAN services, preventing service interruption and improving forwarding reliability.

Precautions

Service holding upon CAPWAP link disconnection can be configured in the VAP profile view and AP system profile view. The configuration in the VAP profile view takes precedence over that in the AP system profile view.

Service holding upon CAPWAP link disconnection is mutually exclusive with the containment function. Service holding upon CAPWAP link disconnection does not take effect when the containment function is also configured.

After service holding upon CAPWAP link disconnection is enabled, the **display access-user** command cannot display information about NAC STAs that are online before the CAPWAP link is disconnected. To display information about such STAs, run the **display station** command.

Example

Configure the AP to continue providing data services after the CAPWAP link between the AP and AC is disconnected.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] keep-service enable
```

11.2.120 keep-service enable allow new-access

Function

The **keep-service enable allow new-access** command enables offline APs to allow access of new STAs.

The **undo keep-service enable** command disables offline APs from allowing access of new STAs.

By default, offline APs cannot allow access of new STAs.

Format

keep-service enable allow new-access [**no-auth**]

undo keep-service enable

Parameters

Parameter	Description	Value
no-auth	Allows access of STAs using Portal or MAC address authentication.	-

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Service holding upon CAPWAP link disconnection controls whether new STAs are allowed to go online. For high-security authentication modes such as MAC address authentication and Portal authentication, **no-auth** must be configured to enable STAs to go online without authentication upon CAPWAP link disconnection. Therefore, this function can be enabled in scenarios with low security requirements.

Precautions

The function of enabling offline APs to allow access of STAs is applicable to scenarios where service data is forwarded in direct mode and the STA authentication mode is Portal, MAC address, WEP, WPA/WPA2-PSK, or open system.

Example

Enable offline APs to allow access of new STAs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] keep-service enable allow new-access
```

11.2.121 learn-client-address enable (AP wired port profile view)

Function

The **learn-client-address enable** command enables STA address learning on an AP's wired interface.

The **undo learn-client-address enable** command disables STA address learning on an AP's wired interface.

By default, STA address learning is disabled on an AP's wired interface.

Format

learn-client-address { **ipv4** | **ipv6** } **enable**

undo learn-client-address { **ipv4** | **ipv6** } **enable**

Parameters

Parameter	Description	Value
ipv4	Indicates the IPv4 address.	-
ipv6	Indicates the IPv6 address.	-

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After STA address learning is enabled on an AP's wired interface, if a wired terminal connected to the AP's wired interface successfully obtains an IP address, the AP automatically reports the IP address of the terminal to the AC, helping to maintain the ARP binding entries of wired terminals.

Follow-up Procedure

Bind the AP wired port profile to an AP group or AP.

Precautions

An AP's wired interface added to an Eth-Trunk does not support this function.

STA address learning on an AP's wired interface takes effect only for STAs that obtain IP addresses through DHCP, and does not take effect for STAs using static IP addresses.

If a bridging device functions as a STA to connect to an AP enabled with STA address learning, the AP cannot learn IP addresses of users connected to the bridging device; therefore, the users cannot communicate with the network. In this situation, disable STA address learning.

Example

Enable STA IPv4 address learning on an AP's wired interface.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wired-port-profile name wire1
[HUAWEI-wlan-wired-port-wire1] learn-client-address ipv4 enable
```

11.2.122 led blink-time

Function

The **led blink-time** command configures the indicator blinking function for an AP.

The **undo led blink-time** command cancels the indicator blinking configuration of an AP.

By default, the indicator blinking function is disabled on an AP.

Format

led blink-time *blink-time* { **ap-mac** *ap-mac* | **ap-name** *ap-name* | **ap-id** *ap-id* }

undo led blink-time { **ap-mac** *ap-mac* | **ap-name** *ap-name* | **ap-id** *ap-id* | **all** }

Parameters

Parameter	Description	Value
blink-time	Specifies the blinking time of an AP.	The value is an integer that ranges from 1 to 86400, in seconds.

Parameter	Description	Value
ap-mac *ap-mac*	Specifies the MAC address of an AP.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.
ap-name *ap-name*	Specifies the AP name.	The AP name must exist.
ap-id *ap-id*	Specifies the AP ID.	The AP ID must exist.
all	Cancels the indicator blinking configuration of all APs.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To locate an AP, run this command on the AC to configure the AP indicator to blink.

When this function is enabled, the SYS indicator blinks red.

Precautions

Offline APs cannot be located by configuring the AP indicator to blink.

The configuration using the **led blink-time** command takes precedence over that using the **led off** command. That is, if AP indicators are configured to blink and to turn off or turn off during the specified time range, the configuration performed using the **led off** command takes effect after the RU indicators blink.

This function is not available for central APs.

Example

Configure the indicator of an AP with the MAC address of 00e0-fc12-3456 to blink for 300 seconds.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] led blink-time 300 ap-mac 00e0-fc12-3456
```

11.2.123 led off

Function

The **led off** command turns off AP indicators.

The **undo led off** command restores the default settings.

By default, AP indicators are allowed to turn on.

Format

led off

undo led off

Parameters

None

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Blinking indicators of indoor APs deployed in hospitals and hotels may affect people's nighttime rest. To prevent this, run the **led off** command to turn off AP indicators.

If you need to locate AP faults by observing AP indicator status, run the **undo led off** command to allow the AP indicators to turn on.

Precautions

The configuration performed using the **led blink-time** command takes precedence over that performed using the **led off** command. That is, if AP indicators are configured to blink and to turn off or turn off during the specified time range, the configuration performed using the **led off** command takes effect after the RU indicators blink.

Example

Turn off AP indicators.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] led off
```

11.2.124 lldp admin-status

Function

The **lldp admin-status** command sets the LLDP operation mode for an AP.

The **undo lldp admin-status** command restores the default LLDP operation mode for an AP.

By default, the LLDP operation mode of an AP is TxRx.

Format

lldp admin-status { **rx** | **tx** | **txrx** }

undo lldp admin-status

Parameters

Parameter	Description	Value
rx	Specifies the LLDP operation mode as Rx. An AP only receives but does not send LLDP packets.	-
tx	Specifies the LLDP operation mode as Tx. An AP only sends but does not receive LLDP packets.	-
txrx	Specifies the LLDP operation mode as TxRx. An AP sends and receives LLDP packets.	-

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

You can configure the LLDP operation mode for an AP based on the site requirements. For example, if you set the LLDP operation mode of an AP to Tx, the AP sends LLDP packets but cannot receive LLDP packets from neighbors. In this situation, the AP cannot discover neighbors.

Example

Set the LLDP operation mode of an AP to Tx.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] lldp admin-status tx
```

11.2.125 lldp dot3-tlv power (AP wired port link profile view)

Function

The **lldp dot3-tlv power** command configures the standard with which the 802.3 Power via MDI TLV advertised by an AP's wired interface complies.

By default, the 802.3 Power via MDI TLV advertised by a UPoE interface and a PoE interface complies with 802.3bt and 802.3at, respectively.

Format

lldp dot3-tlv power { **802.1ab** | **802.3at** | **802.3bt** }

undo lldp dot3-tlv power

Parameters

Parameter	Description	Value
802.1ab	Indicates that the 802.3 Power via MDI TLV advertised an AP's wired interface complies with 802.1ab.	-
802.3at	Indicates that the 802.3 Power via MDI TLV advertised an AP's wired interface complies with 802.3at.	-
802.3bt	Indicates that the 802.3 Power via MDI TLV advertised an AP's wired interface complies with 802.3bt.	-

Views

AP wired port link profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The 802.3 Power via MDI TLV advertised by an AP's wired interface supports the following formats:

- 802.1ab format: [TLV type | TLV information string length | 802.3 OUI | MDI power support | PSE power pair | power class]
- 802.3at format: [TLV type | TLV information string length | 802.3 OUI | MDI power support | PSE power pair | power class | type/source/priority | PD requested power value | PSE allocated power value]
- 802.3bt format: [TLV type | TLV information string length | 802.3 OUI | MDI power support | PSE power pair | power class | type/source/priority | PD requested power value | PSE allocated power value | PD requested power value Mode A | PD requested power value Mode B | PSE allocated power value Alternative A | PSE allocated power value Alternative B | PSE power status | System setup | PSE maximum available power | Autoclass | Power down]

Based on 802.1ab, 802.3at extends three fields: type/source/priority, PD requested power value, and PSE allocated power value. Based on 802.3at, 802.3bt extends the following fields to provide more detailed UPoE information: PD requested power value Mode A, PD requested power value Mode B, PSE allocated power value Alternative A, PSE allocated power value Alternative B, PSE power status, System setup, PSE maximum available power, Autoclass, and Power down.

Prerequisites

- The LLDP function has been enabled in both the WLAN view and AP wired port link profile view.
- APs' wired interfaces are allowed to advertise the 802.3 Power via MDI TLV.

Precautions

Before selecting a format of the 802.3 Power via MDI TLV, you need to know the TLV formats supported by the neighbors. The TLV format on the local device must be the same as that on the neighbors.

Member interfaces of the Eth-Trunk do not support this command.

Example

Configure the 802.3 Power via MDI TLV advertised by the AP's wired interface to comply with 802.3at.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] port-link-profile name port-link1
[HUAWEI-wlan-port-link-prof-port-link1] lldp dot3-tlv power 802.3at
```

11.2.126 lldp enable

Function

The **lldp enable** command enables LLDP on an AP's wired interface.

The **undo lldp enable** command disables LLDP on an AP's wired interface.

By default, LLDP is enabled on an AP's wired interface.

Format

lldp enable

undo lldp enable

Parameters

None

Views

AP wired port link profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

AP wired interfaces can exchange LLDP packets with neighbors to obtain neighbor status and transmit AP status to neighbors. The AP and neighbors save the received information to the Management Information Base (MIB) to query and determine the link status.

Prerequisite

The LLDP function has been enabled in the WLAN view using the **ap lldp enable** command.

Example

Enable LLDP on the AP's wired interface.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap lldp enable
[HUAWEI-wlan-view] port-link-profile name port-link1
[HUAWEI-wlan-port-link-prof-port-link1] lldp enable
```

11.2.127 lldp message-transmission delay (AP system profile view)

Function

The **lldp message-transmission delay** command sets the LLDP packet transmission delay.

The **undo lldp message-transmission delay** command restores the default LLDP packet transmission delay.

The default LLDP packet transmission delay is 2 seconds.

Format

lldp message-transmission delay *delay*

undo lldp message-transmission delay

Parameters

Parameter	Description	Value
delay	Specifies the LLDP packet transmission delay.	The value is an integer that ranges from 1 to 8192, in seconds. The *delay* value depends on the parameter *interval* set by the **lldp message-transmission interval** command. The *delay* value must be less than or equal to a quarter of the *interval* value.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

There is a delay before the AP sends an LLDP packet to the neighbor when the device status changes frequently.

If the AP status changes frequently, extend the delay in preventing the AP from frequently sending packets to the neighbors. A delay suppresses the network topology flapping.

Configuration Impact

The LLDP packet transmission delay must be set properly and adjusted according to network loads.

- A large value reduces the LLDP packet transmission frequency when the local device status frequently changes. This helps save system resources. However, if the value is too large, the device cannot notify neighbors of its status in a timely manner, and the NMS cannot discover the network topology changes in real time.

- A small value increases the LLDP packet transmission frequency and enables the NMS to discover network topology changes in real time when the local device status frequently changes. However, if the value is too small, LLDP packets are exchanged frequently. This increases the system load and wastes resources.
- The default value is recommended.

Precautions

Consider the value of *interval* when adjusting the value of *delay* because it is restricted by the value of *interval*.

- Decreasing the value of *delay* is not restricted by the value of *interval*. *delay* can be any number from 1 to 8192.
- The *delay* value must be less than or equal to a quarter of the *interval* value. Therefore, if you want to set *delay* to be greater than a quarter of *interval*, first increase the *interval* value to at least four times the new *delay* value, and then increase the *delay* value.

NOTE

If the *interval* value is smaller than four times the *delay* value, the system displays an error message when you run the **undo lldp message-transmission delay** command. To run the **undo lldp message-transmission delay** command, increase the *interval* value to at least four times the *delay* value first.

Example

Set the LLDP packet transmission delay to 10 seconds.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] lldp message-transmission delay 10
```

11.2.128 lldp message-transmission hold-multiplier (AP system profile view)

Function

The **lldp message-transmission hold-multiplier** command sets the hold time multiplier of device information stored on neighbors.

The **undo lldp message-transmission hold-multiplier** command restores the default hold time multiplier of device information stored on neighbors.

The default hold time multiplier is 4.

Format

lldp message-transmission hold-multiplier *hold*

undo lldp message-transmission hold-multiplier

Parameters

Parameter	Description	Value
hold	Specifies the hold time multiplier of device information stored on neighbors.	The value is an integer that ranges from 2 to 10.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The time multiplier is used to calculate how long a packet can be saved on a neighboring node. After receiving an LLDP packet, a neighbor updates the aging time of the device information from the sender based on the TTL.

The storage time calculation formula is: TTL = Min (65535, (*interval* x *hold*)).

TTL is the device information storage time. It is the smaller value between 65535 and (*interval* x *hold*).

interval indicates the interval at which the device sends LLDP packets to neighbors. This parameter is set by the **lldp message-transmission interval** command. *hold* indicates the hold time multiplier of device information stored on neighbors.

After the LLDP function is disabled on the device, its neighbors wait until the TTL of the device information expires, and then delete the device information. This prevents network topology flapping.

Configuration Impact

The hold time multiplier of device information stored on neighbors must be set to a proper value.

- A large value of *delay* prevents network topology flapping. However, if the value is too large, the device cannot notify neighbors of its status in a timely manner, and the NMS cannot discover the network topology changes in real time.
- A small value of *delay* enables the NMS to discover topology change in time. However, if the value is too small, the neighbors update device information too frequently. This increases the load on the system and wastes resources.
- The default value is recommended.

Example

Set the hold time multiplier of AP information stored on neighbors to 5.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] lldp message-transmission hold-multiplier 5
```

11.2.129 lldp message-transmission interval (AP system profile view)

Function

The **lldp message-transmission interval** command sets the LLDP packet transmission interval.

The **undo lldp message-transmission interval** command restores the default LLDP packet transmission interval.

The default LLDP packet transmission interval is 30 seconds.

Format

lldp message-transmission interval *interval*

undo lldp message-transmission interval

Parameters

Parameter	Description	Value
interval	Specifies the LLDP packet transmission interval.	The value is an integer that ranges from 5 to 32768, in seconds. The *interval* value depends on the parameter *delay* set by the **lldp message-transmission delay** command. The *interval* value must be greater than or equal to 4 times the *delay* value; otherwise, the system displays an error message when you run the **lldp message-transmission interval** command.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the LLDP status of the AP keeps unchanged or the AP does not discover new neighbors, the AP sends LLDP packets to the neighbors at a specified interval.

If you want to change the network topology detection frequency, run the **lldp message-transmission interval** command to change the LLDP packet transmission interval.

Configuration Impact

The LLDP transmission interval must be set properly and adjusted according to network loads.

- A large value reduces the LLDP packet transmission frequency. This helps save system resources. However, if the value is too large, the device cannot notify neighbors of its status in a timely manner, and the NMS cannot discover the network topology changes in real time.
- A short interval increases the LLDP packet transmission frequency and enables the NMS to discover network topology changes in real time. If the delay is too short, LLDP packets are exchanged frequently. This increases the system load and wastes resources.
- The default value is recommended.

Precautions

Consider the value of *delay* when adjusting the value of *interval* because it is restricted by the value of *interval*.

- Increasing the value of *interval* is not restricted by the value of *delay*. *interval* can be any number from 5 to 32768.
- The *interval* value must be greater than or equal to four times the *delay* value. Therefore, if you want to set *interval* to be smaller than four times the value of *delay*, first reduce the *delay* value to be less than or equal to a quarter of the new *interval* value, and then reduce the *interval* value.

NOTE

If the *delay* value is larger than a quarter of the *interval* value, the system displays an error message when you run the **undo lldp message-transmission interval** command. To run the **undo lldp message-transmission interval** command, reduce the *delay* value to be less than or equal to a quarter of the *interval* value first.

Example

Set the LLDP packet transmission interval to 60 seconds.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] lldp message-transmission interval 60
```

11.2.130 lldp report enable

Function

The **lldp report enable** command enables an AP to report information about its LLDP neighbors.

The **undo lldp report enable** command disables an AP from reporting information about its LLDP neighbors.

By default, an AP does not report information about its LLDP neighbors.

Format

lldp report enable

undo lldp report enable

Parameters

None

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **lldp report enable** command to enable an AP to report information about its LLDP neighbors.

Example

Enable an AP to report information about its LLDP neighbors.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name example
[HUAWEI-wlan-ap-system-prof-example] lldp report enable
```

11.2.131 lldp report-interval

Function

The **lldp report-interval** command sets the interval at which an AP reports LLDP neighbor information.

The **undo lldp report-interval** command restores the default interval at which an AP reports LLDP neighbor information.

By default, an AP reports LLDP neighbor information at an interval of 30 seconds.

Format

lldp report-interval *interval-time*

undo lldp report-interval

Parameters

Parameter	Description	Value
interval-time	Specifies the interval at which an AP reports LLDP neighbor information to an AC.	The value is an integer that ranges from 5 to 3600, in seconds.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

You can run the **lldp report-interval** command to adjust the interval at which an AP reports LLDP neighbor information. This prevents LLDP neighbor information from being frequently reported.

Example

Set the interval at which an AP reports LLDP neighbor information to an AC to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] lldp report-interval 20
```

11.2.132 lldp restart-delay

Function

The **lldp restart-delay** command sets the delay in re-enabling LLDP on an AP.

The **undo lldp restart-delay** command restores the default delay in re-enabling the LLDP function on an AP.

By default, the delay in re-enabling LLDP on an AP is 2 seconds.

Format

lldp restart-delay *delay-time*

undo lldp restart-delay

Parameters

Parameter	Description	Value
delay-time	Specifies the delay in re-enabling LLDP.	The value is an integer that ranges from 1 to 10, in seconds.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

When the LLDP status of an AP changes, the AP reports LLDP neighbor information. Setting the delay in re-enabling LLDP on the AP prevents the AP from frequently reporting LLDP neighboring information when the LLDP status of the AP frequently changes.

Example

Set the delay in re-enabling LLDP on an AP to 1 second.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] lldp restart-delay 1
```

11.2.133 lldp tlv-enable (AP wired port link profile view)

Function

The **lldp tlv-enable** command specifies the types of TLVs that an AP wired interface advertises.

The **undo lldp tlv-enable** command specifies the types of TLVs that an AP wired interface is prohibited from advertising.

By default, an AP wired interface advertises all types of TLVs.

Format

lldp tlv-enable basic-tlv { **all** | **management-address** | **port-description** | **system-capability** | **system-description** | **system-name** }

lldp tlv-enable dot3-tlv power

undo lldp tlv-enable basic-tlv { **all** | **management-address** | **port-description** | **system-capability** | **system-description** | **system-name** }

undo lldp tlv-enable dot3-tlv power

Parameters

Parameter	Description	Value
basic-tlv	Indicates basic TLVs to be advertised: ● Management-address TLV ● Port Description TLV ● System Capabilities TLV ● System Description TLV ● System Name TLV	-
all	Configures the AP wired interface to advertise all types of TLVs when basic TLVs are configured.	-
management-address	Configures the AP wired interface to advertise Management-address TLVs.	-
port-description	Configures the AP wired interface to advertise Port Description TLVs.	-
system-capability	Configures the AP wired interface to advertise System Capabilities TLVs.	-
system-description	Configures the AP wired interface to advertise System Description TLVs.	-
system-name	Configures the AP wired interface to advertise System Name TLVs.	-

Parameter	Description	Value
dot3-tlv	Configures an AP's wired interface to advertise TLVs defined by IEEE 802.3.	-
power	Configures an AP's wired interface to advertise the Power Via MDI TLV defined by IEEE 802.3 and negotiate the PoE power.	-

Views

AP wired port link profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In LLDP, all device information is encapsulated in Link Layer Discovery Protocol data units (LLDPDUs), which are then sent to neighbors. An LLDPDU contains a variety of TLVs. In a TLV, T indicates the information type, L indicates the information length, and V indicates the value or the content to be sent.

Devices exchange LLDPDUs carrying TLVs to obtain neighbor information. The TLVs that can be encapsulated in an LLDP packet include basic TLVs and TLVs in the IEEE 802.3 format.

Basic TLVs are essential for managing network devices. The TLVs in the IEEE 802.3 format are defined by standardization organizations and other organizations, which are used to enhance the network device management. You can determine whether to advertise the TLVs in the IEEE 802.3 format.

Devices on both ends can have different TLV types configured. You only need to configure TLV types according to networking requirements.

Prerequisites

The LLDP function has been enabled in both the WLAN view and AP wired port link profile view.

Precautions

When basic TLVs are configured, if the **all** parameter is specified, all optional basic TLVs are advertised. If the **all** parameter is not specified, TLVs of only one type can be advertised at a time. To advertise multiple types of TLVs, run this command multiple times.

Example

Configure the wired interface of AP to advertise Management-address TLVs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap lldp enable
[HUAWEI-wlan-view] port-link-profile name port-link1
[HUAWEI-wlan-port-link-prof-port-link1] lldp tlv-enable basic-tlv management-address
```

11.2.134 lldp tlv-enable legacy-tlv four-pair-power (AP wired port link profile view)

Function

The **lldp tlv-enable legacy-tlv four-pair-power** command configures an AP's wired interface to advertise Cisco's customized TLVs.

The **undo lldp tlv-enable legacy-tlv four-pair-power** command prohibits an AP's wired interface from advertising Cisco's customized TLVs.

By default, an AP's wired interface advertises Cisco's customized TLVs.

Format

lldp tlv-enable legacy-tlv four-pair-power

undo lldp tlv-enable legacy-tlv four-pair-power

Parameters

None

Views

AP wired port link profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Some Cisco's switches use customized LLDP TLVs to negotiate the UPoE power supply. If such a switch is used to supply UPoE power to an AP, the AP's wired interface connected to the switch must be enabled to advertise Cisco's customized TLVs for UPoE power negotiation. Otherwise, LLDP negotiation fails. If interfaces on the Cisco's switch do not supply UPoE power, the AP is provided with insufficient input power and cannot work properly.

Example

Configure an AP's wired interface to advertise Cisco's customized TLVs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] port-link-profile name port-link1
[HUAWEI-wlan-port-link-prof-port-link1] lldp tlv-enable legacy-tlv four-pair-power
```

11.2.135 lldp tlv-enable legacy-tlv power-capability (AP wired port link profile view)

Function

The **lldp tlv-enable legacy-tlv power-capability** command configures LLDP packets sent by an AP to carry the supported power capability.

The **undo lldp tlv-enable legacy-tlv power-capability** command configures LLDP packets sent by an AP not to carry the supported power capability.

By default, the LLDP packets sent by an AP carry the supported power capability.

Format

lldp tlv-enable legacy-tlv power-capability

undo lldp tlv-enable legacy-tlv power-capability

Parameters

None

Views

AP wired port link profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When directly connected to a Huawei PoE switch, the AP can send its power capability to the switch through LLDP. If the total output power of the PoE switch exceeds the threshold, the switch adjusts the output power of the corresponding Ethernet port based on the power capability of the AP. This reduces the output power without affecting the basic functions of the AP.

Example

Configure the LLDP packets sent by an AP to carry the supported power capability.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] port-link-profile name port-link1
[HUAWEI-wlan-port-link-prof-port-link1] lldp tlv-enable legacy-tlv power-capability
```

11.2.136 location

Function

The **location** command configures the installation position of an AP.

The **undo location** command deletes the installation position of an AP.

By default, an AP's installation position is not configured.

NOTE

This command is not available for the following APs:

- AirEngine 5761-10W and AirEngine 5761S-10W

Format

location *location-value*

undo location

Parameters

Parameter	Description	Value
location-value	Specifies the installation position of an AP.	The value is a string of 1 to 63 case-sensitive characters. If the value contains space, it must start and end with double quotation marks ("), for example, **"hello name1"**. Each double quotation mark in the value occupies one character. The value cannot start or end with spaces and double quotation marks ("). For example, **" HELLO"** and **"HELLO "** are not allowed.

Views

AP group view, AP view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to configure the installation position of an AP.

Example

Configure the installation position of an AP to **B2-5F-01**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 0
[HUAWEI-wlan-ap-0] location B2-5F-01
```

11.2.137 log-record-level

Function

The **log-record-level** command configures the level for AP logs that need to be backed up.

The **undo log-record-level** command restores the default level of AP logs that need to be backed up.

By default, the level of AP logs that need to be backed up is **info**.

Format

log-record-level { **alert** | **critical** | **debug** | **emergency** | **error** | **info** | **notice** | **warning** }

undo log-record-level

Parameters

Parameter	Description	Value
alert	Configures the level of logs as **alert**, that is, the AP backs up logs that need to be processed immediately.	-
critical	Configures the level of logs as **critical**, that is, the AP backs up critical logs.	-
debug	Configures the level of logs as **debug**, that is, the AP backs up debugging logs.	-
emergency	Configures the level of logs as **emergency**, that is, the AP backs up unavailable logs.	-
error	Configures the level of logs as **error**, that is, the AP backs up error logs.	-
info	Configures the level of logs as **info**, that is, the AP backs up normal logs.	-
notice	Configures the level of the logs as **notice**, that is, the AP backs up logs that need to be noticed.	-

Parameter	Description	Value
warning	Configures the level of logs as **warning**, that is, the AP backs up warning logs.	-

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An AP periodically backs up logs to the log server. However, not all the logs need to be backed up. You can run the **log-record-level** command to configure the level of logs to be periodically backed up.

Precautions

The preference order of log levels is emergency, alert, critical, error, warning, notice, info, and debug.

After you specify the level for AP logs that need to be backed up, all logs of the specified level or a higher level will be backed up. For example, if you set the level of AP logs that need to be backed up to **critical**, the logs of the levels **emergency**, **alert**, and **critical** will be backed up.

Example

Set the level of logs that need to be backed up as **alert**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] log-record-level alert
```

11.2.138 log-server

Function

The **log-server** command configures the log server IP address and port number in the AP system profile and enables log backup on the AP.

The **undo log-server** command restores the default log server IP address and port number in the AP system profile and disables log backup on the AP.

By default, the port number of the log server is 514 in UDP mode, the log server IP address is not configured in an AP system profile, and log backup is disabled on an AP.

Format

log-server ip-address *server-ip-address* [**port** *port*]

undo log-server

Parameters

Parameter	Description	Value
ip-address *server-ip-address*	Specifies the IPv4 address of the log server.	The value is in dotted decimal notation.
port *port*	Specifies the port number of the log server.	The value is an integer that ranges from 1 to 65535. The default port number is 514.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

You can run the **log-server** command to configure the log server IP address and port number in the AP system profile and enable log backup on the AP. After log backup is enabled, the AP automatically sends logs to the log server with the specified IP address.

NOTICE

Modifying the configuration of an AP system profile changes configurations of all APs using this profile.

Example

Set the IP address of the log server to 10.0.0.1 and port number to 2000 and enable log backup on the AP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] log-server ip-address 10.0.0.1 port 2000
```

11.2.139 low-temperature threshold

Function

The **low-temperature threshold** command sets a lower device, ambient, CPU, or NP module temperature alarm threshold for APs.

The **undo low-temperature threshold** command restores the default lower device, ambient, CPU, or NP module temperature alarm threshold of APs.

Table 11-127 Default lower temperature alarm threshold for APs

AP Model	Default Value (°C)
/AirEngine 9700D-M1 (AP device and environment)	-3

NOTE

This command is not supported by the following models:

- AirEngine series APs

Format

low-temperature [**ap-environment** | **cpu** | **np**] **threshold** *threshold*

undo low-temperature [**ap-environment** | **cpu** | **np**] **threshold**

Parameters

Parameter	Description	Value
ap-environment	Indicates the ambient temperature.	-
cpu	Indicates the CPU temperature.	-
np	Indicates the NP module temperature.	-
threshold	Specifies the lower temperature alarm threshold.	The value is an integer that ranges from -70 to +10, in °C.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to set the lower temperature alarm threshold for an AP. When an AP's temperature exceeds the lower threshold, the AP generates an alarm and a log, and notifies the AC of the low temperature alarm.

The parameter **ap-environment** is supported only by the AirEngine 9700D-M and AirEngine 9700D-M1. The parameters **cpu** and **np** are supported only by the AirEngine 9700D-M.

If **ap-environment** | **cpu** | **np** is not specified, this command sets a lower temperature alarm threshold for APs.

Example

Set the lower temperature alarm threshold for APs to 5°C.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] low-temperature threshold 5
```

11.2.140 mac-learning (AP wired port profile view)

Function

The **mac-learning** command configures the MAC address learning priority and packet forwarding policy of an AP's wired interface.

The **undo mac-learning** command restores the default MAC address learning priority and packet forwarding policy of an AP's wired interface.

By default, the MAC address learning priority of an AP's wired interface is 0 and the packet forwarding policy is forward.

Format

mac-learning { **priority** *priority* | **action discard** }*

undo mac-learning priority

undo mac-learning action

Parameters

Parameter	Description	Value
priority *priority*	Specifies the MAC address learning priority of an AP's wired interface.	The value is an integer that ranges from 0 to 3. A larger value indicates a higher priority.
action discard	Configures an AP's wired interface to discard the packet if a wired interface with a higher MAC address learning priority has learned the same MAC address as that carried in this packet.	-

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An AP with multiple network interfaces connects to the upper-layer network through its uplink interfaces and provides access to STAs through its downlink interfaces. If the interfaces with different MAC address learning priorities learn the same MAC address, the MAC address entry learned by the interface with the highest priority overrides those learned by other interfaces, but not vice versa.

When an interface with a lower MAC address learning priority receives a packet carrying the MAC address learned by an interface with a higher priority, the local interface can be configured to discard or forward the packet.

Example

Set the MAC address learning priority to 1 in an AP wired port profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wired-port-profile name wired
[HUAWEI-wlan-wired-port-wired] mac-learning priority 1
```

11.2.141 management-vlan (AP system profile view, AP provisioning view, AP view)

Function

The **management-vlan** command configures CAPWAP packets sent from an AP's wired interface to carry a management VLAN tag.

The **undo management-vlan** command configures CAPWAP packets sent from an AP's wired interface not to carry a management VLAN tag.

In the AP system profile view and AP view, the **undo management-vlan** command configures CAPWAP packets sent from an AP's wired interface not to carry a management VLAN tag. In the AP provisioning view, the **undo management-vlan** command disables the AC from delivering this parameter setting to APs after the configuration is delivered using the **commit** command.

By default, CAPWAP packets sent from an AP's wired interface do not carry a management VLAN tag.

Format

management-vlan *vlan-id*

undo management-vlan

Parameters

Parameter	Description	Value
vlan-id	Specifies the VLAN ID of the management VLAN tag carried in CAPWAP packets sent from an AP's wired interface.	The value is an integer that ranges from 1 to 4094.

Views

AP system profile view, AP provisioning view, AP view

Default Level

2: Configuration level

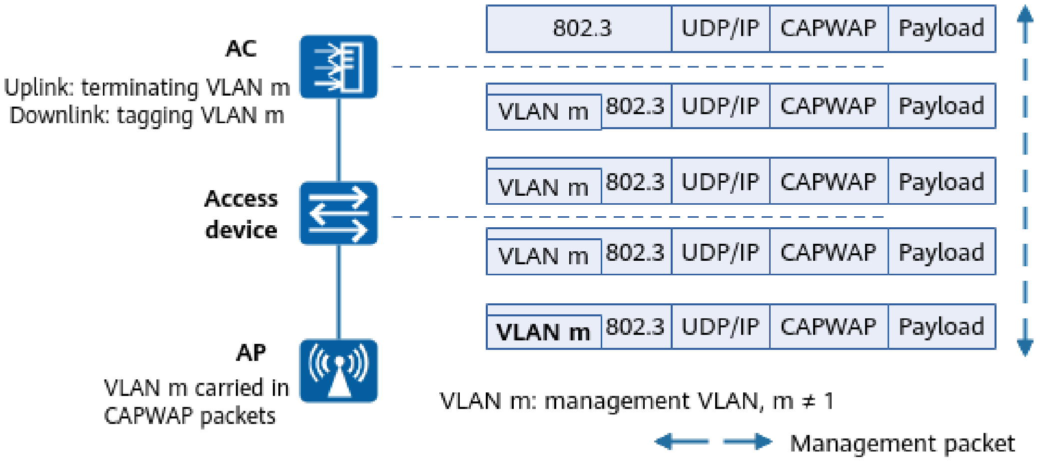
Usage Guidelines

Usage Scenario

By default, CAPWAP packets sent from an AP's wired interface do not carry a management VLAN tag. In most cases, the access switch interface directly connected to the AP adds the tag of the PVID to the CAPWAP packets as the management VLAN ID.

If the access device (for example, an unmanaged switch) does not support the VLAN function or the PVID of the device has been used for other purposes (for example, as the default VLAN ID of wired users), the access device cannot add the management VLAN tag to packets on the interface directly connected to the AP. In this case, you can configure CAPWAP packets sent by an AP's wired interface to carry the management VLAN tag so that the AP adds the management VLAN tag to the CAPWAP packets before sending them to the AC.

Figure 11-1 Flowchart for configuring CAPWAP packets sent by an AP's wired interface to carry the management VLAN tag



Precautions

This configuration takes effect only after the APs restart if the **management-vlan** command is configured in the AP system profile view or AP view.

If the **management-vlan** command is configured in the AP provisioning view, run the **commit** command to deliver the configuration. The configuration takes effect after the APs restart.

On a Mesh network, ensure that CAPWAP packets sent from all APs carry the same management VLAN. Otherwise, Mesh Points (MPs) cannot go online.

Based on the access device capability and PVID configuration, the requirements for configuring CAPWAP packets sent by an AP to carry the management VLAN tag are described in the following table.

Table 11-128 Requirements for configuring CAPWAP packets to carry the management VLAN tag

Access Device Capability and PVID Configuration	AP Configuration Requirements
The access device does not support the VLAN function.	CAPWAP packets are enabled to carry the management VLAN tag. Additionally, ensure that the AP's uplink wired interface is added to the management VLAN in tagged mode. By default, an AP's uplink wired interface joins all VLANs except VLAN 1 in tagged

Access Device Capability and PVID Configuration	AP Configuration Requirements
The access device supports the VLAN function, and the PVID of the interface directly connected to the AP is different from the management VLAN ID.	mode. Therefore, no additional configuration is required. To modify the configuration, run the **vlan tagged** *vlan-id* command in the AP wired port profile view and bind the profile to an AP or AP group.
The access device supports the VLAN function, and the PVID of the interface directly connected to the AP is the same as the management VLAN ID.	CAPWAP packets sent by an AP do not carry the management VLAN tag. The access device adds the management VLAN tag to CAPWAP packets. **NOTE** In this case, to enable CAPWAP packets to carry the management VLAN tag, run the **vlan pvid** *vlan-id* command to configure the PVID of the AP's uplink wired interface to be the same as the management VLAN ID. Otherwise, the AP cannot receive management packets, causing repeated disconnection and restart.

