Setting an RSSI threshold for member devices in a static load balancing group is to filter APs with weak signals, so that STAs can be load balanced between APs with better signals. This prevents STAs from associating with APs with weak signals but light loads. This function does not affect STAs' going online.

Example

Set the RSSI threshold for member devices in a static load balancing group to –70 dBm.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sta-load-balance static-group name coco
[HUAWEI-wlan-sta-lb-static-coco] rssi-threshold -70
```

11.4.92 rx-sensitivity

Function

The **rx-sensitivity** command sets the receiver sensitivity threshold of an AP.

The **undo rx-sensitivity** command restores the default receiver sensitivity threshold of an AP.

By default, the receiver sensitivity threshold of an AP is –128 dBm.

Format

rx-sensitivity *threshold*

undo rx-sensitivity

Parameters

Parameter	Description	Value
threshold	Specifies the receiver sensitivity threshold of an AP.	The value is an integer that ranges from –128 to –40, in dBm.

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The sensitivity threshold can be used to adjust the anti-interference capability of radios.

Precautions

The receiver sensitivity threshold cannot be set higher than the upper AGC threshold.

Modifying the receiver sensitivity threshold will affect the uplink access coverage or user access. It is recommended that the default setting be remained or the threshold be modified under the guidance of professional technical personnel.

Example

Set the receiver sensitivity threshold to –70 dBm in the 2G radio profile **test**.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] radio-2g-profile name test
[HUAWEI-wlan-radio-2g-prof-test] rx-sensitivity -70
Warning: This parameter will affect the uplink access coverage or user access. I
t is recommended that the configuration be modified under the guidance of profes
sional technical personnel. Continue? [Y/N]:y
```

11.4.93 scan-channel-set

Function

The **scan-channel-set** command configures an air scan channel set.

The **undo scan-channel-set** command restores the default air scan channel set.

By default, an air scan channel set contains all channels supported by the country code of an AP.

Format

scan-channel-set { **country-channel** | **dca-channel** | **work-channel** }

undo scan-channel-set

Parameters

Parameter	Description	Value
country-channel	Specifies an air scan channel set that contains all channels supported by the country code of an AP.	-
dca-channel	Specifies a calibration channel set as the air scan channel set. To configure a calibration channel set, run the **dca-channel channel-set** command.	-
work-channel	Specifies an air scan channel set that contains working channels of APs.	-

Views

Air scan profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you run the **scan-channel-set** command to specify an air scan channel set for an AP, the AP scans channels in the channel set. The collected information is reported to the AC or server for radio calibration, smart roaming, spectrum analysis, WLAN location, or WIDS data analysis.

Precautions

- If the air scan channel set you specified contains all channels supported by the country code of the AP, the AP scans data on many channels but the channel scanning lasts for a long time, which may affect real-time data analysis.
- If you specify a calibration channel set as the air scan channel set, the AP scans data on a few channels. This reduces the channel scanning time, increases the terminal location accuracy, and reduces burden on the device.
- If you add only working channels of an AP to the air scan channel set, the AP only scans the working channels.

Example

Configure an air scan channel set that contains all calibration channels.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] air-scan-profile name test
[HUAWEI-wlan-air-scan-prof-test] scan-channel-set dca-channel
```

11.4.94 scan-disable

Function

The **scan-disable** command disables the air scan function.

The **undo scan-disable** command enables the air scan function.

By default, the air scan function is enabled.

Format

scan-disable

undo scan-disable

Parameters

None

Views

Air scan profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an AP does not require air scan, you can run the **scan-disable** command to disable the air scan function. The AP then will stop scanning surrounding wireless signals.

Precautions

Disabling air scan will affect scanning functions, such as radio calibration, spectrum analysis, terminal location, WIDS, smart roaming, and DFS smart selection.

Example

Disable the air scan function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] air-scan-profile name test
[HUAWEI-wlan-air-scan-prof-test] scan-disable
Warning: This operation will affect scanning-related services such as radio calibration, spectrum analysis, terminal location, WIDS
function, smart roaming and DFS smart selection.Continue? [Y/N]y
```

11.4.95 scan-enhancement

Function

The **scan-enhancement** command enables the scanning enhancement function.

The **undo scan-enhancement** command disables the scanning enhancement function.

By default, the scanning enhancement function is disabled.

NOTICE

The scanning enhancement function is supported only by the AirEngine 6761-21, AirEngine 6761-21E, and AirEngine 6761S-21.

Format

scan-enhancement

undo scan-enhancement

Parameters

None

Views

Air scan profile view

Default Level

2: Configuration level

Usage Guidelines

The third radio of some APs is used specifically for radio scanning and does not support configuration or STA access. After the scanning enhancement function is enabled, the current radio works with the third radio to perform radio scanning and provide scanning feature data. When multiple radios collect and provide data simultaneously, the scanning performance and precision are improved. After the scanning enhancement function is disabled, scanning feature data on the current radio is provided by the third radio. The third radio does not involve in scanning. Therefore, scanning features on the radio do not affect STA access.

The third radio of these APs supports scanning only on the single spatial stream. When functions such as location and WIDS detection, it is recommended that the scanning enhancement function be enabled if high performance and precision are required.

When services that are sensitive to packet loss or delay (for example, voice or video services) are used, it is recommended that the scanning enhancement function be disabled.

Example

Enable the scanning enhancement function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] air-scan-profile name test
[HUAWEI-wlan-air-scan-prof-test] scan-enhancement
```

11.4.96 scan-interval

Function

The **scan-interval** command sets an air scan interval.

The **undo scan-interval** command restores the default air scan interval.

By default, the air scan interval is 10000 ms.

Format

scan-interval *scan-time*

undo scan-interval

Parameters

Parameter	Description	Value
scan-time	Specifies an air scan interval. With a smaller air scan interval, more sampling data can be obtained, which increases the performance overhead in turn. An air scan interval of less than 2000 ms may affect service running.	The value is an integer that ranges from 300 to 600000, in milliseconds.

Views

Air scan profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After an air scan interval is specified using the **scan-interval** command, APs scan channels at the specified intervals.

When spectrum analysis is used, the air scan interval range of 3s to 10s and the air scan period of 100 ms are recommended. This helps you obtain sufficient sampled data without compromising normal services.

Precautions

The air scan interval also applies to radio calibration, smart roaming, spectrum analysis, WLAN location, and WIDS functions.

If the customer has high requirements on real-time data analysis, configure a small air scan interval using the **scan-interval** command to improve the scan frequency. However, higher scan frequency indicates much larger impact on the services.

Ensure that the air scan interval meets the following condition: scan-interval ≥ beacon-interval + 100 ms

In vehicle-ground communication scenarios, the air scan interval ranges from 300 ms to 1000 ms.

Example

Set the air scan interval to 3000 ms for APs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] air-scan-profile name test
[HUAWEI-wlan-air-scan-prof-test] scan-interval 3000
```

11.4.97 scan-period

Function

The **scan-period** command sets the air scan period.

The **undo scan-period** command restores the default air scan period.

By default, the air scan period is 60 ms.

Format

scan-period *scan-time*

undo scan-period

Parameters

Parameter	Description	Value
scan-time	Specifies the air scan period.	The value is an integer that ranges from 60 to 100, in milliseconds.

Views

Air scan profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the air scan period is configured using the **scan-period** command, an AP continuously scans surrounding radio signals in the configured period. After the period expires, the AP reports the collected information to an AC or server. The information is used for radio calibration, smart roaming, spectrum analysis, WLAN location, or WIDS data analysis.

When spectrum analysis is used, the air scan interval range of 3s to 10s and the air scan period of 100 ms are recommended. This helps you obtain sufficient sampled data without compromising normal services.

Precautions

A longer air scan period indicates more collected data and a more accurate data analysis result. However, if the air scan period is set too large, WLAN services are affected. You are advised to use the default value.

Example

Set the air scan period to 80 ms for APs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] air-scan-profile name test
[HUAWEI-wlan-air-scan-prof-test] scan-period 80
```

11.4.98 scene

Function

The **scene** command binds a scenario profile to an AP group or a single AP.

The **undo scene** command unbinds a scenario profile from an AP group or a single AP.

By default, no scenario profile is bound to an AP group or a single AP.

Format

scene *scene-name*

undo scene

Parameters

Parameter	Description	Value
scene-name	Specifies the name of a scenario profile.	The value is of the enumerated type. - multi-partition-cross-room: indicates an indoor multi-partition cross-room deployment scenario (capacity first). - multi-partition-cross-room-cov: indicates an indoor multi-partition cross-room deployment scenario (coverage first). - automated-guided-vehicle: indicates an AGV scenario. - high-density-stadium: indicates a high-density stadium scenario. - indoor-high-density: indicates an indoor high-density coverage scenario. - indoor-low-density: indicates an indoor low-density coverage scenario. - indoor-multi-partition: indicates an indoor multi-partition coverage scenario. - indoor-normal-density: indicates an indoor common coverage scenario. - industrial-manufacturing: indicates an industrial manufacturing scenario. - outdoor-continuous: indicates an outdoor continuous coverage scenario.

Parameter	Description	Value
		- virtual-reality: indicates a VR scenario.

Views

AP group view, AP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In actual scenarios, there are fixed recommended settings for radio parameters such as the channel, bandwidth, and transmit power. Recommended settings for these typical scenarios are configured into scenario profiles. When configuring wireless services, you only need to bind a scenario profile to an AP group or a single AP, greatly simplifying service configuration.

To view the parameter settings in preset scenario profiles, run the **display wlan scene** command. If the value of a parameter is empty, a hyphen (-) is displayed, indicating that the parameter is not configured.

Precautions

- The service parameters on an AP take effect in the following sequence: Parameters in the scenario profile bound to an AP > Parameters directly configured for an AP > Parameters in the scenario profile identified and delivered by the analyzer to an AP > Parameters in the scenario profile bound to the AP group to which the AP belongs > Parameters directly configured for the AP group to which the AP belongs.

  The calibration bandwidth of the 5 GHz frequency band is used as an example. Assume that the parameter value in a scenario profile **a** bound to the AP is empty, the parameter value in scenario profile **b** bound to the AP group is **B**, the parameter value corresponding to scenario profile **c** identified and delivered by the analyzer to the AP is **C**, the parameter value configured for an AP is **D**, and the parameter value configured for an AP group is **E**. Then the parameter value takes effect on the AP in the following sequence: null > **D** > **C** > **B** > **E**. That is, the parameter value that takes effect is **D**.
- The wireless service parameters in a scenario profile contain the radio calibration parameter set (**Radio calibration**). After a scenario profile is configured, the radio calibration parameter settings take effect from the next radio calibration.
- Although a series of radio calibration parameters are predefined in a scenario profile, the channel, bandwidth, and transmit power are still restricted by the country code during radio calibration. Bandwidth selection depends on the number of channels allowed by the country code.

Assume that the calibration bandwidth defined in the scenario profile is A, the number of available channels under this bandwidth is B in the country code, and the calibration bandwidth configured in the regulatory domain profile is C.

- If B is greater than or equal to 3, the calibration bandwidth A takes effect.
- If B is smaller than 3, the smaller value between A and C is used as the calibration bandwidth.

Example

Bind the scenario profile **multi-partition-cross-room** to the AP group **mygroup**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name mygroup
[HUAWEI-wlan-ap-group-mygroup] scene multi-partition-cross-room
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.4.99 smart-antenna { enable | disable }

Function

The **smart-antenna** { **enable** | **disable** } command enables or disables the smart antenna selection algorithm for an AP.

The **undo smart-antenna** command restores the smart antenna selection algorithm of an AP to the default state.

By default, the smart antenna selection algorithm is enabled.

Format

smart-antenna { **enable** | **disable** }

undo smart-antenna

Parameters

None

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

With the smart antenna selection algorithm, an AP can adjust the antenna mode for transmitting signals based on STA locations and select a proper combination of antenna arrays to communicate with STAs. This improves the RSSIs of STAs and improves user experience.

Precautions

The smart antenna selection algorithm is supported only by the following APs:

- AirEngine 5760-22W, AirEngine 5760-22WD, AirEngine 5760-51, AirEngine 6760-X1, and AirEngine 8760-X1-PRO

Example

Enable the smart antenna selection algorithm for an AP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] smart-antenna enable
```

11.4.100 smart-antenna throughput-triggered-training

Function

The **smart-antenna throughput-triggered-training** command sets a sudden performance change threshold that triggers smart antenna training.

The **undo smart-antenna throughput-triggered-training** command restores the default sudden performance change threshold that triggers smart antenna training.

The default sudden performance change threshold that triggers smart antenna training is 10%.

Format

smart-antenna throughput-triggered-training threshold *threshold*

undo smart-antenna throughput-triggered-training threshold

Parameters

Parameter	Description	Value
threshold *threshold*	Specifies a sudden performance change threshold that triggers antenna training.	The value is an integer that ranges from 10 to 50, in percentage. In addition, the value must be a multiple of 10.

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

In a smart antenna system, the device monitors performance (throughput) of transmit ends. If the detected throughput of a transmit end exceeds the sudden performance change threshold specified using the **smart-antenna throughput-triggered-training** command, a new round of antenna training is triggered.

- In a good air interface environment, set a high sudden performance change threshold to prevent frequent antenna training from affecting user services.
- In a poor air interface environment, set a low sudden performance change threshold to improve the WLAN's anti-interference capability.

Example

Set the sudden performance change threshold that triggers antenna training to 10%.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] smart-antenna throughput-triggered-training threshold 10
```

11.4.101 smart-antenna training-interval

Function

The **smart-antenna training-interval** command sets the smart antenna training interval.

The **undo smart-antenna training-interval** command restores the default smart antenna training interval.

The default smart antenna training interval is **auto**, indicating that a smart antenna is trained in self-adaptation mode.

Format

smart-antenna training-interval { *training-interval* | **auto** }

undo smart-antenna training-interval

Parameters

Parameter	Description	Value
training-interval	Indicates the smart antenna training interval.	The value is an integer that ranges from 10 to 600, in seconds.

Parameter	Description	Value
auto	Indicates that a smart antenna is trained in self-adaptation mode.	-

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

You can run the **smart-antenna training-interval** command to set the smart antenna training interval. When the period since the last round of smart antenna training exceeds the specified interval, a new round of smart antenna training is triggered.

Configure the smart antenna training interval based on actual situations.

- A short antenna training interval causes frequency antenna training and affects user services.
- A long antenna training interval causes the device's failure to switch the antenna combination in time to adapt to WLAN environment changes.

When the default smart antenna training interval is restored, that is, smart antennas are trained in self-adaptation mode, the device adaptively calculates the antenna training interval based on the number of concurrent STAs.

Example

Set the smart antenna training interval to 100 seconds.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] smart-antenna training-interval 100
```

11.4.102 smart-antenna training-mpdu-number

Function

The **smart-antenna training-mpdu-number** command sets the number of MAC protocol data units (MPDUs) sent by an AP to a STA during smart antenna training.

The **undo smart-antenna training-mpdu-number** command restores the default number of MPDUs sent by an AP to a STA during smart antenna training.

By default, 640 MPDUs are sent by an AP to a STA during smart antenna training.

Format

smart-antenna training-mpdu-number *training-mpdu-number*

undo smart-antenna training-mpdu-number

Parameters

Parameter	Description	Value
training-mpdu-number	Specifies the number of MPDUs sent by an AP to a STA during smart antenna training.	The value is an integer that ranges from 10 to 1000.

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

In the smart antenna algorithm, an AP uses different antenna combinations to send training packets for antenna training. During smart antenna training, the transmit end (AP) sends training packets to a receive end (STA). The receive end measures the PER and RSSI in the received packets, and then sends the PER and RSSI to the transmit end. The transmit end collects information about all antenna combinations and corresponding PERs and RSSIs to determine the optimal antenna combination for the receiver.

You can run the **smart-antenna training-mpdu-number** command to set the number of MPDUs sent by an AP to a STA during smart antenna training.

If the traffic rate, bandwidth, and air interface rate of the STA are high, set a small value. Otherwise, set a large value.

Example

Set the number of MPDUs sent by an AP to a STA during smart antenna training to 600.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] smart-antenna training-mpdu-number 600
```

11.4.103 smart-antenna valid-per-scope

Function

The **smart-antenna valid-per-scope** command sets the upper and lower valid packet error rate (PER) thresholds in the smart antenna algorithm.

The **undo smart-antenna valid-per-scope** command restores the default upper and lower valid PER thresholds in the smart antenna algorithm.

The default upper and lower valid PER thresholds are 80% and 20%, respectively.

Format

smart-antenna valid-per-scope { **high-per-threshold** *high-per-threshold* | **low-per-threshold** *low-per-threshold* }

undo smart-antenna valid-per-scope { **high-per-threshold** | **low-per-threshold** }

Parameters

Parameter	Description	Value
high-per-threshold *high-per-threshold*	Specifies the upper valid PER threshold.	The value is an integer that ranges from 50 to 90, in percentage. In addition, the value must be a multiple of 10.
low-per-threshold *low-per-threshold*	Specifies the lower valid PER threshold.	The value is an integer that ranges from 10 to 30, in percentage. In addition, the value must be a multiple of 10.

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

In the smart antenna algorithm, an AP uses different antenna combinations to send training packets for antenna training. During smart antenna training, the transmit end (AP) sends training packets to a receive end (STA). The receive end measures the PER and RSSI in the received packets, and then sends the PER and RSSI to the transmit end. The transmit end collects information about all antenna combinations and corresponding PERs and RSSIs to determine the optimal antenna combination for the receiver.

The PER is a key basis for the smart antenna algorithm. After proper upper and lower valid PER thresholds are configured, the smart antenna algorithm can select a proper antenna combination to improve the coverage and anti-interference capability of a WLAN in indoor coverage scenarios.

Example

Set the upper valid PER threshold to 80%.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] smart-antenna valid-per-scope high-per-threshold 80
```

11.4.104 smart-roam advanced-scan disable

Function

The **smart-roam advanced-scan disable** command disables coordinated scanning in roaming.

The **undo smart-roam advanced-scan disable** command enables coordinated scanning in roaming.

By default, coordinated scanning in roaming is enabled.

Format

smart-roam advanced-scan disable

undo smart-roam advanced-scan disable

Parameters

None

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During the roaming steering for sticky STAs, real-time information about neighboring APs is required to determine the target AP. If STAs do not support 802.11k radio resource measurement, you can run the **undo smart-roam advanced-scan disable** command to enable coordinated scanning in roaming. In this way, APs can collect real-time information about neighboring APs through synchronized radio resource measurement, and generate a neighbor AP table of the STAs.

After this function is enabled, radios switch channels to scan STA information while ensuring voice and video services. If voice and video services are affected, you can disable this function.

Prerequisites

The smart roaming or AI roaming function has been enabled.