After the **management-vlan** *vlan-id* command is executed to configure AP's wired interfaces to send CAPWAP packets carrying the management VLAN tag (not VLAN 1), the interfaces working in **root** mode are added to VLAN 1 in tagged mode, which cannot be changed.

Example

Configure CAPWAP packets sent from an AP's wired interface to carry management VLAN 2 in the AP system profile view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] management-vlan 2
Warning: The incorrect management VLAN configuration will cause the AP to go out of management. This
operation will make the AP reset. Continue? [Y/N]:y
```

Configure CAPWAP packets sent from a wired interface on AP 0 to carry management VLAN 2.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 0
[HUAWEI-wlan-ap-0] management-vlan 2
Warning: The incorrect configuration will cause the AP to go out of management. This operation will
deliver parameter setting and ma
y cause reboot of AP(s). Continue?[Y/N]:y
```

Configure CAPWAP packets sent from an AP's wired interface to carry management VLAN 2 in the AP provisioning view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] provision-ap
[HUAWEI-wlan-provision-ap] management-vlan 2
Warning: The incorrect management VLAN configuration will cause the AP to go out of management.
```

```
When the configuration is committed,
 the AP will reset.Continue?[Y/N]:y
```

11.2.142 memory-usage threshold

Function

The **memory-usage threshold** command configures a memory usage alarm threshold for APs.

The **undo memory-usage threshold** command restores the default memory usage alarm threshold.

By default, the memory usage alarm threshold on an AP is 80.

Format

memory-usage threshold *threshold*

undo memory-usage threshold

Parameters

Parameter	Description	Value
threshold	Specifies the memory usage alarm threshold of an AP.	The value is an integer that ranges from 30 to 100.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

You can run the **memory-usage threshold** command to configure the memory usage alarm threshold in the AP system profile view. The configuration is delivered to all APs using the profile.

- When the memory usage of an AP exceeds the alarm threshold, .
- When the memory usage of an AP falls below the alarm threshold, .

Example

Set the memory usage alarm threshold of AP 0 to 60.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] memory-usage threshold 60
```

11.2.143 mld-snooping enable (AP wired port profile view)

Function

The **mld-snooping enable** command enables MLD snooping on an AP's wired interface.

The **undo mld-snooping enable** command disables MLD snooping on an AP's wired interface.

By default, MLD snooping is disabled on an AP's wired interface.

Format

mld-snooping enable

undo mld-snooping enable

Parameters

None

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

MLD snooping is a basic IPv6 Layer 2 multicast function that forwards and controls multicast traffic at the data link layer. MLD snooping runs on a Layer 2 device and analyzes MLD messages exchanged between a Layer 3 device and hosts to set up and maintain a Layer 2 multicast forwarding table. The Layer 2 device forwards multicast packets based on the Layer 2 multicast forwarding table.

Prerequisites

An AP wired port profile has been created.

Precautions

The AP wired interfaces added to an Eth-trunk interface do not support this function.

Example

Enable MLD snooping on AP wired port profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] wired-port-profile name p1
[HUAWEI-wlan-wired-port-p1] mld-snooping enable
```

11.2.144 mode (AP wired port profile view)

Function

The **mode** command sets the working mode for an AP's wired interface.

The **undo mode** command restores the default working mode of an AP's wired interface.

By default, the working modes of APs' wired interfaces vary depending on the AP models.

Table 11-129 Working modes of APs' wired interfaces

AP Model	root	endpoint	middle
AirEngine series indoor settled APs	All interfaces (including Eth-Trunk interfaces)	-	-
AirEngine series outdoor APs	All interfaces (including Eth-Trunk interfaces)	-	-
AirEngine series wall plate APs and RUs	Uplink port	Downlink port	-
AirEngine series central APs	Uplink port	-	Downlink port
AirEngine 9700D-S	GE port	-	-

NOTE

The working modes of wired interfaces cannot be changed on the following models:

Format

mode { **root** | **endpoint** | **middle** }

undo mode

Parameters

Parameter	Description	Value
root	Sets the working mode of an AP's wired interface to root, which can connect to an AC.	-
endpoint	Sets the working mode of an AP's wired interface to endpoint, which can connect to a host.	-
middle	Sets the working mode of an AP's wired interface to middle, which allows a central AP to connect to an RU.	-

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When working as an uplink interface to connect to an AC, an AP's wired interface must work in root mode. In root mode, the AP's wired interface automatically joins service VLANs and user-specific VLANs (for example, VLANs assigned by the RADIUS server).

When working as a downlink interface to connect to a wired terminal, the AP's wired interface must work in endpoint mode. In endpoint mode, the AP's wired interface does not join any VLAN by default.

When the central AP connects to RUs through downlink GE interfaces, the working mode of the downlink GE interfaces must be set to **middle**.

Precautions

When the AP's wired interface works in root mode, user isolation cannot be configured. User isolation can be configured on an AP's wired interface only when the interface works in endpoint or middle mode.

When the AP's wired interface works in root mode and has been configured to transmit packets carrying the management VLAN tag using the **management-vlan** *vlan-id* command, the PVID for the AP's wired interface must be configured the same as the management VLAN ID. If the AP's wired interface works in endpoint mode, the PVID can be configured directly. If the AP's wired interface works in middle mode, the PVID cannot be configured.

The configuration of the AP's wired interface takes effect after the AP is restarted.

Example

Set the working mode of the AP's wired interface ETH0 to **endpoint**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name ap-group1
[HUAWEI-wlan-ap-group-ap-group1] quit
[HUAWEI-wlan-view] wired-port-profile name wired
[HUAWEI-wlan-wired-port-wired] mode endpoint
Warning: If the AP goes online through a wired port, the incorrect port mode configuration will cause the
AP to go out of management . This fault can be recovered only by modifying the configuration on the AP.
Continue? [Y/N]:y
[HUAWEI-wlan-wired-port-wired] quit
[HUAWEI-wlan-view] ap-group name ap-group1
[HUAWEI-wlan-ap-group-ap-group1] wired-port-profile wired ethernet 0
```

11.2.145 mtu

Function

The **mtu** command sets the maximum transmission unit (MTU) value for the management VLANIF and CAPWAP on an AP.

The **undo mtu** command restores the default MTU value for the management VLANIF and CAPWAP on an AP.

By default, the MTU value of the management VLANIF and CAPWAP on an AP is 1500 bytes.

Format

mtu *mtu-value*

undo mtu

Parameters

Parameter	Description	Value
mtu-value	Specifies the maximum size of packets sent and received on the management VLANIF and CAPWAP.	The value is an integer that ranges from 1000 to 1700, in bytes.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The MTU determines the maximum number of bytes in IP packets each time a sender can send. The MTU of an IP packet refers to the number of bytes from the IP header of the packet to the data.

The MTU in the AP system profile view is the maximum size of packets sent and received on the management VLANIF and CAPWAP of an AP.

The size of data frames is limited at the network layer. Any time the IP layer receives an IP packet to be sent, it checks to which local interface the packet needs to be sent and obtains the MTU configured on the interface. Then the IP layer compares the MTU with the packet length. If the packet length is longer than the MTU, the IP layer fragments the packet into smaller packets, which are shorter than or equal to the MTU. If unfragmentation is configured, some packets may be discarded during data transmission at the IP layer. To ensure jumbo packets are not dropped during transmission, you need to configure forcible fragmentation. In this case, you can run the **mtu** command to set the size of a fragment.

Therefore, a proper MTU is a prerequisite for normal communication on a network.

- If the configured MTU is excessively small and the packet size is larger, packets are discarded when being forwarded through the forwarding chip; packets are broken into a great number of fragments when being forwarded through the CPU, affecting proper data transmission.
- If the size of packets exceeds the MTU supported by a transit node or a receiver, the transit node or receiver fragments the packets or even discards them, aggravating the network transmission load.

The default MTU is recommended. When the size of packets to be transmitted or the device that receives packets changes, you can change the MTU based on the actual network.

Precautions

- DHCP packets cannot be fragmented. When the MTU value set using the **mtu** command is smaller than the DHCP packet length, DHCP packets cannot be forwarded. Therefore, set a larger MTU value.
- If the MTU value is smaller than the DHCP packet length, the AP may be disconnected. In this case, restart the AP.
- When the MTU is too small and the DF bit is set to 1, packets cannot be fragmented. In this case, use the forced fragmentation function.

Example

Set the MTU value of the management VLANIF and CAPWAP on an AP to 1700 bytes.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] mtu 1700
```

11.2.146 multicast-rate

Function

The **multicast-rate** command configures the multicast rate of wireless packets in a radio profile.

The **undo multicast-rate** command restores the default multicast rate of wireless packets in a radio profile.

By default, the multicast rate of wireless packets is not configured in a radio profile. That is, the multicast rate is set to auto-sensing.

Format

multicast-rate *multicast-rate*

undo multicast-rate

Parameters

Parameter	Description	Value
multicast-rate	Specifies the multicast rate of wireless packets in a radio profile.	The value is of the enumerated type: The values are as follows in a 2G radio profile: ● 1: 1 Mbit/s ● 2: 2 Mbit/s ● 5: 5.5 Mbit/s ● 6: 6 Mbit/s ● 9: 9 Mbit/s ● 11: 11 Mbit/s ● 12: 12 Mbit/s ● 18: 18 Mbit/s ● 24: 24 Mbit/s ● 36: 36 Mbit/s ● 48: 48 Mbit/s ● 54: 54 Mbit/s The values are as follows in a 5G radio profile: ● 6: 6 Mbit/s ● 9: 9 Mbit/s ● 12: 12 Mbit/s ● 18: 18 Mbit/s ● 24: 24 Mbit/s ● 36: 36 Mbit/s ● 48: 48 Mbit/s ● 54: 54 Mbit/s

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

After this command is run, the multicast rate of wireless packets is the configured value and irrelevant to the STA access mode.

If the configured multicast rate is not in the basic rate set and the STA does not support this rate, the STA cannot receive multicast data.

If you run the **radio-type dot11b** command in the 2G radio profile view to set the radio type to **dot11b**, and the 2G radio profile is applied to an AP, *multicast-rate* that takes effect on the 2 GHz radio of the AP is fixed as 1 Mbit/s, and *multicast-rate* configured in the 2G radio profile view does not take effect on the AP.

Example

Set the multicast rate of wireless packets to 54 Mbit/s in the 2G radio profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] multicast-rate 54
```

11.2.147 multicast-suppression auto-detect (AP system profile view)

Function

The **multicast-suppression auto-detect** command configures the rate limit for multicast packets during intelligent flow control.

The **undo multicast-suppression auto-detect** command restores the default rate limit for multicast packets during intelligent flow control.

By default, the rate limit for multicast packets is 256 pps.

NOTE

This function is not supported by the following models:

- AirEngine X760 series APs (excluding the AirEngine 5760-10)
- AirEngine 9700D-S (including matching ORUs)

Format

multicast-suppression auto-detect packets *packets*

undo multicast-suppression auto-detect

Parameters

Parameter	Description	Value
packets *packets*	Specifies the rate limit for multicast packets.	The value is an integer that ranges from 64 to 1024, in pps.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

When there are a large number of broadcast, multicast, and unknown unicast packets, the CPU becomes busy processing these packets and the buffer of the packet for receiving incoming packets is occupied. When the buffer decreases to the specified threshold, the device automatically rate-limits the broadcast, multicast, and unknown unicast packets. You can run this command to specify the rate limit for intelligent flow control as required. Rate limiting takes effect only for incoming traffic.

Example

Set the rate limit for multicast packets during intelligent flow control to 300 pps.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name system1
[HUAWEI-wlan-ap-system-prof-system1] multicast-suppression auto-detect packets 300
```

11.2.148 np capwap-reassembly (AP system profile view)

Function

The **np capwap-reassembly disable** command disables the NP CAPWAP reassembly function of the AP.

The **undo np capwap-reassembly disable** command restores the default status of the NP CAPWAP reassembly function of APs.

By default, the NP CAPWAP reassembly function operates in adaptive mode for APs. That is, this function is enabled when services run properly, and is automatically disabled upon an exception.

NOTE

NP CAPWAP reassembly is supported only by AirEngine X760 series APs and AirEngine 9700D-S (including matching ORUs).

Format

np capwap-reassembly disable

undo np capwap-reassembly disable

Parameters

None

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

With the NP CAPWAP reassembly function, the NP replaces the CPU to reassemble the received CAPWAP fragments. This speeds up the packet processing and improves the forwarding performance.

Precautions

If the **np fast-forwarding disable** command has been run, the NP CAPWAP reassembly function of the AP is also disabled. To enable NP CAPWAP reassembly of the AP, run the **undo np fast-forwarding disable** and **undo np capwap-reassembly disable** commands in sequence.

Example

Disable the NP CAPWAP reassembly function of the AP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name apsys1
[HUAWEI-wlan-ap-system-prof-apsys1] np capwap-reassembly disable
```

11.2.149 np fast-forwarding disable (AP system profile view)

Function

The **np fast-forwarding disable** command disables the NP fast forwarding function of APs.

The **undo np fast-forwarding disable** command enables the NP fast forwarding function of APs.

By default, the NP fast forwarding function of APs is enabled.

NOTE

NP fast forwarding is supported only by the following APs:

- AirEngine 9700D-M, AirEngine 8760-X1-PRO, AirEngine 8760R-X1, AirEngine 8760R-X1E, AirEngine 6760-X1, AirEngine 6760-X1E, AirEngine 6760R-51, AirEngine 6760R-51E, AirEngine 5760-51, AirEngine 5760-22W, AirEngine 5760-22WD
- AirEngine 9700D-S (including matching ORUs)
- AirEngine 5762 series

Format

np fast-forwarding disable

undo np fast-forwarding disable

Parameters

None

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

With the NP fast forwarding function, the NP replaces the CPU to forward some packets. This speeds up the packet processing and improves the forwarding performance.

Example

Disable the NP fast forwarding function of APs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name apsys1
[HUAWEI-wlan-ap-system-prof-apsys1] np fast-forwarding disable
```

11.2.150 password alert before-expire (AP password policy view)

Function

The **password alert before-expire** command sets the password expiration prompt days.

The **undo password alert before-expire** command restores the default password expiration prompt days.

By default, the number of password expiration prompt days is 30 days.

Format

password alert before-expire *days*

undo password alert before-expire

Parameters

Parameter	Description	Value
days	Indicates how long the system displays a prompt before the password expires. If the value is set to 0, the device does not prompt users that the passwords will expire.	The value is an integer that ranges from 0 to 999, in days. The default value is 30.

Views

AP password policy view

Default Level

3: Management level

Usage Guidelines

When a user logs in to the device, the device checks whether the validity period of the user's password is within the prompt days set by using this command. If so, the device prompts the user how long the password will expire and asks the user whether to change the password.

- If the user changes the password, the device records the new password and modification time.
- If the user does not change the password or fails to change the password, the user can still log in as long as the password does not expire.

Example

Set the number of password expiration prompt days to 90.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap password policy
[HUAWEI-wlan-ap-pwd-policy] password alert before-expire 90
```

11.2.151 password alert original (AP password policy view)

Function

The **password alert original** command enables the device to prompt users to change initial passwords upon the login to an AP.

The **undo password alert original** command disables the device from prompting users to change initial passwords upon the login to an AP.

By default, the initial password change prompt function is enabled.

Format

password alert original

undo password alert original

Parameters

None

Views

AP password policy view

Default Level

3: Management level

Usage Guidelines

To improve device security, you can use this command to enable the device to prompt users to change initial passwords upon the login to the AP. Upon login to an AP, if the initial password is used, the system prompts users to change the password.

Executing the **undo password alert original** command will disable the initial password change prompt function upon the login to an AP, which will bring security risks.

Example

Enable the initial password change prompt function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap password policy
[HUAWEI-wlan-ap-pwd-policy] password alert original
```

11.2.152 password expire (AP password policy view)

Function

The **password expire** command sets the password validity period.

The **undo password expire** command restores the default password validity period.

By default, the password validity period is 90 days.

Format

password expire *days*

undo password expire

Parameters

Parameter	Description	Value
days	Indicates the password validity period. If the value is 0, the password is permanently valid.	The value is an integer that ranges from 0 to 999, in days. The default value is 90.

Views

AP password policy view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To improve password security, the administrator can use this command to set the validity period for local user's password. When the validity period expires, the password becomes invalid.

If the local user still uses this password to log in to the device, the device allows the user to log in, prompts the user that the password has expired, and asks the user whether to change the password:

- If the user selects **Y** to change the password, the user needs to enter the old password, new password, and confirm password. The password can be successfully changed only when the old password is correct and the new password and confirm password are the same and meet requirements (password length and complexity). After the password is changed, the user can log in to the device successfully.
- If the user selects **N** or fails to change the password, the user cannot log in.

Precautions

Changing the system time will affect the password validity status.

After this command is executed, the device checks whether the password expires every one minute; therefore, there may be a time difference within one minute.

Example

Set the password validity period to 120 days.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap password policy
[HUAWEI-wlan-ap-pwd-policy] password expire 120
```

11.2.153 password history record number (AP password policy view)

Function

The **password history record number** command sets the maximum number of historical passwords recorded for each AP login user.

The **undo password history record number** command restores the default maximum number of historical passwords recorded for each user.

By default, a maximum of five historical passwords are recorded for each user.

Format

password history record number *number*

undo password history record number

Parameters

Parameter	Description	Value
number	Specifies the maximum number of historical passwords recorded for each user. If the value is set to 0, the device will not check whether a changed password is the same as any historical password.	The value is an integer that ranges from 0 to 12. The default value is 5.

Views

AP password policy view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To improve password security, it is not recommended that you use a previously used password. You can set the maximum number of historical passwords recorded for each user. When a user changes the password, the device compares the new password against the historical passwords stored on the device. If the new password is the same as a stored password, the device displays an error message to prompt the user that password change fails.

Precautions

When the number of recorded historical passwords reaches the maximum value, the later password will overwrite the earliest password on the device.

Example

Set the maximum number of historical passwords recorded for each AP login user to 10.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap password policy
[HUAWEI-wlan-ap-pwd-policy] password history record number 10
```

11.2.154 pki realm (AP PKI realm profile view)

Function

The **pki realm** command configures a name for an AP PKI realm and binds the CA certificate, local certificate, CRL file, and private key file to the realm.

The **undo pki realm** command deletes the configuration of a PKI realm in an AP PKI realm profile.

By default, no name is configured for an AP PKI realm, and the CA certificate, local certificate, CRL file, and private key file are not bound to the realm.

Format

pki realm *realm-name* { { **ca format** { **der** *file-name* | **pem** *file-name* | **pkcs12** *file-name* **password** *password* } } | { **local format** { **der** *file-name* | **pem** *file-name* | **pkcs12** *file-name* **password** *password* } [**private-key format** { **der** *file-name* | **pem** *file-name* **password** *password* | **pkcs12** *file-name* **password** *password* }] } } *

undo pki realm *realm-name*

pki realm *realm-name* **crl-filename** *file-name*

undo pki realm *realm-name* **crl-filename**

Parameters

Parameter	Description	Value
realm-name	Specifies the name of a PKI realm.	The value is a string of 1 to 50 case-sensitive characters without spaces.
ca	Specifies a CA certificate.	-
local	Specifies a local certificate.	-
private-key	Specifies the private key file of a local certificate.	-
format	Specifies the file format.	-

Parameter	Description	Value
der	Sets the file format to DER.	-
pkcs12	Sets the file format to PKCS12.	-
pem	Sets the file format to PEM.	-
file-name	Specifies the name of the CA certificate, local certificate, or private key file to be imported.	The value is a string of 1 to 50 case-sensitive characters without spaces.
password *password*	Specifies the decryption password of a private key file.	The password can be entered in plaintext or ciphertext: ● A plaintext password is a string of 6 to 32 characters. ● A ciphertext password is a string of 48 or 68 characters, and must contain at least two types of the following: uppercase letters, lowercase letters, digits, and special characters.
crl-filename *file-name*	Specifies the name of a CRL file to be imported.	The value is a string of 1 to 50 case-sensitive characters without spaces.

Views

AP PKI realm profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In the AP PKI realm profile view, configure a name for an AP PKI realm and bind the CA certificate, local certificate, CRL file, and private key file to the realm.

Prerequisites

1. An AP PKI realm profile has been created using the **ap-pki-profile (WLAN view)** command.

Follow-up Procedure

1. Run the **ap-pki-profile (AP group view and AP view)** command to bind the AP PKI realm profile to an AP or AP group.
2. Run the **load-file (WLAN view)** command to manually load a certificate file in the AP PKI realm to an AP.

Precautions

A maximum of five PKI realms can be configured in an AP PKI realm profile, and private keys can be configured in a maximum of three PKI realms. To check information about an AP PKI realm profile, run the **display ap-pki-profile** command.

To ensure network security, it is recommended that the public key length and private key length of a certificate file be greater than or equal to 3072 bits.

To update a certificate file, run the **load-file (WLAN view)** command to manually load the certificate file in the AP PKI realm to the AP. The latest configuration overrides the previous one.

Example

In the AP PKI realm profile **default**, set the PKI realm name to **r1**, and set the certificate files in the realm as follows: CA certificate file **1.txt** in **DER** format, local certificate file **2.txt** in **PEM** format, and private key file **3.txt** in **PEM** format (private key decryption password: **YsHsjx_202206**).

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-pki-profile name default
[HUAWEI-wlan-ap-pki-prof-default] pki realm r1 ca format der 1.txt local format pem 2.txt private-key format pem 3.txt password YsHsjx_202206
```

11.2.155 poe af-inrush enable (AP system profile view)

Function

The **poe af-inrush enable** command configures an AP to provide PoE power in compliance with IEEE 802.3af.

The **undo poe af-inrush enable** command restores the default PoE power supply standard of an AP.

By default, an AP provides PoE power in compliance with IEEE 802.3at.

NOTE

This function is supported only by APs that support PoE OUT.

Format

poe af-inrush enable

undo poe af-inrush enable

Parameters

None

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The AP that conforms to IEEE 802.3at cannot power non-IEEE standard PDs that do not support inrush current. To power these PDs, configure the AP to provide power with low current in conformance to IEEE 802.3af. When all PDs connected to the AP are IEEE standard-compliant PDs, run the **undo poe af-inrush enable** command to cancel the configuration.

Precautions

- The **poe af-inrush enable** command does not take effect on an interface if the **poe force-power (AP wired port link profile view)** command has been executed on the interface.
- After this command is configured, the AP cannot provide power for IEEE 802.3at-compliant PDs.

Configuration Impact

After running the **poe af-inrush enable** command, remove the non-IEEE 802.3at PDs and then install them so that the PDs can be powered on.

Example

Set the PoE power supply standard to IEEE 802.3af for an AP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name apsys1
[HUAWEI-wlan-ap-system-prof-apsys1] poe af-inrush enable
```

11.2.156 poe disable (AP wired port link profile view)

Function

The **poe disable** command disables the PoE function on an AP's wired interface.

The **undo poe disable** command enables the PoE function on an AP's wired interface.

By default, the PoE function is enabled on an AP's interface.

NOTE

This function is supported only by APs that support PoE OUT.

Format

poe disable

undo poe disable

Parameters

None

Views

AP wired port link profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before using an AP to provide power for PDs connected to its interfaces, ensure that the PoE function is enabled on the interfaces. To enable the PoE function on an interface, run the **undo poe disable** command.

The power-on and power-off of interfaces are determined by the PoE power and interface power priority. When the PoE power is sufficient, the device does not power off one interface. To stop providing power for one PD, run the **poe disable** command.

Precautions

The AP only supports PoE power supply on downlink interfaces and does not support PoE power supply on uplink interfaces.

Example

Disable the PoE function on an AP's wired interface.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] port-link-profile name port-link1
[HUAWEI-wlan-port-link-prof-port-link1] poe disable
```

11.2.157 poe force-power (AP wired port link profile view)

Function

The **poe force-power** command enables forcible PoE power supply on an interface.

The **undo poe force-power** command disables forcible PoE power supply on an interface.

By default, forcible PoE power supply is disabled on an interface.

NOTE

This function is supported only by APs that support PoE OUT.

Format

poe force-power

undo poe force-power

Parameters

None

Views

AP wired port link profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After this function is configured, an interface forcibly powers on the connected PD even if the PSE cannot identify the PD. Before powering on the interface, ensure that the system power is sufficient.

Precautions

If a PoE interface connects to a non-PoE device, use this command with caution.

Example

Enable forcible PoE power supply on an AP's interface.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] port-link-profile name port-link1
[HUAWEI-wlan-port-link-prof-port-link1] poe force-power
```

11.2.158 poe high-inrush enable (AP system profile view)

Function

The **poe high-inrush enable** command configures an interface to allow high inrush current during power-on.

The **undo poe high-inrush enable** command disables an interface from allowing high inrush current during power-on.

By default, interfaces do not allow high inrush current during power-on.

NOTE

This function is supported only by APs that support PoE OUT.

Format

poe high-inrush enable

undo poe high-inrush enable

Parameters

None

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

High inrush current is generated when a non-standard PD is powered on. In this case, the PSE cuts off the power of the PD to protect itself. If the PSE is required to provide power for the PD, the PSE must allow high inrush current.

Precautions

NOTICE

The high inrush current may damage components of a PD.

Example

Enable the AP to allow high inrush current during power-on.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name apsys1
[HUAWEI-wlan-ap-system-prof-apsys1] poe high-inrush enable
```

11.2.159 poe legacy enable (AP wired port link profile view)

Function

The **poe legacy enable** command enables an AP to check compatibility of the connected PDs.

The **undo poe legacy enable** command disables an AP from checking compatibility of the connected PDs.

By default, an AP does not check compatibility of the connected PDs.

NOTE

This function is supported only by APs that support PoE OUT.

Format

poe legacy enable

undo poe legacy enable

Parameters

None

Views

AP wired port link profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When compatibility check is enabled, an AP (PSE) can detect and provide power for the PDs incompliant with IEEE 802.3af or 802.3at. If compatibility check is disabled, the AP does not identify or provide power for these PDs.

Example

Enable an AP to check compatibility of the connected PDs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] port-link-profile name port-link1
[HUAWEI-wlan-port-link-prof-port-link1] poe legacy enable
```

11.2.160 poe max-power (AP system profile view)

Function

The **poe max-power** command sets the maximum output power of an AP.

The **undo poe max-power** command restores the maximum output power of an AP to the default value.

By default, the maximum output power of the AP is the total power that the PoE power supply provides for PDs.

NOTE

This function is supported only by APs that support PoE OUT.

Format

poe max-power *max-power*

undo poe max-power

Parameters

Parameter	Description	Value
max-power	Specifies the maximum output power of an AP.	The value ranges from 15400 mW to 750000 mW.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, the system automatically obtains the maximum PoE power supported by the AP. You can run the **poe max-power** command to set the maximum output power to ensure stable PoE power supply when the total power of the AP is insufficient.

Precautions

If the maximum output power that you set is smaller than the total power required by PDs, PDs with lower priority are powered off.

The configured maximum output power must be smaller than the total power that the PoE power supply provides for PDs.

Example

Set the maximum output power of an AP to 20000 mW.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name apsys1
[HUAWEI-wlan-ap-system-prof-apsys1] poe max-power 20000
```

11.2.161 poe power-reserved (AP system profile view)

Function

The **poe power-reserved** command configures the percentage of the reserved PoE power against the total PoE power on an AP.

The **undo poe power-reserved** command restores the default percentage of the reserved PoE power against the total PoE power on an AP.

By default, the percentage of the reserved PoE power against the total PoE power on an AP is 0%.

NOTE

This function is supported only by APs that support PoE OUT.

Format

poe power-reserved *power-reserved*

undo poe power-reserved

Parameters

Parameter	Description	Value
power-reserved	Specifies the percentage of the reserved PoE power against the total PoE power.	The value is an integer that ranges from 0 to 100, in percentage.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The AP can dynamically allocate power to each interface according to the power consumption of each interface. The power consumption of a PD keeps changing when the PD is running. The system periodically calculates the total power consumption of all the PDs. If the total power consumption exceeds the upper threshold of the AP, the system cuts off the power of the PDs on the interfaces of low priority to ensure that other PDs can run normally.

Sometimes, however, the power consumption increases sharply and the available power of the system cannot support the burst increase of power. At this time, the system has not calculated and found that the total power consumption exceeded the upper threshold; therefore, the system does not cut off power low-priority interfaces in time. As a result, the PoE power supply is shut down for overload protection, and all PDs are powered off.

This problem can be solved by running the **poe power-reserved** command to set proper reserved power. When there is a burst increase in power consumption, the reserved power can support the system running. Then the system has time to power off interfaces of low priority to ensure stable running of other PDs.

Precautions

You can set the maximum output power of an AP using the **poe max-power (AP system profile view)** command. The available PoE power is the configured maximum output power. If no maximum output power is configured, the available PoE power is the total power provided by the PoE power supply.

Example

Set the percentage of reserved PoE power to the total PoE power to 10%.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name apsys1
[HUAWEI-wlan-ap-system-prof-apsys1] poe power-reserved 10
```

11.2.162 poe power-threshold (AP system profile view)

Function

The **poe power-threshold** command sets the alarm threshold of the PoE power consumption percentage.

The **undo poe power-threshold** command restores the default alarm threshold of the PoE power consumption percentage.

By default, the alarm threshold is 100%.

NOTE

This function is supported only by APs that support PoE OUT.

Format

poe power-threshold *threshold-value*

undo poe power-threshold

Parameters

Parameter	Description	Value
threshold-value	Specifies the alarm threshold of the PoE power consumption percentage. When the power consumption reaches this value, a PoE power alarm is generated.	The value is an integer that ranges from 0 to 100, in percentage.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **poe power-threshold** command sets the alarm threshold of the PoE power consumption percentage. If the total PoE power is 380 W and the alarm threshold is 90%, an alarm is generated when the power consumption is greater than 342 W. When the power consumption falls below 342 W, the alarm is cleared.

Example

Set the alarm threshold of the PoE power consumption percentage to 80%.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name apsys1
[HUAWEI-wlan-ap-system-prof-apsys1] poe power-threshold 80
```

11.2.163 poe priority (AP wired port link profile view)

Function

The **poe priority** command sets the power priority of a PoE interface.

The **undo poe priority** command restores the default power priority of a PoE interface.

By default, the power supply priority of an interface is **low**.

NOTE

This function is supported only by APs that support PoE OUT.

Format

poe priority { **critical** | **high** | **low** }

undo poe priority

Parameters

Parameter	Description	Value
critical	Indicates the highest priority.	-
high	Indicates the second highest priority.	-

Parameter	Description	Value
low	Indicates the lowest priority.	-

Views

AP wired port link profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the output power of a device is insufficient, the device provides power for the interfaces of the higher power supply priorities first and cuts off power of the interfaces of the lower power supply priorities. If all the interfaces are of the same priority, the power supply priority of the interface with a smaller interface number is higher.

Example

Set the power priority of an AP's interface to **Critical**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] port-link-profile name port-link1
[HUAWEI-wlan-port-link-prof-port-link1] poe priority critical
```

11.2.164 port-link-profile (WLAN view)

Function

The **port-link-profile** command creates an AP wired port link profile and displays the AP wired port link profile view, or displays the view of an existing AP wired port link profile.

The **undo port-link-profile** command deletes an AP wired port link profile.

By default, the system provides the AP wired port link profile **default**.

Format

port-link-profile name *profile-name*

undo port-link-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of an AP wired port link profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all AP wired port link profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An AP wired port link profile offers link-layer management and configuration on AP's wired interfaces.

Follow-up Procedure

After you create an AP wired port link profile, run the **port-link-profile (AP wired port profile view)** command to bind it to an AP wired port profile and then run the **wired-port-profile (AP group view and view)** command to bind the AP wired port profile to an AP or AP group. In this way, the AP wired port link profile can take effect.

Precautions

- The AP wired port link profile **default** cannot be deleted.
- The AP wired port link profile referenced by an AP or AP group cannot be deleted. To delete the AP wired port link profile, unbind it from the AP or AP group first.

Example

Create the AP wired port link profile **port-link1** and display the AP wired port link profile view.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] port-link-profile name port-link1
[HUAWEI-wlan-port-link-prof-port-link1]
```

11.2.165 port-link-profile (AP wired port profile view)

Function

The **port-link-profile** command binds an AP wired port link profile to an AP wired port profile.

The **undo port-link-profile** command unbinds an AP wired port link profile from an AP wired port profile.

By default, the AP wired port link profile **default** is bound to an AP wired port profile.

Format

port-link-profile *profile-name*

undo port-link-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of an AP wired port link profile.	The AP wired port link profile must exist.

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you create an AP wired port link profile using the **port-link-profile (WLAN view)** command, bind it to an AP wired port profile so that the AP wired port link profile can take effect.

Precautions

After an AP wired port link profile is bound to an AP wired port profile, parameter settings in the AP wired port link profile apply to specified interfaces of all APs using the AP wired port profile.

Example

Create the AP wired port link profile **port-link1** and bind it to the AP wired port profile **wired-port1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] port-link-profile name port-link1
[HUAWEI-wlan-port-link-prof-port-link1] quit
[HUAWEI-wlan-view] wired-port-profile name wired-port1
[HUAWEI-wlan-wired-port-wired-port1] port-link-profile port-link1
```

11.2.166 port-security enable (AP wired port profile view)

Function

The **port-security enable** command enables the port security function on an interface.

The **undo port-security enable** command disables the port security function on an interface.

By default, port security is disabled on an interface.

Format

port-security enable

undo port-security enable

Parameters

None

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After port security is enabled on an interface, MAC address entries learned by the interface are stored in the MAC address table as secure dynamic MAC address entries. By default, secure dynamic MAC addresses will not be aged out. After the device restarts, secure dynamic MAC address entries are lost and need to be relearned.

- Prevent unauthorized users from using their computers to connect to an enterprise network.
- Prevent employees of a company from moving their computers without permission.

Precautions

The protection action, maximum number of learned secure MAC address entries, and sticky MAC function can be configured only after port security is enabled.

When the AP's wired interface works in root or middle mode, port security cannot be configured. Port security can be configured on an AP's wired interface only when the interface works in endpoint mode.

Example

Enable port security.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wired-port-profile name wire1
[HUAWEI-wlan-wired-port-wire1] mode endpoint
Warning: If the AP goes online through a wired port, the incorrect port mode con
figuration will cause the AP to go out of management. This fault can be recovere
d only by modifying the configuration on the AP. Continue? [Y/N]:y
Warning: This action will take effect after resetting AP.
[HUAWEI-wlan-wired-port-wire1] port-security enable
```

11.2.167 port-security mac-address sticky (AP wired port profile view)

Function

The **port-security mac-address sticky** enables the sticky MAC function on an interface.

The **undo port-security mac-address sticky** disables the sticky MAC function on an interface.

By default, the sticky MAC function is disabled on an interface.

Format

port-security mac-address sticky

undo port-security mac-address sticky

Parameters

None.

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the port security function is enabled on an interface using the **port-security enable** command, the MAC addresses learned by the interface are converted into dynamic secure MAC addresses.

After the sticky MAC function is enabled on the interface, the dynamic secure MAC addresses learned by the interface are converted into sticky MAC addresses.

Before the number of sticky MAC addresses reaches the limit on the interface, the MAC addresses learned subsequently are still converted into sticky MAC addresses. When the number of sticky MAC addresses reaches the limit, non-sticky MAC addresses are discarded. In addition, the system determines whether to send a trap message based on the configuration of the interface protection mode.

Prerequisites

The port security function has been enabled using the **port-security enable** command on the interface.

Example

Enable the sticky MAC function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wired-port-profile name wire1
[HUAWEI-wlan-wired-port-wire1] mode endpoint
Warning: If the AP goes online through a wired port, the incorrect port mode con
figuration will cause the AP to go out of management. This fault can be recovere
d only by modifying the configuration on the AP. Continue? [Y/N]:y
Warning: This action will take effect after resetting AP.
[HUAWEI-wlan-wired-port-wire1] port-security enable
[HUAWEI-wlan-wired-port-wire1] port-security mac-address sticky
```

11.2.168 port-security max-mac-num (AP wired port profile view)

Function

The **port-security max-mac-num** command sets the maximum number of secure MAC addresses that can be learned by an interface.

By default, an interface can learn only one secure MAC address.

Format

port-security max-mac-num *max-number*

Parameters

Parameter	Description	Value
max-number	Specifies the maximum number of secure MAC addresses that can be learned by an interface.	The value is an integer that ranges from 1 to 64.

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After enabling port security on an interface, you can run the **port-security max-mac-num** command to limit the number of secure MAC addresses that can be learned by the interface bound to the AP wired port profile. After the number of secure MAC addresses exceeds the limit, the switch considers that packets with nonexistent source MAC addresses as attack packets regardless of whether the packets have destination MAC addresses. The device then takes the action specified using the **port-security protect-action** command to protect the interface. This prevents STAs with untrusted MAC addresses from communicating with the switch through this interface, improving security of the device and network.

If you run the **undo port-security enable** command to disable port security on an interface, the maximum number of secure MAC addresses that can be learned on the interface will be restored to the default value after port security is enabled again.

Prerequisites

The port security function has been enabled using the **port-security enable** command on the interface.

Precautions

If the sticky MAC function is disabled, *max-number* limits the number of secure dynamic MAC addresses learned by the interface.

If the sticky MAC function is enabled, *max-number* limits the number of sticky MAC addresses learned by the interface.

If you run the **port-security max-mac-num** command multiple times in the same interface view, only the latest configuration takes effect.

Example

Set the maximum number of secure MAC addresses that can be learned by the interface bound to the AP wired port profile to 5.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wired-port-profile name wire1
[HUAWEI-wlan-wired-port-wire1] mode endpoint
Warning: If the AP goes online through a wired port, the incorrect port mode con
figuration will cause the AP to go out of management. This fault can be recovere
d only by modifying the configuration on the AP. Continue? [Y/N]:y
Warning: This action will take effect after resetting AP.
[HUAWEI-wlan-wired-port-wire1] port-security enable
[HUAWEI-wlan-wired-port-wire1] port-security max-mac-num 5
```

11.2.169 port-security protect-action (AP wired port profile view)

Function

The **port-security protect-action** command configures a protection action for the system to perform when the number of learned MAC addresses exceeds the limit.

The **undo port-security protect-action** command restores the default protection action.

The default action is **restrict**.

Format

port-security protect-action { **protect** | **restrict** }

undo port-security protect-action

Parameters

Parameter	Description	Value
protect	Discards packets with new source MAC addresses when the number of learned MAC addresses exceeds the limit.	-
restrict	Discards packets with new source MAC addresses and sends a trap message when the number of learned MAC addresses exceeds the limit.	-

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After enabling port security, you can run the **port-security protect-action** command to configure the action performed on the interface when the number of learned MAC addresses reaches the limit.

Prerequisites

Port security has been enabled by using the **port-security enable** command on the interface.

Precautions

If you run the **port-security protect-action** command multiple times in the same interface view, only the latest configuration takes effect.

Example

Set the protection action on an AP's wired interface to **protect**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wired-port-profile name wire1
[HUAWEI-wlan-wired-port-wire1] mode endpoint
Warning: If the AP goes online through a wired port, the incorrect port mode con
figuration will cause the AP to go out of management. This fault can be recovere
d only by modifying the configuration on the AP. Continue? [Y/N]:y
Warning: This action will take effect after resetting AP.
[HUAWEI-wlan-wired-port-wire1] port-security enable
[HUAWEI-wlan-wired-port-wire1] port-security protect-action protect
```

11.2.170 power force work-mode

Function

The **power force work-mode** command sets the power supply mode for APs.

The **undo power force work-mode** command restores the default power supply mode of APs.

By default, no power supply mode is configured for APs.

Format

power force work-mode { **af** | **at** | **bt60** | **bt90** }

undo power force work-mode

Parameters

Parameter	Description	Value
af	Sets the power supply mode to 802.3af.	-
at	Sets the power supply mode to 802.3at.	-
bt60	Sets the power supply mode to 802.3bt class 6.	-
bt90	Sets the power supply mode to 802.3bt class 8. **NOTE** The parameters **bt60** and **bt90** are valid only for APs that support 802.3bt PoE power supply.	-

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the power supply mode of an AP cannot be correctly identified through LLDP or hardware, you can run the **power force work-mode** command to manually adjust the PoE power supply mode of the AP so that the AP can work in the specified power supply mode.

Configuration Impact

The power supply mode configured using the **power force work-mode** command takes effect for the logic of reducing power consumption on the APs. If this command is not configured, the power supply mode identified by LLDP or hardware is used.

If an AP's input power is low (for example, the power supply mode is 802.3at) but the power supply mode is manually set to 802.3bt class 8 (**bt90**), the AP will work in 802.3bt class 8 mode, which may cause a power failure.

If an AP's input power is high (for example, the power supply mode is 802.3bt class 8) but the power supply mode is manually set to 802.3at, the AP cannot work properly due to insufficient power.

Running this command may interrupt services.

Example

Set the power supply mode for APs to **802.3at**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] power force work-mode at
Warning: If the PSE does not reach the target power supply level, executing this command may cause the
AP to repeatedly restart due to insufficient power. Continue? [Y/N]: y
```

11.2.171 provision-ap

Function

The **provision-ap** command displays the AP provisioning view.

Format

provision-ap

Parameters

None

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

In the AP provisioning view, you can configure provisioning parameters of APs, including the management VLAN, static IP address, gateway, and AC list, which facilitates remote AP management on the AC.

Example

Display the AP provisioning view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] provision-ap
[HUAWEI-wlan-provision-ap]
```

11.2.172 reset ap-type undefined record

Function

The **reset ap-type undefined record** command clears the types of the APs that fail to connect to an AC because the AC does not support these AP types.

Format

reset ap-type undefined record

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

You can run this command to clear the types of the APs that fail to connect to an AC because the AC does not support these AP types.

The cleared records cannot be restored.

Example

Clears the types of the APs that fail to connect to the AC because the AC does not support these AP types.

```
<HUAWEI> reset ap-type undefined record
```

11.2.173 reset mac-address

Function

The **reset mac-address** command deletes all dynamic, dynamic secure, and sticky MAC address entries from an AP's wired interface.

Format

reset mac-address { **ap-id** *ap-id* | **ap-name** *ap-name* } *interface-type interface-number*

Parameters

Parameter	Description	Value
ap-id *ap-id*	Deletes all dynamic, dynamic secure, and sticky MAC address entries from the wired interface of the AP with a specified ID.	The AP ID must exist.

Parameter	Description	Value
ap-name *ap-name*	Deletes all dynamic, dynamic secure, and sticky MAC address entries from the wired interface of the AP with a specified name.	The AP name must exist.
interface-type interface-number	Deletes all dynamic, dynamic secure, and sticky MAC address entries from a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the number of the outbound interface.	The following types of outbound interfaces are supported: - Eth-Trunk - Ethernet - Gigabitethernet - MultiGE - XGigabitethernet

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **reset mac-address** command to delete all dynamic MAC address entries from an AP's wired interface. If the port security and sticky MAC functions are enabled, dynamic secure MAC address and sticky MAC address entries are also deleted.

Example

Delete all dynamic, dynamic secure, and sticky MAC address entries from the wired interface of the AP with ID 0.

```
<HUAWEI> reset mac-address ap-id 0 ethernet 0
```

11.2.174 reset statistics

Function

The **reset statistics** command clears device statistics.

Format

reset statistics { **ap-name** *ap-name* | **ap-id** *ap-id* } [**ssid** *ssid*]

Parameters

Parameter	Description	Value
ap-name *ap-name*	Clears statistics about the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Clears statistics about the AP with a specified ID.	The AP ID must exist.
ssid *ssid*	Clears statistics about a specified SSID.	The SSID must exist. To specify an SSID starting with a space, include the SSID with double quotation marks (" "). For example, in the SSID **" hello"**, the double quotation marks at the start and end of the SSID occupy two characters. To specify an SSID starting with a double quotation mark ("), enter an escape character (\) before the double quotation mark. For example, in the SSID **\"hello**, the escape character (\) occupies one character.

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

You can run the **reset statistics** command to clear device statistics.

Example

Clear AP statistics.

```
<HUAWEI> system view
[HUAWEI] wlan
[HUAWEI-wlan-view] reset statistics ap-name area1
```

11.2.175 reset wlan console ble statistics

Function

The **reset wlan console ble statistics** command clears statistics about Bluetooth-based console port login on an AP.

NOTE

The following models do not support the Bluetooth serial port function:

- AirEngine 5761-10W, AirEngine 5761S-10W, and AirEngine 5761-10WD
- AirEngine 5762-10 and AirEngine 5762-10SW
- AirEngine 9700D-M and AirEngine 9700D-M1

Format

reset wlan console ble statistics { **ap-id** *ap-id* | **ap-name** *ap-name* }

Parameters

Parameter	Description	Value
ap-id *ap-id*	Specifies the AP ID.	The AP ID must exist.
ap-name *ap-name*	Specifies the AP name.	The AP name must exist.

Views

All views

Default Level

3: Management level

Usage Guidelines

You can run this command to clear statistics about Bluetooth-based console port login on an AP.

Example

Clear statistics about Bluetooth-based console port login on an AP named **huawei**.

```
<HUAWEI> reset wlan console ble statistics ap-name huawei
```

11.2.176 sample-time

Function

The **sample-time** command sets the sampling interval for an AP.

The **undo sample-time** command restores the default sampling interval of an AP.

The default sampling interval of an AP is 30s.

Format

sample-time *sample-time*

undo sample-time

Parameters

Parameter	Description	Value
sample-time	Specifies the sampling interval.	The value is an integer that ranges from 2 to 300, in seconds.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An AP collects statistics on data including AP-based, radio-based, and STA-based data. Collected STA-based data statistics only include those that can be displayed using the **display** command on the AC.

Example

Set the sampling interval to 50s.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] sample-time 50
```

11.2.177 sftp server disable

Function

The **sftp server disable** command disables the SFTP server function on an AP.

The **undo sftp server disable** command enables the SFTP server function on an AP.

By default, the SFTP server function is enabled on an AP.

Format

sftp server disable

undo sftp server disable

Parameters

None

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

You do not need to log in to an SFTP-enabled AP from a user terminal for file management. Instead, you can log in to the SFTP-enabled AP through SFTP to manage files of the AP.

Example

Disable the SFTP server function on an AP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] sftp server disable
```

11.2.178 shutdown (AP wired port link profile view)

Function

The **shutdown** command shuts down an AP's wired interface.

The **undo shutdown** command enables an AP's wired interface.

By default, an AP's wired interface is enabled.

Format

shutdown

undo shutdown

Parameters

None

Views

AP wired port link profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If malicious users launch attacks to the network through an AP's wired interface, the administrator can deliver the **shutdown** command on the AC to shut down the interface.

Precautions

Data frames may be lost if you shut down an interface during data transmission. Exercise caution when you use the **shutdown** command.

The **shutdown** command still takes effect after an AP is restarted.

The **shutdown** command takes effect only on AP's wired interfaces working in **endpoint** or **middle** mode but not on those working in **root** mode.

Example

Shut down the AP's wired interface GE0.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] port-link-profile name port-link1
[HUAWEI-wlan-port-link-prof-port-link1] shutdown
Warning: This command does not take effect for root interfaces.
[HUAWEI-wlan-port-link-prof-port-link1] quit
[HUAWEI-wlan-view] wired-port-profile name wired-port1
[HUAWEI-wlan-wired-port-wired-port1] port-link-profile port-link1
[HUAWEI-wlan-wired-port-wired-port1] quit
[HUAWEI-wlan-view] ap-group name ap-group1
[HUAWEI-wlan-ap-group-ap-group1] wired-port-profile wired-port1 gigabitethernet 0
```

11.2.179 ssh client first-time enable (AP system profile view)

Function

The **ssh client first-time enable** command enables the first authentication on the SSH client.

The **undo ssh client first-time enable** command disables the first authentication on the SSH client.

By default, the first authentication is disabled on the SSH client.

Format

ssh client first-time enable

undo ssh client first-time enable

Parameters

None

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the SSH client accesses the SSH server for the first time and the public key of the SSH server is not configured on the SSH client, you can enable the first authentication for the SSH client to access the SSH server and save the public key of the SSH server on the SSH client. When the SSH client accesses the SSH server next time, the saved public key of the SSH server is used to authenticate the SSH server.

Example

Enable the first authentication on the SSH client.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] ssh client first-time enable
```

11.2.180 speed (AP wired port link profile view)

Function

The **speed** command sets the rate for an AP's wired interface in non-auto negotiation mode.

The **undo speed** command restores the default rate of an AP's wired interface.

By default, an AP's wired interface works in auto-negotiation mode, and its rate is negotiated with the peer interface.

Format

speed { **100** | **1000** | **2500** | **5000** | **10000** }

undo speed

Parameters

Parameter	Description	Value
100	Sets the interface rate to 100 Mbit/s.	-
1000	Sets the interface rate to 1000 Mbit/s. **NOTE** FE electrical interfaces do not support this parameter.	-
2500	Sets the interface rate to 2500 Mbit/s. **NOTE** Only multi-GE interfaces support this parameter.	-
5000	Sets the interface rate to 5000 Mbit/s. **NOTE** Only multi-GE interfaces support this parameter.	-
10000	Sets the interface rate to 10000 Mbit/s. **NOTE** Only XGE interfaces support this parameter.	-

Views

AP wired port link profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the peer interface is configured with the forcible rate, you can run this command to set the rate of the corresponding interface on the local AP to prevent communication failures.

Precautions

- Exercise caution when running this command. The default value for this command is recommended unless otherwise required. If this configuration is mandatory, do not run this command in the **default** profile to prevent the configuration from being delivered to all interfaces.
- This command is available only on the FE, GE, multi-GE, and XGE interfaces on an AP but does not take effect on other types of interfaces.
- After the **speed** command is run, the AP changes the working mode of the interface to non-auto-negotiation and changes the interface rate based on the configuration. During this process, the interface may go Down or Up. Therefore, the configuration delivery takes a long time.
- After running the **speed** command to change the negotiation mode and rate of an AP's wired interface, ensure that the remote interface works in full-duplex mode and has the same rate as the local interface; otherwise, communication is affected.

Example

Set the rate of an AP's wired interface to 100 Mbit/s in non-auto-negotiation mode.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] port-link-profile name port-link1
[HUAWEI-wlan-port-link-prof-port-link1] speed 100
Warning: This operation may interrupt user services. If the AP works at the power derating mode, the
configuration may fail to take effect because the rate limit is exceeded, Continue? [Y/N]:y
```

11.2.181 stelnet server disable

Function

The **stelnet server disable** command disables the STelnet server function on an AP.

The **undo stelnet server disable** command enables the STelnet server function on an AP.

By default, the STelnet server function is enabled on an AP.

Format

stelnet server disable

undo stelnet server disable

Parameters

None

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

You do not need to log in to an STelnet-enabled AP from a user terminal to maintain it locally. Instead, you can log in to the STelnet-enabled AP through STelnet to remotely configure and maintain it.

Example

Disable the STelnet server function on an AP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] stelnet server disable
```

11.2.182 stp auto-shutdown enable (AP wired port profile view)

Function

The **stp auto-shutdown enable** command enables the STP-triggered port shutdown function on an AP's wired interface.

The **undo stp auto-shutdown enable** command disables the STP-triggered port shutdown function on an AP's wired interface.

By default, the STP-triggered port shutdown function is disabled on an AP's wired interface.

Format

stp auto-shutdown enable

undo stp auto-shutdown enable

Parameters

None

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the STP-triggered port shutdown function is enabled, the AP automatically shuts down the interface when STP detects a loop. The AP will periodically recover the interface and re-executes STP detection. If the loop still exists on the interface, the AP shuts down the interface again. If the loop is removed, the AP reports a clear alarm to the network management system (NMS).

Prerequisites

STP has been enabled on the AP's wired interface using the **stp enable (AP wired port profile view)** command.

Precautions

The AP wired interfaces added to an Eth-trunk do not support this function.

This function is supported only when a loop exists on the network connected to the AP's wired port, that is, a port receives STP packets sent by itself.

Example

Disable the STP-triggered port shutdown function on an AP's wired interface.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wired-port-profile name wired
[HUAWEI-wlan-wired-port-wired] stp auto-shutdown enable
Warning: The AP may become out of management after the STP-triggered port shutdown function is
enabled (if the port is an uplink por
t). Continue?[Y/N]:y
```

11.2.183 stp auto-shutdown recovery-time (AP wired port profile view)

Function

The **stp auto-shutdown recovery-time** command sets an auto-recovery interval for an AP's wired interface on which the STP-triggered port shutdown function is enabled.

The **undo stp auto-shutdown recovery-time** command restores the default auto-recovery interval for an AP's wired interface on which the STP-triggered port shutdown function is enabled.

By default, the auto-recovery interval is 600s.

Format

stp auto-shutdown recovery-time *recovery-time*

undo stp auto-shutdown recovery-time

Parameters

Parameter	Description	Value
recovery-time	Specifies the auto-recovery interval for an AP's wired interface on which the STP-triggered port shutdown function is enabled.	The value is an integer that ranges from 600 to 3600, in seconds.

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the STP-triggered port shutdown function is enabled, the AP automatically shuts down the interface when STP detects a loop. The AP will periodically recover the interface and re-executes STP detection. If the loop still exists on the interface, the AP shuts down the interface again. If the loop is removed, the AP reports a clear alarm to the network management system (NMS).

Prerequisites

The STP-triggered port shutdown function has been enabled on the AP's wired interface using the **stp auto-shutdown enable (AP wired port profile view)** command.

Precautions

The AP wired interfaces added to an Eth-trunk do not support this function.

Example

Set the auto-recovery interval to 800s for an AP's wired interface on which the STP-triggered port shutdown function is enabled.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wired-port-profile name wired
[HUAWEI-wlan-wired-port-wired] stp auto-shutdown recovery-time 800
```

11.2.184 stp enable (AP wired port profile view)

Function

The **stp enable** command enables STP on an AP's wired interface.

The **stp disable** command disables STP on an AP's wired interface.

The **stp auto** command configures STP in auto-sensing mode on an AP's wired interface.

The **undo stp** command restores the default setting.

By default, STP works in auto-sensing mode on an AP's wired interface.

Format

stp enable

stp disable

stp auto

undo stp

Parameters

None

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **stp enable** command to prevent or eliminate loops on a complex Layer 2 network. STP on the AP's wired interfaces takes effect only when the AP forms a single loop with wired devices. Wireless links (such as WDS or Mesh links) only transparently forward STP BPDUs. An STP-enabled AP does not forward STP BPDUs to the wireless side. STP takes effect only on the AP's wired side.

When the STP function of an AP's wired interface is in auto-sensing mode, downlink interfaces of wall plate APs and RUs are enabled with the STP function and serve as edge interfaces, but STP is disabled on wired interfaces of other APs.

Precautions

The AP wired interfaces added to an Eth-Trunk do not support STP.

Example

Enable STP on the AP's wired interface GE0.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name ap-group1
[HUAWEI-wlan-ap-group-ap-group1] quit
[HUAWEI-wlan-view] wired-port-profile name wired
[HUAWEI-wlan-wired-port-wired] stp enable
[HUAWEI-wlan-wired-port-wired] quit
[HUAWEI-wlan-view] ap-group name ap-group1
[HUAWEI-wlan-ap-group-ap-group1] wired-port-profile wired gigabitethernet 0
```

11.2.185 telnet enable

Function

The **telnet enable** command enables Telnet on an AP.

The **undo telnet enable** command disables Telnet on an AP.

By default, Telnet is disabled on an AP.

Format

telnet enable

undo telnet enable

Parameters

None

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

You do not need to log in to a Telnet-enabled AP from a user terminal to maintain it locally. Instead, you can log in to the Telnet-enabled AP through Telnet to remotely configure and maintain it.

To improve login security, you are advised to run the **undo stelnet server disable** command to enable the STelnet server function and log in to the AP through STelnet.

Example

Enable Telnet on an AP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] telnet enable
```

11.2.186 temporary-management disable (AP system profile view)

Function

The **temporary-management disable** command disables the offline management VAP and antenna alignment VAP functions of APs.

The **undo temporary-management disable** command enables the offline management VAP and antenna alignment VAP functions of APs.

By default, the offline management VAP and antenna alignment VAP functions of APs enabled.

NOTE

The antenna alignment VAP function is not supported by AirEngine series APs.

Format

temporary-management disable

undo temporary-management disable

Parameters

None

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

- APs are often installed in hidden places or at high positions. When an AP becomes faulty, it is inconvenient to connect to the AP through a console port or network cable to troubleshoot faults.

  After the offline management VAP function is configured, if an AP goes offline unexpectedly, maintenance personnel only need to set the IP address of a STA to 169.254.2.*x*/24 (except 169.254.2.1, 169.254.2.100 is recommended). After the STA associates with the offline management VAP, maintenance personnel can connect the STA to the AP in Telnet or STelnet mode to locate and rectify faults, saving the need to connect to the AP through the console port or a network cable.
- During WDS or Mesh network deployment, you can configure antenna alignment VAPs for WDS or Mesh nodes to facilitate antenna alignment between neighboring APs. During onsite commissioning, you can use a mobile terminal to connect to the antenna alignment VAP and enable CloudCampus APP to obtain information such as the signal strength of the peer AP's radio. Based on the obtained information, you can easily complete antenna alignment. The SSID of the generated antenna alignment VAP is hidden and will be automatically deleted 24 hours after being created.

After the offline management VAP and antenna alignment VAP functions are configured, the VAP generated when an AP goes offline is an offline management VAP. When the AP works properly, the VAP generated in the WDS or Mesh scenario is an antenna alignment VAP.

The offline management VAP and antenna alignment VAP functions can be configured in either of the following ways:

- Configure the default offline management VAP and antenna alignment VAP. After the offline management VAP and antenna alignment VAP functions are enabled using this command, an AP automatically creates a management VAP when the AP goes offline unexpectedly. The default SSID of this VAP is **hw_manage_xxxx**, where **xxxx** is the last 4 digits of the AP's MAC address. When an AP works properly in a WDS or Mesh scenario, it automatically creates an antenna alignment VAP. The default SSID of this VAP is **hw_manage_xxxx**, where **xxxx** is the last 4 digits of the AP's MAC address.

- Create an offline management VAP and antenna alignment VAP. Any STA can use the default SSID and password to log in to an AP, which poses security risks. To improve the security of the offline management VAP and antenna alignment VAP, you can bind a security profile of a high security level to a VAP profile, and set a new SSID and password. Additionally, you can run the **temporary-management enable** command in the VAP profile view and the **undo temporary-management disable** command in the AP system profile view to configure the VAPs generated by the VAP profile as the offline management VAP and antenna alignment VAP. The default offline management VAP and antenna alignment VAP will not be created.

Precautions

- The offline management VAP takes effect only when an AP goes offline unexpectedly.
- The offline management VAP function does not take effect on 4.9 GHz radios.
- Before using the offline management VAP function, ensure that the AP has enabled with Telnet or STelnet services.
- The antenna alignment VAP is automatically deleted 24 hours after it is created. To use the deleted antenna alignment VAP, run the **temporary-management disable** command and then the **undo temporary-management disable** command in the AP system profile view to create an antenna alignment VAP again.
- After the offline management VAP function is enabled:
  - If the link between the central AP and RUs is disconnected, the RUs will not generate an offline management VAP.
  - If the link between the central AP and AC is disconnected but RUs are still connected to the central AP, all online RUs connected to the central AP automatically generate an offline management VAP. If an AD9431DN-24X or AirEngine 9700D-M is used as the central AP, STAs log in to RUs through the offline management VAP. If a central AP other than the AD9431DN-24X or AirEngine 9700D-M is used, STAs log in to the central AP through the offline management VAP.
- The central AP does not have radios and therefore do not generate an offline management VAP.
- In offline management VAP scenarios, STA address learning does not take effect.

Example

Enable the offline management VAP and antenna alignment VAP function of APs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name apsys1
[HUAWEI-wlan-ap-system-prof-apsys1] undo temporary-management disable
```

11.2.187 temporary-management enable (VAP profile view)

Function

The **temporary-management enable** command configures a VAP as the offline management VAP and antenna alignment VAP.

The **undo temporary-management enable** command restores a VAP to the default setting.

By default, a VAP is a service VAP.

NOTE

The antenna alignment VAP function is not supported by AirEngine series APs.

Format

temporary-management enable

undo temporary-management enable

Parameters

None

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

- After the offline management VAP function is enabled using the **undo temporary-management disable** command in the AP system profile view, an AP automatically generates an offline management VAP when it becomes faulty. The default SSID of the offline management VAP **hw_manage_xxxx**, where **xxxx** is the last 4 digits of the AP's MAC address. The maintenance personnel can associate the maintenance device with the default VAP and log in to the AP using Telnet or STelnet to troubleshoot the fault. However, using the default management VAP brings security risks. Any wireless user may use the default SSID and password to log in to the offline AP and perform unauthorized operations.
- After the antenna alignment VAP function is enabled using the **undo temporary-management disable** command in the AP system profile view, an AP automatically generates an antenna alignment VAP when it works properly. The default SSID of the antenna alignment VAP is **hw_manage_xxxx**. **xxxx** indicates the last 4 digits of the AP's MAC address. Using the default antenna alignment VAP also brings security risks.

The default username and password are available in *WLAN Default Usernames and Passwords* (**Enterprise Network** or **Carrier**). If you have not obtained the access permission of the document, see **Help** on the website to find out how to obtain it.

To improve the security of the offline management VAP and antenna alignment VAP, you can bind a security profile of a high security level to a VAP profile, set a new SSID and password, configure the VAP generated by the VAP profile as the offline management VAP and antenna alignment VAP, and bind the VAP profile to an AP group or AP to replace the default offline management VAP and antenna alignment VAP.

Follow-up Procedure

After a VAP is configured as the offline management VAP and antenna alignment VAP in a VAP profile, run the **undo temporary-management disable** command in the AP system profile view to configure the offline management VAP and antenna alignment VAP functions of APs so that the offline management VAP and antenna alignment VAP functions of APs in the VAP profile can take effect.

Precautions

- If the VAPs are configured as the offline management VAP and antenna alignment VAP in a VAP profile, the security profile referenced by the VAP profile supports only the WEP or WPA/WPA2/WPA-WPA2 PSK security policy.
- If the VAPs are configured as the offline management VAP and antenna alignment VAP in a VAP profile, VAPs generated by the VAP profile cannot be used as service VAPs for service transmission.
- The offline management VAP and antenna alignment VAP of APs cannot be dynamically modified. To modify the VAPs, delete them first, and then modify the VAP attributes in the VAP profile view.
- The offline management VAP function does not take effect on 4.9 GHz radios.
- In offline management VAP scenarios, STA address learning does not take effect.

Example

Configure the VAP generated by the VAP profile **vap1** as the offline management VAP and antenna alignment VAP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] temporary-management enable
```

11.2.188 temporary-management psk

Function

The **temporary-management psk** command configures the login password for the offline management VAP and antenna alignment VAP.

The **undo temporary-management psk** command restores the preset password of the offline management VAP and antenna alignment VAP.

By default, no login password is configured, and the global password is in effect.

Format

temporary-management psk *psk-value*

undo temporary-management psk

Parameters

Parameter	Description	Value
psk-value	Specifies the login password of the offline management VAP and antenna alignment VAP.	The value is a string of 48 to 108 characters in ciphertext or a string of 8 to 63 characters in plaintext. The password must contain at least two types of uppercase letters, lowercase letters, digits, and special characters.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to configure the login password of the offline management VAP and antenna alignment VAP. If this password has not been configured, the global password is used by default, which is configured using the **temporary-management psk** (WLAN view) command. The password configured in the AP system profile has a higher priority than that configured in the WLAN view.

Example

Set the login password of the offline management VAP and antenna alignment VAP to **YsHsjx_202206**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name default
[HUAWEI-wlan-ap-system-prof-default] temporary-management psk YsHsjx_202206
```

11.2.189 traffic-filter (AP wired port profile view)

Function

The **traffic-filter** command configures ACL-based IPv4, IPv6, or Layer 2 packet filtering on an AP's wired interface.

The **undo traffic-filter** command cancels the ACL-based IPv4, IPv6, or Layer 2 packet filtering configuration on an AP's wired interface.

By default, ACL-based IPv4, IPv6, or Layer 2 packet filtering is not configured on an AP's wired interface.

Format

traffic-filter { **inbound** | **outbound** } { **ipv4** | **ipv6** | **l2** } **acl** { *acl-number* | **name** *acl-name* }

traffic-filter { **inbound** | **outbound** } **ipv4 acl** { *acl-number* | **name** *acl-name* } **l2 acl** { *acl-number* | **name** *acl-name* }

undo traffic-filter { **inbound** | **outbound** } { **ipv4** | **ipv6** | **l2** } **acl** { *acl-number* | **name** *acl-name* }

undo traffic-filter { **inbound** | **outbound** } **ipv4 acl** { *acl-number* | **name** *acl-name* } **l2 acl** { *acl-number* | **name** *acl-name* }

Parameters

Parameter	Description	Value
inbound	Configures ACL-based packet filtering in the inbound direction.	-
outbound	Configures ACL-based packet filtering in the outbound direction.	-
ipv4	Configures ACL-based IPv4 packet filtering.	-
l2	Configures ACL-based Layer 2 packet filtering.	-
ipv6	Configures ACL-based IPv6 packet filtering.	-
acl	Filters packets based on the ACL.	-

Parameter	Description	Value
acl-number	Specifies the number of an ACL.	The value is an integer that ranges from 3000 to 3031 for IPv4 ACLs and IPv6 ACLs and from 4000 to 4031 for Layer 2 ACLs. ● 3000 to 3031: advanced ACLs ● 4000 to 4031: Layer 2 ACLs
name *acl-name*	Filters packets based on a specified named ACL. *acl-name* specifies the name of the ACL.	The ACL name must exist. The value range is the same as that of the *acl-number* parameter.

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a wireless network, administrators want to provide differentiated services for wireless users. The services may include, but are not limited to the following:

- Deny or permit access of specified wireless users to specified LAN devices.
- Deny access of specified wireless users to specified invalid IP addresses.

You can configure ACL-based packet filtering on an AP's wired interface for providing differentiated services.

The rules for an AP's wired interface to filter packets based on ACLs are as follows:

- If the action in an ACL rule is **deny**, the device discards packets matching the rule.
- If the action in an ACL rule is **permit**, the device forwards packets matching the rule.
- If no rule is matched, packets are allowed to pass through.

When multiple commands are configured for ACL-based packet filtering in the same direction in the same AP wired port profile view, packets are matched against ACL rules in the sequence in which the commands are configured. If packets match a rule, the system stops the matching process and executes the specified policy. Otherwise, the system continues to match packets against the next rule. If no rule is matched, packets are allowed to pass through. The following occurs depending on whether packets match ACL rules:

- If a policy contains only one ACL rule and the ACL rule is matched, the **permit** or **deny** action is performed.
- If a policy contains two ACL rules and the specified action is performed only when the two ACL rules are both matched.

  If the actions in the two ACL rules are both **permit**, the **permit** action is performed. Otherwise, the **deny** action is performed.

If an ACL contains multiple rules, packets are matched against the rules in the ascending order of rule IDs.

Prerequisites

A named ACL has been created using the **acl name** or **acl name** command.

Precautions

You can specify an empty ACL in this command, and configure this ACL later.

A maximum of eight ACL-based packet filtering policies can be configured in one direction. The policies take effect in the sequence in which they are configured. To improve match efficiency, you are advised to configure an ACL rule with a high match probability for packet filtering. When configuring each ACL rule, set a small ID for the rule with a high match probability, reducing the number of times ACL rules are matched and saving resources. To change the sequence in which packets are filtered based on ACLs, delete all related configurations and reconfigure ACL-based packet filtering.

Example

Configure the wired interface GE0 on APs in an AP group to filter incoming packets based on ACL 3000.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wired-port-profile name wired
[HUAWEI-wlan-wired-port-wired] traffic-filter inbound ipv4 acl 3000
[HUAWEI-wlan-wired-port-wired] quit
[HUAWEI-wlan-view] ap-group name ap-group1
[HUAWEI-wlan-ap-group-ap-group1] wired-port-profile wired gigabitethernet 0
```

11.2.190 traffic-remark (AP wired port profile view)

Function

The **traffic-remark** command configures ACL-based priority re-marking on an AP's wired interface.

The **undo traffic-remark** command cancels the ACL-based priority re-marking configuration on an AP's wired interface.

By default, ACL-based priority re-marking is not configured on an AP's wired interface.

Format

traffic-remark { **inbound** | **outbound** } { **ipv4** | **ipv6** | **l2** } **acl** { *acl-number* | **name** *acl-name* } { **dot1p** *dot1p-value* | **dscp** *dscp-value* }

undo traffic-remark { **inbound** | **outbound** } { **ipv4** | **ipv6** | **l2** } **acl** { *acl-number* | **name** *acl-name* }

traffic-remark { **inbound** | **outbound** } **ipv4 acl** { *acl-number* | **name** *acl-name* } **l2 acl** { *acl-number* | **name** *acl-name* } { **dot1p** *dot1p-value* | **dscp** *dscp-value* }

undo traffic-remark { **inbound** | **outbound** } **ipv4 acl** { *acl-number* | **name** *acl-name* } **l2 acl** { *acl-number* | **name** *acl-name* }

Parameters

Parameter	Description	Value
inbound	Configures ACL-based priority re-marking in the inbound direction.	-
outbound	Configures ACL-based priority re-marking in the outbound direction.	-
ipv4	Configures priority re-marking for IPv4 packets.	-
ipv6	Configures priority re-marking for IPv6 packets.	-
l2	Configures priority re-marking for Layer 2 packets.	-
acl-number	Specifies the number of an ACL.	The value is an integer that ranges from 3000 to 3031 for IPv4 ACLs and IPv6 ACLs and from 4000 to 4031 for Layer 2 ACLs. • 3000 to 3031: advanced ACLs • 4000 to 4031: Layer 2 ACLs
name *acl-name*	Re-marks packet priorities based on a specified named ACL. *acl-name* indicates an ACL name.	The value is a string of 1 to 32 case-sensitive characters without spaces and must begin with a letter. The value range of *acl-number* corresponding to *acl-name* is 3000 to 3031 and 4000 to 4031.

Parameter	Description	Value
dot1p *dot1p-value*	Re-marks the 802.1p priority of packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.
dscp *dscp-value*	Re-marks the DSCP priorities of packets.	The value is an integer that ranges from 0 to 63. A larger value indicates a higher priority.

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The user wants to re-mark packet priorities based on ACLs to provide differentiated services. The **traffic-remark** command can be used to configure ACL-based priority re-marking.

Prerequisites

An ACL rule has been created before this command is run.

- **acl (system view)**
- **acl ipv6 (system view)**
- **acl name**
- **acl ipv6 name**

Precautions

The **traffic-remark** command can reference a numbered ACL rule that is not configured. You can configure the referenced ACL rule after running this command.

You can only configure a maximum of eight ACL-based packet re-marking rules in the same direction. The sequence in which ACL rules takes effect follows the rule configuration sequence. To change the current packet re-marking rules, delete all the related configurations and reconfigure the ACL-based packet re-marking.

When the **traffic-remark** command and the **traffic-filter (AP wired port profile view)** command are used simultaneously and the same ACL rule is associated:

- If the **deny** action is configured in the ACL rule, the **traffic-remark** command does not take effect.

- If the **permit** action is configured in the ACL rule, the command that is executed first takes effect.

Example

Configure the wired interface GE0 of **ap-group1** and configure ACL-based 802.1p priority re-marking for IPv4 packets in the inbound direction.