Example

Enable coordinated scanning in roaming.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] smart-roam enable
[HUAWEI-wlan-rrm-prof-default] undo smart-roam advanced-scan disable
```

11.4.105 smart-roam { disable | enable | ai-mode }

Function

The **smart-roam { disable | enable | ai-mode }** command enables or disables AI roaming and smart roaming.

The **undo smart-roam** command restores the default state of AI roaming and smart roaming.

By default, AI roaming and smart roaming are enabled.

Format

smart-roam { **disable** | **enable** | **ai-mode** }

undo smart-roam

Parameters

Parameter	Description	Value
disable	Disables AI roaming and smart roaming.	-
enable	Enables smart roaming and disables AI roaming.	-
ai-mode	Enables AI roaming and smart roaming.	-

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a traditional WLAN, when a STA is farther from an AP, the access rate of the STA becomes lower but the STA still associates with the AP without reconnecting the AP or roaming to another AP. This degrades user experience. After the smart roaming function is enabled, when an AP detects that the SNR or access rate of a STA is lower than the specified threshold, the AP sends a BTM packet or Disassociation packet to the STA. The STA then reconnects to the network or roams to an AP with stronger signals.

In practice, the roaming process depends on multiple negotiations between APs and STAs. STAs of different vendors and models have different autonomous behaviors during the negotiation process. As a result, roaming experience cannot be effectively guaranteed. To address this issue, you can enable the AI roaming function. Then the system matches the identified terminal type with the corresponding terminal profile to obtain the behavior characteristics of the terminal during roaming and perform optimization during roaming negotiation. This improves the roaming sensitivity and success rate, enhancing the roaming experience of users.

NOTE

Before enabling the AI roaming function, enable the terminal identification 2.0 function and terminal profiling functions.

If the PMF function is enabled, the AI roaming function does not take effect.

APs must support independent radio scanning to achieve roaming steering based on coordinated measurement. For APs that do not support independent radio scanning, after the AI roaming function is enabled, the STA profiling mechanism is used to perform personalized roaming steering for STAs based on the triggering logic of smart roaming.

Follow-up Procedure

Run the **smart-roam roam-threshold { check-snr | check-rate }** command to configure the trigger mode of smart roaming and the **smart-roam roam-threshold { snr | rate }** command to configure the smart roaming threshold. After that, APs forcibly disconnect STAs with SNR or access rate lower than the threshold.

Example

Enable smart roaming.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] smart-roam enable
```

11.4.106 smart-roam quick-kickoff back-off-time

Function

The **smart-roam quick-kickoff back-off-time** command sets the backoff time for quickly disconnecting STAs.

The **undo smart-roam quick-kickoff back-off-time** command restores the default backoff time for quickly disconnecting STAs.

By default, the backoff time for quickly disconnecting STAs is 60 seconds.

Format

smart-roam quick-kickoff back-off-time *back-off-time*

undo smart-roam quick-kickoff back-off-time

Parameters

Parameter	Description	Value
back-off-time	Specifies the backoff time for quickly disconnecting STAs.	The value is an integer that ranges from 1 to 600, in seconds.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the function of quickly disconnecting STAs is enabled, you can run the **smart-roam quick-kickoff back-off-time** command to set the backoff time for quickly disconnecting STAs to prevent STAs from being disconnected frequently. STAs are not disconnected within the backoff time.

Precautions

Do not set the backoff time to a too small value. Otherwise, STAs may be disconnected frequently.

Example

Set the backoff time for quickly disconnecting STAs to 60 seconds.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] smart-roam quick-kickoff back-off-time 60
```

11.4.107 smart-roam quick-kickoff-threshold disable

Function

The **smart-roam quick-kickoff-threshold disable** command disables the function of quickly disconnecting STAs.

The **undo smart-roam quick-kickoff-threshold disable** command enables the function of quickly disconnecting STAs.

By default, the function of quickly disconnecting STAs is enabled.

Format

smart-roam quick-kickoff-threshold disable

undo smart-roam quick-kickoff-threshold disable

Parameters

None

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the function of quickly disconnecting STAs is enabled and the threshold for quickly disconnecting STAs is specified, the AP disconnects STAs whose SNR or access rate is lower than the specified threshold. The STAs then can connect to or roam to another AP with stronger signals.

Follow-up Procedure

Run the **smart-roam quick-kickoff-threshold { check-snr | check-rate }** command to set the mode for triggering the function of quickly disconnecting STAs, and the **smart-roam quick-kickoff-threshold** command to set the threshold for quickly disconnecting STAs. The AP will disconnect STAs whose SNR or access rate is lower the specified threshold.

Example

Enable the function of quickly disconnecting STAs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] undo smart-roam quick-kickoff-threshold disable
```

11.4.108 smart-roam quick-kickoff-threshold { check-snr | check-rate }

Function

The **smart-roam quick-kickoff-threshold { check-snr | check-rate }** command sets the mode for triggering the function of quickly disconnecting STAs.

The **undo smart-roam quick-kickoff-threshold** command restores the default mode for triggering the function of quickly disconnecting STAs.

The default mode for triggering the function of quickly disconnecting STAs is **check-snr**.

Format

smart-roam quick-kickoff-threshold { **check-snr** | **check-rate** }*

undo smart-roam quick-kickoff-threshold

Parameters

Parameter	Description	Value
check-snr	Specifies that the function of quickly disconnecting STAs is triggered by checking the SNR of STAs.	-
check-rate	Specifies that the function of quickly disconnecting STAs is triggered by checking the rate of STAs. The rate here refers to the negotiated rate based on the protocol and signal strength when a STA associates with an AP, instead of the actual rate of the STA.	-

Usage Guidelines

Usage Scenario

After the function of quickly disconnecting STAs is enabled, you can run the **smart-roam quick-kickoff-threshold { check-snr | check-rate }** command to set the mode for triggering the function of quickly disconnecting STAs, and set the threshold for quickly disconnecting STAs. When the SNR or access rate of a STA detected by an AP is lower than the specified threshold, the AP disconnects the STA. The STA then can connect to or roam to another AP with stronger signals.

Prerequisites

The function of quickly disconnecting STAs has been enabled using the **undo smart-roam quick-kickoff-threshold disable** command.

Follow-up Procedure

Run the **smart-roam quick-kickoff-threshold** command to set the threshold for quickly disconnecting STAs.

Example

Set the mode for triggering the function of quickly disconnecting STAs to **check-rate**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] undo smart-roam quick-kickoff-threshold disable
[HUAWEI-wlan-rrm-prof-default] smart-roam quick-kickoff-threshold check-rate
```

11.4.109 smart-roam quick-kickoff-snr check-interval

Function

The **smart-roam quick-kickoff-snr check-interval** command configures the interval for checking the SNR to determine whether to quickly disconnect STAs.

The **undo smart-roam quick-kickoff-snr check-interval** command restores the default interval for checking the SNR to determine whether to quickly disconnect STAs.

The default interval for checking the SNR to determine whether to quickly disconnect STAs is 500 ms.

Format

smart-roam quick-kickoff-snr check-interval *check-interval*

undo smart-roam quick-kickoff-snr check-interval

Parameters

Parameter	Description	Value
check-interval *check-interval*	Specifies an interval for checking the SNR to determine whether to quickly disconnect STAs.	The value is an integer that ranges from 300 to 3000, in milliseconds.

Views

RRM profile view

2: Configuration level

Usage Guidelines

Usage Scenario

When the mode for quickly disconnecting STAs is set to **check-snr**, you can run the **smart-roam quick-kickoff-snr check-interval** command to set the interval for checking the SNR to determine whether to quickly disconnect STAs. A shorter interval allows the system to determine whether to disconnect STAs more quickly.

Prerequisites

The function of quickly disconnecting STAs has been enabled using the **undo smart-roam quick-kickoff-threshold disable** command.

Example

Set the interval for checking the SNR to determine whether to quickly disconnect STAs to 600 ms.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] undo smart-roam quick-kickoff-threshold disable
[HUAWEI-wlan-rrm-prof-default] smart-roam quick-kickoff-snr check-interval 600
```

11.4.110 smart-roam quick-kickoff-snr p-n criteria

Function

The **smart-roam quick-kickoff-snr p-n criteria** command configures the PN threshold for quickly disconnecting STAs.

The **undo smart-roam quick-kickoff-snr p-n criteria** command restores the default PN threshold for quickly disconnecting STAs.

By default, the number of PN observation times is 6, and the number of times criteria are met is 4.

Format

smart-roam quick-kickoff-snr p-n criteria observe-time *observe-value* **qualify-time** *qualify-value*

undo smart-roam quick-kickoff-snr p-n criteria

Parameters

Parameter	Description	Value
observe-time *observe-value*	Specifies the number of PN observation times.	The value is an integer that ranges from 1 to 10.

Parameter	Description	Value
qualify-time *qualify-value*	Specifies the number of PN observation times criteria are met.	The value is an integer that ranges from 1 to 10.

2: Configuration level

Usage Guidelines

Usage Scenario

When the mode for quickly disconnecting STAs is set to **check-snr**, you can run the **smart-roam quick-kickoff-snr p-n criteria** command to configure the PN threshold for quickly disconnecting STAs.

PN criteria: When N conditions are met in the P range, an event is triggered. Assume that the value of **observe-value** is 6 and that of **qualify-value** is 4, and the interval for checking the SNR to determine whether to quickly disconnect STAs is 500 ms. The system detects the SNR of a STA for six consecutive times and calculates the average SNR value. If the average value is smaller than the total average value four times, the STA is forced offline.

Prerequisites

The function of quickly disconnecting STAs has been enabled using the **undo smart-roam quick-kickoff-threshold disable** command.

Precautions

The value of **observe-value** must be greater than or equal to that of **qualify-value**.

Example

Set the value of **observe-value** to 10 and that of **qualify-value** to 5.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] undo smart-roam quick-kickoff-threshold disable
[HUAWEI-wlan-rrm-prof-default] smart-roam quick-kickoff-snr p-n criteria observe-time 10 qualify-time 5
```

11.4.111 smart-roam quick-kickoff-threshold

Function

The **smart-roam quick-kickoff-threshold** command sets the threshold for quickly disconnecting STAs.

The **undo smart-roam quick-kickoff-threshold** command restores the default threshold for quickly disconnecting STAs.

By default, the SNR-based threshold for quickly disconnecting STAs is 15 dB, and the rate-based threshold is 20%.

Format

smart-roam quick-kickoff-threshold { **snr** *snr-threshold* | **rate** *rate-threshold* }

undo smart-roam quick-kickoff-threshold { **snr** | **rate** }

Parameters

Parameter	Description	Value
snr *snr-threshold*	Specifies the SNR-based threshold for quickly disconnecting STAs.	The value is an integer that ranges from 5 to 45, in dB. If this parameter is set to the default value, the threshold for quickly disconnecting STAs on the AirEngine 5762-16W is 10 dB.
rate *rate-threshold*	Specifies the rate-based threshold for quickly disconnecting STAs. The rate here refers to the negotiated rate based on the protocol and signal strength when a STA associates with an AP, instead of the actual rate of the STA.	The value is an integer that ranges from 1 to 100, in percentage.

Views

RRM profile view

2: Configuration level

Usage Guidelines

Usage Scenario

After the function of quickly disconnecting STAs is enabled and the threshold for quickly disconnecting STAs is specified for an AP using this command, the AP acquires a STA's SNR or rate from data packets sent from the STA. If the STA's SNR or rate is lower than the specified threshold, the AP forcibly disconnects the STA so that the STA can reinitiate a connection with the AP or roam to another AP with strong signals.

- A large threshold may cause STAs to go offline frequently.
- A small threshold may disable STAs from roaming to an AP with stronger signals.

This command is applicable to scenarios that have high requirements on real-time transmission, such as voice and video scenarios.

Prerequisites

The function of quickly disconnecting STAs has been enabled using the **undo smart-roam quick-kickoff-threshold disable** command.

The mode for triggering the function of quickly disconnecting STAs has been set using the **smart-roam quick-kickoff-threshold { check-snr | check-rate }** command.

Precautions

STAs may be forced to go offline through the smart roaming function or the function of quickly disconnecting STAs. If the SNR-based thresholds for the two functions are both configured, the function with a larger value is preferentially effective.

Example

Set the mode for triggering the function of quickly disconnecting STAs to **check-snr** and the threshold for quickly disconnecting STAs to 20 dB.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] undo smart-roam quick-kickoff-threshold disable
[HUAWEI-wlan-rrm-prof-default] smart-roam quick-kickoff-threshold check-snr
[HUAWEI-wlan-rrm-prof-default] smart-roam quick-kickoff-threshold snr 20
```

11.4.112 smart-roam roam-threshold { check-snr | check-rate }

Function

The **smart-roam roam-threshold { check-snr | check-rate }** command configures the trigger mode of smart roaming.

The **undo smart-roam roam-threshold** command restores the default trigger mode of smart roaming.

By default, the trigger mode of smart roaming is **check-snr**.

Format

smart-roam roam-threshold { **check-snr** | **check-rate** }*

undo smart-roam roam-threshold

Parameters

Parameter	Description	Value
check-snr	Specifies the trigger mode of smart roaming as **check SNR**.	-
check-rate	Specifies the trigger mode of smart roaming as **check rate**. The rate here refers to the negotiated rate based on the protocol and signal strength when a STA associates with an AP, instead of the actual rate of the STA.	-

Views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the smart roaming function is enabled, the AP forces STAs to log out based on the configured trigger mode and threshold of smart roaming. When an AP receives a STA's data packet, the AP learns the STA's SNR or rate from the data packet. If the STA's SNR or rate is lower than the configured threshold, roaming is triggered. Then, the AP sends a Disassociation frame to the STA so that the STA can reinitiate a connection with the AP or roam to another AP with strong signals.

Prerequisites

Smart roaming or AI roaming has been enabled.

Follow-up Procedure

Run the **smart-roam roam-threshold { snr | rate }** command to configure the smart roaming threshold.

Example

Set the trigger mode of smart roaming to **check-rate**.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] smart-roam enable
[HUAWEI-wlan-rrm-prof-default] smart-roam roam-threshold check-rate
```

11.4.113 smart-roam roam-threshold { snr | rate }

Function

The **smart-roam roam-threshold { snr | rate }** command sets the smart roaming threshold.

The **undo smart-roam roam-threshold** command restores the default smart roaming threshold.

By default, the SNR threshold for smart roaming is 20 dB, and the rate threshold is 20%.

Format

smart-roam roam-threshold { **snr** *snr-threshold* | **rate** *rate-threshold* }

undo smart-roam roam-threshold { **snr** | **rate** }

Parameters

Parameter	Description	Value
snr *snr-threshold*	Specifies the SNR threshold for smart roaming. If the SNR threshold is 25 dB and noise floor is -95 dBm, a STA's SNR is lower than the threshold when the STA's RSSI is lower than -70 dBm (25 dB + (-95 dBm) = -70 dBm). **NOTE** If the signal strength of a STA is close to the smart roaming threshold, the network experience may be poor. If the default SNR threshold is used and the signal strength of many 2.4 GHz STAs is close to the smart roaming threshold, it is recommended that the 2.4 GHz and 5 GHz radios be bound to different RRM profiles and the SNR threshold be increased to about 25 dB in the RRM profile corresponding to the 2.4 GHz radio. Wait for 1 to 2 minutes and then observe the signal strength and service experience of these STAs.	The value is an integer that ranges from 15 to 45, in dB. If this parameter is set to the default value, the STA roaming threshold on the AirEngine 5762-16W is 15 dB.

Parameter	Description	Value
rate *rate-threshold*	Specifies the rate threshold for smart roaming. The rate here refers to the negotiated rate based on the protocol and signal strength when a STA associates with an AP, instead of the actual rate of the STA. If the maximum capability of the AP and STA is 54 Mbit/s and the rate threshold is 50%, the lower rate threshold is considered 27 Mbit/s (54 Mbit/s x 50% = 27 Mbit/s).	The value is an integer that ranges from 1 to 100, in percentage.

2: Configuration level

Usage Guidelines

Usage Scenario

After the smart roaming function is enabled, the AP forces STAs to log out based on the configured trigger mode and threshold of smart roaming. When an AP receives a STA's data packet, the AP learns the STA's SNR or rate from the data packet. If the STA's SNR or rate is lower than the configured threshold, smart roaming is triggered. Then, the AP sends a Disassociation frame to the STA so that the STA can reinitiate a connection with the AP or roam to another AP with strong signals.

- A large threshold may cause STAs to go offline frequently.
- A small threshold may disable STAs from roaming to an AP with stronger signals.

Prerequisites

Smart roaming or AI roaming has been enabled.

The trigger mode of smart roaming has been configured using the **smart-roam roam-threshold { check-snr | check-rate }** command.

Precautions

STAs may be forced to go offline through the smart roaming function or the function of quickly disconnecting STAs. If the SNR-based thresholds for the two functions are both configured, the function with a larger value is preferentially effective.

Example

Set the trigger mode of smart roaming to **check-snr** and set the smart roaming threshold to 25 dB.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] smart-roam enable
[HUAWEI-wlan-rrm-prof-default] smart-roam roam-threshold check-snr
[HUAWEI-wlan-rrm-prof-default] smart-roam roam-threshold snr 25
```

11.4.114 smart-roam snr-margin

Function

The **smart-roam snr-margin** command sets the RSSI difference thresholds that trigger STA roaming steering.

The **undo smart-roam snr-margin** command restores the default RSSI difference thresholds that trigger STA roaming steering.

By default, the upper and lower RSSI difference thresholds that trigger STA roaming steering are 12 dB and 10 dB, respectively.

Format

smart-roam snr-margin high-level-margin *high-level-margin* **low-level-margin** *low-level-margin*

undo smart-roam snr-margin

Parameters

Parameter	Description	Value
high-level-margin *high-level-margin*	Specifies the upper RSSI difference threshold for triggering STA roaming steering.	The value is an integer that ranges from 10 to 20, in dB.
low-level-margin *low-level-margin*	Specifies the lower RSSI difference threshold for triggering STA roaming steering.	The value is an integer that ranges from 3 to 15, in dB.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In smart roaming and AI roaming scenarios, you can configure the thresholds for determining whether to steer STA roaming. When determining whether to steer a STA to roam to a neighboring AP, the AP compares the RSSIs of the STA on the neighboring AP with that on the current AP, which are reported by the STA through coordinated measurement. If the RSSI difference is higher than a specified threshold, that is, the STA has a significantly increased RSSI after associating with the neighboring AP, the AP steers the STA to roam to the neighboring AP.

The parameters **low-level-margin** and **high-level-margin** are used to determine whether to steer sticky STAs and common STAs, respectively, to roam to neighboring APs in smart roaming scenarios. In most cases, you are advised to set **high-level-margin** larger than **low-level-margin** so that sticky STAs can roam to neighboring APs with better experience as soon as possible.

In AI roaming scenarios based on coordinated measurement, only **high-level-margin** is used to determine whether to steer STAs to roam to neighboring APs.

The default difference thresholds are recommended. If APs are deployed close to each other and have high transmit power, set larger values for the upper and lower RSSI difference thresholds.

Prerequisites

Smart roaming or AI roaming has been enabled.

Example

Set the upper and lower RSSI difference thresholds that trigger STA roaming steering to 10 dB and 6 dB, respectively.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] smart-roam enable
[HUAWEI-wlan-rrm-prof-default] smart-roam snr-margin high-level-margin 10 low-level-margin 6
```

11.4.115 smart-roam unable-roam-client expire-time

Function

The **smart-roam unable-roam-client expire-time** command sets the aging time of the "unable to roam" record for STAs.

The **undo smart-roam unable-roam-client expire-time** command restores the default aging time of the "unable to roam" record for STAs.

By default, the aging time of an "unable to roam" record is 30 minutes.

Format

smart-roam unable-roam-client expire-time *expire-time*

undo smart-roam unable-roam-client expire-time

Parameters

Parameter	Description	Value
expire-time	Specifies the aging time of the "unable to roam" record.	The value is an integer that ranges from 30 to 2880, in minutes.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After smart roaming is enabled, you can run the **smart-roam unable-roam-client expire-time** command to set the aging time of the "unable to roam" record for STAs. When the device requests a STA to roam but the STA keeps sending association requests to the original AP or does not initiate an association request, the device records the terminal as "unable to roam" and does not trigger STA roaming within the specified time. After the aging time is reached, the "unable to roam" record for STAs is automatically cleared, and the system can trigger roaming of the STAs.

A STA is recorded as "unable to roam" due to the following reasons:

- Due to different software configurations, some STAs preferentially send association requests to APs with which they have once associated.
- In some environments, STAs cannot scan APs with strong signals.
- STAs enter the dormancy state and do not roam once they are forcibly disconnected.

The aging time to configure varies for different reasons. A large aging time is used for the software configuration reason so that the AP will trigger roaming of the STAs as less as possible. However, a small aging time is used in other situations so that the AP will attempt to trigger roaming of the STAs marked "unable to roam."

Prerequisites

Smart roaming or AI roaming has been enabled.

Example

Set the aging time of the "unable to roam" record to 50 minutes.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
```

```
[HUAWEI-wlan-rrm-prof-default] smart-roam enable
[HUAWEI-wlan-rrm-prof-default] smart-roam unable-roam-client expire-time 50
```

11.4.116 spatial-reuse disable

Function

The **spatial-reuse disable** command disables the spatial reuse (SR) function.