```
<HUAWEI> system-view
[HUAWEI] acl 3000
[HUAWEI-acl-adv-3000] rule 5 permit ip source 192.168.0.2 0
[HUAWEI-acl-adv-3000] quit
[HUAWEI] wlan
[HUAWEI-wlan-view] wired-port-profile name wired
[HUAWEI-wlan-wired-port-wired] traffic-remark inbound ipv4 acl 3000 dot1p 7
[HUAWEI-wlan-wired-port-wired] quit
[HUAWEI-wlan-view] ap-group name ap-group1
[HUAWEI-wlan-ap-group-ap-group1] wired-port-profile wired gigabitethernet 0
```

11.2.191 traffic-optimize (AP wired port profile view)

Function

The **traffic-optimize** command sets the maximum volume of broadcast, multicast, or unknown unicast traffic on an AP's wired interface.

The **undo traffic-optimize** command restores the default maximum volume of broadcast, multicast, or unknown unicast traffic on an AP's wired interface.

By default, the volume of broadcast, multicast, or unknown unicast traffic is not suppressed on an AP's wired interface.

Format

traffic-optimize { **broadcast-suppression** | **multicast-suppression** | **unicast-suppression** } **packets** *packets-rate*

undo traffic-optimize { **broadcast-suppression** | **multicast-suppression** | **unicast-suppression** }

Parameters

Parameter	Description	Value
broadcast-suppression	Specifies the maximum broadcast traffic volume that can be received on an AP's wired interface.	-
multicast-suppression	Specifies the maximum multicast traffic volume that can be received on an AP's wired interface.	-

Parameter	Description	Value
unicast-suppression	Specifies the maximum unknown unicast traffic volume that can be received on an AP's wired interface.	-
packets *packets-rate*	Specifies the maximum number of packets that can pass every second.	The value is an integer that ranges from 0 to 14881000, in pps.

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a large number of broadcast, multicast, and unknown unicast packets are transmitted on a network, a lot of network resources are occupied, and services on the network are affected. When the traffic volume of broadcast, multicast, and unknown unicast packets reaches the maximum on an AP's wired interface, the system discards excess packets to control the traffic volume in a proper range and prevent flooding attacks.

Follow-up Procedure

Bind the AP wired port profile to an AP group or AP.

Precautions

The uplink interfaces of RUs do not support this command.

This command takes effect only for incoming traffic on an AP's wired interface.

Example

Set the maximum broadcast traffic volume that can be received on an AP's wired interface to 21600 pps.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wired-port-profile name wire1
[HUAWEI-wlan-wired-port-wire1] traffic-optimize broadcast-suppression packets 21600
```

11.2.192 traffic-optimize broadcast-suppression disable (AP system profile view)

Function

The **traffic-optimize broadcast-suppression disable** command disables rate limiting for broadcast and multicast packets on an AP.

The **undo traffic-optimize broadcast-suppression disable** command enables rate limiting for broadcast and multicast packets on an AP.

By default, rate limiting for broadcast and multicast packets is enabled on an AP.

Format

traffic-optimize broadcast-suppression { **all** | **arp** | **igmp** | **nd** | **dhcp** | **dhcpv6** | **mdns** | **other-broadcast** | **other-multicast** } **disable**

undo traffic-optimize broadcast-suppression { **all** | **arp** | **igmp** | **nd** | **dhcp** | **dhcpv6** | **mdns** | **other-broadcast** | **other-multicast** } **disable**

Parameters

Parameter	Description	Value
all	Enables or disables rate limiting for ARP, IGMP, ND, DHCP, DHCPv6, and mDNS multicast and broadcast packets.	-
arp	Enables or disables rate limiting for ARP multicast packets.	-
igmp	Enables or disables rate limiting for IGMP multicast packets.	-
nd	Enables or disables rate limiting for ND broadcast packets.	-
dhcp	Enables or disables rate limiting for DHCP broadcast packets.	-
dhcpv6	Enables or disables rate limiting for DHCPv6 broadcast packets.	-
mdns	Enables or disables rate limiting for mDNS multicast packets.	-

Parameter	Description	Value
other-broadcast	Enables or disables rate limiting for broadcast packets other than ARP, DHCP, DHCPv6, and ND packets.	-
other-multicast	Enables or disables rate limiting for multicast packets other than IGMP and mDNS packets.	-

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

When an AP receives an increasing number of packets, more network resources are occupied and services on the network are affected. To ensure normal running of network services, you can limit the rate of some protocol packets (such as DHCP and ARP packets) on an AP to a proper range.

You can run the **traffic-optimize broadcast-suppression rate-threshold (AP system profile view)** command to configure a rate limit threshold for broadcast and multicast packets of an AP, which will override the default rate threshold.

Precautions

When multicast services are enabled, the multicast services may be affected if rate limiting for multicast packets is enabled on an AP. In this case, you are advised to run the **traffic-optimize broadcast-suppression rate-threshold (AP system profile view)** command to adjust the rate limit threshold for multicast packets.

Rate limiting for broadcast and multicast packets takes effect only for incoming traffic on an AP's wired interface.

Example

Enable rate limiting for ARP broadcast packets in AP system profile **system1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name system1
[HUAWEI-wlan-ap-system-prof-system1] undo traffic-optimize broadcast-suppression arp disable
```

11.2.193 traffic-optimize broadcast-suppression rate-threshold (AP system profile view)

Function

The **traffic-optimize broadcast-suppression rate-threshold** command sets a rate limit threshold for broadcast and multicast packets on an AP.

The **undo traffic-optimize broadcast-suppression rate-threshold** command restores the default rate limit threshold of broadcast and multicast packets on an AP.

By default, the rate limit threshold for **other-broadcast** and **other-multicast** is 16 pps, and that for other parameters is 256 pps.

Format

traffic-optimize broadcast-suppression { **arp** | **igmp** | **nd** | **dhcp** | **dhcpv6** | **mdns** | **other-broadcast** | **other-multicast** } **rate-threshold** *threshold-value*

undo traffic-optimize broadcast-suppression { **arp** | **igmp** | **nd** | **dhcp** | **dhcpv6** | **mdns** | **other-broadcast** | **other-multicast** } **rate-threshold**

Parameters

Parameter	Description	Value
arp	Specifies ARP broadcast packets.	-
igmp	Specifies IGMP multicast packets.	-
nd	Specifies ND broadcast packets.	-
dhcp	Specifies DHCP broadcast packets.	-
dhcpv6	Specifies DHCPv6 broadcast packets.	-
mdns	Specifies mDNS multicast packets.	-
other-broadcast	Specifies broadcast packets other than ARP, DHCP, DHCPv6, and ND packets.	-
other-multicast	Specifies multicast packets other than IGMP and mDNS packets. **NOTE** If **other-multicast** is specified, LLDPDUs are not rate-limited.	-

Parameter	Description	Value
rate-threshold *threshold-value*	Specifies a rate limit threshold.	For **arp**, **nd**, **dhcp**, and **dhcpv6**, the value is an integer that ranges from 64 to 1024, in pps. The default value is 256. For **igmp** and **mdns**, the value is an integer that ranges from 0 to 1024, in pps. The default value is 256. For **other-broadcast** and **other-multicast**, the value is an integer that ranges from 0 to 1024, in pps. The default value is 16.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before setting a rate limit threshold for broadcast and multicast packets, run the **undo traffic-optimize broadcast-suppression disable** command to enable rate limiting for broadcast and multicast packets.

After you run the **traffic-optimize broadcast-suppression rate-threshold** command to configure a rate limit threshold for broadcast and multicast packets on an AP, the configured threshold will override the default rate limit threshold. The actual rate of broadcast and multicast packets will not exceed the configured rate limit threshold. If a large rate limit threshold is set, the expected network protection effect is not achieved. If a small rate limit threshold is set, broadcast and multicast packets may be lost. In most cases, use the default rate limit threshold unless otherwise specified.

Precautions

Rate limiting for broadcast and multicast packets takes effect only for incoming traffic on an AP's wired interface.

The rate limit threshold for multicast and broadcast packets applies to the inbound direction on all AP wired interfaces. That is, the rate of multicast and broadcast packets is limited only when the total rate of multicast and broadcast packets in the inbound direction of all AP wired interfaces exceeds the rate limit.

Example

Set the rate limit threshold for ARP broadcast packets in AP system profile **system1** to 300 pps.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name system1
[HUAWEI-wlan-ap-system-prof-system1] undo traffic-optimize broadcast-suppression all disable
[HUAWEI-wlan-ap-system-prof-system1] traffic-optimize broadcast-suppression arp rate-threshold 300
```

11.2.194 undo capwap dtls server-auth (AP view)

Function

The **undo capwap dtls server-auth** command restores the default state of the AC authentication function for APs.

By default, the AC authentication function for APs is disabled.

Format

undo capwap dtls server-auth

Parameters

None

Views

AP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an AP attempts to go online, it receives Discovery Response packets from ACs and discover an available AC. A bogus AC may maliciously send a Discovery Response packet to the AP, causing the AP to go online on the bogus AC.

After the AC authentication function for APs is enabled, an AP initiates DTLS authentication to the AC before establishing a CAPWAP tunnel with it. The AP then uses the DTLS PSK or initial certificate to authenticate the AC. The CAPWAP tunnel can be established only after the authentication succeeds.

Precautions

After the configuration is delivered, restart the APs to make the configuration take effect.

To enable or disable the AC authentication function for APs, run the **capwap dtls server-auth disable** and **commit** commands in the AP provisioning view to deliver the configuration.

Example

Restore the default state of the AC authentication function for APs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 0
[HUAWEI-wlan-ap-0] undo capwap dtls server-auth
Warning: The incorrect configuration will cause the AP to go out of management. This operation will
deliver parameter setting and may cause reboot of AP(s). Continue?[Y/N]:y
```

11.2.195 undo capwap dtls server-auth cn (AP view)

Function

The **undo capwap dtls server-auth cn** command restores the default CN field used by APs to verify an AC's certificate.

By default, no CN field is specified for APs to verify an AC's certificate.

Format

undo capwap dtls server-auth cn

Parameters

None

Views

AP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to clear the configured CN field used by APs to verify an AC's certificate. Then APs do not verify the CN field of an AC's certificate.

Precautions

After the configuration is delivered, restart the APs to make the configuration take effect.

To configure the CN field used by APs to verify an AC's certificate, run the **capwap dtls server-auth cn** *cn-string* and **commit** commands in the AP provisioning view to deliver the configuration.

Example

Restore the default CN field used by APs to verify an AC's certificate.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] ap-id 0
[HUAWEI-wlan-ap-0] undo capwap dtls server-auth cn
Warning: The incorrect configuration will cause the AP to go out of management. This operation will
deliver parameter setting and may cause reboot of AP(s). Continue?[Y/N]:y
```

11.2.196 unicast-suppression auto-detect (AP system profile view)

Function

The **unicast-suppression auto-detect** command configures the rate limit for unknown unicast packets during intelligent flow control.

The **undo unicast-suppression auto-detect** command restores the default rate limit for unknown unicast packets during intelligent flow control.

By default, the rate limit for unknown unicast packets is 128 pps.

Format

unicast-suppression auto-detect packets *packets*

undo unicast-suppression auto-detect

Parameters

Parameter	Description	Value
packets *packets*	Specifies the rate limit for unknown unicast packets.	The value is an integer that ranges from 64 to 1024, in pps.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

When there are a large number of broadcast, multicast, and unknown unicast packets, the CPU becomes busy processing these packets and the buffer of the packet for receiving incoming packets is occupied. When the buffer decreases to the specified threshold, the device automatically rate-limits the broadcast, multicast, and unknown unicast packets. You can run this command to specify the rate limit for intelligent flow control as required. Rate limiting takes effect only for incoming traffic.

Example

Set the rate limit for unknown unicast packets during intelligent flow control to 300 pps.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name system1
[HUAWEI-wlan-ap-system-prof-system1] unicast-suppression auto-detect packets 300
```

11.2.197 usb enable (AP system profile view)

Function

The **usb enable** command enables the USB function on an AP.

The **undo usb enable** command disables the USB function on an AP.

By default, the USB function on an AP is disabled.

NOTE

The operations of enabling and disabling the USB function are supported only by the following models:

- AirEngine 8760-X1-PRO, AirEngine 6760-X1, AirEngine 6760-X1E, AirEngine 5760-51, AirEngine 5760-22W, AirEngine 9700D-M, AirEngine 5760-22WD
- AirEngine 8761-X1, AirEngine 6761-21, AirEngine 6761-21E, AirEngine 6761-21T, AirEngine 6761S-21, AirEngine 6761S-21T, AirEngine 6761-22T, AirEngine 5761-21, AirEngine 5761S-21, AirEngine 5761-11, AirEngine 5761S-11, AirEngine 5761-11W, AirEngine 5761S-11W, AirEngine 5761-11WD, AirEngine 5761-12, AirEngine 5761-12W, AirEngine 5761S-12, AirEngine 5761S-13
- AirEngine 5762-13W, AirEngine 5762-15HW, AirEngine 5762S-13W, AirEngine 5762-16W, AirEngine 5762-17W
- AirEngine 8771-X1T

For the AirEngine 5762-15HW and AirEngine 8761-X1, the USB power can only be set to 2.5 W.

Format

usb enable [**5w** | **9w**]

undo usb enable

Parameters

Parameter	Description	Value
5w	Sets the USB power to 5 W. If **5w** or **9w** is not specified, the USB power is 2.5 W.	-
9w	Sets the USB power to 9 W. If **5w** or **9w** is not specified, the USB power is 2.5 W.	-

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To use functions of the USB interface on an AP, run the **usb enable** command to enable the USB function. When the USB function is enabled, the power consumption of the AP will increase, which may affect other functions. You are advised to run the **undo usb enable** command to disable the USB function after using it.

Precautions

The USB and other functions of an AP may be restricted at different power supply levels:

- The USB function is unavailable at specific power supply levels.
- When the USB function is available and enabled, other functions (such as the IoT card, number of spatial streams, and transmit power) may be affected differently depending on power supply levels. The affected AP functions are restored after the USB function is disabled.

For details about the restrictions, do as follows: Visit **Info-Finder**, select a product series, and view hardware specifications in the hardware center. You can check the power supply downgrade limits at different power supply levels.

Example

Enable the USB function in the AP system profile view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] usb enable
Warning: When the USB function is enabled, the AP power consumption increases, which may affect the
number of service flows and transmit power over the air interface. Continue? [Y/N]: y
```

11.2.198 user-interface vty acl

Function

The **user-interface vty acl** command uses an ACL to restrict login rights of users on a terminal.

The **undo user-interface vty acl** command cancels the configuration.

By default, login rights are not restricted.

Format

user-interface vty *ui-number* **acl** [**ipv6**] *acl-number* { **inbound** | **outbound** }

undo user-interface vty *ui-number* **acl** [**ipv6**] { **inbound** | **outbound** }

Parameters

Parameter	Description	Value
vty *ui-number*	Specifies the VTY user interface number.	The value is an integer that ranges from 0 to 4.
ipv6	Indicates an ACL6 number.	-
acl-number	Specifies the number of an ACL.	The value is an integer ranging from 3000 to 3031.
inbound	Restricts users with an address or within an address segment to log in to the device.	-
outbound	Restricts users who have logged in to the device from logging in to other devices.	-

Views

AP system profile view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

This command restricts the login rights of a user interface based on the source IP address, destination IP address, source port, or destination port. You can use this command to permit or deny access to a destination or from a source.

Prerequisites

Before running this command, run the **acl (system view)** in the system view and run the **rule (basic ACL view)** or **rule (advanced ACL view)** command to configure an ACL.

If no rule is configured, login rights on the user interface are not restricted when the **acl** command is executed.

Precautions

After the configurations of the ACL take effect, all users on the user interface are restricted by the ACL.

You can configure all of the following ACL types: IPv4 inbound, IPv4 outbound, IPv6 inbound, and IPv6 outbound on a user interface. Only one ACL of each type can be configured on a user interface, and only the latest configuration of an ACL takes effect.

Example

Restrict the Telnet login rights on user interface VTY 0.

```
<HUAWEI> system-view
[HUAWEI] acl 3001
[HUAWEI-acl-adv-3001] rule deny tcp source any destination-port eq telnet
[HUAWEI-acl-adv-3001] quit
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name example
[HUAWEI-wlan-ap-system-prof-example] user-interface vty 0 acl 3001 outbound
```

11.2.199 user-interface vty idle-timeout

Function

The **user-interface vty idle-timeout** command sets the timeout period for disconnection from a user interface.

The **undo user-interface vty idle-timeout** command restores the default timeout period.

By default, the timeout period is 5 minutes.

Format

user-interface vty *ui-number* **idle-timeout** *minutes* [*seconds*]

undo user-interface vty *ui-number* **idle-timeout**

Parameters

Parameter	Description	Value
ui-number	Specifies the VTY user interface number.	The value is an integer that ranges from 0 to 4.
minutes	Specifies the idle timeout period, in minutes.	The value is an integer that ranges from 0 to 35791, in minutes.
seconds	Specifies the idle timeout period, in seconds.	The value is an integer that ranges from 0 to 59, in seconds.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a user logs in to the device and does not perform an operation, the user interface is occupied unnecessarily. You can run the **user-interface vty idle-timeout** command to disconnect the user's terminal from the device.

Precautions

If the parameters *minutes* and *seconds* are both set to **0**, the VTY timeout disconnection function is disabled.

Example

Set the timeout period to 1 minute and 30 seconds.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name example
[HUAWEI-wlan-ap-system-prof-example] user-interface vty 0 idle-timeout 1 30
```

11.2.200 user-interface vty screen-length

Function

The **user-interface vty screen-length** command sets the number of lines on each terminal screen after you run a command.

The **undo user-interface vty screen-length** command restores the default configuration.

By default, the number of lines to be displayed on a terminal screen is 24.

Format

user-interface vty *ui-number* **screen-length** *screen-length*

undo user-interface vty *ui-number* **screen-length**

Parameters

Parameter	Description	Value
ui-number	Specifies the VTY user interface number.	The value is an integer that ranges from 0 to 4.
screen-length	Specifies the number of lines displayed on a terminal screen.	The value is an integer that ranges from 0 to 512. The value **0** indicates that all command output is displayed on one screen.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

If you run a command and its output is displayed in more lines than you can see on one screen, you can set a small number of lines displayed on each screen.

In most cases, you do not need to change the number of lines displayed on each screen. Setting the number of lines to 0 is not recommended. The configuration takes effect after you log in to the system again.

Example

Set the number of lines on each screen of the terminal to 30.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name example
[HUAWEI-wlan-ap-system-prof-example] user-interface vty 0 screen-length 30
```

11.2.201 user-isolate (AP wired port profile view)

Function

The **user-isolate** command enables user isolation on an AP's wired interface.

The **undo user-isolate** command disables user isolation on an AP's wired interface.

By default, user isolation is disabled on an AP's wired interface.

Format

user-isolate { **all** | **l2** }

undo user-isolate

Parameters

Parameter	Description	Value
all	Enables Layer 2 and Layer 3 user isolation.	-
l2	Enables Layer 2 user isolation.	-

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The user isolation function prevents users on the same wired interface from communicating with each other. All user traffic on the wired interface is forwarded by the gateway. Therefore, this function ensures communication security on wired interfaces and allows uniform charging for users.

Precautions

Eth-Trunk member interfaces do not support the user isolation function.

This function is supported only when the AP's wired interface works in endpoint or middle mode.

Example

Set the working mode of the AP's wired interface GE0 to **endpoint** and enable Layer 2 user isolation on GE0.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name ap-group1
[HUAWEI-wlan-ap-group-ap-group1] quit
[HUAWEI-wlan-view] wired-port-profile name wired
[HUAWEI-wlan-wired-port-wired] mode endpoint
Warning: If the AP goes online through a wired port, the incorrect port mode configuration will cause the
AP to go out of management . This fault can be recovered only by modifying the configuration on the AP.
Continue? [Y/N]:y
[HUAWEI-wlan-wired-port-wired] user-isolate l2
[HUAWEI-wlan-wired-port-wired] quit
[HUAWEI-wlan-view] ap-group name ap-group1
[HUAWEI-wlan-ap-group-ap-group1] wired-port-profile wired gigabitethernet 0
```

11.2.202 vlan pvid (AP wired port profile view)

Function

The **vlan pvid** command sets the PVID for an AP's wired interface.

The **undo vlan pvid** command deletes the PVID of an AP's wired interface.

By default, the PVID of an AP's wired interface is 1.

Format

vlan pvid *vlan-id*

undo vlan pvid

Parameters

Parameter	Description	Value
vlan-id	Specifies the PVID of an AP's wired interface.	The value is an integer that ranges from 1 to 4094.

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

APs on a WLAN WDS network only process tagged packets.

When receiving an untagged packet from a peer device, an AP's wired interface adds a VLAN tag to the packet. After the PVID is configured on the wired interface, the interface adds the PVID to all the received untagged packets.

Precautions

Eth-Trunk member interfaces do not support PVID setting.

The PVID can be configured in different modes for an AP's wired interface.

- When the AP's wired interface works in root mode, the PVID can be directly configured.
- When the AP's wired interface works in endpoint mode, the PVID can be directly configured.
- When the AP's wired interface works in middle mode, the PVID cannot be configured.

Example

Set the working mode of the AP's wired interface GE0 to **endpoint** and set the PVID of GE0 to VLAN 1.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name ap-group1
[HUAWEI-wlan-ap-group-ap-group1] quit
[HUAWEI-wlan-view] wired-port-profile name wired
[HUAWEI-wlan-wired-port-wired] mode endpoint
Warning: If the AP goes online through a wired port, the incorrect port mode configuration will cause the
AP to go out of management . This fault can be recovered only by modifying the configuration on the AP.
Continue? [Y/N]:y
[HUAWEI-wlan-wired-port-wired] vlan pvid 1
[HUAWEI-wlan-wired-port-wired] quit
[HUAWEI-wlan-view] ap-group name ap-group1
[HUAWEI-wlan-ap-group-ap-group1] wired-port-profile wired gigabitethernet 0
```

11.2.203 vlan (AP wired port profile view)

Function

The **vlan** command configures the VLAN to which an AP's wired interface belongs.

The **undo vlan** command deletes the VLAN to which an AP's wired interface belongs.

By default, when an AP's wired interface works in **root** mode, it joins VLAN 1 in untagged mode and joins all other VLANs in tagged mode. When the interface does not work in **root** mode, it joins VLAN 1 only in untagged mode.

NOTE

An AP's wired interface can be added to a maximum of 256 VLANs.

Format

vlan { **tagged** | **untagged** } { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

undo vlan { **all** | *vlan-id1* [**to** *vlan-id2*] &<1-10> }

Parameters

Parameter	Description	Value
tagged	Adds a wired interface to a VLAN in tagged mode.	-
untagged	Adds a wired interface to a VLAN in untagged mode.	-

Parameter	Description	Value
vlan-id1 [**to** *vlan-id2*]	Specifies the ID of the VLAN to which the wired interface belongs. - *vlan-id1* specifies the first VLAN ID. - **to** *vlan-id2* specifies the last VLAN ID. *vlan-id2* must be larger than *vlan-id1*. *vlan-id1* and *vlan-id2* specify a range of VLANs. If **to** *vlan-id2* is not specified, the wired interface is added to the VLAN specified by *vlan-id1*. You can specify a maximum of 10 VLAN ranges at a time. The entered VLAN ranges cannot overlap.	- The value of *vlan-id1* is an integer that ranges from 1 to 4094. - The value of *vlan-id2* is an integer that ranges from 1 to 4094.
all	Deletes all VLANs to which the AP's wired interface belongs.	-

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a wired interface connects to a PC or Layer 2 network, the interface is equivalent to a hybrid interface on a switch, and can forward the packets with multiple VLAN tags.

After the **vlan tagged** { *vlan-id1* [**to** *vlan-id2*] } &<1-10> command is executed to add the wired interface to one or more VLANs in tagged mode, the interface does not remove VLAN tags from the packets it forwarded.

After the **vlan untagged** { *vlan-id1* [**to** *vlan-id2*] } &<1-10> command is executed to add the wired interface to one or more VLANs in untagged mode, the interface removes VLAN tags from the packets it forwarded.

Precautions

After you run the **management-vlan** *vlan-id* command to enable CAPWAP packets to carry the management VLAN tag, ensure that the AP's uplink wired interface is added to the management VLAN in tagged mode. By default, the VLAN ID meets the requirement. To change the VLAN ID, run the **vlan tagged** *vlan-id* command.

After the **management-vlan** *vlan-id* command is executed to configure AP's wired interfaces to send CAPWAP packets carrying the management VLAN tag (not VLAN 1), the interfaces working in **root** mode are added to VLAN 1 in tagged mode, which cannot be changed.

Eth-Trunk member interfaces cannot be added to VLANs.

Example

Set the working mode of the AP wired interface GE0 to **endpoint** and add GE0 to VLANs 3, 4, 5, and 10 in **tagged** mode and to VLANs 12, 13, 14, and 20 in **untagged** mode.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name ap-group1
[HUAWEI-wlan-ap-group-ap-group1] quit
[HUAWEI-wlan-view] wired-port-profile name wired
[HUAWEI-wlan-wired-port-wired] mode endpoint
Warning: If the AP goes online through a wired port, the incorrect port mode configuration will cause the
AP to go out of management . This fault can be recovered only by modifying the configuration on the AP.
Continue? [Y/N]:y
[HUAWEI-wlan-wired-port-wired] vlan tagged 3 to 5 10
[HUAWEI-wlan-wired-port-wired] vlan untagged 12 to 14 20
[HUAWEI-wlan-wired-port-wired] quit
[HUAWEI-wlan-view] ap-group name ap-group1
[HUAWEI-wlan-ap-group-ap-group1] wired-port-profile wired gigabitethernet 0
```

11.2.204 wifi-light

Function

The **wifi-light** command specifies the parameter reflected by the blinking frequency of the Wireless indicators on an AP. When a Wireless indicator blinks fast, the signal strength is strong or the service traffic volume is high.

The **undo wifi-light** command restores the default parameter reflected by the blinking frequency of the Wireless indicators on an AP.

By default,

- If the Mesh function is enabled on the AP, the blinking frequency of the Wireless indicators reflects the weakest signal strength of all neighboring APs.
- If WDS is enabled on an AP, the blinking frequency of the Wireless indicators reflects the strength of signals received from a WDS AP.
  - If the AP works in leaf mode, the blinking frequency of the Wireless indicators reflects the strength of signals received from a middle AP.
  - If the AP works in middle mode, the blinking frequency of the Wireless indicators reflects the strength of signals received from a root AP.

  - If the AP works in root mode, the blinking frequency of the Wireless indicators reflects the weakest signal strength of middle APs.
- If the WDS and Mesh functions are disabled on an AP, the blinking frequency of the Wireless indicators reflects the service traffic volume on the radio.

NOTE

Only APs with wireless indicators support this command. For details about whether an AP has wireless indicators, see the indicator description of the corresponding AP model.

Format

wifi-light { **signal-strength** | **traffic** }

undo wifi-light

Parameters

Parameter	Description	Value
signal-strength	Sets the parameter reflected by the blinking frequency of the Wireless indicators on an AP to signal strength. When a Wireless indicator blinks fast, the signal strength is strong.	-
traffic	Sets the parameter reflected by the blinking frequency of the Wireless indicators on an AP to service traffic volume. When a Wireless indicator blinks fast, the service traffic volume is high.	-

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During installation and commissioning of APs that have the WDS or Mesh function enabled, you need to adjust WDS or Mesh AP locations and antenna directions to obtain strong signals. If the blinking frequency of the Wireless indicators shows the signal strength, onsite installation personnel can know the signal strength in real time. The **wifi-light** command allows you to specify the parameter reflected by the blinking frequency of the Wireless indicators. For example, you can specify the parameter to signal strength during installation and service traffic volume after installation.

Precautions

This command takes effect only when the AP has the WDS or Mesh function enabled. If the WDS and Mesh functions are disabled on the AP, the Wireless indicators always show service traffic volume.

Example

Set the parameter reflected by the blinking frequency of the Wireless indicators on an AP to service traffic volume.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name radio-profile1
[HUAWEI-wlan-radio-2g-prof-radio-profile1] wifi-light traffic
```

11.2.205 wired-port-profile (WLAN view)

Function

The **wired-port-profile** command creates an AP wired port profile and displays the AP wired port profile view, or displays the view of an existing AP wired port profile.

The **undo wired-port-profile** command deletes an AP wired port profile.

By default, the system provides the AP wired port profile **default**.

Format

wired-port-profile name *profile-name*

undo wired-port-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of an AP wired port profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all AP wired port profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An AP wired port profile provides convenience for AP wired interface management and configuration. You can configure AP wired interface parameters in an AP wired port profile to manage APs.

Follow-up Procedure

Run the **wired-port-profile (AP group view and AP view)** command to bind the AP wired port profile to an AP or AP group so that the AP wired port profile can take effect.

Precautions

- The AP wired port profile **default** cannot be deleted.
- The AP wired port profile referenced by an AP or AP group cannot be deleted. To delete the AP wired port profile, unbind it from the AP or AP group first.

Example

Create the AP wired port profile **wired-port1** and display the AP wired port profile view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wired-port-profile name wired-port1
[HUAWEI-wlan-wired-port-wired-port1]
```

11.2.206 wired-port-profile (AP group view and AP view)

Function

The **wired-port-profile** command binds an AP wired port profile to an AP or AP group.

The **undo wired-port-profile** command unbinds an AP wired port profile from an AP or AP group.

By default, the AP wired port profile **default** is bound to an AP group, but no AP wired port profile is bound to an AP.

Format

wired-port-profile *profile-name interface-type interface-number*

undo wired-port-profile *interface-type interface-number*

Parameters

Parameter	Description	Value
profile-name	Specifies the name of an AP wired port profile.	The AP wired port profile must exist.
interface-type interface-number	Specifies the type and number of an AP's wired interface.	-

Views

AP group view, AP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you create an AP wired port profile using the **wired-port-profile (WLAN view)** command, bind it to an AP or AP group so that the AP wired port profile can take effect.

Precautions

- After an AP wired port profile is bound to an AP or AP group, parameter settings in the AP wired port profile apply to specified interfaces of all APs using the AP wired port profile.
- For APs with cards, the AP wired port profile can take effect only after being applied in the card view. For detailed configuration, see **wired-port-profile (IoT card interface view)**.

Example

Create the AP wired port profile **wired-port1** and bind it to GE0 on APs in AP group **group1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wired-port-profile name wired-port1
[HUAWEI-wlan-wired-port-wired-port1] quit
[HUAWEI-wlan-view] ap-group name group1
[HUAWEI-wlan-ap-group-group1] wired-port-profile wired-port1 gigabitethernet 0
```

11.3 Cloud-based Management Configuration Commands

11.3.1 Command Support

WLAN-AC commands are supported only by the following models: S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.

11.3.2 ap manage-mode force-tradition

Function

The **ap manage-mode force-tradition** command sets the AP management mode to the local AC mode.

The **undo ap manage-mode force-tradition** command sets the AP management mode to the same as that on the switch. That is, if the NETCONF mode is enabled on the switch, the AP is managed by iMaster NCE-Campus; if the NETCONF mode is disabled on the switch, the AP is locally managed by the switch.

By default, the AP management mode is the same as that on the switch.

Format

ap manage-mode force-tradition

undo ap manage-mode force-tradition

Parameters

None

Views

NETCONF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After NETCONF is enabled on a switch (with the native AC function enabled), Fit APs are managed by iMaster NCE-Campus by default. AP entries delivered by iMaster NCE-Campus take effect, and cloud management license resources are consumed. Additionally, the switch no longer supports the commands listed in **Table 11-130**. To locally manage APs (using local AP entries and local license resources), run the **ap manage-mode force-tradition** command to set the AP management mode to the local AC mode. Then, the commands become available on the switch.

Precautions

When a Fit AP is managed by iMaster NCE-Campus, running the **ap manage-mode force-tradition** command on the switch will disconnect the Fit AP from iMaster NCE-Campus. In this case, deleting the entry of this AP on iMaster NCE-

Campus will delete the corresponding AP entry on the switch synchronously. To enable the AP to go online on the switch, you need to manually confirm the AP by running the **ap-confirm** { **all** | **mac** *ap-mac* | **sn** *ap-sn* } command on the switch.

Table 11-130 Commands that are not supported by the switch in NETCONF mode

Command	Function Description
ap auth-mode { **mac-auth** | **no-auth** | **sn-auth** } **undo ap auth-mode**	Configures the AP authentication mode. For a switch in NETCONF mode, the AP authentication mode is SN authentication.
ap blacklist mac *ap-mac1* [**to** *ap-mac2*] **undo ap blacklist** { **mac** *ap-mac1* [**to** *ap-mac2*] | **all** }	Adds APs to an AP blacklist, or deletes APs from an AP blacklist.
ap modify *ap-id* **mac** *ap-mac*	Modifies the MAC address of an AP.
ap whitelist { **mac** *ap-mac1* [**to** *ap-mac2*] | **sn** *ap-sn1* [**to** *ap-sn2*] } **undo ap whitelist** { **mac** { *ap-mac1* [**to** *ap-mac2*] | **all** } | **sn** { *ap-sn1* [**to** *ap-sn2*] | **all** } }	Adds APs to an AP whitelist, or deletes APs from an AP whitelist.
ap-confirm { **all** | **mac** *ap-mac* | **sn** *ap-sn* }	Confirms unauthorized APs and allows them to go online.
ap-name *ap-name*	Configures an AP name.
ap-rename { **ap-name** *name* | **ap-mac** *ap-mac-address* | **ap-id** *ap-id* } **new-name** *ap-new-name*	Changes the name of an AP.

Example

Set the AP management mode to the local AC mode.

```
<HUAWEI> system-view
[HUAWEI] netconf
[HUAWEI-netconf] ap manage-mode force-tradition
```

11.3.3 ap up-report-cloud

Function

The **ap up-report-cloud** command reports the AP status to iMaster NCE-Campus.

Format

ap up-report-cloud { **all** | **ap-id** *ap-id* }

Parameters

Parameter	Description	Value
all	Specifies all APs.	-
ap-id *ap-id*	Specifies an AP ID.	The AP ID must already exist.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

In a cloud AC scenario, if the AP status on iMaster NCE-Campus is different from that on the AC, you can run this command on the AC to report the AP status to iMaster NCE-Campus again to ensure that the AP status is correctly displayed.

Example

Report the status of AP with the ID of 5 to iMaster NCE-Campus.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap up-report-cloud ap-id 5
```

11.3.4 ap-id synchronize

Function

The **ap-id synchronize** command synchronizes newly added AP IDs to the SDN controller.

Format

ap-id synchronize

Parameters

None

Views

NETCONF view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When an AC uses NETCONF to register with the SDN controller, if AP capacity expansion is required, you can add AP IDs offline to the AC and then run this command to synchronize the newly added AP IDs to the SDN controller.

Example

Synchronize newly added AP IDs to the SDN controller.

```
<HUAWEI> system-view
[HUAWEI] netconf
[HUAWEI-netconf] ap-id synchronize
```

11.3.5 display cloud license

Function

The **display cloud license** command displays license resources delivered by iMaster NCE-Campus to the AC.

Format

display cloud license

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display cloud license** command displays license resources delivered by iMaster NCE-Campus to the AC.

In CloudCampus Solution, licenses are used to control the number of APs that can be managed by iMaster NCE-Campus and the service duration. Users need to purchase licenses from service providers and import the licenses to iMaster NCE-Campus. After an AC goes online, iMaster NCE-Campus converts license resources into the expiration date and delivers the date to the AC. If the AC is out of management by iMaster NCE-Campus, AP entries and license resources on the AC are still available within the grace period of 90 days, and the AC can still manage and configure Fit APs.

You can query only the expiration date of the license on the AC. To query the number of license resources, log in to iMaster NCE-Campus to check license information.

Only devices in NETCONF mode support this command.

Example

Display license resources delivered by iMaster NCE-Campus to the AC.

```
<HUAWEI> display cloud license
------------------------------------------------------------------------
License type          Expire time
------------------------------------------------------------------------
Indoor AP             -
Outdoor AP             2020-12-11
Indoor AP-S           2020-12-11
Outdoor AP-S           2020-12-11
Indoor AP-EC           -
Outdoor AP-EC          2020-12-11
Common AP              -
Indoor Wi-Fi 6 AP      2020-12-11
Outdoor Wi-Fi 6 AP      2020-12-11
Wi-Fi 7 AP            2020-12-11
Agile distributed AP   2020-12-11
------------------------------------------------------------------------
Total: 11
```

Table 11-131 Description of the **display cloud license** command output

Item	Description
License type	License type. - Indoor AP: license for indoor APs - Outdoor AP: license for outdoor APs - Indoor AP-S: license for indoor APs (AP models ending with -S) - Outdoor AP-S: license for outdoor APs (AP models ending with -S) - Indoor AP-EC: license for indoor APs (AP models ending with EC) - Outdoor AP-EC: license for outdoor APs (AP models ending with EC) - Common AP: common license for ACs and APs (trial license) - Indoor Wi-Fi 6 AP: license for indoor APs (Wi-Fi 6 series indoor APs) - Outdoor Wi-Fi 6 AP: license for outdoor APs (Wi-Fi 6 series outdoor APs) - Wi-Fi 7 AP: license for Wi-Fi 7 series APs - Agile distributed AP: license for central APs and distributed APs

Item	Description
Expire time	License expiration date. The value **-** indicates no license resource. **NOTE** - If license resources for **Common AP** and a series of APs both expire or do not exist, all APs of this series cannot go online on the AC.

11.4 WLAN Radio Resource Management Configuration Commands

11.4.1 Command Support

- WLAN-AC commands are supported only by the following models: S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.

11.4.2 agc-threshold

Function

The **agc-threshold** command sets the AGC threshold for APs.

The **undo agc-threshold** command restores the default AGC threshold for APs.

By default, the AGC threshold is not configured.

Format

agc-threshold high *high-threshold*

undo agc-threshold high

Parameters

Parameter	Description	Value
high	Configures the upper AGC threshold or restores the default value.	-
high-threshold	Specifies the upper AGC threshold.	The value is an integer that ranges from –128 to –40, in dBm.

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The AGC threshold is used to adjust the receiver sensitivity of packets received over the air interface.

In high-density office or stadium scenarios, you can set the AGC threshold to reduce co-channel interference in some areas. The recommended value is -82 dBm. In other scenarios, you are advised to retain the default value or set this parameter under the guidance of technical support personnel.

Precautions

The anti-interference algorithm dynamically adjusts the CCA and AGC thresholds of APs. If the CCA or AGC threshold is manually configured when the anti-interference algorithm is enabled, the manually configured threshold takes effect.

Before configuring the AGC threshold, ensure that the uplink signal strength of all STAs associated with the radio is 3 dB higher than the AGC threshold. For example, if the lowest uplink signal strength of associated STAs is -83 dBm, you are advised to set the AGC threshold to -86 dBm.

Example

Set the upper AGC threshold to –70 dBm in the 2G radio profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] agc-threshold high -70
Warning: This parameter will affect the uplink access coverage or user access.
It is recommended that the configuration be modified under the guidance of profe
ssional technical personnel. The manually configured AGC threshold takes precede
nce over the anti-interference algorithm. If the anti-interference function is e
nabled, dynamic AGC adjustment does not take effect and the manually configured
AGC threshold takes effect. Continue? [Y/N]:y
```

11.4.3 amc-policy

Function

The **amc-policy** command configures an adaptive modulation and coding (AMC) algorithm for a radio.

The **undo amc-policy** command restores the default AMC algorithm for a radio.

By default, a radio uses the AMC algorithm **auto-balance**.

NOTE

This command does not take effect for the following APs:

- AirEngine X77X
- AirEngine X761
- AirEngine X762
- Wi-Fi 5 series APs

Format

amc-policy { **auto-balance** | **high-stability** | **high-throughput** }

undo amc-policy

Parameters

Parameter	Description	Value
auto-balance	Indicates the **auto-balance** algorithm.	-
high-stability	Indicates the **high-stability** algorithm.	-
high-throughput	Indicates the **high-throughput** algorithm.	-

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Radios need to adjust the AMC algorithm according to different scenarios to deliver the optimal user experience. Three AMC algorithms are available:

- **auto-balance**: applicable to most wireless scenarios
- **high-stability**: applicable to scenarios with continuous interference.
- **high-throughput**: applicable to scenarios with good wireless signals and non-continuous interference.

Example

Set the AMC algorithm of a radio to **high-stability**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name test
[HUAWEI-wlan-rrm-prof-test] amc-policy high-stability
```

11.4.4 air-scan-profile

Function

The **air-scan-profile** command creates an air scan profile and displays the air scan profile view.

The **undo air-scan-profile** command deletes an air scan profile.

By default, the system provides the air scan profile **default**. You can run the **display air-scan-profile** command to view configuration of the air scan profile **default**.

Format

air-scan-profile name *profile-name*

undo air-scan-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of an air scan profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all air scan profiles.	The air scan profile **default** can be modified but cannot be deleted.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After an air scan profile is created using the **air-scan-profile** command and bound to a radio profile, and scanning functions are enabled, such as radio calibration, smart roaming, spectrum analysis, WLAN location, and WIDS, the AP periodically scans surrounding radio signals and reports the collected information to an AC or a server. The information is used for radio calibration, smart roaming spectrum analysis, WLAN location, or WIDS data analysis.

Follow-up Procedure

Run the **air-scan-profile (radio profile view)** command to bind the air scan profile to a 2G radio profile or 5G radio profile so that the air scan profile can take effect.

Example

Create the air scan profile **air-scan01**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] air-scan-profile name air-scan01
[HUAWEI-wlan-air-scan-prof-air-scan01]
```

11.4.5 air-scan-profile (radio profile view)

Function

The **air-scan-profile** command binds an air scan profile to a radio profile.

The **undo air-scan-profile** command unbinds an air scan profile from a radio profile.

By default, the air scan profile **default** is bound to a radio profile.

Format

air-scan-profile *profile-name*

undo air-scan-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of an air scan profile.	The air scan profile name must already exist.

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

After you create an air scan profile using the **air-scan-profile** command, bind it to a radio profile so that the air scan profile can take effect.

Example

Bind the air scan profile **air-scan01** to the radio profile **office01**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] air-scan-profile name air-scan01
[HUAWEI-wlan-air-scan-prof-air-scan01] quit
[HUAWEI-wlan-view] radio-2g-profile name office01
[HUAWEI-wlan-radio-2g-prof-office01] air-scan-profile air-scan01
```

11.4.6 antenna-mode

Function

The **antenna-mode** command configures the antenna mode for an AP.

The **undo antenna-mode** command restores the default antenna mode of an AP.

By default, the automatic antenna mode is used on an AP.

Format

antenna-mode { **omnidirection** | **direction** | **auto** }

undo antenna-mode

Parameters

Parameter	Description	Value
omnidirection	Indicates the omnidirectional antenna mode.	-
direction	Indicates the directional antenna mode.	-
auto	Indicates the automatic antenna mode.	-

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

For APs with built-in Dynamic-Zoom Smart Antennas, 5 GHz radios can work in omnidirectional or directional antenna mode to meet the requirements of common coverage scenarios (AP spacing > 12 m) or indoor high-density coverage scenarios (AP spacing: 10 m to 12 m). This function takes effect only for 5 GHz radios but not for APs without built-in Dynamic-Zoom Smart Antennas.

Built-in dynamic-zoom smart antennas are supported only by the AirEngine 6761-21, AirEngine 8771-X1T, and AirEngine 6761S-21.

The omnidirectional antenna mode is used for omnidirectional coverage, enabling a single AP to provide wider coverage. The directional antenna mode is used for indoor high-density deployment, allowing more APs to be deployed in an area and therefore providing a larger network capacity. In automatic antenna mode, the directional or omnidirectional mode is automatically selected based on the radio calibration algorithm. In actual project delivery, select a proper antenna mode based on the deployment scenario:

- Configure the directional antenna mode in indoor high-density coverage scenarios.
- Configure the omnidirectional antenna mode in common coverage scenarios.

NOTE

For APs with built-in Dynamic-Zoom Smart Antennas, if the directional antenna mode is used, the edge RSSI decreases by 3 dB. In this case, to ensure network coverage, run the **calibrate tpc threshold** *threshold* command to increase the TPC coverage threshold by 3 dB.

When the distance between APs with built-in Dynamic-Zoom Smart Antennas is 10 m to 12 m, co-channel interference may occur in the following scenarios:

- If there is no obstacle between two APs: Another AP is deployed between the APs, and the directional antenna mode is configured on both the APs.
- If there are obstacles between two APs (for example, two neighboring APs are deployed on two sides of a corner): The attenuation caused by obstacles is between 15 dB and 20 dB, and the directional antenna mode is configured on either AP. In this case, the two APs cannot detect each other.

Example

Configure an AP to work in directional antenna mode.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] antenna-mode direction
Warning: The directional mode is recommended only for high-density scenarios. In
 other scenarios, this configuration may deteriorate AP coverage performance. If
 radio calibration is ongoing, this configuration takes effect after calibration
 is complete. Continue? [Y/N]y
```

11.4.7 anti-interference disable

Function

The **anti-interference disable** command disables the anti-interference algorithm.

The **undo anti-interference disable** command enables the anti-interference algorithm.

By default, the anti-interference algorithm is enabled.

Format

anti-interference disable

undo anti-interference disable

Parameters

None

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In high-density scenarios, the device supports the anti-interference algorithm to improve the overall throughput in the environment.

This function takes effect only for the AirEngine X760 and AirEngine 9700D-S (including matching ORUs).

Precautions

The anti-interference algorithm may cause signal deterioration or flapping. As a result, new STAs far from an AP may encounter difficulties in accessing the network.

The anti-interference algorithm dynamically adjusts the CCA and AGC thresholds of APs. If the CCA or AGC threshold is manually configured when the anti-interference algorithm is enabled, the manually configured threshold takes effect.

Example

Disable the anti-interference algorithm.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] anti-interference disable
Warning: The per-packet-TPC function and AGC check function will become invalid when anti-interference
function is disable. Continue? [Y/N]y
```

11.4.8 anti-interference agc-check disable

Function

The **anti-interference agc-check disable** command disables the automatic gain control (AGC) algorithm before packet transmission.

The **undo anti-interference agc-check disable** command enables the AGC algorithm before packet transmission.

By default, the AGC algorithm before packet transmission is enabled.

NOTE

This function takes effect only for AirEngine X760 series APs.

Format

anti-interference agc-check disable

undo anti-interference agc-check disable

Parameters

None

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In high-density scenarios, the device uses the AGC algorithm to detect air interface conflicts before sending packets and determines whether to send packets to the air interface, thereby improving the overall throughput.

Prerequisites

The anti-interference algorithm has been enabled.

Precautions

The anti-interference algorithm may cause signal deterioration or flapping. As a result, new STAs far from the AP may encounter difficulties in accessing the network.

Example

Disable the AGC algorithm before packet transmission.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] anti-interference agc-check disable
```

11.4.9 anti-interference per-packet-tpc disable

Function

The **anti-interference per-packet-tpc disable** command disables the per-packet power adjustment function.

The **undo anti-interference per-packet-tpc disable** command enables the per-packet power adjustment function.

By default, per-packet power adjustment is enabled.

NOTE

This command takes effect only for AirEngine X760 series APs.

Format

anti-interference per-packet-tpc disable

undo anti-interference per-packet-tpc disable

Parameters

None

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In high-density scenarios, the per-packet power adjustment function can properly control the transmit power of radios in an area, which reduces interference to neighboring devices while meeting wireless communication requirements.

Prerequisites

The anti-interference algorithm has been enabled.

Precautions

The anti-interference algorithm may cause signal deterioration or flapping. As a result, new STAs far from the AP may encounter difficulties in accessing the network.

Example

Disable the per-packet power adjustment function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] anti-interference per-packet-tpc disable
```

11.4.10 band-steer balance gap-threshold

Function

The **band-steer balance gap-threshold** command sets the percentage threshold for access STAs on 5 GHz radios during band steering.

The **undo band-steer balance gap-threshold** command restores the default percentage threshold for access STAs on 5 GHz radios during band steering.

By default, the percentage threshold for access STAs on 5 GHz radios during band steering is 90%.

Format

band-steer balance gap-threshold *gap-threshold*

undo band-steer balance gap-threshold

Parameters

Parameter	Description	Value
gap-threshold *gap-threshold*	Specifies the percentage threshold for access STAs on 5 GHz radios during band steering.	The value is an integer that ranges from 1 to 100, in percentage.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

After the band steering function is configured on a multi-radio AP, the AP instructs STAs that support multiple frequency bands to preferentially connect to a 5 GHz radio.

When a STA requests to connect to an AP radio, the AP enabled with band steering will collect statistics about access STAs on each radio.

1. If the number of access STAs on the AP does not exceed the start threshold configured using the **band-steer balance start-threshold** command, the STA can preferentially associate with the 5 GHz radio.
2. If the number of access STAs exceeds the value specified by the start threshold, the AP calculates the percentage of access STAs on the 5 GHz radio using the formula: (number of access STAs on the 5 GHz radio/total number of access STAs) x 100%. If the percentage exceeds the percentage threshold for access STAs on the 5 GHz radio configured using the **band-steer balance gap-threshold** command, the STA randomly selects a frequency band.

NOTE

In most cases, you are advised to use the default values of the start threshold for the number of access STAs and the percentage threshold for access STAs on 5 GHz radios. If the two thresholds are set low, the AP may allow STAs to freely select the access frequency band when the number of STAs on 5 GHz radios is small. As a result, the 5G-prior access mechanism does not take effect, and the 5 GHz band utilization cannot be maximized.

Example

Set the percentage threshold for access STAs on 5 GHz radios to 85% in the RRM profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] band-steer balance gap-threshold 85
```

11.4.11 band-steer balance start-threshold

Function

The **band-steer balance start-threshold** command sets the start threshold for the number of access STAs during band steering.

The **undo band-steer balance start-threshold** command restores the default start threshold for the number of access STAs during band steering.

By default, the start threshold for the number of access STAs during band steering is 100.

Format

band-steer balance start-threshold *start-threshold*

undo band-steer balance start-threshold

Parameters

Parameter	Description	Value
start-threshold *start-threshold*	Specifies the start threshold for the number of access STAs during band steering.	The value is an integer that ranges from 0 to 100.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

After the band steering function is configured on a multi-radio AP, the AP instructs STAs that support multiple frequency bands to preferentially connect to a 5 GHz radio.

1. If the number of access STAs on the AP does not exceed the start threshold configured using the **band-steer balance start-threshold** command, the STA can preferentially associate with the 5 GHz radio.
2. If the number of access STAs exceeds the value specified by the start threshold, the AP calculates the percentage of access STAs on the 5 GHz radio using the formula: (number of access STAs on the 5 GHz radio/total number of access STAs) x 100%. If the percentage exceeds the percentage threshold for access STAs on the 5 GHz radio configured using the **band-steer balance gap-threshold** command, the STA randomly selects a frequency band.

NOTE

In most cases, you are advised to use the default values of the start threshold for the number of access STAs and the percentage threshold for access STAs on 5 GHz radios. If the two thresholds are set low, the AP may allow STAs to freely select the access frequency band when the number of STAs on 5 GHz radios is small. As a result, the 5G-prior access mechanism does not take effect, and the 5 GHz band utilization cannot be maximized.

Example

Set the start threshold for the number of access STAs during band steering to 90 in the RRM profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] band-steer balance start-threshold 90
```

11.4.12 band-steer client-band-expire

Function

The **band-steer client-band-expire** command sets the aging condition for terminal band information.

The **undo band-steer client-band-expire** command restores the default aging condition for terminal band information.

By default, band information of a terminal will be aged out under conditions that an AP has consecutively received Probe frames of the terminal more than 35 times from the same frequency band.

Format

band-steer client-band-expire *probe-counters*

undo band-steer client-band-expire

Parameters

Parameter	Description	Value
probe-counters	Sets the aging condition of terminal band information to the number of times that an AP has consecutively received Probe frames of a terminal from the same frequency band.	The value is an integer that ranges from 10 to 65535.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the band steering function is enabled on an AP, the AP records frequency band information of terminals so that the terminals can preferentially access the supported and lightly loaded frequency band.

Users may change terminals' configurations, which causes the supported frequency band of terminals to change. Therefore, the AP needs to update frequency band information of terminals in a timely manner. If the AP keeps receiving Probe frames of a terminal from a specific frequency band, and the number of receiving times exceeds a certain threshold, the AP updates the frequency band information of the terminal and considers that the terminal supports only the frequency band.

For example, the supported frequency bands of a terminal are 2.4 and 5 GHz frequency bands on an AP. If the AP only receives Probe frames of the terminal from the 2.4 GHz frequency band, and the number of times that the AP consecutively receives Probe frames from the 2.4 GHz frequency band exceeds the specified threshold, the AP considers that users change the terminal configuration and the terminal supports only the 2.4 GHz frequency band.

Precautions

If you set the aging condition to a large number of times that an AP consecutively receives Probe frames of a terminal from the same frequency band, the AP detects terminal band change more slowly. A smaller number indicates quicker response. Set the aging condition according to the difference in the number of Probe frames sent from the two frequency bands.

Example

Configure the supported band information of the terminal named **default** to age out when the number of times that an AP consecutively receives Probe frames from a frequency band exceeds 80.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] band-steer client-band-expire 80
```

11.4.13 band-steer deny-threshold

Function

The **band-steer deny-threshold** command sets the maximum number of times an AP rejects association requests of a STA for band steering.

The **undo band-steer deny-threshold** command restores the default maximum number of times an AP rejects association requests of a STA for band steering.

By default, the maximum number of rejections is 0.

Format

band-steer deny-threshold *deny-threshold*

undo band-steer deny-threshold

Parameters

Parameter	Description	Value
deny-threshold	Specifies the maximum number of times an AP rejects association requests of a STA.	The value is an integer that ranges from 0 to 10.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

If a STA requests to associate with an AP from the 2.4 GHz frequency band but the AP steers the STA to the 5 GHz frequency band according to the band steering algorithm, the AP will reject the association. However, after the number of rejections exceeds the maximum value specified by the **band-steer deny-threshold** command, the AP allows the STA to associate from the 2.4 GHz frequency band.

NOTE

The following APs do not suppress Probe Response frames on the 2.4 GHz radio before STA association. However, after STAs are associated with these APs, the STAs will be steered to the 5 GHz radio.

- AirEngine 9700D-S (including matching ORUs)
- AirEngine X77X
- AirEngine X76X

Example

Set the maximum number of rejections to 8.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] band-steer deny-threshold 8
```

11.4.14 band-steer disable

Function

The **band-steer disable** command disables the band steering function.

The **undo band-steer disable** command enables the band steering function.

By default, the band steering function is enabled.

Format

band-steer disable

undo band-steer disable

Parameters

None

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Compared with the 2.4 GHz frequency band, the 5 GHz frequency band has less interference and more available channels, and provides higher access capability.

Most STAs support both 5 GHz and 2.4 GHz frequency bands and usually associate with the 2.4 GHz radio by default when connecting to the Internet. To connect the STAs to the 5 GHz radio, you must manually select the 5 GHz radio. The band steering function frees you from the manual selection.

After you enable band steering for a specific SSID on the AC, the AP preferentially associates the terminals connected to the SSID with the 5 GHz frequency band. After the 5 GHz frequency band is fully loaded, the AP steers the terminals to the 2.4 GHz frequency band.

Configuration Impact

After the band steering function is enabled, it takes a long time for dual-band terminals to associate or roam. You are advised to disable band steering for delay-sensitive services.

Precautions

If both radios of an AP use the same VAP profile, the band steering function takes effect on both radios as long as the function is enabled for an SSID on one radio of the AP. For example, if band steering is enabled for the SSID **test** on the 2.4 GHz radio but not on the 5 GHz radio, the AP preferentially steers terminals associated with the SSID to the 5 GHz radio.

Single-radio devices do not support the band steering function.

Example

Disable band steering.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name test
[HUAWEI-wlan-vap-prof-test] band-steer disable
```

11.4.15 band-steer snr-threshold

Function

The **band-steer snr-threshold** command configures a start SNR threshold for triggering 5G-prior access.

The **undo band-steer snr-threshold** command restores the default start SNR threshold for triggering 5G-prior access.

The default start SNR threshold for triggering 5G-prior access is 20 dB.

Format

band-steer snr-threshold *snr-threshold*

undo band-steer snr-threshold

Parameters

Parameter	Description	Value
snr-threshold	Specifies a start SNR threshold for triggering 5G-prior access.	The value is an integer that ranges from 10 to 35, in dB.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

You can run the **undo band-steer disable** command to enable the band steer function and the **band-steer snr-threshold** command to configure a start SNR threshold for triggering 5G-prior access. When the SNR in 5G Probe frames sent by a multi-band STA to a multi-radio AP exceeds the specified threshold, the STA connects to the 5G radio preferentially, improving user experience.

Example

Set the start SNR threshold for triggering 5G-prior access in the RRM profile **default** to 20 dB.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] band-steer snr-threshold 20
```

11.4.16 bss-color disable

Function

The **bss-color disable** command disables the basic service set (BSS) coloring function.

The **undo bss-color disable** command enables the BSS coloring function.

By default, the BSS coloring function is enabled.

Format

bss-color disable

undo bss-color disable

Parameters

None

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In high-density scenarios, the 802.11ax protocol proposes the BSS coloring mechanism to improve system performance and channel usage efficiency. When detecting 802.11ax signals, STAs can identify the signals from the overlapping basic service set (OBSS) based on the BSS color bit or MAC address, and then determine air interface conflicts and perform interference management according to related information. The BSS coloring function enables a device to distinguish between the transmissions on the local and neighboring networks. Then, it can adaptively adjust the power and the sensitivity threshold to allow dynamic adjustment of the transmit power and the signal detection threshold to increase spatial reuse efficiency and minimize co-channel interference.

Precautions

Disabling the BSS coloring function will automatically disable the spatial reuse (SR) function.

The BSS coloring function does not take effect when the radio scanning function is enabled on an AP.

Example

Disable the BSS coloring function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] bss-color disable
Warning: The spatial reuse function will become invalid when BSS color function is disable. Continue?
[Y/N]y
```

11.4.17 btm-fail-times

Function

The **btm-fail-times** command sets the maximum number of attempts to steer STAs in BTM mode.

The **undo btm-fail-times** command restores the default maximum number of attempts to steer STAs in BTM mode.

By default, the maximum number of attempts to steer STAs in BTM mode is 5.

Format

btm-fail-times *btm-fail-times*

undo btm-fail-times

Parameters

Parameter	Description	Value
btm-fail-times	Specifies the number of attempts to steer STAs in BTM mode.	The value is an integer that ranges from 0 to 10. The value 0 indicates that the BTM mode is not used to steer STAs.

Views

Static load balancing group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The device preferentially uses the BTM mode to trigger STA steering to the target AP. Due to differences of STAs, some STAs can be successfully steered in BTM mode after multiple attempts. You can run the **btm-fail-times** command to set the maximum number of attempts to steer STAs in BTM mode. If the number of attempts exceeds the specified value, the device attempts to steer STAs in deauthentication mode.

Precautions

You are advised to retain the default value. If the success rate of STA steering in BTM mode is low, you can set a smaller value to improve the steering efficiency.

Example

Set the maximum number of attempts to steer STAs in BTM mode to 4.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sta-load-balance static-group name coco
[HUAWEI-wlan-sta-lb-static-coco] btm-fail-times 4
```

11.4.18 calibrate auto-bandwidth-select

Function

The **calibrate auto-bandwidth-select** { **enable** | **disable** } command enables or disables the dynamic bandwidth selection (DBS) function.

The **undo calibrate auto-bandwidth-select** command restores the default DBS state.

By default, the DBS function is disabled in the AP group radio view and not configured in the AP radio view. This command takes effect only for 5 GHz and 6 GHz radios.

Format

calibrate auto-bandwidth-select { **enable** | **disable** }

undo calibrate auto-bandwidth-select

Parameters

Parameter	Description	Value
enable	Enables the DBS function.	-
disable	Disables the DBS function.	-

Views

AP group radio view, AP radio view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In non-high-density indoor scenarios, the DBS function can leverage the radio calibration mechanism to automatically select proper bandwidth, improving the overall system capacity.

Prerequisites

- Radio calibration has been enabled using the **calibrate enable** { **auto** | **manual** | **schedule time** } command.
- Automatic channel selection has been enabled using the **calibrate auto-channel-select enable** command.

Precautions

- The DBS function is valid only for 5 GHz and 6 GHz radios.
- The DBS function is applicable only to indoor APs with omnidirectional antennas. The adjustment effect cannot be ensured for indoor APs with directional antennas and outdoor APs.
- The DBS function takes effect only between Fit APs connected to the same AC but not between APs connected to different ACs.
- The DBS effect is not obvious for high-density scenarios.

To view historical records of channel, bandwidth, and transmit power changes caused by radio calibration, run the **display channel switch-record calibrate** command.

Example

Enable the DBS function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] radio 1
[HUAWEI-wlan-group-radio-default/1] calibrate auto-bandwidth-select enable
```

11.4.19 calibrate auto-channel-select

Function

The **calibrate auto-channel-select** { **enable** | **disable** } command enables or disables automatic channel selection.

The **undo calibrate auto-channel-select** command restores the automatic channel selection state.

By default, the automatic channel selection function is enabled in the AP group radio view and not configured in the AP radio view.

Format

calibrate auto-channel-select { **enable** | **disable** }

undo calibrate auto-channel-select

Parameters

None

Views

AP group radio view, AP radio view

Default Level

2: Configuration level

Usage Guidelines

Two channel selection modes are available:

- Automatic mode (enabling automatic channel selection): An AP automatically selects a proper channel based on the WLAN radio environment, removing the need to specify channels manually.
- Fixed mode (disabling automatic channel selection): Channels must be manually specified.

The automatic mode (automatic channel selection) is recommended because you do not need to specify a channel for each radio. The fixed mode provides users with an alternative way when they want to specify channels by themselves or to avoid frequent channel adjustment (this may cause intermittent service interruption).

If an AP needs radio calibration, automatic channel selection must be enabled.

To view historical records of channel, bandwidth, and transmit power changes caused by radio calibration, run the **display channel switch-record calibrate** command.

NOTE

When automatic channel selection is enabled, the manually configured channels do not take effect to ensure that the radio works in the optimal channel environment.

Example

Disable automatic channel selection.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] radio 0
[HUAWEI-wlan-group-radio-default/0] calibrate auto-channel-select disable
```

11.4.20 calibrate auto-txpower-select

Function

The **calibrate auto-txpower-select** { **enable** | **disable** } command enables or disables automatic transmit power selection.

The **undo calibrate auto-txpower-select** command restores the automatic transmit power selection state.

By default, the automatic transmit power selection function is enabled in the AP group radio view and not configured in the AP radio view.

Format

calibrate auto-txpower-select { **enable** | **disable** }

undo calibrate auto-txpower-select

Parameters

Parameter	Description	Value
enable	Enables the automatic transmit power selection function.	-
disable	Disables the automatic transmit power selection function.	-

Views

AP group radio view, AP radio view

Default Level

2: Configuration level

Usage Guidelines

Two power selection modes are available:

- Automatic mode (enabling automatic transmit power selection): An AP automatically selects or adjusts the transmit power based on the WLAN radio environment, removing the need to specify AP power manually.
- Fixed mode (disabling automatic transmit power selection): The transmit power must be manually specified.

If an AP needs radio calibration, automatic transmit power selection must be enabled.

To view historical records of channel, bandwidth, and transmit power changes caused by radio calibration, run the **display channel switch-record calibrate** command.

Example

Disable automatic transmit power selection.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] radio 0
[HUAWEI-wlan-group-radio-default/0] calibrate auto-txpower-select disable
```

11.4.21 calibrate enable { auto | manual | schedule time }

Function

The **calibrate enable** { **auto** | **manual** | **schedule time** } command configures the radio calibration mode.

The **undo calibrate enable** command disables radio calibration.

By default, the radio calibration mode is **auto**, the radio calibration interval is 1440 minutes, and the start time for radio calibration is 03:00:00.

Format

calibrate enable { **auto** [**interval** *interval-value* [**start-time** *start-time*]] | **manual** | **schedule time** *time-value* [**time-range** *time-range-name*] }

undo calibrate enable

Parameters

Parameter	Description	Value
auto	Sets the radio calibration mode to automatic calibration.	-
interval *interval-value*	Specifies the calibration interval in automatic radio calibration mode.	The value is an integer that ranges from 30 to 1440, in minutes. If **interval** is not specified, the radio calibration interval in auto mode is 1440 minutes.
start-time *start-time*	Specifies the start time for automatic radio calibration.	The value is in the format of hh:mm:ss. ● hh: indicates the hour. The value is an integer that ranges from 0 to 23. ● mm: indicates the minute. The value is an integer that ranges from 0 to 59. ● ss: indicates the second. The value is an integer that ranges from 0 to 59.
manual	Sets the radio calibration mode to manual calibration.	-
schedule	Sets the radio calibration mode to scheduled calibration.	-
time *time-value*	Specifies the time for triggering the scheduled radio calibration.	The value is in the format of hh:mm:ss. ● hh: indicates the hour. The value is an integer that ranges from 0 to 23. ● mm: indicates the minute. The value is an integer that ranges from 0 to 59. ● ss: indicates the second. The value is an integer that ranges from 0 to 59.

Parameter	Description	Value
time-range *time-range-name*	Specifies the name of a time range for scheduled radio calibration.	The specified time range must exist. You can run the **time-range** command to configure a time range. **NOTE** Ensure that the scheduled radio calibration time is within the time range specified by **time-range**. Otherwise, the scheduled radio calibration function does not take effect.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

There are three radio calibration modes:

- Automatic radio calibration mode: The device continuously monitors the wireless environment quality by scanning the air interface. If the air interface environment deteriorates (for example, high bit error rate or matching the policy of high noise floor), the device automatically triggers partial radio calibration to avoid interference. To prevent service interruption caused by radio calibration, you are advised to set the calibration start time during off-peak hours. To prevent frequent calibration, you are advised to set a proper calibration interval. In addition, the device performs global radio calibration periodically based on the specified start time and interval.
- Manual radio calibration mode: Global radio calibration is not automatically implemented by the device but manually triggered through the **calibrate manual startup** command.
- Schedule radio calibration mode: The device triggers radio calibration only at a specified time point (specified by **time**) or in a specified time range (specified by **time-range**).

The three modes cannot be configured simultaneously. You can choose any of the modes as required.

In any mode, you can run the **calibrate manual startup** command to trigger global radio calibration. In manual radio calibration mode, the device implements global radio calibration only after the **calibrate manual startup** command is executed.

NOTE

Regardless of the calibration mode, an AP triggers partial radio calibration when detecting the following situations:

- The packet retransmission rate exceeds the threshold. (You can run the **calibrate retransmission-rate-threshold** command to configure the threshold.)
- The air interface environment deteriorates. (You can run the **calibrate interference-check threshold** command in the diagnostic view to configure the threshold.)

Example

Set the radio calibration mode to manual calibration.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] calibrate enable manual
```

Set the radio calibration mode to scheduled calibration and set the scheduled calibration time to 20:30:00.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] calibrate enable schedule time 20:30:00
```

11.4.22 calibrate environment-deterioration-blacklist

Function

The **calibrate environment-deterioration-blacklist** command sets the blacklist threshold for the number of times the channel environment deteriorates.

The **undo calibrate environment-deterioration-blacklist** command restores the default blacklist threshold for the number of times the channel environment deteriorates.

By default, the blacklist threshold for the number of times the channel environment deteriorates is 16.

Format

calibrate environment-deterioration-blacklist threshold *threshold*

undo calibrate environment-deterioration-blacklist

Parameters

Parameter	Description	Value
threshold *threshold*	Specifies the blacklist threshold for the number of times the channel environment deteriorates.	The value is an integer that ranges from 1 to 48.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

When detecting that the environment of a channel deteriorates, the device generates an environment deterioration alarm and accumulates the number of environment deterioration times on the channel. If this number exceeds the threshold, the channel is added to the calibration blacklist. The device will skip this channel when performing radio calibration next time. If the number of environment deterioration times does not exceed the threshold, interference penalty is performed accordingly.

NOTE

If the number of environment deterioration times on more than half of calibration channels exceeds the threshold, the device performs interference penalty on all channels in the next calibration but does not add the channels to the blacklist.