The **undo spatial-reuse disable** command enables the SR function.

By default, the SR function is enabled.

NOTE

The SR function is not supported by the following APs:

- AirEngine 5761-10W, AirEngine 5761-10WD, and AirEngine 5761S-10W
- AirEngine X762

Format

spatial-reuse disable

undo spatial-reuse disable

Parameters

None

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Prerequisites

The BSS coloring function has been enabled.

Precautions

Disabling the BSS coloring function will automatically disable the spatial reuse (SR) function.

Example

Disable the SR function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] spatial-reuse disable
```

11.4.117 sta-load-balance dynamic btm-fail-times

Function

The **sta-load-balance dynamic btm-fail-times** command sets the maximum number of attempts to steer STAs in BTM mode.

The **undo sta-load-balance dynamic btm-fail-times** command restores the default maximum number of attempts to steer STAs in BTM mode.

By default, the maximum number of attempts to steer STAs in BTM mode is 5.

Format

sta-load-balance dynamic btm-fail-times *btm-fail-times*

undo sta-load-balance dynamic btm-fail-times

Parameters

Parameter	Description	Value
btm-fail-times	Specifies the maximum number of attempts to steer STAs in BTM mode.	The value is an integer that ranges from 0 to 10. The value 0 indicates that the BTM mode is not used to steer STAs.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The device preferentially uses the BTM mode to trigger STA steering to the target AP. Due to differences of STAs, some STAs can be successfully steered in BTM mode after multiple attempts. You can run the **sta-load-balance dynamic btm-fail-times** command to set the maximum number of attempts to steer STAs in BTM mode. If the number of attempts exceeds the specified value, the device attempts to steer STAs in deauthentication mode.

Precautions

You are advised to retain the default value. If the success rate of STA steering in BTM mode is low, you can set a smaller value to improve the steering efficiency.

Example

Set the maximum number of attempts to steer STAs in BTM mode to 4 in RRM profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] sta-load-balance dynamic btm-fail-times 4
```

11.4.118 sta-load-balance dynamic deauth-fail-times

Function

The **sta-load-balance dynamic deauth-fail-times** command sets the maximum number of attempts to steer STAs in deauthentication mode.

The **undo sta-load-balance dynamic deauth-fail-times** command restores the default maximum number of attempts to steer STAs in deauthentication mode.

By default, the maximum number of attempts to steer STAs in deauthentication mode is 0.

Format

sta-load-balance dynamic deauth-fail-times *deauth-fail-times*

undo sta-load-balance dynamic deauth-fail-times

Parameters

Parameter	Description	Value
deauth-fail-times	Specifies the maximum number of attempts to steer STAs in deauthentication mode.	The value is an integer that ranges from 0 to 5. The value 0 indicates that the deauthentication mode is not used to steer STAs.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The device attempts to use the 802.11v and deauthentication modes to trigger STA steering to the target AP. Due to differences of STAs, some STAs can be successfully steered in deauthentication mode after multiple attempts. You can run the **sta-load-balance dynamic deauth-fail-times** command to set the maximum number of attempts to steer STAs in deauthentication mode. If the number of attempts exceeds the specified value, STAs cannot be steered.

Precautions

You are advised to retain the default value. If the success rate of STA steering in deauthentication mode is low or STA services are affected, set the parameter value to 0 to disable STA steering in deauthentication mode.

Example

Set the maximum number of attempts to steer STAs in deauthentication mode to 1 in RRM profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] sta-load-balance dynamic deauth-fail-times 1
```

11.4.119 sta-load-balance dynamic disable

Function

The **sta-load-balance dynamic disable** command disables the dynamic load balancing function.

The **undo sta-load-balance dynamic disable** command enables the dynamic load balancing function.

By default, the dynamic load balancing function is enabled.

Format

sta-load-balance dynamic disable

undo sta-load-balance dynamic disable

Parameters

None

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Static load balancing limits the maximum number of AP radios to 16 and allows only radios on the same frequency band to join a load balancing group.

Additionally, a load balancing group needs to be manually specified. Dynamic load balancing overcomes the limitations of static load balancing.

After a STA connects to an AP, the AC checks whether the AP reaches the load balancing threshold, and determines whether to steer the STA to a neighboring AP that meets load balancing requirements based on the load balancing algorithm.

Example

Disable dynamic load balancing.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] sta-load-balance dynamic disable
```

11.4.120 sta-load-balance dynamic sta-number gap-threshold

Function

The **sta-load-balance dynamic sta-number gap-threshold** command sets the load difference threshold for dynamic load balancing based on the number of users.

The **undo sta-load-balance dynamic sta-number gap-threshold** command restores the default load difference threshold for dynamic load balancing based on the number of users.

By default, the load difference threshold of a dynamic load balancing group is specified based on the number of users, and the default value is 3.

Format

sta-load-balance dynamic sta-number gap-threshold { **percentage** *percentage-value* | **number** *number-value* }

undo sta-load-balance dynamic sta-number gap-threshold

Parameters

Parameter	Description	Value
percentage *percentage-value*	Specifies the load difference threshold for dynamic load balancing based on the percentage of users.	The value is an integer that ranges from 1 to 100. It indicates the threshold of the load difference among radios in a load balancing group, in percentage. The load difference refers to the difference between the percentages of users on radios.

Parameter	Description	Value
number *number-value*	Specifies the load difference threshold for dynamic load balancing based on the number of users.	The value is an integer that ranges from 1 to 20. It indicates the threshold of the load difference among radios in a load balancing group. The load difference refers to the difference between the numbers of users on radios.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a user requests to connect to an AP, the AP counts the total number of access users on all radios. If the total number of access users does not exceed the start threshold configured using the **sta-load-balance dynamic sta-number start-threshold** command, the AP does not implement dynamic load balancing. The AP implements dynamic load balancing only when the total number of access users on all radios exceeds the start threshold.

The following load balancing algorithm is used after the user access to determine whether to steer the user to a new AP:

One of the conditions for steering a user to a new AP is that the radio of the target load is lower than that of the current access radio. The radio load is identified by the number or percentage (Number of users associated with the current radio/Maximum number of access users supported by the radio x 100%) of access users. If the load difference between the target radio and current radio exceeds the specified threshold, the condition is met.

NOTE

The start threshold and load difference threshold for dynamic load balancing are used to adjust the sensitivity for triggering load balancing, and the default values are recommended. If the start and load difference thresholds are set low, load balancing becomes far easier to be triggered. As a result, STAs are frequently switched between APs, affecting user experience. If the start and load difference thresholds are set high, the load balancing mechanism may become invalid.

Precautions

If you configure the load difference threshold based on both the number of users and the percentage of users, only the latest configuration takes effect.

Example

Set the load difference threshold for dynamic load balancing based on the number of users to 25% in RRM profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] sta-load-balance dynamic sta-number gap-threshold percentage 25
```

11.4.121 sta-load-balance dynamic sta-number start-threshold

Function

The **sta-load-balance dynamic sta-number start-threshold** command sets the start threshold for dynamic load balancing based on the number of users.

The **undo sta-load-balance dynamic sta-number start-threshold** command restores the default start threshold for dynamic load balancing based on the number of users.

By default, the start threshold for dynamic load balancing based on the number of users is 10.

Format

sta-load-balance dynamic sta-number start-threshold *start-threshold*

undo sta-load-balance dynamic sta-number start-threshold

Parameters

Parameter	Description	Value
start-threshold *start-threshold*	Specifies the start threshold for dynamic load balancing based on the number of users.	The value is an integer that ranges from 1 to 40.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

When a user requests to connect to an AP, the AP counts the total number of access users on all radios. If the number of access users on the requested radio does not exceed the start threshold, the AP does not implement dynamic load balancing based on the number of users. The AP implements dynamic load balancing based on the number of users only after the number of access users exceeds the start threshold.

NOTE

The start and load difference thresholds for dynamic load balancing configured using the **sta-load-balance dynamic sta-number gap-threshold** command can be used to adjust sensitivity for triggering load balancing. The default values are recommended in typical scenarios. A higher threshold is recommended in high-density scenarios. If the start and load difference thresholds are set low, load balancing becomes far easier to be triggered. As a result, STAs are frequently switched between APs, affecting user experience. If the start and load difference thresholds are set high, the load balancing mechanism may become invalid.

Example

Set the start threshold for dynamic load balancing based on the number of users to 20 in RRM profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] sta-load-balance dynamic sta-number start-threshold 20
```

11.4.122 sta-load-balance static-group

Function

The **sta-load-balance static-group** command creates a static load balancing group and displays the static load balancing group view.

The **undo sta-load-balance static-group** command deletes a static load balancing group.

By default, no static load balancing group is configured.

Format

sta-load-balance static-group name *group-name*

undo sta-load-balance static-group { **name** *group-name* | **all** }

Parameters

Parameter	Description	Value
name *group-name*	Specifies the name of a load balancing group.	The value is a string of 1 to 35 plaintext characters. It does not contain any question mark (?) and cannot begin or end with double quotation marks (" ").
all	Deletes all static load balancing groups.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

In static load balancing mode, APs providing the same services are manually added to a load balancing group. When a STA needs to access a WLAN, it sends an Association Request packet to an AC through an AP. The AC determines whether to allow access from the STA according to the load balancing algorithm.

To configure static load balancing, run the **sta-load-balance static-group** command in the WLAN view to create a static load balancing group and **member (static load balancing group view)** command to add APs to the group.

Example

Configure the static load balancing group named **new**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sta-load-balance static-group name new
[HUAWEI-wlan-sta-lb-static-new]
```

11.4.123 sta-number start-threshold

Function

The **sta-number start-threshold** command sets the start threshold for load balancing based on the number of users in a static load balancing group.

The **undo sta-number start-threshold** command deletes the configured start threshold for load balancing based on the number of users in a static load balancing group.

By default, the start threshold for load balancing based on the number of users in a static load balancing group is 10.

Format

sta-number start-threshold *start-threshold-value*

undo sta-number start-threshold

Parameters

Parameter	Description	Value
start-threshold *start-threshold-value*	Specifies the start threshold for load balancing based on the number of users in a static load balancing group.	The value is an integer that ranges from 1 to 40.

Views

Static load balancing group view

Default Level

2: Configuration level

Usage Guidelines

You can use this command to set the start threshold for load balancing based on the number of users in a static load balancing group. If the load on a radio does not reach the start threshold, the device does not implement load balancing control on access STAs.

Example

Set the start threshold for load balancing based on the number of users in the static load balancing group to 5.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sta-load-balance static-group name coco
[HUAWEI-wlan-sta-lb-static-coco] sta-number start-threshold 5
```

11.4.124 sta-load-balance dynamic probe-report interval

Function

The **sta-load-balance dynamic probe-report interval** command sets the interval for reporting Probe frames.

The **undo sta-load-balance dynamic probe-report interval** command restores the default interval for reporting Probe frames.

By default, Probe frames are reported at an interval of 120 seconds.

Format

sta-load-balance dynamic probe-report interval *interval*

undo sta-load-balance dynamic probe-report interval

Parameters

Parameter	Description	Value
interval	Specifies the interval for reporting Probe frames.	The value is an integer that ranges from 30 to 300, in seconds.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An AP collects information about neighboring APs of STAs and reports the information to the AC for determining the target APs to which the STAs will roam. You can run this command to set the interval at which an AP reports information about neighboring APs of STAs.

Precautions

You are advised to retain the default value. If the device has high performance pressure, you can set a longer interval.

Example

Set the interval for reporting Probe frames to 125 seconds in RRM profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] sta-load-balance dynamic probe-report interval 125
```

11.4.125 sta-load-balance dynamic rssi-diff-gap

Function

The **sta-load-balance dynamic rssi-diff-gap** command sets the RSSI difference threshold for members in a dynamic load balancing group.

The **undo sta-load-balance dynamic rssi-diff-gap** command restores the default RSSI difference threshold of members in a dynamic load balancing group.

By default, the RSSI difference threshold of members in a dynamic load balancing group is 5 dB.

Format

sta-load-balance dynamic rssi-diff-gap *diff-gap-threshold*

undo sta-load-balance dynamic rssi-diff-gap

Parameters

Parameter	Description	Value
diff-gap-threshold	Specifies the RSSI difference threshold of members in a dynamic load balancing group.	The value is an integer that ranges from 0 to 15, in dB.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To achieve load balancing, an AP may steer connected STAs to other APs with smaller RSSIs. If the RSSI of the AP with which a STA currently associates minus the RSSI of the target AP is larger than the specified RSSI difference threshold, the STA is denied from being steered to the target AP; otherwise, the STA can be steered to the target AP.

Precautions

If STAs have high signal quality deterioration tolerance for the target AP, you can set a larger RSSI difference threshold to achieve better load balancing effect. If STAs have low signal quality deterioration tolerance for the target AP, set a smaller RSSI difference threshold. You are advised to retain the default value.

Example

Set the RSSI difference threshold of members in a dynamic load balancing group to 6 dB in RRM profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] sta-load-balance dynamic rssi-diff-gap 6
```

11.4.126 sta-load-balance dynamic rssi-threshold

Function

The **sta-load-balance dynamic rssi-threshold** command sets an RSSI threshold for member devices in a dynamic load balancing group.

The **undo sta-load-balance dynamic rssi-threshold** command restores the default RSSI threshold of member devices in a dynamic load balancing group.

By default, the RSSI threshold of member devices in a dynamic load balancing group is –65 dBm.

Format

sta-load-balance dynamic rssi-threshold *rssi-threshold*

undo sta-load-balance dynamic rssi-threshold

Parameters

Parameter	Description	Value
rssi-threshold	Specifies the RSSI threshold of member devices in a dynamic load balancing group.	The value is an integer that ranges from –75 to –55, in dBm.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the RSSI threshold of member devices in a dynamic load balancing group is configured, an AP compares the RSSI of a STA with the configured RSSI threshold after receiving the Probe Request packet sent by the STA. If the STA's RSSI exceeds the threshold, the AP reports STA information to the AC, and the AP is added to the dynamic load balancing group. If the STA's RSSI does not exceed the threshold, the AP directly filters STA information and does not report the information to the AC, and the AP is not added to the dynamic load balancing group.

Setting an RSSI threshold for member devices in a dynamic load balancing group is to filter APs with weak signals, so that STAs can be load-balanced between APs with better signals. This prevents STAs from associating with APs with weak signals but light loads. This function does not affect STAs' going online.

Example

Set the RSSI threshold for member devices in a dynamic load balancing group to –70 dBm in the RRM profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] sta-load-balance dynamic rssi-threshold -70
```

11.4.127 sta-load-balance dynamic steer-restrict auth-threshold

Function

The **sta-load-balance dynamic steer-restrict auth-threshold** command sets the maximum number of times non-target APs suppress authentication of STAs during STA steering.

The **undo sta-load-balance dynamic steer-restrict auth-threshold** command restores the default maximum number of times non-target APs suppress authentication of STAs during STA steering.

By default, the maximum number of times non-target APs suppress authentication of STAs during STA steering is 0.

Format

sta-load-balance dynamic steer-restrict auth-threshold *auth-threshold*

undo sta-load-balance dynamic steer-restrict auth-threshold

Parameters

Parameter	Description	Value
auth-threshold	Specifies the maximum number of times non-target APs suppress authentication of STAs during STA steering.	The value is an integer that ranges from 0 to 5.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a STA is triggered to steer to a specified target AP, non-target APs will suppress association of the STA temporarily to improve the STA's steering success rate. You can run the **sta-load-balance dynamic steer-restrict auth-threshold** command to set the maximum number of times non-target APs suppress authentication of STAs during STA steering.

Precautions

You can set a larger value of this parameter to improve the STAs' steering success rate, which, however, may affect users' network experience.

The default value is applicable to mainstream STAs. You are advised to retain the default value. If users' service experience deteriorates due to STA steering, set a smaller value for this parameter.

Example

Set the maximum number of times non-target APs suppress authentication of STAs during STA steering to 1 in RRM profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] sta-load-balance dynamic steer-restrict auth-threshold 1
```

11.4.128 sta-load-balance dynamic steer-restrict probe-threshold

Function

The **sta-load-balance dynamic steer-restrict probe-threshold** command sets the maximum number of times non-target APs suppress probing of STAs during STA steering.

The **undo sta-load-balance dynamic steer-restrict probe-threshold** command restores the default maximum number of times non-target APs suppress probing of STAs during STA steering.

By default, the maximum number of times non-target APs suppress probing of STAs during STA steering is 5.

Format

sta-load-balance dynamic steer-restrict probe-threshold *probe-threshold*

undo sta-load-balance dynamic steer-restrict probe-threshold

Parameters

Parameter	Description	Value
probe-threshold	Specifies the maximum number of times non-target APs suppress probing of STAs during STA steering.	The value is an integer that ranges from 0 to 10.

Views

RRM profile view

The default value is applicable to mainstream STAs. You are advised to retain the default value. If users' service experience deteriorates due to STA steering, set a smaller value for this parameter.

Example

Set the maximum number of times non-target APs suppress probing of STAs during STA steering to 4 in RRM profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] sta-load-balance dynamic steer-restrict probe-threshold 4
```

11.4.129 sta-load-balance dynamic steer-restrict restrict-time

Function

The **sta-load-balance dynamic steer-restrict restrict-time** command sets the duration within which non-target APs suppress association of STAs during STA steering.

The **undo sta-load-balance dynamic steer-restrict restrict-time** command restores the default duration within which non-target APs suppress association of STAs during STA steering.

By default, the duration within which non-target APs suppress association of STAs during STA steering is 5 seconds.

Format

sta-load-balance dynamic steer-restrict restrict-time *restrict-time*

undo sta-load-balance dynamic steer-restrict restrict-time

Parameters

Parameter	Description	Value
restrict-time	Specifies the duration within which non-target APs suppress association of STAs during STA steering.	The value is an integer that ranges from 0 to 10, in seconds.

[HUAWEI-wlan-rrm-prof-default] sta-load-balance dynamic steer-restrict restrict-time 4
```

11.4.130 sta-profiling disable

Function

The **sta-profiling disable** command disables the STA profiling function.

The **undo sta-profiling disable** command enables the STA profiling function.

By default, the STA profiling function is enabled.

Format

sta-profiling disable

undo sta-profiling disable

Parameters

None

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

On a traditional WLAN, when a STA is far away from an AP, the signal strength of the STA gradually weakens and the Internet access rate of the STA becomes lower and lower. If the STA is always associated with an existing AP, user experience deteriorates. With the smart roaming mechanism, the system can automatically steer STAs encountered with poor network quality to APs providing better signals. In practice, the roaming process depends on multiple negotiations between APs and STAs. STAs of different vendors and models have different autonomous behaviors during the negotiation process. As a result, roaming experience cannot be effectively guaranteed. After the STA profiling function is enabled, the system can create profiles for STAs of this type based on the STA behaviors and learn how to steer roaming for these STAs more effectively. This improves the roaming sensitivity and success rate, enhancing the roaming experience of users.