Example

Set the blacklist threshold for the number of times the channel environment deteriorates to 20.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] calibrate environment-deterioration-blacklist threshold 20
```

11.4.23 calibrate retransmission-rate-check

Function

The **calibrate retransmission-rate-check** command configures the interval and traffic threshold for checking the retransmission rate.

The **undo calibrate retransmission-rate-check** command restores the default interval and traffic threshold for checking the retransmission rate.

The default interval and traffic threshold for checking the retransmission rate are 1 minute and 1250 kbit/s, respectively.

Format

calibrate retransmission-rate-check interval *interval* **traffic-threshold** *traffic-threshold*

undo calibrate retransmission-rate-check

Parameters

Parameter	Description	Value
interval *interval*	Specifies the interval for checking the retransmission rate.	The value is an integer that ranges from 1 to 10, in minutes.
traffic-threshold *traffic-threshold*	Specifies the traffic threshold for checking the retransmission rate.	The value is an integer that ranges from 1 to 20000, in kbit/s.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

You can run the **calibrate retransmission-rate-check** command to lower the sensitivity for collecting radio retransmission rate statistics. When the rate of network traffic reaches the threshold, retransmission rate check is performed at the specified interval.

Example

Set the interval and traffic threshold for checking the retransmission rate in the RRM profile **80211b** to 2 minutes and 1000 kbit/s, respectively.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name 80211b
[HUAWEI-wlan-rrm-prof-80211b] calibrate retransmission-rate-check interval 2 traffic-threshold 1000
```

11.4.24 calibrate retransmission-rate-threshold

Function

The **calibrate retransmission-rate-threshold** command sets the retransmission rate threshold.

The **undo calibrate retransmission-rate-threshold** command restores the default retransmission rate threshold.

By default, the retransmission rate threshold is 60%.

Format

calibrate retransmission-rate-threshold *retransmission-rate-threshold*

undo calibrate retransmission-rate-threshold

Parameters

Parameter	Description	Value
retransmission-rate-threshold	Specifies the retransmission rate threshold.	The value is an integer that ranges from 20 to 100, in percentage.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

The retransmission rate is the ratio of retransmitted packets to all packets sent by a radio.

The retransmission rate threshold determines whether the radio environment is normal. When the retransmission rate of a radio reaches the threshold, the system considers that the radio environment deteriorates. When this occurs, the system may start radio calibration or take measures to avoid signal interference.

Example

Set the retransmission rate threshold to 70% in the RRM profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] calibrate retransmission-rate-threshold 70
```

11.4.25 calibrate flexible-radio

Function

The **calibrate flexible-radio** { **auto-switch** | **auto-off** } command enables global dynamic frequency assignment (DFA) and sets the mode for processing redundant radios.

The **undo calibrate flexible-radio** command disables global DFA.

By default, global DFA is disabled.

Format

calibrate flexible-radio { **auto-switch** | **auto-off** }

undo calibrate flexible-radio

Parameters

Parameter	Description	Value
auto-switch	Automatically switches redundant 2.4 GHz radios to 5 GHz radios. If no channel is available on a 5 GHz radio or the current radio cannot be switched to a 5 GHz radio, the current radio is switched to the monitor mode.	-
auto-off	Automatically disables redundant 2.4 GHz radios.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

DFA applies to scenarios where indoor APs with omnidirectional antennas are densely deployed, the 2.4 GHz frequency band has severe co-channel interference, and most STAs on the network support the 5 GHz frequency band.

DFA automatically switches or disables redundant radios.

- If an AP does not support radio switchover, you are advised to specify **auto-off** in the command to reduce co-channel interference and save energy.
- If an AP supports radio switchover, you are advised to specify **auto-switch** in the command to increase network capacity. If most redundant 2.4 GHz radios are automatically switched to the monitor mode, channel resources on the current network are properly used. In this case, you can specify **auto-off** in the command.

Prerequisites

The radio calibration function has been enabled using the **calibrate enable** { **auto** | **manual** | **schedule time** } command.

Precautions

DFA reduces the deployment density of 2.4 GHz radios and increases the transmit power of 2.4 GHz radios. To ensure the 5 GHz access ratio of STAs, keep the band steering function enabled.

When DFA is disabled, redundant radios are switched back to 2.4 GHz radios and the system automatically triggers radio calibration, which may degrade wireless service experience.

Example

Enable global DFA and set the mode for processing redundant radios to automatic switchover.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] calibrate enable auto
[HUAWEI-wlan-view] calibrate flexible-radio auto-switch
```

11.4.26 calibrate flexible-radio disable

Function

The **calibrate flexible-radio disable** command disables DFA of specified radios.

The **undo calibrate flexible-radio disable** command enables DFA of specified radios.

By default, the DFA function of a radio is enabled.

Format

calibrate flexible-radio disable

undo calibrate flexible-radio disable

Parameters

None

Views

AP radio view, AP group radio view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After global DFA is enabled, you can run this command to disable DFA of a single AP radio or radios of an AP group in some areas.

Prerequisites

Global DFA has been enabled using the **calibrate flexible-radio** { **auto-switch** | **auto-off** } command.

Example

Disable DFA of radio 0 of AP 1.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] calibrate enable auto
[HUAWEI-wlan-view] calibrate flexible-radio auto-switch
[HUAWEI-wlan-view] ap-id 1
[HUAWEI-wlan-ap-1] radio 0
[HUAWEI-wlan-radio-1/0] calibrate flexible-radio disable
```

11.4.27 calibrate flexible-radio manual-recognize

Function

The **calibrate flexible-radio manual-recognize** command triggers identification of redundant radios.

Format

calibrate flexible-radio manual-recognize

Parameters

None

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The network administrator can run this command to manually trigger identification of redundant radios, and can enable DFA if discovering that redundant radios exist on the network.

Prerequisites

The radio calibration function has been enabled using the **calibrate enable** { **auto** | **manual** | **schedule time** } command.

Precautions

This command only triggers identification of redundant radios but does not switch or disable identified redundant radios.

Radio scanning is required for identifying redundant radios, which may degrade wireless service experience.

Follow-up Procedure

After redundant radios are identified, you can run the **display flexible-radio status** command to check the status of the redundant radios.

Example

Trigger identification of redundant radios.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] calibrate enable auto
[HUAWEI-wlan-view] calibrate flexible-radio manual-recognize
```

11.4.28 calibrate grouping interference-threshold

Function

The **calibrate grouping interference-threshold** command sets the interference threshold of a calibration group.

The **undo calibrate grouping interference-threshold** command restores the default interference threshold of a calibration group.

The default interference threshold of a calibration group is –127 dBm.

Format

calibrate grouping interference-threshold *threshold*

undo calibrate grouping interference-threshold

Parameters

Parameter	Description	Value
threshold	Specifies the interference threshold of a calibration group.	The value is an integer that ranges from –127 to –1, in dBm.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During radio calibration, the system adds neighboring APs to the same calibration group and allocates channels to them. If there are a large number of APs in a calibration group but only a few channels are available, the same channel may be allocated to neighboring APs. In scenarios where APs are blocked by walls or deployed regularly, such as dormitories and hotels, you can set a proper RSSI interference threshold to control the number of APs in the same calibration group. This effectively reduces the probability that neighboring APs use the same channel. If the RSSI of a neighbor working at the maximum power exceeds the threshold, the neighbor is added to the same calibration group. **In other scenarios, use the default value.**

Precautions

In typical scenarios, it is recommended that the interference threshold in a calibration group be set to –70 dBm. If severe co-channel interference exists between APs and neighboring APs, you can sample 1/10 of APs on each floor and calculate the accurate threshold so that the calibration algorithm can stagger the channels of neighboring APs. The specific calculation method is as follows:

1. Run the **display radio all** command and query the maximum power of each radio based on the **ME** field in the command output.
2. Run the **display ap neighbor** command to query information about neighboring APs of the target AP. Based on the **RSSI pathloss** field in the command output, calculate the maximum power values of the neighboring APs.
3. Sort the RSSIs of neighboring APs in descending order (for example, –58 dBm, –60 dBm, –62 dBm, –80 dBm, –84 dBm, –86 dBm, –90 dBm), and calculate the differences between RSSIs of neighboring APs (for example, 2 dB, 2 dB, 18 dB, 4 dB, 2 dB, 4 dB).
4. Find the first edge point where the RSSI difference is greater than or equal to 15 dB in descending order of neighboring APs' RSSIs. Divide the neighboring APs into two groups at the point: one group with strong detected RSSIs and the other with weak detected RSSIs.

   In the preceding example, the point where the RSSI difference is 18 dB is between the neighbors with –62 dBm and –80 dBm. Therefore, the seven neighbors of the AP are divided into two groups: a group with strong detected RSSIs (–58 dBm, –60 dBm, –62 dBm) and a group with weak detected RSSIs (–80 dBm, –84 dBm, –86 dBm, –90 dBm).
5. Calculate the average value between the minimum RSSI value of the group with strong detected RSSIs and the maximum RSSI value of the group with weak detected RSSIs. Use this average value as the RSSI threshold of the calibration group.

   In the preceding example, –62 dBm and –80 dBm are extracted from the two groups. The average value of the two values is –76 dBm, which is used as the recommended RSSI interference threshold.

NOTE

If the average threshold value calculated based on the sampled APs can meet the grouping requirements of all sampled APs, you can use this value for all APs in this scenario. Otherwise, it is recommended that different thresholds be configured for specific APs.

Example

Set the interference threshold of a calibration group to –70 dBm.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] calibrate grouping interference-threshold -70
```

11.4.29 calibrate max-tx-power

Function

The **calibrate max-tx-power** command sets the maximum transmit power that can be adjusted through radio calibration.

The **undo calibrate max-tx-power** command restores the default maximum transmit power that can be adjusted through radio calibration.

By default, the maximum transmit power that can be adjusted through radio calibration is 127 dBm.

Format

calibrate max-tx-power { *2g-power* | **radio-5g** *5g-power* | **radio-6g** *6g-power* }

undo calibrate max-tx-power [**radio-5g** | **radio-6g**]

Parameters

Parameter	Description	Value
2g-power	Specifies the maximum transmit power that can be adjusted through 2.4 GHz radio calibration.	The value is an integer that ranges from 1 to 127, in dBm.
radio-5g *5g-power*	Specifies the maximum transmit power that can be adjusted through 5 GHz radio calibration.	The value is an integer that ranges from 1 to 127, in dBm.
radio-6g *6g-power*	Specifies the maximum transmit power that can be adjusted through 6 GHz radio calibration.	The value is an integer that ranges from 1 to 127, in dBm.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After radio calibration is enabled, an AP uses the Transmit Power Control (TPC) algorithm to calculate the transmit power to be adjusted based on detected neighbor information. If the transmit power to be adjusted calculated using the

TPC algorithm is to large, signal interference between APs may occur. You can run the **calibrate max-tx-power** command to set the maximum transmit power that can be adjusted through TPC.

Precautions

The maximum radio calibration power must be greater than or equal to the minimum radio calibration power. You can run the **calibrate min-tx-power** command to set the minimum calibration power.

You can adjust the maximum and minimum calibration power values using the **calibrate max-tx-power** and **calibrate min-tx-power** commands. The valid AP power after radio calibration is between the two values.

Example

Set the maximum transmit power that can be adjusted through 2.4 GHz radio calibration to 30 dBm.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] calibrate max-tx-power 30
```

11.4.30 calibrate min-tx-power

Function

The **calibrate min-tx-power** command sets the minimum transmit power that can be adjusted through radio calibration.

The **undo calibrate min-tx-power** command restores the default minimum transmit power that can be adjusted through radio calibration.

By default, the minimum transmit power that can be adjusted through 2.4 GHz radio calibration is 9 dBm, and that through 5 GHz or 6 GHz radio calibration is 12 dBm.

Format

calibrate min-tx-power { *2g-power* | **radio-5g** *5g-power* | **radio-6g** *6g-power* }

undo calibrate min-tx-power [**radio-5g** | **radio-6g**]

Parameters

Parameter	Description	Value
2g-power	Specifies the minimum transmit power that can be adjusted through 2.4 GHz radio calibration.	The value is an integer that ranges from 1 to 127, in dBm.

Parameter	Description	Value
radio-5g *5g-power*	Specifies the minimum transmit power that can be adjusted through 5 GHz radio calibration.	The value is an integer that ranges from 1 to 127, in dBm.
radio-6g *6g-power*	Specifies the minimum transmit power that can be adjusted through 6 GHz radio calibration.	The value is an integer that ranges from 1 to 127, in dBm.

Views

RRM profile view

2: Configuration level

Usage Guidelines

Usage Scenario

After radio calibration is enabled, an AP uses the Transmit Power Control (TPC) algorithm to calculate the transmit power to be adjusted based on detected neighbor information. If the transmit power calculated using the TPC algorithm is too small, radio coverage requirements may not be met. You can run the **calibrate min-tx-power** command to set the minimum transmit power that can be adjusted through TPC.

Precautions

The minimum radio calibration power must be less than or equal to the maximum radio calibration power. You can run the **calibrate max-tx-power** command to set the maximum calibration power.

You can adjust the maximum and minimum calibration power values using the **calibrate max-tx-power** and **calibrate min-tx-power** commands. The valid AP power after radio calibration is between the two values.

Example

Set the minimum transmit power that can be adjusted through 2.4 GHz radio calibration to 10 dBm.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] calibrate min-tx-power 10
```

11.4.31 calibrate manual startup

Function

The **calibrate manual startup** command manually triggers radio calibration.

Format

calibrate manual startup [{ **ap-group** *group-name* }&<1-4> | **ap-id** *ap-list*]

Parameters

Parameter	Description	Value
ap-group *group-name*	Specifies an AP group. **NOTE** A maximum of four AP groups can be specified.	The AP group must exist.
ap-id *ap-list*	Specifies AP IDs in a batch.	The value is a string of 1 to 255 characters. When multiple APs are selected, use commas (,) or hyphens (-) to separate AP IDs. For example, 5,8,10-13,20 indicates the list of APs with IDs 5, 8, 10, 11, 12, 13, and 20.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

To trigger radio calibration immediately, run the **calibrate enable** { **auto** | **manual** | **schedule time** } command to enable radio calibration and then run the **calibrate manual startup** command to manually trigger radio calibration.

You can select an AP group or list to implement radio calibration for specified APs.

Example

Manually trigger radio calibration.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] calibrate enable auto
[HUAWEI-wlan-view] calibrate manual startup
Warning: The operation may cause business interruption, Continue? [Y/N]:y
```

11.4.32 calibrate noise-floor-threshold

Function

The **calibrate noise-floor-threshold** command specifies the noise floor threshold for triggering radio calibration.

The **undo calibrate noise-floor-threshold** command restores the default noise floor threshold for triggering radio calibration.

The default noise floor threshold for triggering radio calibration is -75 dBm.

Format

calibrate noise-floor-threshold *threshold*

undo calibrate noise-floor-threshold

Parameters

Parameter	Description	Value
noise-floor-threshold *threshold*	Specifies the noise floor threshold for triggering radio calibration.	The value is an integer that ranges from -95 to 0, in dBm.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The noise floor indicates the noise strength in the current environment. A high noise floor value will make noise drown out valid data, affecting user services.

The noise floor threshold for triggering radio calibration can be used to determine whether the environment noise is normal. When detecting a noise floor value higher than the threshold, an AP reports a high noise floor message to the AC. The AC then performs radio calibration to avoid channels with high noise floor values to improve user experience.

Precautions

In most cases, the default noise floor threshold is recommended. When high noise floor leads to poor user experience, you can increase the threshold based on the real-time noise floor. To check the noise floor of an AP, run the **display ap traffic statistics wireless** command.

Example

Set the noise floor threshold for triggering radio calibration to -60 dBm.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] calibrate noise-floor-threshold -60
```

11.4.33 calibrate policy

Function

The **calibrate policy** command creates a radio calibration policy.

The **undo calibrate policy** command deletes a radio calibration policy.

By default, no radio calibration policy is created.

Format

calibrate policy { **non-wifi** | **noise-floor** }

undo calibrate policy { **non-wifi** | **noise-floor** }

Parameters

Parameter	Description	Value
non-wifi	Specifies the non-Wi-Fi mode.	-
noise-floor	Specifies the noise floor mode.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Radio calibration policies are classified into:

- Non-Wi-Fi: If non-Wi-Fi devices exist on the network, the radio calibration algorithm takes interference that may be caused by them into account when radio calibration is performed next time.
- Noise floor policy: When the noise floor of APs is high due to special external interference, service experience may deteriorate. With this radio calibration policy, the device takes actions to avoid interference. When detecting that the noise floor of the current channel exceeds the threshold for three consecutive

times, an AP notifies the AC of the high noise floor. The AC then allocates another channel to the AP and does not allocate the current channel to the AP in 30 minutes.

NOTE

Partial radio calibration triggered based on the noise floor takes effect only in automatic radio calibration mode.

The non-Wi-Fi policy is only supported by APs that support spectrum analysis.

To disable rogue interference calibration, run the **calibrate reference rogue-ap-interference disable** command.

Radio calibration triggers channel changes. Some STAs may go offline and then go online again. If these STAs exist on the network, to ensure service experience, you are advised to perform radio calibration when no service is running and disable policies that frequently trigger radio calibration. You can run the **display channel switch-record calibrate** command to check policies that frequently trigger radio calibration.

The three radio calibration policies can be used together. You can run the command multiple times to configure different radio calibration policies according to service requirements.

Prerequisites

The noise floor threshold for triggering radio calibration has been specified using the **calibrate noise-floor-threshold** *threshold* command.

Example

Create a radio calibration policy in non-Wi-Fi mode.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] calibrate policy non-wifi
```

11.4.34 calibrate reference 3d-data

Function

The **calibrate reference 3d-data** { **enable** | **disable** } command enables or disables the 3D radio calibration function.

The **undo calibrate reference 3d-data** command restores the default state of the 3D radio calibration function.

By default, 3D radio calibration is enabled in the AP group radio view and is not configured in the AP radio view.

Format

calibrate reference 3d-data { **enable** | **disable** }

undo calibrate reference 3d-data

Parameters

None

Views

AP group radio view, AP radio view

Default Level

2: Configuration level

Usage Guidelines

Traditional radio calibration can only construct a topology between APs based on inter-AP probe data and automatically adjust the channels and transmit power of the APs. The latest calibration algorithm can construct a 3D network topology (AP-STA-AP) based on the probe data between APs and STAs during radio calibration. This helps accurately identify the topology relationship between APs (for example, APs installed at heights). In this way, the calibration effect is improved. You can run this command to enable 3D radio calibration to achieve optimization based on the analysis result of STA measurement data.

NOTE

- The 3D radio calibration function takes effect only for APs running V200R021C10 or later.
- APs running versions earlier than V200R021C10 cannot collect or report STA measurement data. Enabling the 3D radio calibration function will affect the accuracy of identification results. If these APs exist on the network, you are advised to upgrade all APs to V200R021C10 or later, or disable the 3D radio calibration function.

Example

Enable 3D radio calibration.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-ap-group1] radio 0
[HUAWEI-wlan-group-radio-ap-group1/0] calibrate reference 3d-data enable
```

11.4.35 calibrate reference data-analysis disable

Function

The **calibrate reference data-analysis disable** disables the Big Data calibration function.

The **undo calibrate reference data-analysis** command restores the default configuration.

By default, Big Data calibration is enabled.

Format

calibrate reference data-analysis disable

undo calibrate reference data-analysis

Parameters

None

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

After Big Data calibration is enabled, the device performs calculation based on the variations in interference and load according to Big Data information obtained from the iMaster NCE-CampusInsight. This function helps better avoid interference and improve network capacity. If the Big Data calibration function is disabled, radio calibration is performed based only on the locally collected data.

The Big Data calibration function takes effect only when radio calibration is enabled.

Example

Disable the Big Data calibration function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] calibrate reference data-analysis disable
```

11.4.36 calibrate reference data-analysis

Function

The **calibrate reference data-analysis disable** command disables Big Data calibration on radio interfaces of APs and AP groups.

The **calibrate reference data-analysis enable** command enables Big Data calibration on radio interfaces of APs and AP groups.

The **undo calibrate reference data-analysis** command restores the default Big Data calibration configuration on radio interfaces of APs and AP groups.

By default, Big Data calibration is disabled on radio interfaces of APs but enabled on radio interfaces in an AP group.

Format

calibrate reference data-analysis { disable | enable }

undo calibrate reference data-analysis

Parameters

None

Views

AP group radio view, AP radio view

Default Level

2: Configuration level

Usage Guidelines

After Big Data calibration is enabled, the device performs calculation based on the variations in interference and load according to Big Data information obtained from the iMaster NCE-CampusInsight. This function helps better avoid interference and improve network capacity. If the Big Data calibration function is disabled, radio calibration is performed based only on the locally collected data.

NOTE

The Big Data calibration function takes effect on an AP only when the following configurations are performed:

- Configure the function of reporting KPIs to the Big Data analyzer.
- Enable radio calibration.
- Run the **undo calibrate reference data-analysis** command in the WLAN view to enable the global Big Data calibration function.
- Enable the Big Data calibration function on the AP. (If the Big Data calibration function is not configured on a single AP, the configuration of the AP group takes effect.)

Example

Enable Big Data calibration on radio 0 in AP group **ap-group1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name ap-group1
[HUAWEI-wlan-ap-group-ap-group1] radio 0
[HUAWEI-wlan-group-radio-ap-group1/0] calibrate reference data-analysis enable
```

11.4.37 calibrate reference rogue-ap-interference disable

Function

The **calibrate reference rogue-ap-interference disable** command disables rogue interference calibration so that the device performs radio calibration only based on information about authorized neighbors.

The **undo calibrate reference rogue-ap-interference disable** command enables rogue interference calibration so that the device performs radio calibration based on information about both authorized and rogue neighbors.

By default, rogue interference calibration is enabled.

Format

calibrate reference rogue-ap-interference disable

undo calibrate reference rogue-ap-interference disable

Parameters

None

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Rogue neighbors often interfere with radio signals of APs. Therefore, a WLAN usually takes rogue neighbors as one of the factors for radio calibration and avoids the channels used by the rogue neighbors. If only a few channels are available, authorized APs on the same channel may be deployed too close to each other, affecting wireless network coverage. In actual delivery, if rogue interference is low (no or little interference traffic), you can run the **calibrate reference rogue-ap-interference disable** command to adjust the radio calibration policy so that the device does not consider external Wi-Fi interference from rogue neighbors during radio calibration. In this way, more channel resources are available for allocation during radio calibration.

To take non-Wi-Fi interference into account during radio calibration, run the **calibrate policy non-wifi** command.

Example

Disable rogue interference calibration so that the device performs radio calibration only based on information about authorized neighbors.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] calibrate reference rogue-ap-interference disable
```

11.4.38 calibrate sensitivity

Function

The **calibrate sensitivity** command configures the calibration sensitivity for a device.

The **undo calibrate sensitivity** command restores the default calibration sensitivity.

By default, the calibration sensitivity of the device is **medium**.

Format

calibrate sensitivity [**2.4g** | **5g** | **6g**] { **high** | **medium** | **low** | **insensitivity** | **custom-percent** *custom-percent* }

undo calibrate sensitivity [**2.4g** | **5g** | **6g**]

Parameters

Parameter	Description	Value
high	Indicates high calibration sensitivity.	-
medium	Indicates medium calibration sensitivity.	-
low	Indicates low calibration sensitivity.	-
insensitivity	Indicates calibration insensitivity.	-
custom-percent *custom-percent*	Specifies the calibration sensitivity based on the customized threshold.	The value ranges from 0 to 100, in percentage (%). A larger value indicates a lower sensitivity.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Radio calibration sensitivity is valid only in automatic radio calibration mode (enabled using the **calibrate enable auto** command). The default value is recommended.

If the percentage of radios with severe interference reaches the calibration sensitivity threshold, global channels are adjusted during radio calibration. Otherwise, the algorithm adjusts the operating channels of only radios with severe interference.

- high: equivalent to the custom threshold of 25%
- medium: equivalent to the custom threshold of 50%
- low: equivalent to the custom threshold of 75%
- insensitivity: equivalent to the custom threshold of 100%

Example

Set the calibration sensitivity to high for radios on all frequency bands.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] calibrate sensitivity high
```

11.4.39 calibrate tpc threshold

Function

The **calibrate tpc threshold** command sets the Transmit Power Control (TPC) coverage threshold.

The **undo calibrate tpc threshold** command restores the default TPC coverage threshold.

The default TPC coverage threshold is –60 dBm.

Format

calibrate tpc threshold *threshold*

undo calibrate tpc threshold

Parameters

Parameter	Description	Value
threshold *threshold*	Specifies the TPC coverage threshold.	The value is an integer that ranges from -85 to -35, in dBm.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

When radio calibration is enabled, the TPC coverage threshold is different depending on AP deployment scenarios because the AP deployment distance or height differs. To ensure the optimal coverage effect, adjust the TPC coverage threshold based on the actual AP deployment situations. A large threshold indicates a wider transmit power range that can be adjusted through TPC.

Example

Set the TPC coverage threshold to -70 dBm.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] calibrate tpc threshold -70
```

11.4.40 calibrate virtual-group-size

Function

The **calibrate virtual-group-size** command sets the channel calibration group size and K value.

The **undo calibrate virtual-group-size** command restores the default channel calibration group size and K value.

By default, the channel calibration group size is 50, and the K value is 70.

Format

calibrate virtual-group-size *size-value* **k-value** *k-value*

undo calibrate virtual-group-size

Parameters

Parameter	Description	Value
size-value	Sets the channel calibration group size. This parameter is an algorithm parameter. Set it under the assistance of technical support personnel.	The value is an integer that ranges from 10 to 50.
k-value *k-value*	Sets the K value. This parameter is an algorithm parameter. Set it under the assistance of technical support personnel.	The value is an integer that ranges from 20 to 100.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

You can set internal algorithm parameters for radio calibration to optimize radio calibration time costs and effects. Set the parameters under the assistance of technical support personnel.

Example

Set the channel calibration group size to 40 and K value to 80.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] calibrate virtual-group-size 40 k-value 80
```

11.4.41 cca-threshold

Function

The **cca-threshold** command sets the clear channel assessment (CCA) threshold for APs.

The **undo cca-threshold** command restores the default CCA threshold of APs.

By default, no CCA threshold is specified. APs use the default CCA threshold of the chip.

NOTE

The CCA threshold does not take effect for the following APs:

- AirEngine X771
- AirEngine X761
- AirEngine X762

Format

cca-threshold *cca-threshold*

undo cca-threshold

Parameters

Parameter	Description	Value
cca-threshold	Specifies the CCA threshold for APs.	The value is an integer that ranges from –85 to –40, in dBm.

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The CCA mechanism enables a WLAN chip to determine whether the channel is idle before transmitting signals to the air interface. If so, the chip transmits signals. If not, the chip waits until the channel is idle.

The CCA threshold is used by the WLAN chip to evaluate whether a channel is idle. If the detected Wi-Fi signal strength on the current channel exceeds the threshold, the current channel is busy. Otherwise, the current channel is idle.

When deploying a WLAN, you can set a proper CCA threshold to reduce interference of co-channel Wi-Fi signals in the surrounding environment to the current AP and improve channel reuse rate.

In high-density coverage scenarios such as a stadium, you are advised to set the CCA threshold to -75 dBm. In other scenarios, you are advised to retain the default value or set this parameter under the guidance of technical support personnel.

Precautions

The anti-interference algorithm dynamically adjusts the CCA and AGC thresholds of APs. If the CCA or AGC threshold is manually configured when the anti-interference algorithm is enabled, the manually configured threshold takes effect.

Example

Set the CCA threshold for a 2G radio to -70 dBm.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] cca-threshold -70
Warning:  This parameter will affect the uplink access coverage or user access.
It is recommended that the configuration be modified under the guidance of profe
ssional technical personnel. The manually configured CCA threshold takes precede
nce over the anti-interference algorithm. If the anti-interference function is e
nabled, dynamic CCA adjustment does not take effect and the manually configured
CCA threshold takes effect. Continue? [Y/N]:y
```

11.4.42 co-sr disable

Function

The **co-sr disable** command disables the Coordinated Spatial Reuse (CoSR) function.

The **undo co-sr disable** command enables the CoSR function.

By default, the CoSR function is enabled.

Format

co-sr disable

undo co-sr disable

Parameters

None

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

On a high-density office network, you can run the **undo co-sr disable** command to enable the CoSR function to improve the overall network throughput.

The CoSR function is supported only by AirEngine X760 series APs.

Example

Disable the CoSR function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] co-sr disable
```

11.4.43 dca-channel bandwidth

Function

The **dca-channel bandwidth** command configures the calibration bandwidth.

The **undo dca-channel bandwidth** command restores the default calibration bandwidth.

By default, the calibration bandwidth value is **auto**.

Format

dca-channel 5g bandwidth { **20mhz** | **40mhz** | **80mhz** | **auto** }

dca-channel 6g bandwidth { **20mhz** | **40mhz** | **80mhz** | **160mhz** | **320mhz** | **auto** }

undo dca-channel 5g bandwidth

undo dca-channel 6g bandwidth

Parameters

Parameter	Description	Value
5g	Specifies the 5 GHz frequency band on which radio calibration is implemented.	-
6g	Specifies the 6 GHz frequency band on which radio calibration is implemented.	-

Parameter	Description	Value
20mhz | **40mhz** | **80mhz** | **160mhz** | **320mhz** | **auto**	Specifies the calibration bandwidth. If **auto** is specified and the number of channels supported by the country code is greater than or equal to 6, the device uses 40 MHz bandwidth on the 5 GHz frequency band and 80 MHz bandwidth on the 6 GHz frequency band by default during radio calibration. This achieves larger calibration bandwidth without manual configuration. If the number of available channels is less than 6, the device decreases the calibration bandwidth (from 80 MHz to 40 MHz and to 20 MHz) on the corresponding frequency band until the number of available channels is greater than or equal to 6 or the calibration bandwidth is reduced to 20 MHz.	-

Views

Regulatory domain profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Richer spectrum resources are available on the 5 GHz and 6 GHz frequency bands, enabling APs to work on 40 MHz or larger-bandwidth channels in addition to 20 MHz channels. Larger-bandwidth channels mean higher transmission rates. However, at least three channels are required in radio calibration to achieve the optimal calibration effect. When configuring the calibration bandwidth, ensure that enough calibration channels are available for use.

You can use the **dca-channel bandwidth** command to configure the calibration bandwidth and the **dca-channel channel-set** command to configure calibration channels as prompted.

Configuration Impact

When the calibration bandwidth is changed, the device recalculates the calibration channels.

Precautions

When configuring 40 MHz or larger calibration bandwidth, check whether channels of the corresponding bandwidth exist under the country code.

Example

Set the calibration bandwidth of 5 GHz radios to 40 MHz.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] regulatory-domain-profile name default
[HUAWEI-wlan-regulate-domain-default] dca-channel 5g bandwidth 40mhz
```

11.4.44 dca-channel channel-set

Function

The **dca-channel channel-set** command configures a calibration channel set.

The **undo dca-channel channel-set** command restores the default calibration channel set.

By default, a calibration channel set contains channels 1, 6, and 11 on 2.4 GHz radios and contains all channels supported by the corresponding country code on 5 GHz and 6 GHz radios. When configuring a calibration channel set, you can specify channels as prompted.

Format

dca-channel { **2.4g** | **5g** | **6g** } **channel-set** *channel-value*

undo dca-channel { **2.4g** | **5g** | **6g** } **channel-set**

Parameters

Parameter	Description	Value
2.4g | **5g** | **6g**	Specifies the frequency band on which radio calibration is performed. The options are as follows: • **2.4g**: Radios work on the 2.4 GHz frequency band. • **5g**: Radios work on the 5 GHz frequency band. • **6g**: Radios work on the 6 GHz frequency band.	-

Parameter	Description	Value
channel-set *channel-value*	Specifies a calibration channel set.	The value is a character string. You can select calibration channels as prompted. If you select multiple channels, use commas (,) to separate channel names.

Views

Regulatory domain profile view

Default Level

2: Configuration level

Usage Guidelines

Richer spectrum resources are available on the 5 GHz and 6 GHz frequency bands, enabling APs to work on 40 MHz or larger-bandwidth channels in addition to 20 MHz channels. Larger-bandwidth channels mean higher transmission rates. However, at least three channels are required in radio calibration to achieve the optimal calibration effect. When configuring the calibration bandwidth, ensure that enough calibration channels are available for use.

You can run this command to specify a calibration channel set for an AP. The AP selects channels from the channel set to calibrate. This reduces the burden on the AP.

NOTE

To ensure a good calibration effect, you are advised to configure at least three calibration channels.

To prevent signal interference, ensure that adjacent APs work in non-overlapping channels. The 2.4 GHz frequency band has overlapping channels. When configuring calibration channels, you are advised to configure a non-overlapping calibration channel set containing channels 1, 6, and 11 or containing channels 1, 5, 9, and 13.

To specify a 40 MHz calibration channel, you need to specify two consecutive 20 MHz channels. To specify an 80 MHz calibration channel, you need to specify four consecutive 20 MHz channels. The combinations of 20 MHz channels making up the 40 MHz and 80 MHz channels are fixed.

You can also use the **dca-channel bandwidth** command to configure the calibration bandwidth and the **dca-channel channel-set** command to configure calibration channels as prompted.

If no calibration channel set is configured, the device probes channels based on the calibration channels corresponding to the country code.

NOTE

When configuring a calibration channel set, avoid using radar channels.

The configured channels must be supported by STAs; otherwise, the STAs cannot discover radio signals.

Channels 184, 188, 192, and 196 on the 4.9 GHz frequency band can be used for radio scanning but cannot be used for channel calibration.

If the AP has three 5 GHz radios, configure at least five calibration channels. If the AP has two 5 GHz radios, configure at least three calibration channels.

Example

Configure a calibration channel set composed of 40 MHz channels 149, 153, 157, and 161 on the 5 GHz frequency band.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] regulatory-domain-profile name default
[HUAWEI-wlan-regulate-domain-default] dca-channel 5g bandwidth 40mhz
[HUAWEI-wlan-regulate-domain-default] dca-channel 5g channel-set 149,153,157,161
```

11.4.45 deauth-fail-times

Function

The **deauth-fail-times** command sets the maximum number of attempts to steer STAs in deauthentication mode.

The **undo deauth-fail-times** command restores the default maximum number of attempts to steer STAs in deauthentication mode.

By default, the maximum number of attempts to steer STAs in deauthentication mode is 0.

Format

deauth-fail-times *deauth-fail-times*

undo deauth-fail-times

Parameters

Parameter	Description	Value
deauth-fail-times	Specifies the maximum number of attempts to steer STAs in deauthentication mode.	The value is an integer that ranges from 0 to 5. The value 0 indicates that the deauthentication mode is not used to steer STAs.

Views

Static load balancing group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The device attempts to use the 802.11v and deauthentication modes to trigger STA steering to the target AP. Due to differences of STAs, some STAs can be successfully steered in deauthentication mode after multiple attempts. You can run the **deauth-fail-times** command to set the maximum number of attempts to steer STAs in deauthentication mode. If the number of attempts exceeds the specified value, STAs cannot be steered.

Precautions

You are advised to retain the default value. If the success rate of STA steering in deauthentication mode is low or STA services are affected, set the parameter value to 0 to disable STA steering in deauthentication mode.

Example

Set the maximum number of attempts to steer STAs in deauthentication mode to 1.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sta-load-balance static-group name coco
[HUAWEI-wlan-sta-lb-static-coco] deauth-fail-times 1
```

11.4.46 dfs radar-filter sensitivity

Function

The **dfs radar-filter sensitivity** command sets the sensitivity level of correction for false DFS radar detection.