Example

Disable the STA profiling function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sta-profiling disable
```

11.4.131 steer-restrict auth-threshold

Function

The **steer-restrict auth-threshold** command sets the maximum number of times non-target APs suppress authentication of STAs during STA steering.

The **undo steer-restrict auth-threshold** command restores the default maximum number of times non-target APs suppress authentication of STAs during STA steering.

By default, the maximum number of times non-target APs suppress authentication of STAs during STA steering is 0.

Format

steer-restrict auth-threshold *auth-threshold*

undo steer-restrict auth-threshold

Parameters

Parameter	Description	Value
auth-threshold	Specifies the maximum number of times non-target APs suppress authentication of STAs during STA steering.	The value is an integer that ranges from 0 to 5.

11.4.134 terminal-identify disable

Function

The **terminal-identify disable** command disables the terminal identification 2.0 function on an AP.

The **undo terminal-identify disable** command enables the terminal identification 2.0 function on an AP.

By default, the terminal identification 2.0 function is enabled on an AP.

Format

terminal-identify disable

undo terminal-identify disable

Parameters

None

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

After a terminal accesses an AP enabled with the terminal identification 2.0 function, the system extracts terminal type information from the DHCP, mDNS, and HTTP packets from the terminal to identify the terminal type.

NOTE

The AI roaming and terminal identification 2.0 functions are not supported by the following APs:

- AirEngine 5761-10W, AirEngine 5761-10WD, and AirEngine 5761S-10W
- AirEngine X762
- AirEngine 9700D series central APs (including matching RUs)
- AirEngine 9700D-S (including matching ORUs)

Example

Enable the terminal identification 2.0 function on the target AP in the AP system profile **ap-system1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] undo terminal-identify disable
```

11.4.135 uac enable

Function

The **uac enable** command enables user CAC.

The **undo uac enable** command disables user CAC.

By default, user CAC is disabled.

Format

uac { **client-number** | **client-snr** } **enable**

undo uac { **client-number** | **client-snr** } **enable**

Parameters

Parameter	Description	Value
client-number	Controls user access based on the number of users.	-
client-snr	Controls user access based on the terminal SNR.	-

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On WLANs where many users exist, such as WLANs in high density scenarios, users compete fiercely to occupy resources as the number of online users increases. As a result, network quality deteriorates. To ensure network access experience of online users, configure the user CAC function. The user CAC function allows an AP to control user access based on the number of online users or terminal SNR, which enables provisioning of high-quality network access services.

CAC is implemented in the following modes:

- User CAC based on the number of users uses a simple algorithm. This mode is recommended when most users have the same type of services and similar service traffic volumes.
- SNR-based user CAC controls access from weak-signal users, and is applicable to scenarios where the WLAN has good signal coverage and weak signals only at the edge of WLAN coverage areas.

CAC based on the number of users can be configured together with SNR-based CAC.

Follow-up Procedure

Run the **uac client-number threshold** command to set the user CAC threshold based on the number of users.

Run the **uac client-snr threshold** command to set the user CAC threshold based on terminal SNR.

Run the **uac reach-access-threshold** { **hide-ssid** | **priority-replace** } command to configure the action to take for subsequent access control when the number of access users reaches the user CAC threshold.

Example

Enable user CAC based on the number of users.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name test
[HUAWEI-wlan-rrm-prof-test] uac client-number enable
```

11.4.136 uac client-number threshold

Function

The **uac client-number threshold** command configures the user CAC threshold based on the number of users.

The **undo uac client-number threshold** command restores the default user CAC threshold based on the number of users.

By default, the user CAC access and roaming thresholds based on the number of users are both 64.

Format

uac client-number threshold access *access-threshold* [**roam** *roam-threshold*]

undo uac client-number threshold

Parameters

Parameter	Description	Value
access *access-threshold*	Specifies the user CAC access threshold based on the number of users.	The value is an integer that ranges from 1 to 512.
roam *roam-threshold*	Specifies the user CAC roaming threshold based on the number of users. This threshold is the total number of users who can be associate with the AP, including all local and reassociated roaming users.	The value is an integer that ranges from 1 to 512.

Views

RRM profile view

2: Configuration level

Usage Guidelines

Usage Scenario

On WLANs where many users exist, such as WLANs in high density scenarios, users compete fiercely to occupy resources as the number of online users increases. As a result, network quality deteriorates. To ensure network access experience of online users, configure the user CAC function. The user CAC function allows an AP to control user access based on the number of online users or terminal SNR, which enables provisioning of high-quality network access services.

NOTE

The user CAC access threshold is invalid for roaming users. For example, the user CAC access threshold is 20, and the user CAC roaming threshold is 24. If 20 local users have already connected to the network, not more local users can connect to the network but another four roaming users can.

CAC is implemented in the following modes:

- User CAC based on the number of users uses a simple algorithm. This mode is recommended when most users have the same type of services and similar service traffic volumes.

- SNR-based user CAC controls access from weak-signal users, and is applicable to scenarios where the WLAN has good signal coverage and weak signals only at the edge of WLAN coverage areas.

CAC based on the number of users can be configured together with SNR-based CAC.

Prerequisites

The user CAC function based on the number of users has been enabled using the **uac client-number enable** command.

Example

Set the user CAC access threshold based on the number of users to 50 and the roaming threshold to 60.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name test
[HUAWEI-wlan-rrm-prof-test] uac client-number enable
[HUAWEI-wlan-rrm-prof-test] uac client-number threshold access 50 roam 60
```

11.4.137 uac client-snr threshold

Function

The **uac client-snr threshold** command configures the user CAC threshold based on terminal SNR.

The **undo uac client-snr threshold** command restores the default user CAC threshold based on terminal SNR.

By default, the user CAC threshold based on terminal SNR is 15 dB.

Format

uac client-snr threshold *threshold*

undo uac client-snr threshold

Parameters

Parameter	Description	Value
threshold	Specifies the user CAC threshold based on terminal SNR.	The value is an integer that ranges from 5 to 45, in dB.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On WLANs where many users exist, such as WLANs in high density scenarios, users compete fiercely to occupy resources as the number of online users increases. As a result, network quality deteriorates. To ensure network access experience of online users, configure the user CAC function. The user CAC function allows an AP to control user access based on the number of online users or terminal SNR, which enables provisioning of high-quality network access services.

The configured user CAC threshold based on terminal SNR takes effect for new STAs. When a new STA (or a roaming STA) attempts to connect to an AP, the AP checks the STA's SNR. If the SNR is smaller than the threshold, the AP denies the STA's access.

CAC is implemented in the following modes:

- User CAC based on the number of users uses a simple algorithm. This mode is recommended when most users have the same type of services and similar service traffic volumes.
- SNR-based user CAC controls access from weak-signal users, and is applicable to scenarios where the WLAN has good signal coverage and weak signals only at the edge of WLAN coverage areas.

CAC based on the number of users can be configured together with SNR-based CAC.

Prerequisites

The user CAC function based on terminal SNR has been enabled using the **uac client-snr enable** command.

Example

Set the user CAC threshold based on terminal SNR to 16 dB.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] uac client-snr enable
[HUAWEI-wlan-rrm-prof-default] uac client-snr threshold 16
```

11.4.138 uac reach-access-threshold

Function

The **uac reach-access-threshold** command configures the user CAC function and specifies the action to take when the number of access users reaches the user CAC threshold.

The **undo uac reach-access-threshold** command disables SSID hiding or priority-based user replacement.

By default, SSID hiding and priority-based user replacement are disabled.

Format

uac reach-access-threshold { **hide-ssid** | **priority-replace** }

undo uac reach-access-threshold

Parameters

Parameter	Description	Value
hide-ssid	Indicates SSID hiding.	-
priority-replace	Indicates priority-based user replacement.	-

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After user CAC is configured, you can configure the action to take when the number of access users reaches the threshold. The following actions are available:

- Deny new user access. This is the default configuration.
- Deny new user access and hide the SSID.
- Disconnect common users to make room for access of high-priority users.

Prerequisites

User CAC has been enabled using the **uac** { **client-number** | **client-snr** } **enable** command.

Precautions

- When you run the **undo uac** { **client-number** | **client-snr** } **enable** command to disable user CAC, SSID hiding is automatically canceled.
- The **uac reach-access-threshold priority-replace** command takes effect only when UAC based on the number of users is enabled.

Example

Enable SSID hiding.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name test
[HUAWEI-wlan-rrm-prof-test] uac client-number enable
[HUAWEI-wlan-rrm-prof-test] uac reach-access-threshold hide-ssid
```

Enable priority-based user replacement.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name test
[HUAWEI-wlan-rrm-prof-test] uac client-number enable
[HUAWEI-wlan-rrm-prof-test] uac reach-access-threshold priority-replace
Info: This configuration only takes effective when uac client-number enabled.
```

Deny new user access.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name test
[HUAWEI-wlan-rrm-prof-test] undo uac reach-access-threshold
```

11.5 WLAN Spectrum Analysis Configuration Commands

11.5.1 Command Support

- WLAN-AC commands are supported only by the following models: S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.
- Starting from V200R020C10, AirEngine X760 series APs support spectrum analysis. To implement spectrum analysis on the following APs, upgrade them to V200R020C10 or later: AirEngine 8760-X1-PRO, AirEngine 8760R-X1, AirEngine 8760R-X1E, AirEngine 6760-X1, AirEngine 6760-X1E, AirEngine 6760R-51, AirEngine 6760R-51E, AirEngine 5760-51, AirEngine 5760-22W, AirEngine 5760-22WD. If the AC version is earlier than V200R020C10, run the **undo ap-type** command on the AC to delete the AP type, which will cause corresponding APs to go offline. Then manually add the AP type again. Alternatively, upgrade the AC to V200R020C10 or later.
- Spectrum analysis is not supported by the following APs:
  - AirEngine 8771-X1T
  - AirEngine 5761-10W, AirEngine 5761S-10W, and AirEngine 5761-10WD
  - AirEngine X762

11.5.2 channel-monitor enable

Function

The **channel-monitor enable** command enables the function of monitoring the status of all channels.

The **undo channel-monitor enable** command disables the function of monitoring the status of all channels.

By default, the function of monitoring the status of all channels is disabled.

Format

channel-monitor enable

undo channel-monitor enable

Parameters

None

Views

AP group radio view, AP radio view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During spectrum analysis, APs report air scan results to a spectrum server. Then the spectrum server analyzes interference source types and identifies non-Wi-Fi interference devices. After you run the **channel-monitor enable** command, APs can scan the status of all channels (normally occupied, Wi-Fi interference, non-Wi-Fi interference, or idle) over the air interface to identify all interference sources.

Precautions

To identify non-Wi-Fi interference, you also need to enable spectrum analysis.

Channels to be monitored are the same as those in the air scan channel set. To collect as much interference source information as possible within the range allowed by local laws and regulations, you are advised to run the **scan-channel-set country-channel** command to add all channels supported by the country code to the air scan channel set.

Follow-up Procedure

To display and analyze monitoring results on iMaster NCE-CampusInsight, configure interconnection with iMaster NCE-CampusInsight through the WMI mechanism and run the **collect-item radio-data** command to enable the function of reporting radio monitoring data to iMaster NCE-CampusInsight.

Example

Enable the function of monitoring the status of all channels.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name group1
[HUAWEI-wlan-ap-group-group1] radio 0
[HUAWEI-wlan-group-radio-group1/0] channel-monitor enable
```

11.5.3 display spectrum-analysis server-reporter

Function

The **display spectrum-analysis server-reporter** command displays a list of APs that report spectrum packets to the spectrum server.

Format

display spectrum-analysis server-reporter

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display spectrum-analysis server-reporter** command displays a list of APs that report spectrum packets to the spectrum server.

Example

Display all APs that report spectrum packets to the spectrum server.

```
<HUAWEI> display spectrum-analysis server-reporter
------------------------------------------------------------
ID    AP name                          Radio ID
------------------------------------------------------------
1     AP_1                          0
------------------------------------------------------------
Total: 1
```

Table 11-157 Description of the **display spectrum-analysis server-reporter** command output

Item	Description
ID	ID of the AP that reports spectrum data. To configure this parameter, run the **spectrum-report** command.
AP name	Name of the AP that reports spectrum data. To configure this parameter, run the **spectrum-report** command.
Radio ID	ID of the radio on which the function of reporting spectrum data is enabled. To configure this parameter, run the **spectrum-report** command.

11.5.4 display wlan non-wifi-device

Function

The **display wlan non-wifi-device** command displays information about detected non-Wi-Fi devices.

Format

display wlan non-wifi-device { **all** | { **ap-name** *ap-name* | **ap-id** *ap-id* } **radio** *radio-id* }

Parameters

Parameter	Description	Value
all	Displays information about the non-Wi-Fi devices detected by all APs.	-
ap-name *ap-name*	Displays information about the non-Wi-Fi devices detected by a specified AP name.	The AP name must exist.
ap-id *ap-id*	Displays information about the non-Wi-Fi devices detected by a specified AP ID.	The AP ID must exist.
radio *radio-id*	Displays information about the non-Wi-Fi devices detected by a specified AP radio.	The value is an integer that ranges from 0 to 2. Three radios are available only on the following models: ● AirEngine 8760-X1-PRO, AirEngine 8760R-X1E, AirEngine 6760-X1, AirEngine 6760-X1E, AirEngine 5760-51 ● AirEngine 6761-21T, AirEngine 6761S-21T, AirEngine 6761-22T ● AirEngine 8771-X1T

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After the function of reporting spectrum data is enabled on an AP radio using the **spectrum-report** command, you can run the **display wlan non-wifi-device** command to check information about the detected non-Wi-Fi devices.

Example

Display information about the non-Wi-Fi devices detected by all APs.

```
<HUAWEI> display wlan non-wifi-device all
Info: This operation may take a few seconds. Please wait for a moment.done.
----------------------------------------------------------------
Detect AP ID                           : 11

Table 11-158 Description of the **display wlan non-wifi-device** command output

Item	Description
Detect AP ID	ID of the AP that has detected a non-Wi-Fi device.
Detect AP name	Name of the AP that has detected a non-Wi-Fi device.
Detect AP radio ID	ID of the AP radio on which a non-Wi-Fi device is detected.

Item	Description
Detect AP channel	ID of the AP channel on which a non-Wi-Fi device is detected.
Non-Wi-Fi device type	Type of the detected non-Wi-Fi device. ● 0: Cordless phone ● 1: Cordless phone base ● 2: ZigBee device ● 3: Microwave oven ● 4: Bluetooth ● 5: Game controller ● 6: 2.4G wireless video and audio device ● 7: 5G wireless video and audio device ● 8: Baby monitor ● 9: Fixed-frequency device
Non-Wi-Fi device name	Name of the non-Wi-Fi device.
Non-Wi-Fi device frequency type	Frequency type of the non-Wi-Fi device.
Non-Wi-Fi device channel	Channel of the non-Wi-Fi device.
Non-Wi-Fi device RSSI	RSSI of the non-Wi-Fi device.
Non-Wi-Fi device detect time last	Detection time for the non-Wi-Fi device.
Non-Wi-Fi device center frequency(MHz)	Center frequency of the non-Wi-Fi device.
Non-Wi-Fi device bandwidth(KHz)	Bandwidth of the non-Wi-Fi device.
Non-Wi-Fi device duty(%)	Duty cycle of the non-Wi-Fi device.
Non-Wi-Fi device interfere level	Interference level of the non-Wi-Fi device. The value ranges from 0 to 3. A larger value indicates stronger interference.

11.5.5 display wlan non-wifi-device history

Function

The **display wlan non-wifi-device history** command displays information about non-Wi-Fi devices in the historical list.

Format

display wlan non-wifi-device history { **all** | { **ap-name** *ap-name* | **ap-id** *ap-id* } **radio** *radio-id* }

Parameters

Parameter	Description	Value
all	Displays information about all the non-Wi-Fi devices in the historical list.	-
ap-name *ap-name*	Displays information about the non-Wi-Fi devices detected by an AP with a specified name in the historical list.	The AP name must exist.
ap-id *ap-id*	Displays information about the non-Wi-Fi devices detected by an AP with a specified ID in the historical list.	The AP ID must exist.
radio *radio-id*	Displays information about the non-Wi-Fi devices detected by a specified AP radio in the historical list.	The value is an integer that ranges from 0 to 2. Three radios are available only on the following models: ● AirEngine 8760-X1-PRO, AirEngine 8760R-X1E, AirEngine 6760-X1, AirEngine 6760-X1E, AirEngine 5760-51 ● AirEngine 6761-21T, AirEngine 6761S-21T, AirEngine 6761-22T ● AirEngine 8771-X1T

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If information about a non-Wi-Fi device is not detected within the aging time configured using the **spectrum-analysis non-wifi-device aging-time** command, the AC adds the device to the historical list.

Example

Display information about non-Wi-Fi devices in the historical list.

```
<HUAWEI> display wlan non-wifi-device history all
------------------------------------------------------------------
S/No.                               : 0
Detect AP name                      : MyAP
Detect AP radio ID                  : 1
Detect AP channel                   : 44
Non-Wi-Fi device type               : 9
Non-Wi-Fi device name               : Unknown fix freq device
Non-Wi-Fi device frequency type     : Narrow bandwidth
Non-Wi-Fi device channel            : 147,148
Non-Wi-Fi device RSSI               : -59,-66
Non-Wi-Fi device detect time last   : 2014-11-19/17:05:05
Non-Wi-Fi device center frequency(MHz) : 5739
Non-Wi-Fi device bandwidth(KHz)     : 2708
Non-Wi-Fi device duty(%)            : 79
Non-Wi-Fi device interfere level    : 3
------------------------------------------------------------------
Total: 1
```

Table 11-159 Description of the **display wlan non-wifi-device history** command output

Item	Description
S/No.	No.of historical records.
Detect AP name	Name of the AP that has detected a non-Wi-Fi device.
Detect AP radio ID	ID of the AP radio on which a non-Wi-Fi device is detected.
Detect AP channel	AP channel on which a non-Wi-Fi device is detected.
Non-Wi-Fi device type	Type of the detected non-Wi-Fi device.
Non-Wi-Fi device name	Name of the non-Wi-Fi device.
Non-Wi-Fi device frequency type	Frequency type of the non-Wi-Fi device.
Non-Wi-Fi device RSSI	RSSI of the non-Wi-Fi device.
Non-Wi-Fi device channel	Channel of the non-Wi-Fi device.
Non-Wi-Fi device detect time last	Detection time for the non-Wi-Fi device.
Non-Wi-Fi device center frequency(MHz)	Center frequency of the non-Wi-Fi device.

Item	Description
Non-Wi-Fi device bandwidth(KHz)	Bandwidth of the non-Wi-Fi device.
Non-Wi-Fi device duty(%)	Duty cycle of the non-Wi-Fi device.
Non-Wi-Fi device interfere level	Interference level of the non-Wi-Fi device. The value ranges from 0 to 3. A larger value indicates stronger interference.

11.5.6 spectrum-analysis enable

Function

(AP group radio view) The **spectrum-analysis enable** command enables spectrum analysis on a specified radio in an AP group.

(AP group radio view) The **undo spectrum-analysis enable** command disables spectrum analysis on a specified radio in an AP group.

(AP radio view) The **spectrum-analysis enable** command enables spectrum analysis on a specified AP radio.

(AP radio view) The **undo spectrum-analysis enable** command restores the AP radio configuration to that in the AP group radio view.

By default, spectrum analysis is disabled on an AP radio.

Format

spectrum-analysis enable

undo spectrum-analysis enable

Parameters

None

Views

AP radio view, AP group radio view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If interference exists on a WLAN, enable spectrum analysis on AP radios to implement spectrum scanning, sampling, and analysis on the wireless signals. The spectrum analysis function helps identify non-Wi-Fi interference on the WLAN and locate non-Wi-Fi devices to optimize the WLAN.

Precautions

If the WDS or Mesh service is configured on a radio, the command cannot be executed in the radio view.

Example

Enable spectrum analysis on radio 0 of the AP with ID 1.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 1
[HUAWEI-wlan-ap-1] radio 0
[HUAWEI-wlan-radio-1/0] spectrum-analysis enable
```

11.5.7 spectrum-analysis non-wifi-device aging-time

Function

The **spectrum-analysis non-wifi-device aging-time** command configures the aging time for non-Wi-Fi device information during spectrum analysis.

The **undo spectrum-analysis non-wifi-device aging-time** command restores the default aging time for non-Wi-Fi device information during spectrum analysis.

By default, the aging time for non-Wi-Fi device information is 3 minutes.

Format

spectrum-analysis non-wifi-device aging-time *aging-time*

undo spectrum-analysis non-wifi-device aging-time

Parameters

Parameter	Description	Value
aging-time	Specifies the aging time for non-Wi-Fi device information.	The value is an integer that ranges from 1 to 30, in minutes.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a spectrum analysis server is configured using the **spectrum-analysis server** command, the AC stores information about analyzed non-Wi-Fi device information. If information about a non-Wi-Fi device is not reported again within the aging time configured using the **spectrum-analysis non-wifi-device aging-time** command, the AC adds the non-Wi-Fi device to the historical list. You can run the **display wlan non-wifi-device history** command to check information about non-Wi-Fi devices in the historical list.

Precautions

Currently, the device cannot identify different devices of the same type. For example, when the device detects Bluetooth devices A and B, the device can only record them as Bluetooth devices and update the detection time of the Bluetooth device.

Example

Set the aging time for non-Wi-Fi device information to 5 minutes.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] spectrum-analysis non-wifi-device aging-time 5
```

11.5.8 spectrum-analysis server

Function

The **spectrum-analysis server** command specifies the IP address and port number of a spectrum server.

The **undo spectrum-analysis server** command deletes the specified IP address and port number of a spectrum server.

By default, no spectrum server is configured.

Format

spectrum-analysis server ip-address *ip-address* **port** *port-number* [**via-ac ac-port** *ac-port-number*]

undo spectrum-analysis server

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies the IPv4 address of a spectrum server.	The value is in dotted decimal notation.
port *port-number*	Specifies the port number (UDP port number) of a spectrum server.	The value is an integer that ranges from 1 to 65535. **NOTE** The port number of eSight is 32181, and that of iMaster NCE-CampusInsight is 27371.

Parameter	Description	Value
via-ac	Configures the AP to report spectrum data to the spectrum server via the AC.	-
ac-port *ac-port-number*	Specifies the port number used by the AC to receive spectrum data (in UDP packets) from the AP.	The value is an integer that ranges from 5000 to 65535.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After collecting the spectrum data, an AP encapsulates the collected data into UDP packets and sends the packets to the spectrum server. The spectrum server draws a spectrum and displays the spectrum information of the detected non-Wi-Fi devices to users through images.

- If the AP uploads the collected data directly to the spectrum server, you do not need to configure the **via-ac ac-port** *ac-port-number* command.
- If the AP uploads the collected data to the spectrum server via the AC, configure the **via-ac ac-port** *ac-port-number* command.
- If no spectrum server is available, to view the spectrum in the web system of an AC, specify a valid IP address and port number for the spectrum server (which do not take effect) and configure the **via-ac ac-port** *ac-port-number* command.

Follow-up Procedure

Run the **spectrum-report** { **ap-name** *ap-name* | **ap-id** *ap-id* } **radio** *radio-id* command to enable the function of reporting spectrum data on an AP radio.

Example

Set the IP address and port number of a spectrum server to 10.137.43.4 and 27371, respectively.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] spectrum-analysis server ip-address 10.137.43.4 port 27371
```

11.5.9 spectrum-analysis source

Function

The **spectrum-analysis source** command configures the source IP address of packets sent by the AC to a spectrum server.

The **undo spectrum-analysis source** command deletes the configured source IP address of packets sent by the AC to a spectrum server.

By default, the AC uses the IP address of the outbound interface on the matched route as the source IP address of packets sent to a spectrum server.

Format

spectrum-analysis source ip-address *ip-address*

undo spectrum-analysis source

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies the source IPv4 address of packets sent by the AC to a spectrum server.	The value is in dotted decimal notation.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, when sending data packets to a spectrum server, the AC uses the IP address of the outbound interface on the matched route between them to communicate with the spectrum server.

After the source IP address is configured using the **spectrum-analysis source** command, the AC uses this IP address to communicate with the spectrum server.

Precautions

- Ensure that the AC's IP address manually configured on the spectrum server is the same as that configured using the **spectrum-analysis source** command.
- The configured source IP address must exist on the AC and is routable with the spectrum server.

Example

Configure 10.102.25.23 as the source IP address of packets sent by the AC to a spectrum server.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] spectrum-analysis source ip-address 10.102.25.23
```

11.5.10 spectrum-report

Function

The **spectrum-report** command enables the function of reporting spectrum data on an AP radio.

The **undo spectrum-report** command disables the function of reporting spectrum data on an AP radio.

By default, the function of reporting spectrum data is disabled on an AP radio.

Format

spectrum-report { **ap-name** *ap-name* | **ap-id** *ap-id* } **radio** *radio-id*

undo spectrum-report { { **ap-name** *ap-name* | **ap-id** *ap-id* } [**radio** *radio-id*] | **all** }

Parameters

Parameter	Description	Value
ap-name *ap-name*	Specifies an AP name. The AP name and radio ID identify a radio.	The AP name must exist.
ap-id *ap-id*	Specifies an AP ID. The AP ID and radio ID identify a radio.	The AP ID must exist.

Parameter	Description	Value
radio *radio-id*	Specifies a radio ID.	The value is an integer that ranges from 0 to 2. Three radios are available only on the following models: ● AirEngine 8760-X1-PRO, AirEngine 8760R-X1E, AirEngine 6760-X1, AirEngine 6760-X1E, AirEngine 5760-51 ● AirEngine 6761-21T, AirEngine 6761S-21T, AirEngine 6761-22T ● AirEngine 8771-X1T
all	Specifies all APs.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the function of reporting spectrum data is enabled on an AP radio, the AP encapsulates collected data into UDP packets and sends the packets to the spectrum server. After receiving the data, the spectrum server analyzes the data and then displays radio information of non-Wi-Fi devices to users through images or tables.

Prerequisites

The spectrum analysis function has been enabled on a radio using the **spectrum-analysis enable** command.

Follow-up Procedure

Run the **spectrum-analysis server** command in the spectrum profile view to specify the IP address and port number of the spectrum server.

Precautions

The **spectrum-report** command becomes invalid after the AC restarts, and needs to be configured again.

Example

Enable the function of reporting spectrum data on radio 0 of the AP named **test**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] spectrum-report ap-name test radio 0
```

11.5.11 reset wlan non-wifi-device

Function

The **reset wlan non-wifi-device** command clears information about detected non-Wi-Fi devices.

Format

reset wlan non-wifi-device { **all** | { **ap-name** *ap-name* | **ap-id** *ap-id* } **radio** *radio-id* }

Parameters

Parameter	Description	Value
all	Clears information about the non-Wi-Fi devices detected by all APs.	-
ap-name *ap-name*	Clears information about the non-Wi-Fi devices detected by a specified AP name.	The AP name must exist.
ap-id *ap-id*	Clears information about the non-Wi-Fi devices detected by a specified AP ID.	The AP ID must exist.

Parameter	Description	Value
radio *radio-id*	Clears information about the non-Wi-Fi devices detected by a specified AP radio.	The value is an integer that ranges from 0 to 2. Three radios are available only on the following models: ● AirEngine 8760-X1-PRO, AirEngine 8760R-X1E, AirEngine 6760-X1, AirEngine 6760-X1E, AirEngine 5760-51 ● AirEngine 6761-21T, AirEngine 6761S-21T, AirEngine 6761-22T ● AirEngine 8771-X1T

Views

All views

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Before re-collecting information about detected non-Wi-Fi devices in a period, you can run this command to clear existing information so that the AC can re-collect information.

Prerequisites

The spectrum analysis function has been enabled on a radio.

Impact

The cleared non-Wi-Fi device information cannot be restored. Exercise caution when you run this command. After the command is run, you can run the **display wlan non-wifi-device history** command to view related information.

Example

Clear information about the non-Wi-Fi devices detected by all APs.

```
<HUAWEI> reset wlan non-wifi-device all
```

11.5.12 reset wlan non-wifi-device history

Function

The **reset wlan non-wifi-device history** command clears information about non-Wi-Fi devices in the historical list.

Format

reset wlan non-wifi-device history { **all** | { **ap-name** *ap-name* | **ap-id** *ap-id* } **radio** *radio-id* }

Parameters

Parameter	Description	Value
all	Clears information about all the non-Wi-Fi devices in the historical list.	-
ap-name *ap-name*	Clears information about the non-Wi-Fi devices detected by a specified AP name in the historical list.	The AP name must exist.
ap-id *ap-id*	Clears information about the non-Wi-Fi devices detected by a specified AP ID in the historical list.	The AP ID must exist.
radio *radio-id*	Clears information about the non-Wi-Fi devices detected by a specified AP radio in the historical list.	The value is an integer that ranges from 0 to 2. Three radios are available only on the following models: ● AirEngine 8760-X1-PRO, AirEngine 8760R-X1E, AirEngine 6760-X1, AirEngine 6760-X1E, AirEngine 5760-51 ● AirEngine 6761-21T, AirEngine 6761S-21T, AirEngine 6761-22T ● AirEngine 8771-X1T

Views

3: Management level

Usage Guidelines

You can run this command to clear information about non-Wi-Fi devices in the historical list.

Example

Clear information about the non-Wi-Fi devices detected by all APs in the historical list.

```
<HUAWEI> reset wlan non-wifi-device history all
```

11.6 WLAN Roaming Commands

11.6.1 Command Support

WLAN-AC commands are supported only by the following models: S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.

11.6.2 beacon disable

Function

The **beacon disable** command disables an RU from sending Beacon frames.

The **undo beacon disable** command allows an RU to send Beacon frames.

By default, an RU is allowed to send Beacon frames.

NOTE

This command does not take effect for the following APs:

- AirEngine 9700D-S
- AirEngine X77X
- AirEngine X76X (including RUs)

Format

beacon disable

undo beacon disable

Parameters

None

Usage Guidelines

Usage Scenario

To ensure synchronization of Beacon frames in scenarios with densely deployed RUs, you can run the **beacon disable** command to disable some RUs from sending Beacon frames. This configuration is recommended on a network enabled with agile distributed SFN roaming. In other scenarios, the default configuration is recommended.

Precautions

Disabling an RU from sending Beacon frames may cause STAs to go offline due to a failure to receive Beacon frames.

Example

Disable an RU from sending Beacon frames.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 1
[HUAWEI-wlan-ap-1] radio 0
[HUAWEI-wlan-radio-1/0] beacon disable
Warning: This configuration is recommended in SFN roaming scenarios. This action
 may cause service interruption. Continue? [Y/N]Y
```

11.6.3 capwap dtls inter-controller control-link encrypt

Function

The **capwap dtls inter-controller control-link encrypt** command configures DTLS encryption for an inter-AC control tunnel.

The **undo capwap dtls inter-controller control-link encrypt** command restores the default configuration of DTLS encryption for an inter-AC control tunnel.

By default, DTLS encryption for an inter-AC control tunnel is disabled.

Format

capwap dtls inter-controller control-link encrypt

undo capwap dtls inter-controller control-link encrypt

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

At the discovery stage of inter-AC tunnel establishment, the AC obtains the IP address of another AC through the discovery mechanism. After that, the ACs enter the DTLS negotiation stage, in which the ACs use DTLS to set up a tunnel and encrypt UDP packets forwarded in the tunnel.

After this command is executed, packets transmitted over an inter-AC control tunnel are encrypted using DTLS. The ACs implement DTLS negotiation in PSK encryption mode. If DTLS negotiation fails, the inter-AC tunnel cannot be set up.

Precautions

If you modify the DTLS configuration after an inter-AC tunnel is set up, the modification takes effect at the next tunnel setup.

When DTLS encryption is enabled for an inter-AC control tunnel on the server-side AC, the inter-AC tunnel can be set up only when this function is enabled on client-side AC. When DTLS encryption is enabled for an inter-AC control tunnel on the client-side AC, the inter-AC tunnel can be set up if even this function is disabled on the server-side AC.

Before enabling this function, run the **capwap dtls inter-controller psk** command to configure a PSK.

Example

Enable DTLS encryption for an inter-AC control tunnel.

```
<HUAWEI> system-view
[HUAWEI] capwap dtls inter-controller control-link encrypt
Warning: This operation may cause devices using CAPWAP connections to reset or go offline. Continue?
[Y/N]:y
```

11.6.4 capwap dtls inter-controller psk

Function

The **capwap dtls inter-controller psk** command configures a pre-shared key (PSK) for DTLS encryption of inter-AC tunnels.

By default, no PSK is configured for DTLS encryption.

Format

capwap dtls inter-controller psk *psk-value*

Parameters

Parameter	Description	Value
psk-value	Specifies a PSK for DTLS encryption.	The value is string of 48 or 68 characters in ciphertext (for example, **%^%#u(Oz:BL,QKYZw%-JWC*P8aGC,="C&M'OI*Gmt.V(%^%#**) or a string of 8 to 32 characters in plaintext (for example, **YsHsjx_202206**). The key must contain at least two types of the following: uppercase letters, lowercase letters, digits, and special characters.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In scenarios such as inter-AC roaming and centralized license control, ACs synchronize data and forward packets through CAPWAP tunnels. If DTLS encryption for inter-AC tunnels is configured, DTLS negotiation is initiated when an AC negotiates with the peer AC to establish a CAPWAP link. Subsequent UDP packets are encrypted using DTLS to improve transmission security.

DTLS supports PSK encryption. When a PSK is used for DTLS encryption, you can use this command to change the value of the PSK on the AC.

Follow-up Procedure

Run the **capwap dtls inter-controller control-link encrypt** command to enable DTLS encryption for inter-AC control tunnels.

Precautions

If you modify the PSK after an inter-AC tunnel is set up, the modification takes effect at the next tunnel setup.

DTLS encryption must be enabled on ACs at both ends of the tunnel, and the ACs must have the same PSK.

It is recommended that you configure the same PSK on the ACs at both ends before enabling DTLS encryption. In this way, the ACs have the same PSK. If you enable DTLS encryption but the ACs have different PSKs, DTLS negotiation fails. As a result, the tunnel cannot be set up between the ACs.

NOTE

To implement roaming between ACs running different versions, you must manually configure the same PSK on the ACs in the mobility group.

Example

Configure the PSK **YsHsjx_202206** for DTLS encryption of an inter-AC tunnel.

```
<HUAWEI> system-view
[HUAWEI] capwap dtls inter-controller psk YsHsjx_202206
```

11.6.5 capwap inter-controller sensitive-info psk

Function

The **capwap inter-controller sensitive-info psk** command configures a pre-shared key (PSK) used for encrypting sensitive information between ACs.

The **undo capwap inter-controller sensitive-info psk** command deletes the configured PSK used for encrypting sensitive information between ACs.

By default, no PSK is configured for encrypting sensitive information between ACs.

Format

capwap inter-controller sensitive-info psk *key-value*

undo capwap inter-controller sensitive-info psk

Parameters

Parameter	Description	Value
key-value	Specifies a PSK for encrypting sensitive information between ACs.	The value is a string of 6 to 32 case-sensitive characters without question marks (?) or spaces. For a plaintext PSK, the length must be 48 or 68 bits. If the string is enclosed in double quotation marks ("), the string can contain spaces. **NOTE** For security purposes, it is recommended that the PSK contain at least eight characters from at least two of the following types: uppercase letters, lowercase letters, digits, and special characters.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In multi-AC scenarios where inter-AC communication is established through CAPWAP tunnels (such as inter-AC roaming and centralized license control), ACs may need to exchange sensitive information such as the user name and password. You can configure a PSK to protect sensitive data transmitted between ACs.

Precautions

- Ensure that the ACs have the same PSK. Otherwise, the CAPWAP tunnel cannot be set up between the ACs.
- This function must be configured on the ACs at both ends of a CAPWAP tunnel, and the ACs must have the same PSK. Otherwise, the CAPWAP tunnel cannot be set up between the ACs.

Example

Set the PSK used for encrypting sensitive information between ACs to **YsHsjx_202206**.

```
<HUAWEI> system-view
[HUAWEI] capwap inter-controller sensitive-info psk YsHsjx_202206
Warning: The ACs must have the same configuration. Otherwise, the link between them cannot be set up.
Warning: This operation may cause devices using CAPWAP connections to reset or go offline. Continue?
[Y/N]:Y
```

11.6.6 cts delay

Function

The **cts delay** command sets a delay for RUs to respond to STAs with CTS packets.

The **undo cts delay** command deletes the delay configured for RUs to respond to STAs with CTS packets.

By default, RUs respond to STAs with CTS packets with no delay.

Format

cts delay *delay-time*

undo cts delay

Parameters

Parameter	Description	Value
delay-time	Specifies the delay time after which RUs respond to STAs with CTS packets.	The value is an integer that ranges from 1 to 255, in microseconds.

Views

AP radio view, AP group radio view

Default Level

2: Configuration level

Usage Guidelines

After the **undo cts disable** command is executed to enable RUs to respond to STAs with CTS packets, you can configure a response delay. When multiple RUs respond to STAs with CTS packets, you can configure the delay for some RUs to prevent conflicts.

Example

Set the delay for RUs to respond to STAs with CTS packets to 60 microseconds.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 1
```

```
[HUAWEI-wlan-ap-1] radio 0
[HUAWEI-wlan-radio-1/0] undo cts disable
[HUAWEI-wlan-radio-1/0] cts delay 60
```

11.6.7 cts disable

Function

The **cts disable** command disables RUs from responding to STAs with CTS packets.

The **undo cts disable** command enables RUs to respond to STAs with CTS packets.

By default, RUs are enabled to respond to STAs with CTS packets.

Format

cts disable

undo cts disable

Parameters

None

Views

AP radio view, AP group radio view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To prevent CTS conflicts in scenarios with densely deployed RUs, you can run the **cts disable** command to disable some RUs from responding to STAs with CTS packets. This configuration is recommended on a network enabled with agile distributed SFN roaming. In other scenarios, the default configuration is recommended.

Precautions

Disabling RUs from responding to STAs with CTS packets may cause STAs to go offline due to a failure to receive CTS packets.

This command does not take effect on the R250D, R250D-E, R251D, R251D-E, or R450D.

Example

Disable RUs from responding to STAs with CTS packets.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 1
```

```
[HUAWEI-wlan-ap-1] radio 0
[HUAWEI-wlan-radio-1/0] cts disable
Warning: This configuration is recommended in SFN roaming scenarios. This action
 may cause service interruption. Continue? [Y/N]y
```

11.6.8 display mobility-group

Function

The **display mobility-group** command displays configurations of mobility groups.

Format

display mobility-group { **name** *group-name* | **all** }

Parameters

Parameter	Description	Value
name *group-name*	Specifies the name of a mobility group.	The mobility group name must already exist.
all	Specifies all mobility groups.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display mobility-group** command to view configurations of mobility groups.