The **undo dfs radar-filter sensitivity** command restores the default sensitivity level of correction for false DFS radar detection.

By default, the sensitivity level of correction for false DFS radar detection is 0.

Format

dfs radar-filter sensitivity *level*

undo dfs radar-filter sensitivity

Parameters

Parameter	Description	Value
level	Specifies the sensitivity level of correction for false DFS radar detection.	The value is an integer that ranges from 0 to 10. - Level 0: The sensitivity of correction for false DFS radar detection is moderate. - Levels 1 to 9: A larger value indicates that correction for false DFS radar detection is more sensitive. That is, DFS radar detection is less sensitive and radar signals are less likely to be detected. - Level 10: DFS radar detection is disabled.

Views

5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

In most cases, you are advised to retain the default sensitivity level of correction for false DFS radar detection However, some APs may frequently detect radar signals by mistake. To prevent unnecessary channel switching, you can run the **dfs radar-filter sensitivity** command to adjust the sensitivity level as required to reduce false radar detection.

If radar signals are often falsely detected, you are advised to set the sensitivity level to 5 and then adjust the value properly based on the false radar detection events. For example, if an AP often falsely detects radar signals, the sensitivity level for radar detection is high. In this case, set the sensitivity level to 5 and continuously observe the false radar detection events. If false radar detection events persist, gradually increase the sensitivity level.

Example

Set the sensitivity level of correction for false DFS radar detection to 9 in the 5G radio profile **test1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-5g-profile name test1
[HUAWEI-wlan-radio-5g-prof-test1] dfs radar-filter sensitivity 9
```

11.4.47 dfs recover-delay

Function

The **dfs recover-delay** command sets the delay in switching back the DFS channel.

The **undo dfs recover-delay** command restores the default delay in switching back the DFS channel.

By default, the delay in switching back the DFS channel is 0 minutes. That is, the channel is switched back to the manually planned channel when the legitimate aging time (30 minutes) expires.

Format

dfs recover-delay *delay-time*

undo dfs recover-delay

Parameters

Parameter	Description	Value
delay-time	Specifies a delay in switching back the DFS channel.	The value is an integer that ranges from 0 to 2880, in minutes.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

For an AP operating on a manually planned channel, it randomly selects a channel (calibration channel preferred) within the range defined by the country code after detecting radar signals. The AP channel will be switched back to the manually planned channel after the configured switchback delay and legitimate aging time (30 minutes). A proper delay in switching back the DFS channel will prevent frequent channel switchovers.

Example

Set the delay in switching back the DFS channel to 10 minutes.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] dfs recover-delay 10
```

11.4.48 dfs smart-selection disable

Function

The **dfs smart-selection disable** command disables the DFS smart selection function.

The **undo dfs smart-selection disable** command enables the DFS smart selection function.

By default, the DFS smart selection function is enabled.

Format

dfs smart-selection disable

undo dfs smart-selection disable

Parameters

None

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the DFS smart selection function is enabled, an AP working on the 5 GHz band detects radar signals. Upon detecting radar channels, the AP automatically switches to another channel to prevent radar interference.

When an AP switches its working channel upon detecting radar signals, it randomly selects a channel (the calibration channel preferentially) allowed by the country code. The selected channel may be the same as or adjacent to the working channel of surrounding 5 GHz radios, thereby causing severe interference and poor network access experience. By default, the DFS smart selection function is enabled so that the AP switches to a 5 GHz channel with the minimum interference, preventing interference.

After the **dfs smart-selection disable** command is executed, the DFS smart selection function is disabled, affecting user experience. Configure this function as required.

Precautions

The DFS smart selection function is valid only when the air scan is enabled.

Example

Disable DFS smart selection.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] dfs smart-selection disable
Info: This function does not take effect when air scan is disabled.
```

11.4.49 display air-scan-profile

Function

The **display air-scan-profile** command displays information about air scan profiles.

Format

display air-scan-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays information about all air scan profiles.	-
name *profile-name*	Displays information about a specified air scan profile.	The air scan profile name must already exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display air-scan-profile** command to view information about air scan profiles.

Example

Display information about all air scan profiles.

```
<HUAWEI> display air-scan-profile all
------------------------------------------------------------
Profile name        Reference
------------------------------------------------------------
default            2
test               1
------------------------------------------------------------
Total: 2
```

Table 11-132 Description of the **display air-scan-profile all** command output

Item	Description
Profile name	Name of an air scan profile.

Item	Description
Reference	Number of times that the air scan profile is referenced.

Display information about the air scan profile **test**.

```
<HUAWEI> display air-scan-profile name test
------------------------------------------------------------
Scan switch        : enable
Scan period(ms)    : 80
Scan interval(ms) : 3000
Scan channel-set  : dca-channel
Scan enhancement  : enable
------------------------------------------------------------
```

Table 11-133 Description of the **display air-scan-profile name** command output

Item	Description
Scan switch	Whether air scanning is enabled. To configure the parameter, run the **scan-disable** command.
Scan period(ms)	Air scan period. To set the air scan period, run the **scan-period** command.
Scan interval(ms)	Air scan interval. To set the air scan interval, run the **scan-interval** command.
Scan channel-set	Air scan channel set. To set the air scan channel set, run the **scan-channel-set** command.
Scan enhancement	Whether the scanning enhancement function is enabled. To configure the scanning enhancement function, run the **scan-enhancement** command.

11.4.50 display anti-interference config

Function

The **display anti-interference config** command displays the configuration of the anti-interference algorithm.

Format

display anti-interference config

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display anti-interference config** command displays the configuration of the anti-interference algorithm.

Example

Display the configuration of the anti-interference algorithm.

```
<HUAWEI> display anti-interference config
------------------------------------------
Anti-interference switch       : enable
Per-packet-TPC switch          : enable
AGC check switch               : enable
Dynamic CCA upper threshold    : -70
Dynamic CCA lower threshold    : -82
Edge STA SNR threshold         : 22
Edge STA RSSI threshold        : -70
------------------------------------------
```

Table 11-134 Description of the **display anti-interference config** command output

Item	Description
Anti-interference switch	Whether the anti-interference algorithm is enabled. To configure this parameter, run the **anti-interference disable** command.
Per-packet-TPC switch	Whether the packet-based power adjustment function is enabled. To configure this parameter, run the **anti-interference per-packet-tpc disable** command.

Item	Description
AGC check switch	Whether the AGC algorithm before packet transmission is enabled. To configure this parameter, run the **anti-interference agc-check disable** command.
Dynamic CCA upper threshold	Upper dynamic CCA threshold.
Dynamic CCA lower threshold	Lower dynamic CCA threshold.
Edge STA SNR threshold	Threshold for determining an edge STA based on the SNR.
Edge STA RSSI threshold	Threshold for determining an edge STA based on the RSSI.

11.4.51 display flexible-radio status

Function

The **display flexible-radio status** command displays the status and switching result of the redundant radio.

Format

display flexible-radio status

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display flexible-radio status** command to check the status and switching result of the redundant radio.

Example

Display the status and switching result of the redundant radio.

```
<HUAWEI> display flexible-radio status
Redundancy Results:
R: The current radio is a redundant radio that has not been switched
```

```
S(5G): The redundant radio is switched to the 5 GHz mode
S(monitor): The redundant radio is switched to the monitor mode
S(off): This redundant radio is disabled
-: This radio is not a redundant radio
Recognize time: 2019-06-11/16:59:52 DST
------------------------------------------------------------
AP ID  Name           RfID  Band ST  Redundancy Result
------------------------------------------------------------
2      00e0-fc12-3455  0    2.4G on  R
3      00e0-fc12-3456  0    2.4G on  S(5G)
------------------------------------------------------------
Total:4
```

Table 11-135 Description of the **display flexible-radio status** command output

Item	Description
Recognize time	Time when the redundant radio is identified. **DST** indicates that the daylight saving time is set through the **clock daylight-saving-time** command.
AP ID	AP ID.
Name	AP name.
RfID	Radio ID.
Band	Frequency band of the radio.
ST	Radio status.
Redundancy Result	Switching result of the redundant radio. ● R: The current radio is a redundant radio that has not been switched. ● S(5G): The redundant radio is switched to the 5 GHz mode. ● S(monitor): The redundant radio is switched to the monitor mode. ● S(off): This redundant radio is disabled. ● -: This radio is not a redundant radio.

11.4.52 display flexible-radio switch-record

Function

The **display flexible-radio switch-record** command displays the switching record of the redundant radio.

Format

display flexible-radio switch-record [**detail**]

Parameters

Parameter	Description	Value
detail	Displays the detailed switching record of the redundant radio.	-

Views

Table 11-142 Description of the **display rrm-profile name** command output

Item	Description
Retransmission rate threshold for trigger channel/power select(%)	Retransmission rate threshold for triggering channel or power adjustment. To configure this parameter, run the **calibrate retransmission-rate-threshold** command.

Item	Description
Noise-floor threshold for trigger channel/power select(dBm)	Noise-floor threshold for triggering channel or power adjustment. To configure this parameter, run the **calibrate noise-floor-threshold** command.
Calibrate tpc threshold(dBm)	Transmit Power Control (TPC) coverage threshold. To configure this parameter, run the **calibrate tpc threshold** command.
Maximum 2.4G calibration TX power(dBm)	Maximum transmit power that can be adjusted through 2.4 GHz radio calibration. To configure this parameter, run the **calibrate max-tx-power** command.
Maximum 5G calibration TX power(dBm)	Maximum transmit power that can be adjusted through 5 GHz radio calibration. To configure this parameter, run the **calibrate max-tx-power radio-5g** command.
Maximum 6G calibration TX power(dBm)	Maximum transmit power that can be adjusted through 6 GHz radio calibration. To configure this parameter, run the **calibrate max-tx-power radio-6g** command.
Minimum 2.4G calibration TX power(dBm)	Minimum transmit power that can be adjusted through 2.4 GHz radio calibration. To configure this parameter, run the **calibrate min-tx-power** command.
Minimum 5G calibration TX power(dBm)	Minimum transmit power that can be adjusted through 5 GHz radio calibration. To configure this parameter, run the **calibrate min-tx-power radio-5g** command.
Minimum 6G calibration TX power(dBm)	Minimum transmit power that can be adjusted through 6 GHz radio calibration. To configure this parameter, run the **calibrate min-tx-power radio-6g** command.

Item	Description
Calibrate retransmission rate check interval(min)	Interval for checking the retransmission rate. To configure this parameter, run the **calibrate retransmission-rate-check** command.
Calibrate retransmission rate check traffic threshold(kbps)	Traffic threshold for checking the retransmission rate. To configure this parameter, run the **calibrate retransmission-rate-check** command.
Calibrate grouping interference threshold(dBm)	RSSI interference threshold of a calibration group. To configure this parameter, run the **calibrate grouping interference-threshold** command.
Airtime fairness schedule	Whether airtime fair scheduling is enabled. To configure this parameter, run the **airtime-fair-schedule enable** command.
Dynamic adjust EDCA parameter	Whether dynamic EDCA parameter adjustment is enabled. To configure this parameter, run the **dynamic-edca enable** command.
Dynamic EDCA be-service threshold	Threshold for the dynamic EDCA Best-Effort service. To configure this parameter, run the **dynamic-edca threshold** command.
UAC check client's SNR	Whether user CAC based on the STA's SNR is enabled. To configure this parameter, run the **uac enable** command.
UAC client's SNR threshold(dB)	User CAC SNR threshold. To configure this parameter, run the **uac client-snr threshold** command.
UAC check client number	Whether user CAC based on the number of users is enabled. To configure this parameter, run the **uac enable** command.

Item	Description
UAC client number access threshold	User CAC access threshold based on the number of users. To configure this parameter, run the **uac client-number threshold** command.
UAC client number roam threshold	User CAC roaming threshold based on the number of users. To configure this parameter, run the **uac client-number threshold** command.
Action upon reaching the UAC threshold	Action to take when the number of access users reaches the user CAC threshold. ● SSID hide: hiding the SSID ● SSID broadcast: broadcasting the SSID ● priority-based STA replacement: allowing access of VIP users instead of non-VIP users based on priorities To configure this parameter, run the **uac reach-access-threshold** command.
Band steer deny threshold	Maximum number of times an AP rejects association requests of a STA for band steering. To configure this parameter, run the **band-steer deny-threshold** command.
Band steer SNR threshold(dB)	Start SNR threshold for triggering 5G-prior access. To configure this parameter, run the **band-steer snr-threshold** command.
Band balance start threshold	Start threshold for load balancing between radios. To configure this parameter, run the **band-steer balance start-threshold** command.
Band balance gap threshold(%)	Load difference threshold for load balancing between radios. To configure this parameter, run the **band-steer balance gap-threshold** command.

Item	Description
Client's band expire based on continuous probe counts	Aging condition of terminal band information, that is, the number of times that an AP has continuously received Probe frames of a terminal from the same frequency band. To configure this parameter, run the **band-steer client-band-expire** command.
Station load balance	Whether the load balancing function is enabled. To configure this parameter, run the **sta-load-balance dynamic disable** command.
Station load balance mode	Dynamic load balancing mode. sta-number: dynamic load balancing based on the number of STAs.
Station load balance RSSI threshold(dBm)	RSSI threshold of members in a dynamic load balancing group. To configure this parameter, run the **sta-load-balance dynamic rssi-threshold** command.
Station load balance RSSI-diff-gap threshold(dBm)	RSSI difference threshold for members in a dynamic load balancing group. To configure this parameter, run the **sta-load-balance dynamic rssi-diff-gap** command.
Station load balance sta-number start threshold	Start threshold for dynamic load balancing based on the number of users. To configure this parameter, run the **sta-load-balance dynamic sta-number start-threshold** command.
Station load balance sta-number gap threshold(percentage)	Load difference threshold for dynamic load balancing based on the percentage of users. To configure this parameter, run the **sta-load-balance dynamic sta-number gap-threshold** command.

Item	Description
Station load balance sta-number gap threshold(number)	Load difference threshold for dynamic load balancing based on the number of users. To configure this parameter, run the **sta-load-balance dynamic sta-number gap-threshold** command.
Station load balance deauth fail times	Maximum number of attempts to steer STAs in deauthentication mode. To configure this parameter, run the **sta-load-balance dynamic deauth-fail-times** command.
Station load balance BTM fail times	Maximum number of attempts to steer STAs in BTM mode. To configure this parameter, run the **sta-load-balance dynamic btm-fail-times** command.
Station load balance steer-restrict restrict time(s)	Duration within which non-target APs suppress association of STAs during STA steering. To configure this parameter, run the **sta-load-balance dynamic steer-restrict restrict-time** command.
Station load balance steer-restrict probe threshold	Maximum number of times non-target APs perform probe suppression for STAs during STA steering. To configure this parameter, run the **sta-load-balance dynamic steer-restrict probe-threshold** command.
Station load balance steer-restrict auth threshold	Maximum number of times non-target APs suppress authentication of STAs during STA steering. To configure this parameter, run the **sta-load-balance dynamic steer-restrict auth-threshold** command.
Station load balance probe-report interval(s)	Interval for reporting Probe frames. To configure this parameter, run the **sta-load-balance dynamic probe-report interval** command.
BSS color switch	Whether the BSS coloring function is enabled. To configure this parameter, run the **bss-color disable** command.

Item	Description
Spatial reuse switch	Whether the spatial reuse (SR) function is enabled. To configure this parameter, run the **spatial-reuse disable** command.
Smart-roam	Whether smart roaming is enabled. To configure this parameter, run the **smart-roam { enable | disable }** command.
Smart-roam AI mode	Whether the AI roaming function is enabled. To configure this parameter, run the **smart-roam ai-mode** command.
Smart-roam quick kickoff	Whether the function of quickly disconnecting STAs is enabled. To configure this parameter, run the **smart-roam quick-kickoff-threshold disable** command.
Smart-roam check SNR	Whether the trigger mode of smart roaming is specified as **check SNR**. To configure this parameter, run the **smart-roam roam-threshold { check-snr | check-rate }** command.
Smart-roam quick kickoff check SNR	Whether the function of quickly disconnecting STAs is triggered by checking the SNR of STAs. To configure this parameter, run the **smart-roam quick-kickoff-threshold { check-snr | check-rate }** command.
Smart-roam check rate	Whether the trigger mode of smart roaming is specified as **check rate**. To configure this parameter, run the **smart-roam roam-threshold { check-snr | check-rate }** command.
Smart-roam quick kickoff check rate	Whether the function of quickly disconnecting STAs is triggered by checking the rate of STAs. To configure this parameter, run the **smart-roam quick-kickoff-threshold { check-snr | check-rate }** command.

Item	Description
Smart-roam standing SNR threshold(dB)	SNR threshold for smart roaming. To configure this parameter, run the **smart-roam roam-threshold { snr | rate }** command.
Smart-roam SNR quick-kickoff-threshold(dB)	SNR threshold for quickly disconnecting STAs. To configure this parameter, run the **smart-roam quick-kickoff-threshold** command.
Smart-roam rate threshold(%)	Rate threshold for smart roaming. To configure this parameter, run the **smart-roam roam-threshold { snr | rate }** command.
Smart-roam rate quick-kickoff-threshold(%)	Rate threshold for quickly disconnecting STAs. To configure this parameter, run the **smart-roam quick-kickoff-threshold** command.
Smart-roam high level SNR margin(dB)	Higher SNR difference threshold that triggers STA roaming. To configure this parameter, run the **smart-roam snr-margin** command.
Smart-roam low level SNR margin(dB)	Lower SNR difference threshold that triggers STA roaming. To configure this parameter, run the **smart-roam snr-margin** command.
Smart-roam SNR check interval(s)	Interval for checking the SNR of STAs.
Smart-roam unable roam client expire time(min)	Aging time of "unable to roam" record. To configure this parameter, run the **smart-roam unable-roam-client expire-time** command.
Smart-roam quick-kickoff SNR check interval(ms)	Interval for checking the SNR to determine whether to quickly disconnect STAs. To configure this parameter, run the **smart-roam quick-kickoff-snr check-interval** command.

Item	Description
Smart-roam quick-kickoff SNR P-N observe time	Number of PN observation times to determine whether to quickly disconnect STAs. To configure this parameter, run the **smart-roam quick-kickoff-snr p-n criteria** command.
Smart-roam quick-kickoff SNR P-N qualify time	Number of PN observation times to determine whether to quickly disconnect STAs. To configure this parameter, run the **smart-roam quick-kickoff-snr p-n criteria** command.
Smart-roam advanced scan	Whether coordinated scanning function of smart roaming is enabled. To configure this parameter, run the **smart-roam advanced-scan disable** command.
Smart-roam quick-kickoff back off time	Backoff time for quickly disconnecting STAs. To configure this parameter, run the **smart-roam quick-kickoff back-off-time** command.
AMC policy	Adaptive modulation and coding (AMC) algorithm. To configure this parameter, run the **amc-policy** command.
High density AMC optimize	Whether the AMC optimization function in high-density scenarios is enabled. To configure this parameter, run the **high-density amc-optimize enable** command.
Antenna-mode	Antenna mode. To configure this parameter, run the **antenna-mode** command.
SFN roam check high threshold(dBm)	Upper RSSI threshold for agile distributed SFN roaming. To configure this parameter, run the **sfn-roam roam-check high-threshold** command.

Item	Description
SFN roam check low threshold(dBm)	Lower RSSI threshold for agile distributed SFN roaming. To configure this parameter, run the **sfn-roam roam-check low-threshold** command.
SFN roam check interval(ms)	Decision period for agile distributed SFN roaming. To configure this parameter, run the **sfn-roam roam-check check-interval** command.
SFN roam report interval(ms)	Interval for RUs to report the STA RSSI. To configure this parameter, run the **sfn-roam report-interval** command.
SFN roam check rssi-accumulate threshold(dB)	Cumulative RSSI change threshold for agile distributed SFN roaming. To configure this parameter, run the **sfn-roam roam-check rssi-accumulate** command.
SFN roam check sta-holding times	Number of STA holding times for agile distributed SFN roaming. To configure this parameter, run the **sfn-roam roam-check sta-holding times** command.
SFN roam check gap-rssi(dB)	RSSI gap for agile distributed SFN roaming RUs. To configure this parameter, run the **sfn-roam roam-check gap-rssi** command.
SFN roam check better-times	Number of times the RSSI of agile distributed SFN roaming RUs is higher than that of the local RU. To configure this parameter, run the **sfn-roam roam-check better-times** command.

Item	Description
DFS smart select	Whether DFS smart selection is enabled. ● enable: DFS smart selection is enabled. ● disable: DFS smart selection is disabled. To configure this parameter, run the **dfs smart-selection disable** command.
DFS recover delay time(min)	Delay in switching back the DFS channel. To configure this parameter, run the **dfs recover-delay** command.
Switch	Whether the intelligent multimedia scheduling algorithm is enabled. ● disable: The intelligent multimedia scheduling algorithm is disabled. ● enable: The intelligent multimedia scheduling algorithm is enabled. To configure this parameter, run the **multimedia-air-optimize disable** command.
Voice threshold	Voice packet threshold. To configure this parameter, run the **multimedia-air-optimize threshold** command.
Video threshold	Video packet threshold. To configure this parameter, run the **multimedia-air-optimize threshold** command.
Voice downlink-slice-ratio	Slicing ratio for voice packets. To configure this parameter, run the **multimedia-air-optimize downlink-slice-ratio** command.
Video downlink-slice-ratio	Slicing ratio for video packets. To configure this parameter, run the **multimedia-air-optimize downlink-slice-ratio** command.
Voice downlink-delay-guarantee	Guaranteed delay for voice packets. To configure this parameter, run the **multimedia-air-optimize downlink-delay-guarantee** command.

Item	Description
Video downlink-delay-guarantee	Guaranteed delay for video packets. To configure this parameter, run the **multimedia-air-optimize downlink-delay-guarantee** command.
Best effort downlink-delay-guarantee	Guaranteed delay for BE flows. To configure this parameter, run the **multimedia-air-optimize downlink-delay-guarantee** command.
Background downlink-delay-guarantee	Guaranteed delay for BK flows. To configure this parameter, run the **multimedia-air-optimize downlink-delay-guarantee** command.
Congestion-control tcp-window-tuning switch	Whether the TCP window adjustment function for voice and video services is enabled. ● disable: The TCP window adjustment function for voice and video services is disabled. ● enable: The TCP window adjustment function for voice and video services is enabled. To configure this parameter, run the **multimedia-air-optimize congestion-control tcp-window-tuning disable** command.
Uplink-delay-guarantee	Whether the delay guarantee function for uplink services is enabled. ● disable: The function is disabled. ● enable: The function is enabled. To configure this parameter, run the **multimedia-air-optimize uplink-delay-guarantee disable** command.
Rate limit dynamic interval	Detection interval for dynamic rate limiting. To configure this parameter, run the **rate-limit dynamic interval** command.
Rate limit dynamic threshold	Detection threshold for dynamic rate limiting. To configure this parameter, run the **rate-limit dynamic interval** command.

Item	Description
CO-SR	Whether the CoSR function is enabled. - disable: The function is disabled. - enable: The function is enabled. To configure this parameter, run the **co-sr disable** command.
Switch	Whether the WLAN high-reliability slicing function is enabled. To configure this parameter, run the **wlan-slice high-reliability enable** command.
rtt	Expected RTT of WLAN high-reliability slicing. To configure this parameter, run the **wlan-slice high-reliability rtt** command.
time-ratio	Time proportion of WLAN high-reliability slicing. To configure this parameter, run the **wlan-slice high-reliability time-ratio** command.
FRER-enhance	Whether the enhanced dual fed and selective receiving function for WLAN high-reliability slicing scenarios is enabled. To configure this parameter, run the **wlan-slice high-reliability frer-enhance** command.

11.4.58 display sta-load-balance static-group

Function

The **display sta-load-balance static-group** command displays information about static load balancing groups.

Format

display sta-load-balance static-group { **all** | **name** *group-name* }

Parameters

Parameter	Description	Value
all	Displays information about all static load balancing groups.	-
name *group-name*	Displays information about a specified static load balancing group.	The static load balancing group must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display sta-load-balance static-group** command to view information about a specified static load balancing group or all static load balancing groups.

Example

Display information about all static load balancing groups.

```
<HUAWEI> display sta-load-balance static-group all
------------------------------------------------------------
Index  Group name
------------------------------------------------------------
0      cc
1      coco
------------------------------------------------------------
Total: 2
```

Table 11-143 Description of the **display sta-load-balance static-group all** command output

Item	Description
Index	Index.
Group name	Name of a static load balancing group.

Display information about the static load balancing group **cc**.

```
<HUAWEI> display sta-load-balance static-group name cc
-------------------------------------------------------------------
Group name                            : cc
Load-balance mode                       : sta-number
Sta-number start threshold               : 40
```

```
Sta-number gap threshold(percentage)   : 20
Sta-number gap threshold(number)       : -
RSSI threshold(dBm)                    : -70
RSSI diff gap(dBm)                     : 5
Deauth fail times                      : 2
Btm fail times                         : 5
Steer-restrict restrict time(s)        : 5
Steer-restrict probe threshold         : 5
Steer-restrict auth threshold          : 2
--------------------------------------------------------------------
```

Table 11-144 Description of the **display sta-load-balance static-group name** command output

Item	Description
Group name	Name of a static load balancing group.
Load-balance mode	Static load balancing mode. - sta-number: static load balancing based on the number of users
Sta-number start threshold	Start threshold for load balancing based on the number of users in the static load balancing group. To configure this parameter, run the **sta-number start-threshold** command.
Sta-number gap threshold(percentage)	Load difference threshold for static load balancing based on the percentage of users. To configure this parameter, run the **sta-number gap-threshold** command.
Sta-number gap threshold(number)	Load difference threshold for static load balancing based on the number of users. To configure this parameter, run the **sta-number gap-threshold** command.
RSSI threshold(dBm)	RSSI threshold of members in the static load balancing group. To configure this parameter, run the **rssi-threshold** command.
RSSI diff gap(dBm)	RSSI difference threshold of members in the static load balancing group. To configure this parameter, run the **rssi-diff-gap** command.
Deauth fail times	Maximum number of attempts to steer STAs in deauthentication mode. To configure this parameter, run the **deauth-fail-times** command.

Item	Description
Btm fail times	Maximum number of attempts to steer STAs in BTM mode. To configure this parameter, run the **btm-fail-times** command.
Steer-restrict restrict time(s)	Duration within which non-target APs suppress association of STAs during STA steering. To configure this parameter, run the **steer-restrict restrict-time** command.
Steer-restrict probe threshold	Maximum number of times non-target APs suppress probing of STAs during STA steering. To configure this parameter, run the **steer-restrict probe-threshold** command.
Steer-restrict auth threshold	Maximum number of times non-target APs suppress authentication of STAs during STA steering. To configure this parameter, run the **steer-restrict auth-threshold** command.

11.4.59 display sta-load-balance fairness

Function

The **display sta-load-balance fairness** command displays the load balancing fairness.

Format

display sta-load-balance fairness

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

STAs may access 2.4 GHz or 5 GHz radios on a WLAN. Even STA access indicates high fairness.

Example

Display the load balancing fairness.

```
<HUAWEI> display sta-load-balance fairness
2.4G sta-load-balance fairness : -
5G sta-load-balance fairness   : 0.85
```

Table 11-145 Description of the **display sta-load-balance fairness** command output

Item	Description
2.4G sta-load-balance fairness	Load balancing fairness of 2.4 GHz radios. A high value indicates high fairness. The value ranges from 0 to 1. When the value is 0, **-** is displayed.
5G sta-load-balance fairness	Load balancing fairness of 5 GHz radios. A high value indicates high fairness. The value ranges from 0 to 1. When the value is 0, **-** is displayed.

11.4.60 display station neighbor

Function

The **display station neighbor** command displays the neighbor list of a specified STA.

Format

display station neighbor sta-mac *mac-address*

Parameters

Parameter	Description	Value
sta-mac *mac-address*	Specifies the MAC address of a STA.	The MAC address must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check the neighbor list of the STA with a specified MAC address.

Example

Display the neighbor list of the STA with a specified MAC address.

```
<HUAWEI> display station neighbor sta-mac 00e0-fc00-0001
UL info: Uplink measurement neighbor info
DL info: Downlink measurement neighbor info
------------------------------------------------------------------------------------------------------------------------------
--
Device MAC        Device ID   Device Name        Radio ID  Channel  UL info[RSSI/DATE]        DL info[RCPI/
RSSI/RSNI/DATE]
------------------------------------------------------------------------------------------------------------------------------
--
00e0-fc76-e360     0          00e0-fc76-e360     1         165      -44/2023-03-01/09:49:39   130/-45/-/
2023-03-01/09:49:39
------------------------------------------------------------------------------------------------------------------------------
--
Total neighbors: 1, total records: 1
```

System Response

Table 11-146 Description of the **display station neighbor** command output

Item	Description
Device MAC	MAC address of a neighboring device.
Device ID	ID of a neighboring device.
Device Name	Name of a neighboring device.
Radio ID	Radio ID of a neighboring device.
Channel	Channel of a neighboring device.
UL info[RSSI/DATE]	RSSI: signal strength of the neighboring device measured in the uplink direction, in dBm. DATE: timestamp. **NOTE** If a hyphen (-) is displayed, the STA does not support or perform uplink scanning.

Item	Description
DL info[RCPI/RSSI/RSNI/DATE]	RCPI: received channel power indicator (RCPI) of the neighbor device measured in the downlink direction, in dBm. RSSI: RSSI converted from the RCPI of the neighboring device measured in the downlink direction, in dBm. RSNI: received signal-to-noise indicator (RSNI), in dB DATE: timestamp. **NOTE** If a hyphen (-) is displayed, the STA does not support or perform downlink scanning, or an invalid value is returned.

11.4.61 display station neighbor all

Function

The **display station neighbor all** command displays STA neighbor information.

Format

display station neighbor all

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view STA neighbor information.

Example

Display STA neighbor information.

```
<HUAWEI> display station neighbor all
UL neighbor number    : Number of neighbors detected through uplink measurement in 5 minutes
DL neighbor number    : Number of neighbors detected through downlink measurement in 5 minutes
Last update time      : Time when neighbors are detected through uplink or downlink measurement in 5 
minutes
                        formatted: uplink/downlink
------------------------------------------------------------------------------------------------------------------
```

```
STA MAC          UL neighbor number     DL neighbor number      Last update time
--------------------------------------------------------------------------------------------------------------------
00e0-fca2-a1c5    2                     2                     2022-10-14/14:07:02/2022-10-14/14:04:06
--------------------------------------------------------------------------------------------------------------------
Total:1
```

Table 11-147 Description of the **display station neighbor all** command output

Item	Description
STA MAC	MAC address of a STA.
UL neighbor number	Number of neighbors measured in the uplink direction in 5 minutes.
DL neighbor number	Number of neighbors measured in the downlink direction in 5 minutes.
Last update time	Time when a neighbor is detected in 5 minutes (uplink/downlink measurement).

11.4.62 display station steer-history

Function

The **display station steer-history** command displays historical information about STA steering.

Format

display station steer-history

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After the load balancing, band steering, or smart roaming function is enabled, STAs are steered. You can run this command to check historical information about STA steering.

Example

Display historical information about steering of all STAs.

```
<HUAWEI> display station steer-history
S/T/A:Source/Target/Actual
Flag:P[AI Profiling STA] V[Voice/Video/Active STA]

```

Table 11-148 Description of the **display station steer-history** command output

Item	Description
Time	Time when a STA is triggered to steer.
Sta	MAC address of a STA.
Device(S/T/A)	ID of the source device/ID of the target device/ID of the device to which a STA is actually steered.
Radio(S/T/A)	ID of the source radio/ID of the target radio/ID of the radio to which a STA is actually steered.
Rssi(S/T/A)	RSSI of the source radio/RSSI of the target radio/RSSI of the radio to which a STA is actually steered.
Reason	Reason why a STA is triggered to steer. ● Sticky: Smart roaming is enabled. ● Sticky(A): The device periodically detects whether the STA is a sticky STA to proactively trigger smart roaming. ● LoadBalance: Load balancing is enabled. ● BandSteer: Band steering is enabled. ● AI: AI roaming is enabled.
Move-mode	Steering mode of a STA. ● BTM ● Deauth

Item	Description
BTM_CODE	BTM steering status code. ● 0: Accept ● 1: Reject-Unspecified reject reason. ● 2: Reject-Insufficient Beacon or Probe Response frames received from all candidates. ● 3: Reject-Insufficient available capacity from all candidates. ● 4: Reject-BSS termination undesired. ● 5: Reject-BSS termination delay requested. ● 6: Reject-STA BSS Transition Candidate List provided. ● 7: Reject-No suitable BSS transition candidates. ● 8: Reject-Leaving ESS. ● -: A STA is steered in deauthentication mode or the device does not receive any BTM response.
Flag	● V: voice/video/active STA flag ● P: steering flag by STA profile ● -: other

Item	Description
Result	Steering result of a STA. ● Success: The steering is successful. ● Success(NT): The steering is successful but the STA is not steered to the expected target. ● Time Out: The steering times out. ● Not Move: The steering is complete, but the STA is still associated with the source AP. ● Failed: The steering fails. (The steering result does not meet the expectation. For example, the STA is not steered to the 5 GHz radio in the band steering scenario, is steered to an AP with poor signal quality in the smart roaming scenario, or is steered to a high-load AP in the load balancing scenario.) ● Protect: The AP detects that the STA is a voice, video, or active STA and protects the STA by not sending a steering message. ● Error(1) or Error(2): An internal error occurs during the steering.

11.4.63 display station steer-info

Function

The **display station steer-info** command displays STA migration information based on the weak RSSI, non-optimal load, and migration inability.

Format

display station steer-info { **all** | **weak-rssi** | **non-best-load** | **unsteerable** }

Parameters

Parameter	Description	Value
all	Displays migration information about all STAs, including the weak RSSI, non-optimal load, and migration inability.	-

Parameter	Description	Value
weak-rssi	Displays STA information based on the weak RSSI.	-
non-best-load	Displays STA information based on the non-optimal load.	-
unsteerable	Displays STA information based on the migration inability.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view STA migration information based on the weak RSSI, non-optimal load, and migration inability.

Example

Display migration information about all STAs, including the weak RSSI, non-optimal load, and migration inability.

```
<HUAWEI> display station steer-info all
-----------------------------------------------------------------------
Sta-MAC              Weak RSSI       Non-best-load    Unsteerable
-----------------------------------------------------------------------
00e0-fc12-3456        Y              N               Y
-----------------------------------------------------------------------
Total STA          : 1
Weak-RSSI STA      : 1
Non-best-load STA  : 0
Unsteerable STA    : 1
```

Table 11-149 Description of the **display station steer-info** command output

Item	Description
Sta-MAC	MAC address of a STA.
Weak RSSI	Whether a STA has a weak RSSI.
Non-best-load	Whether a STA has the non-optimal load.
Unsteerable	Whether the STA cannot be migrated.

11.4.64 display station steer-statistics

Function

The **display station steer-statistics** command displays STA steering statistics.

Format

display station steer-statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After the load balancing, band steering, or smart roaming function is enabled, STAs are steered. You can run this command to check STA steering statistics.

Example

Display steering statistics of all STAs.