Example

Display configurations of the mobility group **hello**.

```
<HUAWEI> display mobility-group name hello
--------------------------------------------------------------------------------
State        IP address                     Description
--------------------------------------------------------------------------------
normal       192.168.10.1                     -
normal       192.168.10.2                     -
fault        192.168.10.3                     -
--------------------------------------------------------------------------------
Total: 3
```

Table 11-160 Description of the **display mobility-group** command output

Item	Description
State	Status of the CAPWAP links between members in the mobility group and the local AC. ● normal: The CAPWAP links are working properly. ● fault: The CAPWAP links are disconnected. ● vmiss: The versions of members in the mobility group and the local AC do not match. ● -: No CAPWAP link is established between members in the mobility group and the local AC.
IP address	AC's IP address.
Description	Description of the AC.

Display configurations of all mobility groups.

```
<HUAWEI> display mobility-group all
------------------------------------------------------------------------------------------
Group name
------------------------------------------------------------------------------------------
group1
mobility-test
------------------------------------------------------------------------------------------
Total: 2
```

Table 11-161 Description of the **display mobility-group all** command output

Item	Description
Group name	Mobility group name.

11.6.9 display station roam-statistics

Function

The **display station roam-statistics** command displays STA roaming statistics.

Format

display station roam-statistics [**ap-name** *ap-name* | **ap-id** *ap-id*]

Parameters

Parameter	Description	Value
ap-name *ap-name*	Displays statistics about STAs associated with the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Displays statistics about STAs associated with the AP with a specified ID.	The AP ID must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display station roam-statistics** command to view STA roaming statistics.

- If no parameter is specified, roaming statistics about all associated STAs are displayed.
- If an AP name or ID is specified, roaming statistics about all STAs associated with the AP are displayed.

Example

Display roaming statistics about all STAs.

```
<HUAWEI> display station roam-statistics
--------------------------------------------------------------------------------
 Online STAs                                                :0
 Online roaming stations                                    :0
--------------------------------------------------------------------------------
```

Table 11-162 Description of the **display station roam-statistics** command output

Item	Description
Online STAs	Number of online STAs.
Online roaming stations	Number of online roaming STAs.

Display roaming statistics about STAs associated with a specified AP.

```
<HUAWEI> display station roam-statistics ap-name N1-2
----------------------------------------------------------------------------
```

```
Online STAs                                    :0
Online roaming stations                            :0
Online L3 roam stations                            :0
L3 roam-in                                    :0
L3 roam-out                                    :0
------------------------------------------------------------------------------
```

Table 11-163 Description of the **display station roam-statistics ap-name** *ap-name* command output

Item	Description
Online STAs	Number of online STAs.
Online roaming stations	Number of online roaming STAs.
Online L3 roam stations	Number of Layer 3 roaming STAs.
L3 roam-in	Number of STAs roaming from another AP to the local AP.
L3 roam-out	Number of STAs roaming from the local AP to another AP.

11.6.10 display station roam-track

Function

The **display station roam-track** command displays the roaming track of a STA.

Format

display station roam-track sta-mac *mac-address*

Parameters

Parameter	Description	Value
sta-mac *mac-address*	Specifies the MAC address of a specified STA.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

During the roaming process of a STA, the AC records the STA's roaming track (that is, information about the APs that the STA connects to). You can run the **display station roam-track** command to view the roaming track of the STA.

Example

Display the roaming track of the STA with the MAC address 00e0-fc00-0001.

```
<HUAWEI> display station roam-track sta-mac 00e0-fc00-0001
Access SSID:test

Number: 1
```

Table 11-164 Description of the **display station roam-track** command output

Item	Description
Access SSID	SSID associated with a STA.
Rx/Tx	Negotiated rate between the STA and AP.
L2/L3	Roaming mode. Suffix description: ● s: agile distributed SFN roaming ● c: PMK fast roaming. ● r: 802.11r fast roaming (over-the-air mode) ● d: 802.11r fast roaming (standard over-the-DS mode) ● p: 802.11r fast roaming (proprietary over-the-DS mode)
AP-AC IP	CAPWAP source IP address used by the AC that the STA is associated with for setting up a CAPWAP tunnel with the AP that the STA is associated with.
AC-AC IP	CAPWAP source IP address used by the AC that the STA is associated with for setting up CAPWAP tunnels with other ACs.

Item	Description
AP name	Name of an AP that the STA is associated with.
Radio ID	ID of a radio that the STA is associated with.
BSSID	BSSID of an AP that the STA is associated with.
TIME	Time duration when the STA is associated with an AP.
In/Out RSSI	RSSI of the AP that the STA is associated with and RSSI of the AP away from which the STA has left.
Out Rx/Tx	Negotiated rate of the STA when it disconnects from an AP.
Number	Number of STA roaming tracks.

11.6.11 dot11r enable

Function

The **dot11r enable** command enables 802.11r.

The **undo dot11r enable** command disables 802.11r.

By default, 802.11r is disabled.

Format

dot11r enable [**over-the-ds**]

undo dot11r enable

Parameters

Parameter	Description	Value
over-the-ds	Indicates 802.11r roaming in over-the-DS mode.	-

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During roaming, the STA needs to be reauthenticated and re-negotiate a key, so services are interrupted for a short period of time. You can enable 802.11r to reduce the number of information exchanges during roaming, thus reducing latency.

Precautions

- Security policies supported by 802.11r include open system, WPA2+PSK+AES, WPA2+PPSK+AES, and WPA2+802.1X+AES.
- The 802.11r and Protected Management Frame (PMF) functions are mutually exclusive. If the 802.11r function has been configured, the PMF function cannot be configured.
- Over-the-DS 802.11r roaming across ACs is not supported.

Example

Enable the 802.11r function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] dot11r enable
```

11.6.12 dot11r proprietary

Function

The **dot11r proprietary** command enables the Huawei's proprietary 802.11r function (device-pipe synergy roaming).

The **undo dot11r proprietary** command disables the Huawei's proprietary 802.11r function.

By default, Huawei's proprietary 802.11r function is disabled.

Format

dot11r proprietary

undo dot11r proprietary

Parameters

None

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Due to the characteristics of Wi-Fi and different behaviors of different terminals on the WLAN, the actual roaming experience for the terminals varies. The roaming experience for latency-sensitive services such as audio, video, and gaming cannot be guaranteed. Roaming optimization policies are different for terminals and APs and may conflict with each other. Therefore, simply optimization for terminals or APs cannot solve the problem. APs are optimized for Huawei's terminals running EMUI 10.0 or later. After the Huawei's proprietary 802.11r function is enabled, APs can carry the interworking IE in Beacon and Probe Response frames and perform roaming negotiation with Huawei terminals based on the specified frame format and interaction action. This function implements mutual trust and interworking between devices and pipes, reduces resource overheads during roaming negotiation, and effectively improves roaming experience.

Precautions

- Security policies supported by 802.11r include open system, WPA2+PSK+AES, WPA2+PPSK+AES, and WPA2+802.1X+AES.
- The 802.11r and Protected Management Frame (PMF) functions are mutually exclusive. If the 802.11r function has been configured, the PMF function cannot be configured.

Example

Enable the Huawei's proprietary 802.11r function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] dot11r proprietary
```

11.6.13 dot11r reassociate-timeout

Function

The **dot11r reassociate-timeout** command sets the 802.11r reassociation timeout period.

The **undo dot11r reassociate-timeout** command restores the default 802.11r reassociation timeout period.

By default, the 802.11r reassociation timeout period is 1s.

Format

dot11r reassociate-timeout *time*

undo dot11r reassociate-timeout

Parameters

Parameter	Description	Value
reassociate-timeout *time*	Specifies the reassociation timeout period. After successful authentication, if the STA does not initiate a reassociation request within this period, the roaming fails.	The value is an integer that ranges from 1 to 10, in seconds.

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During roaming, the STA needs to be reauthenticated and re-negotiate a key, so services are interrupted for a short period of time. You can enable 802.11r to reduce the number of information exchanges during roaming, thus reducing latency.

Precautions

- Security policies supported by 802.11r include open system, WPA2+PSK+AES, WPA2+PPSK+AES, and WPA2+802.1X+AES.
- The 802.11r and Protected Management Frame (PMF) functions are mutually exclusive. If the 802.11r function has been configured, the PMF function cannot be configured.

Example

Set the 802.11r reassociation timeout period to 3s.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] dot11r reassociate-timeout 3
```

11.6.14 member (mobility group view)

Function

The **member** command adds a member AC to a mobility group.

The **undo member** command deletes a member AC from a mobility group.

By default, no member AC is added to a mobility group.

Format

member ip-address *ipv4-address* [**description** *description*]

undo member ip-address *ipv4-address*

Parameters

Parameter	Description	Value
ip-address *ipv4-address*	Specifies the IPv4 address of a mobility group member.	The value is in dotted decimal notation.
description *description*	Description of a mobility group member.	The value is a string of 1 to 31 case-sensitive characters without spaces.

Views

mobility group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To enable a STA to roam between ACs, run the **mobility-group name** *group-name* command to configure a mobility group. The STA can roam between the ACs in the group. You can run the **member** command to add a member AC to the mobility group.

Precautions

An AC can be added only to one mobility group.

Example

Add the AC with IPv4 address 192.168.100.1 to the mobility group **mobility**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mobility-group name mobility
[HUAWEI-mc-mg-mobility] member ip-address 192.168.100.1
```

Remove the AC with IPv4 address 192.168.100.1 from the mobility group **mobility**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mobility-group name mobility
[HUAWEI-mc-mg-mobility] undo member ip-address 192.168.100.1
```

11.6.15 mobility-group

Function

The **mobility-group** command creates a mobility group and displays the mobility group view. If the specified mobility group exists, you can directly enter the specified mobility group view.

The **undo mobility-group** command deletes a mobility group.

By default, no mobility group is created.

Format

mobility-group name *group-name*

undo mobility-group { **name** *group-name* | **all** }

Parameters

Parameter	Description	Value
name *group-name*	Specifies the name of a mobility group.	The value is a string of 1 to 31 characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Indicates all mobility groups.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

STAs can roam between ACs in a mobility group. You can run the **mobility-group** command to create a mobility group and add required ACs to the group.

Follow-up Procedure

Run the **member ip-address** *ipv4-address* [**description** *description*] command to add member ACs to the mobility group.

Example

Create a mobility group named **mobility** and display the mobility group view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mobility-group name mobility
[HUAWEI-mc-mg-mobility]
```

Delete a mobility group.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] undo mobility-group name mobility
Warning:The mobility group will be deleted, are you sure to continue?[Y/N]:y
```

Delete all mobility groups.

11.6.16 mobility-server local

Function

The **mobility-server local** command configures a local IP address for setting up links between ACs in a mobility group.

The **undo mobility-server local** command deletes the local IP address for setting up links between ACs in a mobility group.

By default, no local IP address is configured for setting up links between ACs in a mobility group.

Format

mobility-server local ip-address *ipv4-address*

undo mobility-server local

Parameters

Parameter	Description	Value
ip-address *ipv4-address*	Specifies an IPv4 address for setting up links between ACs in a mobility group.	The value is in dotted decimal notation.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In inter-AC roaming scenarios, you need to specify a local IP address for STAs to roam between ACs.

Precautions

The specified IP address must be the same as the CAPWAP source IP address. When multiple CAPWAP source addresses are configured, only one can be specified as the local IP address for setting up links between ACs.

Example

Configure 192.168.10.1 as the local IP address for setting up links between ACs in a mobility group.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mobility-server local ip-address 192.168.10.1
```

11.6.17 sfn-roam enable

Function

The **sfn-roam enable** command enables agile distributed SFN roaming.

The **undo sfn-roam enable** command disables agile distributed SFN roaming.

By default, agile distributed SFN roaming is disabled.

Format

sfn-roam enable

undo sfn-roam enable

Parameters

None

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In the agile distributed Wi-Fi networking, some scenarios require high network connection stability, such as healthcare scenarios. In this case, you can run the **sfn-roam enable** command to enable agile distributed SFN roaming. All RUs are deployed to work on the same channel and use the same BSSID for communicating with STAs. When the STAs move within the signal coverage of the same SSID, they are not aware of roaming and services are not interrupted.

Example

Enable agile distributed SFN roaming.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] sfn-roam enable
Warning: This feature requires that radios work on the same channel. Enabling th
is feature will disable the channel calibration, channel scanning, and smart roa
ming functions on the AP and disconnect STAs connected to the VAP. Open, WEP, an
d WAPI encryption modes are not supported. The PSK + WPA2 mode is recommended. A
 radio allows SFN to be enabled only for one VAP. Continue?[Y/N]:y
```

11.6.18 sfn-roam report-interval

Function

The **sfn-roam report-interval** command sets an interval at which RUs report STA RSSIs.

The **undo sfn-roam report-interval** command restores the default interval at which RUs report STA RSSIs.

By default, RUs report STA RSSIs to the central AP at an interval of 400 milliseconds.

Format

sfn-roam report-interval *report-interval-value*

undo sfn-roam report-interval

Parameters

Parameter	Description	Value
report-interval-value	Specifies an interval for RUs to report STA RSSIs.	The value is an integer that ranges from 200 to 1000, in milliseconds.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

The interval at which RUs report STA RSSIs helps you adjust the roaming sensitivity. A shorter interval indicates a higher sensitivity. A large value causes a slow roaming handover, affecting user experience. A small value causes frequent roaming handovers, affecting system performance. This interval must be smaller than the decision period for agile distributed SFN roaming.

Example

Set the interval for RUs to report the STA RSSI to 500 milliseconds.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name wlan-rrm
[HUAWEI-wlan-rrm-prof-wlan-rrm] sfn-roam report-interval 500
```

11.6.19 sfn-roam roam-check better-times

Function

The **sfn-roam roam-check better-times** command sets the number of times the RSSI of agile distributed SFN roaming RUs is higher than that of the local RU.

The **undo sfn-roam roam-check better-times** command restores the default number of times the RSSI of agile distributed SFN roaming RUs is higher than that of the local RU.

By default, the number of times the RSSI of agile distributed SFN roaming RUs is higher than that of the local RU is 2.

Format

sfn-roam roam-check better-times *better-times*

undo sfn-roam roam-check better-times

Parameters

Parameter	Description	Value
better-times	Specifies the number of times the RSSI of agile distributed SFN roaming RUs is higher than that of the local RU.	The value is an integer that ranges from 1 to 32.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

You can adjust the roaming sensitivity by setting the number of times the RSSI of agile distributed SFN roaming RUs is higher than that of the local RU. A roaming handover occurs when the RSSI of a surrounding RU is higher than that of the local RU for the specified times within the roaming decision period. A large value causes a slow roaming handover, affecting user experience. A small value causes frequent roaming handovers, affecting system performance.

Example

Set the number of times the RSSI of agile distributed SFN roaming RUs is higher than that of the local RU to 5.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name wlan-rrm
[HUAWEI-wlan-rrm-prof-wlan-rrm] sfn-roam roam-check better-times 5
```

11.6.20 sfn-roam roam-check check-interval

Function

The **sfn-roam roam-check check-interval** command sets the decision period for agile distributed SFN roaming.

The **undo sfn-roam roam-check check-interval** command restores the default decision period for agile distributed SFN roaming.

The default decision period for agile distributed SFN roaming is 700 milliseconds.

Format

sfn-roam roam-check check-interval *check-interval-value*

undo sfn-roam roam-check check-interval

Parameters

Parameter	Description	Value
check-interval-value	Specifies the decision period for agile distributed SFN roaming.	The value is an integer that ranges from 300 to 1500, in milliseconds.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

The decision period for agile distributed SFN roaming helps you adjust the roaming sensitivity. A shorter period indicates a higher sensitivity. A large value causes a slow roaming handover, affecting user experience. A small value causes frequent roaming handovers, affecting system performance. The default value is recommended. Ensure that the interval at which RUs report STA RSSIs is smaller than the decision period for agile distributed SFN roaming.

Example

Set the default decision period for agile distributed SFN roaming to 800 milliseconds.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name wlan-rrm
[HUAWEI-wlan-rrm-prof-wlan-rrm] sfn-roam roam-check check-interval 800
```

11.6.21 sfn-roam roam-check gap-rssi

Function

The **sfn-roam roam-check gap-rssi** command sets the RSSI gap for agile distributed SFN roaming RUs.

The **undo sfn-roam roam-check gap-rssi** command restores the default RSSI gap for agile distributed SFN roaming RUs.

The default RSSI gap for agile distributed SFN roaming RUs is 6 dB.

Format

sfn-roam roam-check gap-rssi *gap-rssi*

undo sfn-roam roam-check gap-rssi

Parameters

Parameter	Description	Value
gap-rssi	Specifies the RSSI gap for agile distributed SFN roaming RUs.	The value is an integer that ranges from 1 to 32, in dB.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

The RSSI gap for agile distributed SFN roaming RUs helps you adjust the roaming sensitivity. A roaming handover occurs when the RSSI gap between the local RU and a surrounding RU reaches the specified value. A large value causes a slow roaming handover, affecting user experience. A small value causes frequent roaming handovers, affecting system performance.

Example

Set the RSSI gap for agile distributed SFN roaming RUs to 10 dB.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name wlan-rrm
[HUAWEI-wlan-rrm-prof-wlan-rrm] sfn-roam roam-check gap-rssi 10
```

11.6.22 sfn-roam roam-check high-threshold

Function

The **sfn-roam roam-check high-threshold** command sets the upper RSSI threshold for agile distributed SFN roaming.

The **undo sfn-roam roam-check high-threshold** command restores the default upper RSSI threshold for agile distributed SFN roaming.

By default, the upper RSSI threshold for agile distributed SFN roaming is -55 dBm.

Format

sfn-roam roam-check high-threshold *high-threshold-value*

undo sfn-roam roam-check high-threshold

Parameters

Parameter	Description	Value
high-threshold-value	Specifies the upper RSSI threshold for agile distributed SFN roaming.	The value is an integer that ranges from -60 to -45, in dBm.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can set the STA RSSI threshold to control the sensitivity of agile distributed SFN roaming and prevent STAs from frequently roaming at radio borders of RUs. A roaming handover occurs when the total number of records in the following conditions exceeds the value specified by the **sfn-roam roam-check better-times** command:

- When the HAP detects that the STA RSSI is lower than the lower threshold: The central AP makes a record if the SNR of the FAP is higher than that of the HAP.
- When the HAP detects that the STA RSSI is between the upper and lower thresholds: The central AP makes a record if the SNR of the FAP is 3 dB higher than that of the HAP.
- When the HAP detects that the STA RSSI is higher than the upper threshold: The central AP makes a record if the SNR of the FAP is 5 dB higher than that of the HAP.

Precautions

The lower RSSI threshold for agile distributed SFN roaming must be no higher than the upper threshold.

Example

Set the upper RSSI threshold for agile distributed SFN roaming to -50 dBm.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name wlan-rrm
[HUAWEI-wlan-rrm-prof-wlan-rrm] sfn-roam roam-check high-threshold -50
```

11.6.23 sfn-roam roam-check low-threshold

Function

The **sfn-roam roam-check low-threshold** command sets the lower RSSI threshold for agile distributed SFN roaming.

The **undo sfn-roam roam-check low-threshold** command restores the default lower RSSI threshold for agile distributed SFN roaming.

By default, the lower RSSI threshold for agile distributed SFN roaming is -60 dBm.

Format

sfn-roam roam-check low-threshold *low-threshold-value*

undo sfn-roam roam-check low-threshold

Parameters

Parameter	Description	Value
low-threshold-value	Specifies the lower RSSI threshold for agile distributed SFN roaming.	The value is an integer that ranges from -70 to -55, in dBm.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can set the STA RSSI threshold to control the sensitivity of agile distributed SFN roaming and prevent STAs from frequently roaming at radio borders of RUs. A roaming handover occurs when the total number of records in the following conditions exceeds the value specified by the **sfn-roam roam-check better-times** command:

- When the HAP detects that the STA RSSI is lower than the lower threshold: The central AP makes a record if the SNR of the FAP is higher than that of the HAP.
- When the HAP detects that the STA RSSI is between the upper and lower thresholds: The central AP makes a record if the SNR of the FAP is 3 dB higher than that of the HAP.
- When the HAP detects that the STA RSSI is higher than the upper threshold: The central AP makes a record if the SNR of the FAP is 5 dB higher than that of the HAP.

Precautions

The lower RSSI threshold for agile distributed SFN roaming must be no higher than the upper threshold.

Example

Set the lower RSSI threshold for agile distributed SFN roaming to -65 dBm.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name wlan-rrm
[HUAWEI-wlan-rrm-prof-wlan-rrm] sfn-roam roam-check low-threshold -65
```

11.6.24 sfn-roam roam-check rssi-accumulate

Function

The **sfn-roam roam-check rssi-accumulate** command sets the cumulative RSSI change threshold for agile distributed SFN roaming STAs.

The **undo sfn-roam roam-check rssi-accumulate** command restores the default cumulative RSSI change threshold for agile distributed SFN roaming STAs.

By default, the cumulative RSSI change threshold of agile distributed SFN roaming STAs is 8 dB.

Format

sfn-roam roam-check rssi-accumulate threshold *rssi-accumulate-value*

undo sfn-roam roam-check rssi-accumulate

Parameters

Parameter	Description	Value
threshold *rssi-accumulate-value*	Specifies the cumulative RSSI change threshold for agile distributed SFN roaming STAs.	The value is an integer that ranges from 1 to 32, in dB.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

The cumulative RSSI change threshold of agile distributed SFN roaming STAs helps you adjust the roaming sensitivity. A roaming handover occurs when the cumulative RSSI change value reaches the specified threshold. A large value causes a slow roaming handover, affecting user experience. A small value causes frequent roaming handovers, affecting system performance.

Example

Set the cumulative RSSI change threshold for agile distributed SFN roaming STAs to 10 dB.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name wlan-rrm
[HUAWEI-wlan-rrm-prof-wlan-rrm] sfn-roam roam-check rssi-accumulate threshold 10
```

11.6.25 sfn-roam roam-check sta-holding times

Function

The **sfn-roam roam-check sta-holding times** command sets the number of STA holding times for agile distributed SFN roaming.

The **undo sfn-roam roam-check sta-holding times** command restores the default number of STA holding times for agile distributed SFN roaming.

By default, the number of STA holding times for agile distributed SFN roaming is 3.

Format

sfn-roam roam-check sta-holding times *sta-holding-times*

undo sfn-roam roam-check sta-holding times

Parameters

Parameter	Description	Value
sta-holding-times	Specifies the number of STA holding times for agile distributed SFN roaming.	The value is an integer that ranges from 1 to 32.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

To prevent frequent agile distributed SFN roaming handovers, you can specify a proper number of STA holding times. A large value causes a slow roaming handover, affecting user experience. A small value causes frequent roaming handovers, affecting system performance.

Example

Set the number of STA holding times for agile distributed SFN roaming to 5.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name wlan-rrm
[HUAWEI-wlan-rrm-prof-wlan-rrm] sfn-roam roam-check sta-holding times 5
```

11.6.26 inter-ac roam disable

Function

The **inter-ac roam disable** command disables inter-AC roaming.

The **undo inter-ac roam disable** command enables inter-AC roaming.

By default, inter-AC roaming is enabled.

Format

inter-ac roam disable

undo inter-ac roam disable

Parameters

None

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

If STAs roam from one AC to another, they have to be re-authenticated to access the network. To limit the STA roaming scope within an AC, you can run the **inter-ac roam disable** command to disable inter-AC roaming.

Example

Disable inter-AC roaming.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name default
[HUAWEI-wlan-ssid-prof-default] inter-ac roam disable
```

11.7 WLAN QoS Configuration Commands

11.7.1 Command Support

WLAN-AC commands are supported only by the following models: S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.

11.7.2 airtime-fair-schedule enable

Function

The **airtime-fair-schedule enable** command enables airtime fair scheduling on an AP radio.

The **undo airtime-fair-schedule enable** command disables airtime fair scheduling on an AP radio.

By default, airtime fair scheduling is disabled on an AP radio.

Format

airtime-fair-schedule enable

undo airtime-fair-schedule enable

Parameters

None

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a WLAN, the physical layer rates of users have great differences due to different radio modes supported by the terminals or radio environment where the terminals reside. If the users with lower physical layer rates occupy wireless channels for a long period, user experience of the entire WLAN is affected. Airtime fair scheduling calculates the channel occupation time of users transmitting the same service and preferentially schedules resources for the users who occupy the wireless channel for a shorter period. This ensures fairness in channel usage.

After airtime fair scheduling is enabled, the device collects statistics on the channel occupation time used by users connected to the same radio for sending packets, creates the mapping table for the channel occupation time of each user in accumulated mode, and establishes a sorted link table based on the time in an ascending order. Based on the mapping table, an AP transmits data with the user who occupies the channel for the shortest time, ensuring that each user can equally occupy the wireless channels. The data packets of high-speed users are transmitted quickly, which is not affected by the data transmission time of low-speed users. This improves the overall user experience.

After WMM is enabled on the device and terminals, user packets are scheduled based on different types (service types include VI, VO, BE, and BK). For example, voice packets are scheduled only with other voice packets, and video packets are scheduled only with other video packets.

Precautions

If the packets of multiple users are of different types, airtime fair scheduling is not performed. For example, two users perform packet transmission: one transmits voice packets and the other transmits video packets. In this case, airtime fair scheduling is not performed for the two users.

When the command is executed, the system displays the message "Warning: This action may cause service interruption. Continue?[Y/N]", asking you whether you want to continue.

The airtime fair scheduling function is supported by the following models (enabled by default and cannot be configured using commands):

- AirEngine X760 series APs
- AirEngine X761 series APs

- AirEngine X762 series APs
- AirEngine X771 series APs
- AirEngine series central APs and RUs
- AirEngine 9700D-S (including matching ORUs)

Example

Enable airtime fair scheduling in RRM profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name default
[HUAWEI-wlan-rrm-prof-default] airtime-fair-schedule enable
```

11.7.3 app-share remark

Function

The **app-share remark** command sets a priority for Lync desktop sharing packets.

The **undo app-share remark** command deletes the priority of Lync desktop sharing packets.

By default, the priority of Lync desktop sharing packets is not set.

Format

app-share remark { **8021p** *8021p-value* | **dscp** { *dscp-value* | *dscp-name* } | **local-precedence** { *local-precedence-value* | *local-precedence-name* } }

undo app-share remark { **8021p** | **dscp** | **local-precedence** }

Parameters

Parameter	Description	Value
8021p *8021p-value*	Specifies the 802.1p priority.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.

Parameter	Description	Value
dscp { *dscp-value* | *dscp-name* }	Specifies the DSCP priority.	The value is a Diff-Serv code that is an integer ranging from 0 to 63, or a DSCP service type that can be af11, af12, af13, af21, af22, af23, af31, af32, af33, af41, af42, af43, cs1 to cs7, default, or ef. The values of service types are as follows: • af11: 10 • af12: 12 • af13: 14 • af21: 18 • af22: 20 • af23: 22 • af31: 26 • af32: 28 • af33: 30 • af41: 34 • af42: 36 • af43: 38 • cs1: 8 • cs2: 16 • cs3: 24 • cs4: 32 • cs5: 40 • cs6: 48 • cs7: 56 • default: 0 • ef: 46

Parameter	Description	Value
local-precedence { *local-precedence-value* | *local-precedence-name* }	Specifies the local priority.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority. Or, the value is a service type that can be af1, af2, af3, af4, be, cs6, cs7, or ef. The values of service types are as follows: ● af1: 1 ● af2: 2 ● af3: 3 ● af4: 4 ● be: 0 ● cs6: 6 ● cs7: 7 ● ef: 5

Views

UCC profile view

Default Level

2: Configuration level

Usage Guidelines

Application Scenarios

Microsoft Lync is a set of communication software that provides voice, video, desktop sharing, and file transfer functions. You can run the **app-share remark** command to change the priority of Lync desktop sharing packets.

Precautions

The 802.1p priority and local priority cannot be set for the Lync desktop sharing packets of one Lync session.

If you run the **app-share remark** command in the same UCC profile view multiple times to set the 802.1p priority, DSCP priority, or local priority of Lync desktop sharing packets, only the latest configuration takes effect.

Example

Set the DSCP priority of Lync desktop sharing packets to 1 in the UCC profile **test**.

```
<HUAWEI> system-view
[HUAWEI] ucc-profile name test
[HUAWEI-ucc-prof-test] app-share remark dscp 1
```

11.7.4 display references traffic-profile

Function

The **display references traffic-profile** command displays reference information about a traffic profile.

Format

display references traffic-profile name *profile-name*

Parameters

Parameter	Description	Value
name *profile-name*	Displays reference information about a specified traffic profile.	The traffic profile must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check the VAP profiles by which a specified traffic profile is referenced.

Example

Display reference information about the traffic profile **p1**.

```
<HUAWEI> display references traffic-profile name p1
----------------------------------------------------
Reference type     Reference name
----------------------------------------------------
VAP profile        default
VAP profile        wlan-vap
VAP profile        exam
VAP profile        test
VAP profile        wlan-vap1
VAP profile        example
VAP profile        2
----------------------------------------------------
Total: 7
```

Table 11-165 Description of the **display references traffic-profile** command output

Item	Description
Reference type	Type of the profile that references a traffic profile.
Reference name	Name of the profile that references a traffic profile.

11.7.5 display service-experience-analysis monitor-list

Function

The **display service-experience-analysis monitor-list** command displays information about applications monitored based on SEA.

Format

display service-experience-analysis monitor-list [**sta-mac** *sta-mac-address*]

Parameters

Parameter	Description	Value
sta-mac *sta-mac-address*	Displays information about SEA-monitored applications on the STA with a specified MAC address.	The STA's MAC address must exist.

Views

All views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to check information about applications monitored based on SEA, including the STA's MAC address, AP with which the STA is associated, and 5-tuple information in the flow table.

Example

Display information about applications monitored based on SEA.

```
<HUAWEI> display service-experience-analysis monitor-list
-------------------------------------------------------------------------------------------------------------------
STA MAC         AP ID AP name Radio ID Protocol Source IP/Port Destination IP/Port
-------------------------------------------------------------------------------------------------------------------
1000-0000-0001   1     AP1     1        23       1.1.1.1/100    2.2.2.2/2000
-------------------------------------------------------------------------------------------------------------------
Total: 1
```

Table 11-166 Description of the **display service-experience-analysis monitor-list** command output

Item	Description
STA MAC	MAC address of a STA.
AP ID	ID of the AP with which a STA is associated.
AP name	Name of the AP with which a STA is associated.
Radio ID	Radio ID of the AP with which a STA is associated.
Protocol	IP protocol number.
Source IP/Port	Source IP address and source port number.
Destination IP/Port	Destination IP address and destination port number.

11.7.6 display traffic-profile

Function

The **display traffic-profile** command displays configuration information about traffic profiles.

Format

display traffic-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays configuration information about all traffic profiles.	-

Parameter	Description	Value
name *profile-name*	Displays configuration information about a specified traffic profile.	The value is a string of 1 to 35 characters without spaces and question marks (?). It cannot begin or end with a double quotation mark (").

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check the default configurations of a new traffic profile or configurations of an existing traffic profile.

Example

Display configuration information about a traffic profile that maps the trusted user priority from 802.11 packets to tunnel packets when packets are sent from an AP to the AC.

```
<HUAWEI> display traffic-profile name p1
------------------------------------------------------------------------------------------

```

Table 11-167 Description of the **display traffic-profile** command output

Item	Description
Profile ID	Traffic profile ID.

Item	Description
Priority map downstream trust	Mapping from the 802.1p or DSCP priority of 802.3 packets to the 802.11 user priority when 802.3 packets are sent to an AP from upper-layer devices. To configure this parameter, run the **priority-map downstream trust** command.
User isolate mode	Whether user isolation is enabled. To configure this parameter, run the **user-isolate (traffic profile view)** command.
Rate limit client up(Kbps)	Upstream rate limit configured for STAs. To configure this parameter, run the **rate-limit** command.
Rate limit client up(Kbps) with time-range	Upstream rate limit configured for STAs in a specified time range. To configure this parameter, run the **rate-limit client time-range** command.
Rate limit client down(Kbps)	Downstream rate limit configured for STAs. To configure this parameter, run the **rate-limit** command.
Rate limit client down(Kbps) with time-range	Downstream rate limit configured for STAs in a specified time range. To configure this parameter, run the **rate-limit client time-range** command.
Rate limit VAP up(Kbps)	Upstream rate limit configured for a VAP. To configure this parameter, run the **rate-limit** command.
Rate limit VAP down(Kbps)	Downstream rate limit configured for a VAP. To configure this parameter, run the **rate-limit** command.

Item	Description
Rate limit client dynamic switch	Whether dynamic rate limiting is enabled for a single STA on a VAP. To configure this parameter, run the **rate-limit client dynamic disable** command.
Rate limit client dynamic(Mbps)	Dynamic rate limit threshold for a single STA on a VAP. To configure this parameter, run the **rate-limit client dynamic** command.
Traffic optimize ARP proxy	Whether proxy ARP is enabled for STAs. To configure this parameter, run the **traffic-optimize arp-proxy enable** command.
Traffic optimize ND proxy	Whether ND proxy is enabled for STAs. To configure this parameter, run the **traffic-optimize np-proxy enable** command.
Traffic optimize ARP unicast send	Whether the air interface is enabled to convert broadcast ARP packets into unicast packets. To configure this parameter, run the **traffic-optimize bcmc unicast-send** command.
Traffic optimize ND unicast send	Whether the air interface is enabled to convert multicast ND packets into unicast packets. To configure this parameter, run the **traffic-optimize bcmc unicast-send** command.
Traffic optimize DHCP unicast send	Whether the air interface is enabled to convert broadcast DHCP packets into unicast packets. To configure this parameter, run the **traffic-optimize bcmc unicast-send** command.
Traffic optimize mDNS unicast send	Whether the air interface is enabled to convert broadcast mDNS packets into unicast packets. To configure this parameter, run the **traffic-optimize bcmc unicast-send** command.

Item	Description
Traffic optimize multicast send deny	Whether the air interface is disabled from forwarding multicast packets. To configure this parameter, run the **traffic-optimize bcmc deny all** command.
Traffic optimize mdns forward	Whether the air interface allows mDNS packets to pass through. ● enable: The function of denying multicast packets on the air interface is disabled, or this function is enabled but mDNS packets are excluded. ● disable: The air interface is disabled from forwarding multicast packets and does not allow mDNS packets to pass through. To configure this parameter, run the **traffic-optimize bcmc deny all** command.
Traffic optimize sta bridge forward	Whether the air interface is configured to deny packets destined for bridge STAs. To configure this parameter, run the **traffic-optimize sta-bridge-forward disable** command.
Traffic optimize bcmc unicast send mismatch action	Action to be taken when the air interface fails to convert broadcast or multicast protocol packets into unicast packets. To configure this parameter, run the **traffic-optimize bcmc unicast-send mismatch-action drop** command.
MLD snooping	Whether MLD snooping is enabled. To configure this parameter, run the **mld-snooping enable (traffic profile view)** command.
IGMP snooping	Whether IGMP snooping is enabled. To configure this parameter, run the **igmp-snooping enable (traffic profile view)** command.

Item	Description
Spectralink voice priority	Whether SVP voice traffic optimization is enabled. To configure this parameter, run the **svp-voice enable** command.
IGMP snooping report suppress	IGMP message suppression time. To configure this parameter, run the **igmp-snooping report-suppress (traffic profile view)** command.
IGMP snooping max bandwidth(kbps)	Maximum multicast bandwidth of a VAP. To configure this parameter, run the **igmp-snooping max-bandwidth (traffic profile view)** command.
IGMP snooping max user	Maximum number of multicast group memberships on a VAP. To configure this parameter, run the **igmp-snooping max-user (traffic profile view)** command.
Traffic optimize broadcast suppression(pps)	Maximum broadcast traffic volume allowed on an interface. To configure this parameter, run the **traffic-optimize broadcast-suppression** command.
Traffic optimize multicast suppression(pps)	Maximum multicast traffic volume allowed on an interface. To configure this parameter, run the **traffic-optimize multicast-suppression** command.
Traffic optimize unicast suppression(pps)	Maximum unicast traffic volume allowed on an interface. To configure this parameter, run the **traffic-optimize unicast-suppression** command.
Traffic optimize multicast to unicast	Whether multicast-to-unicast conversion is enabled. To configure this parameter, run the **traffic-optimize multicast-unicast enable** command.

Item	Description
Dynamic adaptive	Whether adaptive multicast-to-unicast conversion is enabled. To configure this parameter, run the **traffic-optimize multicast-unicast dynamic-adaptive disable** command.
CAPWAP priority upstream map mode	Mapping from the WMM priority of upstream tunnel packets to the DSCP priority.
Priority map tunnel upstream trust	Trusted priority mapping from 802.11 packets to tunnel packets when data packets are sent to the AC from an AP. To configure this parameter, run the **priority-map tunnel-upstream trust** command.
Priority map upstream trust	Trusted priority mapping from 802.11 packets to 802.3 packets when data packets are sent to the AC from an AP. To configure this parameter, run the **priority-map upstream trust** command.
WMM priority downstream map mode	Mapping from the DSCP priority of downstream packets to the WMM priority.
priority upstream map mode	Tunnel upstream mapping when the trusted mapping from 802.11 packets to tunnel packets is DSCP, and data packets are sent to the AC from an AP.
Traffic Type	Traffic control type.
Direction(Traffic Type: traffic-filter)	Direction to which packet filtering is applied. To configure this parameter, run the **traffic-filter (traffic profile view)** command.
AppliedRecord(Traffic Type: traffic-filter)	Application records of ACL-based packet filtering. To configure this parameter, run the **traffic-filter (traffic profile view)** command.

Item	Description
Direction(Traffic Type: traffic-remark)	Direction to which packet priority re-marking is applied. To configure this parameter, run the **traffic-remark (traffic profile view)** command.
RemarkType	Packet priority re-marking type. To configure this parameter, run the **traffic-remark (traffic profile view)** command.
RemarkValue	Re-marked packet priority value. To configure this parameter, run the **traffic-remark (traffic profile view)** command.
AppliedRecord(Traffic Type: traffic-remark)	Application records of ACL-based packet priority re-marking. To configure this parameter, run the **traffic-remark (traffic profile view)** command.
AppliedRecord(Wlan-slice high-reliability traffic filter info)	ACL-based rule records for air interface slicing. To configure this parameter, run the **wlan-slice high-reliability acl** command.

Display configurations of all traffic profiles.