```
<HUAWEI> display station steer-statistics

```

Table 11-150 Description of the **display station steer-statistics** command output

Item	Description
Reason	Reason why a STA is triggered to steer. - Sticky(Tradition): The STA is sticky (STA steering triggered by traditional smart roaming). - Sticky(Profile): The STA is sticky (STA steering based on STA profiles, not blind handover). - Sticky(Profile Blind): The STA is sticky (STA steering based on STA profiles, blind handover). - Load-balance(Tradition): Load balancing is implemented (STA steering triggered by traditional smart roaming). - Load-balance(Profile): Load balancing is implemented (STA steering based on STA profiles, not blind handover). - Load-balance(Profile Blind): Load balancing is implemented (STA steering based on STA profiles, blind handover). - Band-steer(Tradition): Band steering is implemented (STA steering triggered by traditional smart roaming). - Band-steer(Profile): Band steering is implemented (STA steering based on STA profiles, not blind handover). - Band-steer(Profile Blind): Band steering is implemented (STA steering based on STA profiles, blind handover). - AI: AI roaming steering based on coordinated scanning is implemented. - Total: total steering reason count.
Total/Success	Total number of triggered STA steering times/Number of successful STA steering times.

Item	Description
Deauth(Total/Success)	Total number of times STA steering is triggered in deauthentication mode/ Number of times STA steering is successfully triggered in deauthentication mode.
BTM(Total/Accept/REJ1/REJ2/REJ3/ REJ4/REJ5/REJ6/REJ7/REJ8/TimeOut)	Total number of times STA steering is triggered in BTM mode/Number of times STA steering is successfully triggered in BTM mode/Number of times STA steering is rejected in BTM mode/Number of times STA steering is timed out in BTM mode. The options are as follows: ● REJ1: Reject-Unspecified reject reason. ● REJ2: Reject-Insufficient Beacon or Probe Response frames received from all candidates. ● REJ3: Reject-Insufficient available capacity from all candidates. ● REJ4: Reject-BSS termination undesired. ● REJ5: Reject-BSS termination delay requested. ● REJ6: Reject-STA BSS Transition Candidate List provided. ● REJ7: Reject-No suitable BSS transition candidates. ● REJ8: Reject-Leaving ESS.

11.4.65 display station unsteerable

Function

The **display station unsteerable** command displays "unable to roam" records of STAs.

Format

display station unsteerable

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display station unsteerable** command to check "unable to roam" records of STAs.

Example

Display "unable to roam" records of STAs.

```
<HUAWEI> display station unsteerable
--------------------------------------------------------------------------------
STA MAC              Left aging time          Status
--------------------------------------------------------------------------------
00e0-fc12-3456        3h 20m                   online
00e0-fc45-7890        2h 30m                   offline
--------------------------------------------------------------------------------
Total: 2
```

Table 11-151 Description of the **display station unsteerable** command output

Item	Description
STA MAC	MAC address of the "unable to roam" STA.
Left aging time	Remaining aging period.
Status	Status of the STA. ● online ● offline

11.4.66 display sta-profiling

Function

The **display sta-profiling** command displays STA profile information on the device.

Format

display sta-profiling

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

STAs of different models use different Wi-Fi chips and WLAN module drivers, and therefore have different roaming steering behaviors. To improve roaming experience, WLAN devices need to use different roaming steering policies for STAs of different types (distinguished by STA profiles). During the steering roaming for a STA, the system matches STA information against the existing STA profiles based on the model and operating system, and selects a more suitable roaming steering policy, improving the roaming success rate. You can run the **display sta-profiling** command to check information about the learned STA profiles on the device.

Prerequisites

The STA profiling function has been enabled using the **undo sta-profiling disable** command.

Example

Display STA profile information on the device.

```
<HUAWEI> display sta-profiling
----------------------------------------------------------------------------------------------------
Vendor   Type                    Type ID      OS               OS ID      Priority    Version
----------------------------------------------------------------------------------------------------
...
Huawei   Mate 40                 32455       Android 10       17765      1190       0
Huawei   Mate 40 Pro             32454       Android 10       17765      1188       0
Huawei   Mate 40 Pro Plus        32456       Android 10       17765      1192       0
Huawei   Mate RS                 7348        Android 10       17765      149        0
...
----------------------------------------------------------------------------------------------------
 Total:313
```

Table 11-152 Description of the **display sta-profiling** command output

Item	Description
Vendor	Terminal brand.
Type	STA model.
Type ID	STA model ID.
OS	STA operating system.
OS ID	STA operating system ID.

Item	Description
Priority	Priority of the matching between a STA profile and the STA. A smaller value indicates a higher priority. If a STA matches multiple profiles based on the model and operating system, the profile with the highest priority is used.
Version	STA profile version. This version number increases with STA profile updates.

11.4.67 display wlan calibrate channel-set

Function

The **display wlan calibrate channel-set** command displays the effective calibration channels and bandwidth.

Format

display wlan calibrate channel-set ap-group { **name** *ap-group-name* | **all** }

Parameters

Parameter	Description	Value
ap-group name *ap-group-name*	Displays the effective calibration channels and bandwidth in a specified AP group.	The AP group must exist.
ap-group all	Displays the effective calibration channels and bandwidth in all AP groups.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After configuring the radio calibration function, you can run the **display wlan calibrate channel-set** command to check the effective calibration channels and bandwidth.

Example

Display the calibration channels and bandwidth that take effect globally.

```
<HUAWEI> display wlan calibrate channel-set ap-group all
AP group    : default
Country code: CN
-------------------------------------------------------------------------------
Radio band  Bandwidth  Channel Set
-------------------------------------------------------------------------------
2.4G        20MHz      1,6,11
5G          20MHz      149,153,157,161,165
6G          20MHz      -
-------------------------------------------------------------------------------

AP group    : mainland
Country code: CN
-------------------------------------------------------------------------------
Radio band  Bandwidth  Channel Set
-------------------------------------------------------------------------------
2.4G        20MHz      1,6,11
5G          20MHz      149,153,157,161,165
6G          20MHz      -
-------------------------------------------------------------------------------
```

Table 11-153 Description of the **display wlan calibrate channel-set** command output

Item	Description
AP group	Name of an AP group.
Country code	Country code.
Radio band	Radio type.
Bandwidth	Effective calibration bandwidth.
Channel Set	Effective calibration channel set.

11.4.68 display wlan calibrate global configuration

Function

The **display wlan calibrate global configuration** command displays the global configuration of radio calibration.

Format

display wlan calibrate global configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display wlan calibrate global configuration** command to check the global configuration of radio calibration.

Example

Display the global configuration of radio calibration.

```
<HUAWEI> display wlan calibrate global configuration
--------------------------------------------------------------------------------
----------
Mode                                             : manual

5G sensitivity                                   : high
6G sensitivity                                   : medium
Virtual group size                               : 50
K-value                                          : 70
Reference data analysis                          : enable
Reference rogue ap interference                  : enable
Environment deterioration blacklist threshold    : 16
--------------------------------------------------------------------------------
----------
```

Table 11-154 Description of the **display wlan calibrate global configuration** command output

Item	Description
Mode	Radio calibration mode. To configure this parameter, run the **calibrate enable** { **auto** | **manual** | **schedule time** } command.
Auto start time	Start time of automatic radio calibration (only for the automatic radio calibration mode). To configure this parameter, run the **calibrate enable auto** [**interval** *interval-value* [**start-time** *start-time*]] command.

Item	Description
Auto interval(min)	Interval for automatic radio calibration (only for the automatic radio calibration mode). To configure this parameter, run the **calibrate enable auto** [**interval** *interval-value* [**start-time** *start-time*]] command.
Schedule time	Time of scheduled radio calibration (only for the scheduled radio calibration mode). To configure this parameter, run the **calibrate enable schedule time** *time-value* command.
Schedule time-range	Time range for scheduled radio calibration (only for the scheduled radio calibration mode). To configure this parameter, run the **calibrate enable schedule time** *time-value* [**time-range** *time-range-name*] command.
Calibration progress	Progress of manual or scheduled radio calibration.
Flexible radio mode	Redundant radio switchover mode. To configure this parameter, run the **calibrate flexible-radio** { **auto-switch** | **auto-off** } command.
Policy	Radio calibration policy. To configure this parameter, run the **calibrate policy** { **non-wifi** | **noise-floor** } command.
2.4G sensitivity 5G sensitivity 6G sensitivity	Radio calibration sensitivity. To configure this parameter, run the **calibrate sensitivity** [**2.4g** | **5g** | **6g**] { **high** | **medium** | **low** | **insensitivity** | **custom-percent** *custom-percent* } command.
Virtual group size	Parameter of the radio calibration algorithm. To configure this parameter, run the **calibrate virtual-group-size** *size-value* **k-value** *k-value* command.

Item	Description
K-value	Parameter of the radio calibration algorithm. To configure this parameter, run the **calibrate virtual-group-size** *size-value* **k-value** *k-value* command.
Reference data analysis	Whether to enable Big Data calibration. To configure this parameter, run the **calibrate reference data-analysis disable** command.
Reference rogue ap interference	Whether rogue interference calibration is enabled. To configure this parameter, run the **calibrate reference rogue-ap-interference disable** command.
Environment deterioration blacklist threshold	Blacklist threshold for the number of times the channel environment deteriorates. To configure this parameter, run the **calibrate environment-deterioration-blacklist threshold** command.

11.4.69 display wlan calibrate statistics

Function

The **display wlan calibrate statistics** command displays radio calibration statistics.

Format

display wlan calibrate statistics { **ap-name** *ap-name* | **ap-id** *ap-id* } **radio** *radio-id*

Parameters

Parameter	Description	Value
ap-name *ap-name*	Displays radio calibration statistics on the specified AP name. The AP name and radio ID together identify a radio.	The AP name must already exist.
ap-id *ap-id*	Displays radio calibration statistics on the specified AP ID. The AP ID and radio ID together identify a radio.	The AP ID must already exist.

Parameter	Description	Value
radio *radio-id*	Displays radio calibration statistics on the specified radio.	The radio ID must already exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display wlan calibrate statistics** command to view radio calibration statistics, helping check whether the radio environment is stable.

Example

Display calibration statistics about radio 0 on AP0.

```
<HUAWEI> display wlan calibrate statistics ap-id 0 radio 0
------------------------------------------------------------------------
Signal environment deterioration :1
Power calibration                :1
Channel calibration              :0
------------------------------------------------------------------------
```

Table 11-155 Description of the **display wlan calibrate statistics** command output

Item	Description
Signal environment deterioration	Number of times the radio environment deteriorates.
Power calibration	Number of times the power of the radio is calibrated.
Channel calibration	Number of times the channel of the radio is calibrated.

11.4.70 display wlan scene

Function

The **display wlan scene** command displays information about a scenario profile.

Format

display wlan scene { **name** *scene-name* | **all** }

Parameters

Parameter	Description	Value
name *scene-name*	Specifies the name of a scenario profile.	The value is of the enumerated type. ● multi-partition-cross-room: indicates an indoor multi-partition cross-room deployment scenario (capacity first). ● multi-partition-cross-room-cov: indicates an indoor multi-partition cross-room deployment scenario (coverage first). ● automated-guided-vehicle: indicates an AGV scenario. ● high-density-stadium: indicates a high-density stadium scenario. ● indoor-high-density: indicates an indoor high-density coverage scenario. ● indoor-low-density: indicates an indoor low-density coverage scenario. ● indoor-multi-partition: indicates an indoor multi-partition coverage scenario. ● indoor-normal-density: indicates an indoor common coverage scenario. ● industrial-manufacturing: indicates an industrial manufacturing scenario. ● outdoor-continuous: indicates an outdoor continuous coverage scenario.

Parameter	Description	Value
		- virtual-reality: indicates a VR scenario.
all	Displays all scenario profiles.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display wlan scene** command to view detailed information about a scenario profile to learn about wireless service parameters and their settings involved in the scenario.

Example

Display all scenario profiles.

```
<HUAWEI> display wlan scene all
--------------------------------------------------------------------------------------
Name                          Description
--------------------------------------------------------------------------------------
automated-guided-vehicle        Applicable to smart warehousing scenarios.
high-density-stadium            Applicable to high-density stadiums.
indoor-high-density             Applicable to indoor high-density scenarios, such as cafes and high-density
office.
indoor-low-density              Applicable to indoor low-density scenarios, such as retail scenarios.
indoor-multi-partition          Applicable to indoor multi-partition scenarios, such as dormitories, hotel
rooms, and wards.
indoor-normal-density           Applicable to indoor normal-density scenarios, such as normal office.
industrial-manufacturing        Applicable to industrial manufacturing scenarios.
multi-partition-cross-room      Applicable to indoor scenarios (capacity first), where one AP covers multiple
rooms and APs are blocked from each other by walls.
multi-partition-cross-room-cov  Applicable to indoor scenarios (coverage first), where one AP covers
multiple rooms and APs are blocked from each other by walls.
outdoor-continuous              Applicable to outdoor continuous coverage scenarios, such as roadways and
parks.
virtual-reality                 Applicable to VR scenarios.

Table 11-156 Description of the **display wlan scene** command output

Item	Description
WLAN service parameters	To view the description of a specific parameter, search for the parameter and view the description in the corresponding display command. If a hyphen (-) is displayed, this parameter is not configured in the scenario profile.

11.4.71 dynamic-edca enable

Function

The **dynamic-edca enable** command enables dynamic EDCA parameter adjustment.

The **undo dynamic-edca enable** command disables dynamic EDCA parameter adjustment.

By default, dynamic EDCA parameter adjustment is disabled.

Format

dynamic-edca enable

undo dynamic-edca enable

Parameters

None

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

A WLAN has only three non-overlapping channels on the 2.4 GHz frequency band. When APs are deployed densely, multiple APs have to work in the same channel, resulting in co-channel interference. This interference degrades network performance.

The dynamic EDCA parameter adjustment function allows APs to adjust EDCA parameters flexibly to reduce the possibility of collision, improve the throughput, and enhance user experience.

Example

Enable dynamic EDCA parameter adjustment.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name test
[HUAWEI-wlan-rrm-prof-test] dynamic-edca enable
```

11.4.72 dynamic-edca threshold

Function

The **dynamic-edca threshold** command configures the threshold for the dynamic EDCA Best-Effort service.

The **undo dynamic-edca threshold** command restores the default threshold for the dynamic EDCA Best-Effort service.

The default threshold for the dynamic EDCA Best-Effort service is 6 pps.

Format

dynamic-edca threshold be-service *be-service-threshold*

undo dynamic-edca threshold be-service

Parameters

Parameter	Description	Value
be-service *be-service-threshold*	Specifies the threshold for the dynamic EDCA Best-Effort service.	The value is an integer that ranges from 1 to 1000, in pps.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

When dynamic EDCA is enabled, the system dynamically adjusts EDCA parameters for the Best-Effort service and Background service based on the number of Best-Effort users, improving user experience.

If the number of Best-Effort service packets from a user in the radio's internal statistics queue exceeds the threshold (specified using the **dynamic-edca threshold** command) per unit time (1s), the user is considered a Best-Effort user.

Before running this command, you must run the **dynamic-edca enable** command to enable dynamic EDCA.

Example

Set the threshold for the dynamic EDCA Best-Effort service to 10 pps.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] dynamic-edca enable
[HUAWEI-wlan-rrm-prof-default] dynamic-edca threshold be-service 10
```

11.4.73 sta-number gap-threshold

Function

The **sta-number gap-threshold** command sets the load difference threshold for load balancing based on the number of users in a static load balancing group.

The **undo sta-number gap-threshold** command restores the default load difference threshold for load balancing based on the number of users in a static load balancing group.

By default, the load difference threshold of a static load balancing group is specified based on the number of users, and the default value is 3.

Format

sta-number gap-threshold { **percentage** *percentage-value* | **number** *number-value* }

undo sta-number gap-threshold

Parameters

Parameter	Description	Value
percentage *percentage-value*	Specifies the load difference threshold for static load balancing based on the percentage of users.	The value is an integer that ranges from 1 to 100. It indicates the threshold of the load difference among radios in a load balancing group, in percentage. The load difference refers to the difference between the percentages of users on radios.
number *number-value*	Specifies the load difference threshold for static load balancing based on the number of users.	The value is an integer that ranges from 1 to 20. It indicates the threshold of the load difference among radios in a load balancing group. The load difference refers to the difference between the numbers of users on radios.

Views

Static load balancing group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The following load balancing algorithm is used after the user access to determine whether to steer the user to a new AP:

One of the conditions for steering a user to a new AP is that the radio of the target load is lower than that of the current access radio. The radio load is identified by the number or percentage (Number of users associated with the current radio/Maximum number of access users supported by the radio x 100%) of access users. If the load difference between the target radio and current radio exceeds the specified threshold, the condition is met.

Precautions

If you configure the load difference threshold based on both the number of users and the percentage of users, only the latest configuration takes effect.

Example

Set the load difference threshold for load balancing based on the percentage of users in the static load balancing group to 40%.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sta-load-balance static-group name coco
[HUAWEI-wlan-sta-lb-static-coco] sta-number gap-threshold percentage 40
```

11.4.74 high-density amc-optimize enable

Function

The **high-density amc-optimize enable** command enables the adaptive modulation and coding (AMC) optimization function in high-density scenarios.

The **undo high-density amc-optimize enable** command disables the AMC optimization function in high-density scenarios.

By default, the AMC optimization function is disabled in high-density scenarios.

Format

high-density amc-optimize enable

undo high-density amc-optimize enable

Parameters

None

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In typical high-density scenarios, a large number of hidden nodes exist, which interfere in communication between APs and STAs and affect product performance. The AMC optimization function can reduce such interference and improve the AMC algorithm performance.

- It is recommended that this function be enabled in high-density scenarios where directional antennas are used.
- This function is not applicable to scenarios where STAs move fast between APs.

Precautions

- The AMC optimization in high-density scenarios is not supported by the following APs:
  - AirEngine 9700D-S (including matching ORUs)
  - AirEngine X77X
  - AirEngine X76X
- This function does not take effect in MU-MIMO mode.

Example

Enable the AMC optimization function in high-density scenarios on the RRM profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] high-density amc-optimize enable
```

11.4.75 interference adjacent-channel threshold

Function

The **interference adjacent-channel threshold** command configures the alarm threshold for adjacent-channel interference.

The **undo interference adjacent-channel threshold** command restores the default alarm threshold for adjacent-channel interference.

By default, the alarm threshold for adjacent-channel interference is 50%.

Format

interference adjacent-channel threshold *threshold-value*

undo interference adjacent-channel threshold

Parameters

Parameter	Description	Value
threshold-value	Specifies the alarm threshold, which is the percentage of the adjacent-channel interference power against the maximum power.	The value is an integer that ranges from 1 to 100, in percentage.

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

Two APs with different center frequencies have overlapping areas, resulting in adjacent-channel interference. When APs are placed too close to each other or have strong signals, more noise is produced, degrading network performance.

After the **interference detect-enable** command is executed to enable interference detection, an AP can detect adjacent-channel interference. When the AP detects that adjacent-channel interference exceeds the alarm threshold configured using the **interference adjacent-channel threshold** command, the AP sends an alarm to the AC.

Example

Set the alarm threshold for adjacent-channel interference to 52%.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name radio0
[HUAWEI-wlan-radio-2g-prof-radio0] interference detect-enable
[HUAWEI-wlan-radio-2g-prof-radio0] interference adjacent-channel threshold 52
```

11.4.76 interference co-channel threshold

Function

The **interference co-channel threshold** command configures the alarm threshold for co-channel interference.

The **undo interference co-channel threshold** command restores the default alarm threshold for co-channel interference.

By default, the alarm threshold for co-channel interference is 50%.

Format

interference co-channel threshold *threshold-value*

undo interference co-channel threshold

Parameters

Parameter	Description	Value
threshold-value	Specifies the alarm threshold, which is the percentage of the co-channel interference power against the maximum power.	The value is an integer that ranges from 1 to 100, in percentage.

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

Two APs working in the same frequency band interfere with each other. For example, on a large-scale WLAN (a university campus network), different APs often use the same channel. When there are overlapping areas among these APs, co-channel interference exists, degrading network performance.

After the **interference detect-enable** command is executed to enable interference detection, an AP can detect adjacent-channel interference. When the AP detects that co-channel interference exceeds the alarm threshold configured using the **interference co-channel threshold** command, the AP sends an alarm to the AC.

Example

Set the alarm threshold for co-channel interference to 60%.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name radio0
[HUAWEI-wlan-radio-2g-prof-radio0] interference detect-enable
[HUAWEI-wlan-radio-2g-prof-radio0] interference co-channel threshold 60
```

11.4.77 interference detect-enable

Function

The **interference detect-enable** command enables interference detection.

The **undo interference detect-enable** command disables interference detection.

By default, interference detection is disabled.

Format

interference detect-enable

undo interference detect-enable

Parameters

None

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

WLAN wireless channels are vulnerable to interference in surrounding radio environments, and the service quality is therefore degraded. If interference detection is configured, a monitor AP can know the radio environment in real time and report alarms to the AC in a timely manner.

Interference detection enables an AP to detect AP co-channel interference, AP adjacent-channel interference, and STA interference.

- AP co-channel interference: Two APs working on the same frequency band interfere with each other. For example, on a large-scale WLAN (a university campus network), different APs often use the same channel. When there are overlapping areas among these APs, co-channel interference exists, degrading network performance.
- AP adjacent-channel interference: Two APs with different center frequencies have overlapping areas, resulting in adjacent-channel interference. Therefore, if APs are placed too close to each other or they have strong signals, more noise will be produced, degrading network performance.
- STA interference: If there are many STAs that are managed by other APs around an AP, services of the STAs managed by the local AP may be affected.

Example

Enable interference detection.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name radio0
[HUAWEI-wlan-radio-2g-prof-radio0] interference detect-enable
```

11.4.78 interference station threshold

Function

The **interference station threshold** command configures the alarm threshold for STA interference.

The **undo interference station threshold** command restores the default alarm threshold for STA interference.

By default, the alarm threshold for STA interference is 32.

Format

interference station threshold *threshold-value*

undo interference station threshold

Parameters

Parameter	Description	Value
threshold-value	Specifies the alarm threshold.	The value is an integer that ranges from 1 to 256.

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

If there are many STAs that are managed by other APs around an AP, services of the STAs managed by the local AP may be affected.

After the **interference detect-enable** command is executed to enable interference detection, an AP can detect STAs that are managed by other APs. When the AP detects that the number of such STAs exceeds the alarm threshold configured using the **interference station threshold** command, the AP sends an alarm to the AC.

Example

Set the alarm threshold for STA interference to 50.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name radio0
[HUAWEI-wlan-radio-2g-prof-radio0] interference station threshold 50
```

11.4.79 interference-visualization enable

Function

The **interference-visualization enable** command enables interference visualization on AP radios.

The **undo interference-visualization enable** command disables interference visualization on AP radios.

By default, interference visualization is disabled on AP radios.

NOTE

Interference visualization is not available for the following models:

- AirEngine x761
- AirEngine x762

Format

interference-visualization enable

undo interference-visualization enable

Parameters

None

Views

AP radio view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the AP is connected to an analyzer, you can enable interference visualization on radios of co-channel APs so that packet transmission information on the co-channel APs can be displayed on the analyzer, thereby showing air interface interference behavior.

Pre-configuration Tasks

Configure KPI reporting, and run the **ap log module mid** *ffdc0000* command in the WMI profile view to report logs of the interference visualization module to the analyzer.

Precautions

Interference visualization can be enabled on a maximum of 20 AP radios. To view information about all AP radios on which interference visualization is enabled, run the **display interference-visualization configuration** command.

Example

Enable interference visualization on radio 1 of AP 1.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 1
[HUAWEI-wlan-ap-1] radio 1
[HUAWEIwlan-radio-1/1] interference-visualization enable
```

11.4.80 member (static load balancing group view)

Function

The **member** command adds an AP radio to a static load balancing group.

The **undo member** command deletes an AP radio from a load balancing group.

By default, no AP radio is added to a static load balancing group.

Format

member { { **ap-name** *ap-name* | **ap-id** *ap-id* } [**radio** *radio-id*] }&<1-16>

undo member { { **ap-name** *ap-name* | **ap-id** *ap-id* } [**radio** *radio-id*] }&<1-16>

Parameters

Parameter	Description	Value
ap-name *ap-name*	Specifies the name of an AP. The AP name and radio ID identify a radio.	The AP name must exist.
ap-id *ap-id*	Specifies the ID of an AP. The AP ID and radio ID identify a radio.	The AP ID must exist.
radio *radio-id*	Specifies a radio ID. The radio ID and AP name identify a radio.	The radio ID must exist.

Views

Static load balancing group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can use this command to add an AP radio to or delete an AP radio from a static load balancing group. When a STA requests to connect to an AP radio in a static load balancing group, the AC compares the load of the radio and other working radios in the load balancing group and determines whether to allow the STA to connect to the radio according to a load balancing algorithm.

Precautions

- If dual-band APs are used, traffic is load balanced among APs working on the same frequency band.
- Each load balancing group supports a maximum of 16 AP radios.
- Under the agile distributed network architecture, you only need to add radios of the RUs to a static load balancing group. Central APs are not supported in static load balancing groups.
- A radio configured with channel 184, 188, 192, or 196 on the 4.9 GHz frequency band cannot be used for load balancing.

Example

Add radio 0 of AP **office** to the static load balancing group **coco**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sta-load-balance static-group name coco
[HUAWEI-wlan-sta-lb-static-coco] member ap-name office radio 0
```

11.4.81 power auto-adjust enable

Function

The **power auto-adjust enable** command enables signal-strength-based power adjustment for APs.

The **undo power auto-adjust enable** command disables signal-strength-based power adjustment for APs.

By default, signal-strength-based power adjustment is disabled for an AP.

NOTE

This command does not take effect for the following APs:

- AirEngine X77X
- AirEngine X76X

Format

power auto-adjust enable

undo power auto-adjust enable

Parameters

None

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The traditional radio power control function sets the power of an AP to a fixed value to keep the power of all STAs connecting to the AP the same.

You can run the **power auto-adjust enable** command to enable signal-strength-based power adjustment. This function enables an AP to detect the signal strength of a STA in a timely manner. If the AP detects that the signal strength of the STA is strong (for example, the STA is near the AP), the AP reduces its transmit power when sending packets. If the AP detects that the signal strength of the STA is weak (for example, the STA is far from the AP), the AP uses the normal transmit power to send radio signals.

Prerequisites

The power mode has been set to automatic using the **calibrate auto-txpower-select enable** command.

Example

Enable signal-strength-based power adjustment for APs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] power auto-adjust enable
```

11.4.82 radio-reload time-range

Function

The **radio-reload time-range** command enables scheduled radio reloading on APs.

The **undo radio-reload time-range** command disables scheduled radio reloading on APs.

By default, scheduled radio reloading is disabled on APs.

Format

radio-reload time-range *time-range*

undo radio-reload time-range

Parameters

Parameter	Description	Value
time-range	Specifies a time range during which radios are reloaded as scheduled.	The specified time range must exist.

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After APs run for a long time, some unknown exceptions may occur. You can run this command to configure a scheduled policy for APs to reload radios during off-peak hours. This prevents potential exceptions or addresses existing exceptions.

Prerequisites

A time range for scheduled radio reloading has been specified by using the **time-range** command.

Precautions

After scheduled radio reloading is configured, APs reload radios in batches within the specified time range. During radio reloading on an AP, STAs associated with the AP are steered to neighboring APs. To prevent impact on services, it is recommended that radio reloading be performed during a time range when no service traffic is transmitted.

This function is not recommended in industrial scenarios where services need to run continuously for a long time.

Example

Enable the scheduled radio reloading function for 5 GHz radios of APs and specify the time range of 01:00 to 05:00 every day for scheduled radio reloading.

```
<HUAWEI> system-view
[HUAWEI] time-range test 01:00 to 05:00 daily
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-5g-profile name wlan-radio5g
[HUAWEI-wlan-radio-5g-prof-wlan-radio5g] radio-reload time-range test
```

11.4.83 reset ap traffic statistics wireless

Function

The **reset ap traffic statistics wireless** command clears packet statistics on a specified AP radio.

Format

reset ap traffic statistics wireless { **ap-name** *ap-name* | **ap-id** *ap-id* } **radio** *radio-id*

Parameters

Parameter	Description	Value
ap-name *ap-name*	Clears packet statistics on the AP with a specified name.	The AP name must exist.

Parameter	Description	Value
ap-id *ap-id*	Clears packet statistics on the AP with a specified ID.	The AP ID must exist.
radio *radio-id*	Clears packet statistics on a specified radio.	The radio ID must already exist.

Views

All views

Default Level

3: Management level

Usage Guidelines

You can run this command to clear packet statistics on a specified AP radio.

Example

Clear packet statistics on radio 2 of the AP with the ID 0.

```
<HUAWEI> reset ap traffic statistics wireless ap-id 0 radio 2
```

11.4.84 reset station steer-history

Function

The **reset station steer-history** command deletes historical information about STA migrations.

Format

reset station steer-history

Parameters

None

Default Level

3: Management level

Usage Guidelines

You can run this command to delete historical information about STA migrations.

Example

Delete historical information about migrations of all STAs.

```
<HUAWEI> reset station steer-history
```

11.4.85 reset flexible-radio switch-record

Function

The **reset flexible-radio switch-record** command clears switching records of redundant radios.

Format

reset flexible-radio switch-record all

Parameters

Parameter	Description	Value
all	Clears switching records of all redundant radios.	-

Views

All views

Default Level

3: Management level

Usage Guidelines

You can run the **reset flexible-radio switch-record** command to clear switching records of redundant radios.

Example

Clear switching records of all redundant radios.

```
<HUAWEI> reset flexible-radio switch-record all
```

11.4.86 reset station steer-statistics

Function

The **reset station steer-statistics** command deletes statistics about STA steering.

Format

reset station steer-statistics

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

You can run this command to delete statistics about STA steering.

Example

Delete statistics about STA steering.

```
<HUAWEI> reset station steer-statistics
```

11.4.87 reset wlan calibrate statistics

Function

The **reset wlan calibrate statistics** command clears radio calibration statistics.

Format

reset wlan calibrate statistics { **ap-name** *ap-name* | **ap-id** *ap-id* } **radio** *radio-id*

Parameters

Parameter	Description	Value
ap-name *ap-name*	Clears radio calibration statistics on the AP with the specified AP name. The AP name and radio ID together identify a radio.	The AP name must exist.
ap-id *ap-id*	Clears radio calibration statistics on the AP with the specified AP ID. The AP ID and radio ID together identify a radio.	The AP ID must exist.

Parameter	Description	Value
radio *radio-id*	Clears calibration statistics about the radio with the specified radio ID. The radio ID and AP name together identify a radio.	The radio ID must exist.

Views

All views

Default Level

3: Management level

Usage Guidelines

Run the **reset wlan calibrate statistics** command to clear radio calibration statistics, including the number of times the radio environment deteriorates and number of times the radio channel and power are calibrated.

Example

Clear calibration statistics about radio 0 on AP0.

```
<HUAWEI> reset wlan calibrate statistics ap-id 0 radio 0
```

11.4.88 rrm-profile (WLAN view)

Function

The **rrm-profile** command creates an RRM profile and displays the RRM profile view.

The **undo rrm-profile** command deletes an RRM profile.

By default, the system provides the RRM profile **default**.

Format

rrm-profile name *profile-name*

undo rrm-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of an RRM profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all RRM profiles.	The RRM profile **default** can be modified but cannot be deleted.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

WLAN technology uses radio signals (such as 2.4 GHz or 5 GHz radio waves) as transmission medium. Radio signals will attenuate when transmitted over the air, degrading service quality for wireless users. Radio resource management (RRM) enables a WLAN to adapt to changes in the radio environment by dynamically adjusting radio resources. This improves service quality for wireless users.

Follow-up Procedure

Run the **rrm-profile (radio profile view)** command to bind the RRM profile to a radio profile so that the RRM profile can take effect.

Example

Create the RRM profile **rrm01**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name rrm01
[HUAWEI-wlan-rrm-prof-rrm01]
```

11.4.89 rrm-profile (radio profile view)

Function

The **rrm-profile** command binds an RRM profile to a radio profile.

The **undo rrm-profile** command unbinds an RRM profile from a radio profile.

By default, the RRM profile **default** is bound to a radio profile.

Format

rrm-profile *profile-name*

undo rrm-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of an RRM profile.	The RRM profile name must already exist.

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

After you create an RRM profile using the **rrm-profile (WLAN view)** command, bind the RRM profile to a radio profile so that the RRM profile can take effect.

Example

Bind the RRM profile **rrm01** to the radio profile **office01**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name rrm01
[HUAWEI-wlan-rrm-prof-rrm01] quit
[HUAWEI-wlan-view] radio-2g-profile name office01
[HUAWEI-wlan-radio-2g-prof-office01] rrm-profile rrm01
```

11.4.90 rssi-diff-gap

Function

The **rssi-diff-gap** command sets the RSSI difference threshold for members in a static load balancing group.

The **undo rssi-diff-gap** command restores the default RSSI difference threshold of members in a static load balancing group.

By default, the RSSI difference threshold of members in a static load balancing group is 5 dB.

Format

rssi-diff-gap *diff-gap-threshold*

undo rssi-diff-gap

Parameters

Parameter	Description	Value
diff-gap-threshold	Specifies the RSSI difference threshold of members in a static load balancing group.	The value is an integer that ranges from 0 to 15, in dB.

Views

Static load balancing group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To achieve load balancing, an AP may steer connected STAs to other APs with smaller RSSIs. If the RSSI of the AP with which a STA currently associates minus the RSSI of the target AP is larger than the specified RSSI difference threshold, the STA is denied from being steered to the target AP; otherwise, the STA can be steered to the target AP.

Precautions

If STAs have high signal quality deterioration tolerance for the target AP, you can set a larger RSSI difference threshold to achieve better load balancing effect. If STAs have low signal quality deterioration tolerance for the target AP, set a smaller RSSI difference threshold. You are advised to retain the default value.

Example

Set the RSSI difference threshold for members in a static load balancing group to 6 dB.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sta-load-balance static-group name coco
[HUAWEI-wlan-sta-lb-static-coco] rssi-diff-gap 6
```

11.4.91 rssi-threshold

Function

The **rssi-threshold** command sets an RSSI threshold for member devices in a static load balancing group.

The **undo rssi-threshold** command restores the default RSSI threshold of member devices in a static load balancing group.

By default, the RSSI threshold of member devices in a static load balancing group is –65 dBm.

Format

rssi-threshold *rssi-threshold*

undo rssi-threshold

Parameters

Parameter	Description	Value
rssi-threshold	Specifies the RSSI threshold of members in a static load balancing group.	The value is an integer that ranges from –75 to –55, in dBm.