```
<HUAWEI> display traffic-profile all
----------------------------------------------------
Profile name                      Reference
----------------------------------------------------
default                          3
1                                1
p1                               0
----------------------------------------------------
Total: 3
```

Table 11-168 Description of the **display traffic-profile all** command output

Item	Description
Profile name	Profile name. To configure this parameter, run the **traffic-profile (WLAN view)** command.
Reference	Number of times a traffic profile is referenced.

11.7.7 display ucc-profile

Function

The **display ucc-profile** command displays the UCC profile configuration and application.

Format

display ucc-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays information about all UCC profiles.	-
name *profile-name*	Displays information about the specified UCC profile.	The value must be the name of an existing UCC profile.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After a UCC profile is configured, run the **display ucc-profile** command to check the UCC profile configuration and information about the UCC profile bound to a VAP profile.

Example

Display information about all UCC profiles.

```
<HUAWEI> display ucc-profile all
----------------------------------------------------------
Profile name                  Reference
----------------------------------------------------------
test                        1
----------------------------------------------------------
```

Table 11-169 Description of the **display ucc-profile all** command output

Item	Description
Profile name	Name of the UCC profile.
Reference	Number of times the UCC profile is bound to the VAP profile.

Display information about the UCC profile **test**.

```
<HUAWEI> display ucc-profile name test
----------------------------------------------------------------------------------
Lync app share 802.1p precedence     : -
Lync app share DSCP precedence       : -
Lync app share local precedence      : -
Lync file transfer 802.1p precedence : -
Lync file transfer DSCP precedence   : -
Lync file transfer local precedence  : -
Lync video 802.1p precedence         : 6
Lync video DSCP precedence           : -
Lync video local precedence          : -
Lync voice 802.1p precedence         : -
Lync voice DSCP precedence           : -
Lync voice local precedence          : -
----------------------------------------------------------------------------------
```

Table 11-170 Description of the **display ucc-profile name test** command output

Item	Description
Lync app share 802.1p precedence	802.1p priority of Lync desktop sharing packets. To configure the 802.1p priority of Lync desktop sharing packets, run the **app-share remark** command.
Lync app share DSCP precedence	DSCP priority of Lync desktop sharing packets. To configure the DSCP priority of Lync desktop sharing packets, run the **app-share remark** command.
Lync app share local precedence	Local priority of Lync desktop sharing packets. To configure the local priority of Lync desktop sharing packets, run the **app-share remark** command.
Lync file transfer 802.1p precedence	802.1p priority of Lync file transfer packets. To configure the 802.1p priority of Lync file transfer packets, run the **file-transfer remark** command.

Item	Description
Lync file transfer DSCP precedence	DSCP priority of Lync file transfer packets. To configure the DSCP priority of Lync file transfer packets, run the **file-transfer remark** command.
Lync file transfer local precedence	Local priority of Lync file transfer packets. To configure the local priority of Lync file transfer packets, run the **file-transfer remark** command.
Lync video 802.1p precedence	802.1p priority of Lync video packets. To configure the 802.1p priority of Lync video packets, run the **video remark** command.
Lync video DSCP precedence	DSCP priority of Lync video packets. To configure the DSCP priority of Lync video packets, run the **video remark** command.
Lync video local precedence	Local priority of Lync video packets. To configure the local priority of Lync video packets, run the **video remark** command.
Lync voice 802.1p precedence	802.1p priority of Lync voice packets. To configure the 802.1p priority of Lync voice packets, run the **voice remark** command.
Lync voice DSCP precedence	DSCP priority of Lync voice packets. To configure the DSCP priority of Lync voice packets, run the **voice remark** command.
Lync voice local precedence	Local priority of Lync voice packets. To configure the local priority of Lync voice packets, run the **voice remark** command.

11.7.8 file-transfer remark

Function

The **file-transfer remark** command sets a priority for Lync file transfer packets.

The **undo file-transfer remark** command deletes the priority of Lync file transfer packets.

By default, the priority of Lync file transfer packets is not set.

Format

file-transfer remark { **8021p** *8021p-value* | **dscp** { *dscp-value* | *dscp-name* } | **local-precedence** { *local-precedence-value* | *local-precedence-name* } }

undo file-transfer remark { **8021p** | **dscp** | **local-precedence** }

Parameters

Parameter	Description	Value
8021p *8021p-value*	Specifies the 802.1p priority.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.

Parameter	Description	Value
dscp { *dscp-value* | *dscp-name* }	Specifies the DSCP priority.	The value is a Diff-Serv code that is an integer ranging from 0 to 63, or a DSCP service type that can be af11, af12, af13, af21, af22, af23, af31, af32, af33, af41, af42, af43, cs1 to cs7, default, or ef. The values of service types are as follows: ● af11: 10 ● af12: 12 ● af13: 14 ● af21: 18 ● af22: 20 ● af23: 22 ● af31: 26 ● af32: 28 ● af33: 30 ● af41: 34 ● af42: 36 ● af43: 38 ● cs1: 8 ● cs2: 16 ● cs3: 24 ● cs4: 32 ● cs5: 40 ● cs6: 48 ● cs7: 56 ● default: 0 ● ef: 46

Parameter	Description	Value
local-precedence { *local-precedence-value* | *local-precedence-name* }	Specifies the local priority.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority. Or, the value is a service type that can be af1, af2, af3, af4, be, cs6, cs7, or ef. The values of service types are as follows: ● af1: 1 ● af2: 2 ● af3: 3 ● af4: 4 ● be: 0 ● cs6: 6 ● cs7: 7 ● ef: 5

2: Configuration level

Usage Guidelines

Application Scenarios

Microsoft Lync is a set of communication software that provides voice, video, desktop sharing, and file transfer functions. You can run the **file-transfer remark** command to change the priority of Lync file transfer packets.

Precautions

The 802.1p priority and local priority cannot be set for the Lync file transfer packets of one Lync session.

If you run the **file-transfer remark** command in the same UCC profile view multiple times to set the 802.1p priority, DSCP priority, or local priority of Lync file transfer packets, only the latest configuration takes effect.

Example

Set the DSCP priority of Lync file transfer packets to 1 in the UCC profile **test**.

```
<HUAWEI> system-view
[HUAWEI] ucc-profile name test
[HUAWEI-ucc-prof-test] file-transfer remark dscp 1
```

11.7.9 game-turbo disable

Function

The **game-turbo disable** command disables the game-turbo function.

The **undo game-turbo disable** command enables the game-turbo function.

By default, the game-turbo function is enabled.

NOTE

The game turbo function is not supported by the following models:

- AirEngine 5761-10W, AirEngine 5761-10WD, and AirEngine 5761S-10W

Format

game-turbo disable

undo game-turbo disable

Parameters

None

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When you are playing online games through a WLAN, a network latency may easily lead to skill out-of-control or slow response to actions, deteriorating user experience. In this case, you can enable the game-turbo function to optimize game traffic and reduce the game latency.

Currently, the game-turbo function is available for the following mobile games: *Game for Peace*, *Arena of Valor*, and *World of Tanks Blitz*.

Precautions

Before enabling the game-turbo function, enable the DFI function for application identification.

Example

Enable the game-turbo function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name p1
[HUAWEI-wlan-ssid-prof-p1] undo game-turbo disable
```

11.7.10 lync acl

Function

The **lync acl** command configures the switch to use an ACL to filter packets sent by the Lync server.

The **undo lync acl** command cancels the configuration.

By default, the switch does not use any ACL to filter packets sent by the Lync server.

Format

lync acl *acl-number*

undo lync acl

Parameters

Parameter	Description	Value
acl-number	Specifies the number of an ACL. The basic or advanced ACL must have been created.	The value is an integer. ● A basic ACL ranges from 2000 to 2999. ● An advanced ACL ranges from 3000 to 3999.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the switch communicates with the Lync server, to prevent the switch against many packets sent by bogus Lync servers, run the **lync acl** command to configure the switch to use an ACL to filter packets sent by the Lync server.

Prerequisites

A basic or advanced ACL has been created and rules have been configured.

Example

Configure ACL 2001 to allow packets that carry the source address of 192.168.32.1 and are sent by the Lync server.

```
<HUAWEI> system-view
[HUAWEI] acl 2001
[HUAWEI-acl-basic-2001] rule permit source 192.168.32.1 0
[HUAWEI-acl-basic-2001] quit
[HUAWEI] lync acl 2001
```

11.7.11 lync listener

Function

The **lync listener** command configures the switch to communicate with the Lync server and specifies the port number.

The **undo lync listener** command cancels the configuration.

By default, the switch is not configured to communicate with the Lync server and the port number is not specified.

Format

lync listener { **http-port** *port-num* | **https-port** *port-num* **ssl-policy** *ssl-policy* }

undo lync listener

Parameters

Parameter	Description	Value
http-port *port-num*	Specifies the port number of the HTTP service.	The value is an integer that ranges from 1025 to 55535.
https-port *port-num*	Specifies the port number of the HTTPS service.	The value is an integer that ranges from 1025 to 55535.
ssl-policy *ssl-policy*	Specifies the SSL policy to be bound. The SSL policy must be a server SSL policy.	The value must be the name of an existing SSL policy.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Microsoft Lync is a set of communication software that provides voice, video, desktop sharing, and file transfer functions. To ensure normal running of Lync software, configure the switch to communicate with the Lync server.

Precautions

To prevent the impact on the exchange with the Lync server, you are advised to use the port number that is not in use. You can run the **display ip socket register-port** command to check used port numbers.

Example

Configure the switch to communicate with the Lync server and specify HTTP port 2000.

```
<HUAWEI> system-view
[HUAWEI] lync listener http-port 2000
```

11.7.12 multimedia-air-optimize congestion-control tcp-window-tuning disable

Function

The **multimedia-air-optimize congestion-control tcp-window-tuning disable** command disables the TCP window adjustment function for voice and video services.

The **undo multimedia-air-optimize congestion-control tcp-window-tuning disable** command enables the TCP window adjustment function for voice and video services.

By default, the TCP window adjustment function for voice and video services is enabled.

NOTE

The intelligent multimedia scheduling algorithm is supported only by the following models:

- AirEngine X760 series APs
- AirEngine X761 series APs (excluding the AirEngine 5761-10W, AirEngine 5761-10WD, and AirEngine 5761S-10W)
- AirEngine 9700D-S (including matching ORUs)

Format

multimedia-air-optimize congestion-control tcp-window-tuning disable

undo multimedia-air-optimize congestion-control tcp-window-tuning disable

Parameters

None

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a STA has heavy-traffic services of the AC_BE or AC_BK type in the uplink, packets are frequently sent, and the duration of a single packet transmission is long, the delay of key services in the downlink of the AP is significantly increased. If key downlink services are affected, the system considers performing congestion control on heavy-traffic services of the AC_BE or AC_BK type. The **multimedia-air-optimize congestion-control tcp-window-tuning disable** command is involved for AP uplink congestion control. After the **undo multimedia-air-optimize congestion-control tcp-window-tuning disable** command is executed, the TCP window adjustment function is enabled for voice and video services. If the delay of voice or video services reaches the threshold and the packet transmission duration of heavy-traffic TCP background services in the uplink reaches the threshold within the unit time (1s), the receiver window (RWND) in TCP ACK packets can be dynamically adjusted. This process takes about 5s to 10s. After the adjustment, the uplink data volume sent by STAs is reduced, thereby ensuring user experience of voice and video services.

Prerequisites

The intelligent multimedia scheduling algorithm has been enabled using the **undo multimedia-air-optimize disable** command.

Example

Enable the TCP window adjustment function for voice and video services.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name p1
[HUAWEI-wlan-rrm-prof-p1] undo multimedia-air-optimize disable
[HUAWEI-wlan-rrm-prof-p1] undo multimedia-air-optimize congestion-control tcp-window-tuning
disable
```

11.7.13 multimedia-air-optimize downlink-delay-guarantee

Function

The **multimedia-air-optimize downlink-delay-guarantee** command configures the guaranteed delay for services of different categories.

The **undo multimedia-air-optimize downlink-delay-guarantee** command restores the default guaranteed delay for services of different categories.

The default guaranteed delay for services of different categories is **medium**.

NOTE

The intelligent multimedia scheduling algorithm is supported only by the following models:

- AirEngine X760 series APs
- AirEngine X761 series APs (excluding the AirEngine 5761-10W, AirEngine 5761-10WD, and AirEngine 5761S-10W)
- AirEngine 9700D-S (including matching ORUs)

Format

multimedia-air-optimize downlink-delay-guarantee { **voice** | **video** | **best-effort** | **background** } { **low** | **medium** | **high** | **off** }

undo multimedia-air-optimize downlink-delay-guarantee

Parameters

Parameter	Description	Value
voice	Specifies voice (AC_VO) packets.	-
video	Specifies video (AC_VI) packets.	-
best-effort	Specifies best-effort (AC_BE) packets.	-
background	Specifies background (AC_BK) packets.	-
low	Sets the guaranteed delay for the service of a specified category to **low**. For specific values, see **Table 11-171**.	-
medium	Sets the guaranteed delay for the service of a specified category to **medium**. For specific values, see **Table 11-171**.	-
high	Sets the guaranteed delay for the service of a specified category to **high**. For specific values, see **Table 11-171**.	-
off	Specifies no delay guarantee for the service of a specified category.	-

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If users have requirements for the delay of voice, best-effort, background, and video services on the air interface, run the **multimedia-air-optimize downlink-delay-guarantee** command to configure the guaranteed delay for voice and video services. With this configuration, the system monitors the delay of services on the air interface in real time. When detecting the delay exceeding the guaranteed delay, the system triggers delay optimization for the corresponding service to ensure that the delay after optimization does not exceed the guaranteed delay.

Table 11-171 Delay guarantee for services

Parameter	Video (UP: 4)	Video (UP: 5)	Voice	Best-Effort	Background
low	Delay < 300 ms	Delay < 100 ms	Delay < 50 ms	Delay < 400 ms	Delay < 500 ms
medium	Delay < 200 ms	Delay < 50 ms	Delay < 20 ms	Delay < 300 ms	Delay < 400 ms
high	Delay < 100 ms	Delay < 20 ms	Delay < 5 ms	Delay < 200 ms	Delay < 300 ms
off	No delay guarantee	No delay guarantee	No delay guarantee	No delay guarantee	No delay guarantee

- UP 4: video applications that support caching, such as online network video and live streaming
- UP 5: video applications that do not support caching, such as network videoconferencing

Prerequisites

The intelligent multimedia scheduling algorithm has been enabled using the **undo multimedia-air-optimize disable** command.

Example

Set the guaranteed delay for video services to **low** and that for voice services to **high**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name p1
[HUAWEI-wlan-rrm-prof-p1] undo multimedia-air-optimize disable
[HUAWEI-wlan-rrm-prof-p1] multimedia-air-optimize downlink-delay-guarantee video low
[HUAWEI-wlan-rrm-prof-p1] multimedia-air-optimize downlink-delay-guarantee voice high
```

11.7.14 multimedia-air-optimize disable

Function

The **multimedia-air-optimize disable** command disables the intelligent multimedia scheduling algorithm.

The **undo multimedia-air-optimize disable** command enables the intelligent multimedia scheduling algorithm.

By default, the intelligent multimedia scheduling algorithm is enabled.

NOTE

The intelligent multimedia scheduling algorithm is supported only by the following models:

- AirEngine X760 series APs
- AirEngine X761 series APs (excluding the AirEngine 5761-10W, AirEngine 5761-10WD, and AirEngine 5761S-10W)
- AirEngine 9700D-S (including matching ORUs)

Format

multimedia-air-optimize disable

undo multimedia-air-optimize disable

Parameters

None

Views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the intelligent multimedia scheduling algorithm is enabled, the system optimizes the air interface traffic in the following aspects:

- Delay guarantee for downlink VI/VO/BE/BK services on an AP

  The system periodically calculates the air interface delay of downlink VI/VO/BE/BK services. When detecting that the current delay exceeds the configured guaranteed delay, the system triggers service delay optimization. The guaranteed delay for VI/VO/BE/BK services is configured using the **multimedia-air-optimize downlink-delay-guarantee** command. After delay optimization for services is complete, the system tries its best to ensure that the service delay does not exceed the guaranteed delay. In addition, the system restricts the VI/VO/BE/BK services of low-speed STAs. Low-speed STAs typically have low transmission efficiency and occupy air interface resources for a long time, increasing the overall delay of VI/VO/BE/BK services. Therefore, the transmission opportunity for such STAs needs to be reduced.

- Delay guarantee for uplink services on an AP

  The system periodically calculates the air interface delay of uplink services (mainly voice and video services, with a user priority of 5 or higher). When detecting that the current delay exceeds the guaranteed delay, the system triggers service delay optimization. The delay guarantee function for uplink services on an AP can be enabled by using the **undo multimedia-air-optimize uplink-delay-guarantee disable** command. After delay optimization for services is complete, the system tries its best to ensure that the service delay does not exceed the guaranteed delay. In addition, the system restricts the uplink services of low-speed STAs. Low-speed STAs typically have low transmission efficiency and occupy air interface resources for a long time, increasing the overall delay of uplink services. Therefore, the transmission opportunity for such STAs needs to be reduced.

- Preferential scheduling for downlink VI/VO services on an AP

  During software scheduling, VI/VO services are preferentially scheduled. That is, each time the scheduler queries queue information, if the total packet sending time of the current VI/VO queue does not exceed the threshold, the services in the video/voice queue are preferentially scheduled. The threshold is calculated based on the slicing ratio for voice and video services configured using the **multimedia-air-optimize downlink-slice-ratio** command.

- Uplink congestion control for an AP

  When a STA has heavy-traffic services of the AC_BE or AC_BK type in the uplink, packets are frequently sent, and the duration of a single packet transmission is long, the delay of key services in the downlink of the AP is significantly increased. If key downlink services are affected, the system considers performing congestion control on heavy-traffic services of the AC_BE or AC_BK type. The **multimedia-air-optimize congestion-control tcp-window-tuning disable** command is involved for AP uplink congestion control. After the **undo multimedia-air-optimize congestion-control tcp-window-tuning disable** command is executed, the TCP window adjustment function is enabled for voice and video services. If the delay of voice or video services reaches the threshold and the packet transmission duration of heavy-traffic TCP background services in the uplink reaches the threshold within the unit time (1s), the receiver window (RWND) in TCP ACK packets can be dynamically adjusted. This process takes about 5s to 10s. After the adjustment, the uplink data volume sent by STAs is reduced, thereby ensuring user experience of voice and video services.

- WMM parameter adjustment based on the number of access STAs

  After the intelligent multimedia scheduling algorithm is enabled, the system dynamically adjusts WMM parameters based on the number of access users, improving voice and video service experience.

  The number of voice/video users is identified based on the user packet threshold configured using the **multimedia-air-optimize threshold** command. If the number of voice or video packets sent by a user in the internal statistics queue of a radio within the unit time (1 second) exceeds the threshold, the user is considered a voice or video user.

Ensure that the WMM function is enabled (default). To enable the WMM function, run the **undo wmm disable**.

Precautions

After the **undo multimedia-air-optimize disable** command is executed, the **wmm edca-ap** and **wmm edca-client (SSID profile view)** commands do not take effect.

Example

Enable the intelligent multimedia scheduling algorithm in the RRM profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name p1
[HUAWEI-wlan-rrm-prof-p1] undo multimedia-air-optimize disable
```

11.7.15 multimedia-air-optimize threshold

Function

The **multimedia-air-optimize threshold** command sets a user packet threshold in the intelligent multimedia scheduling algorithm.

The **undo multimedia-air-optimize threshold** command restores the default user packet threshold.

By default, the video user packet threshold is 100 pps, and the default voice user packet threshold is 30 pps.

NOTE

The intelligent multimedia scheduling algorithm is supported only by the following models:

- AirEngine X760 series APs
- AirEngine X761 series APs (excluding the AirEngine 5761-10W, AirEngine 5761-10WD, and AirEngine 5761S-10W)
- AirEngine 9700D-S (including matching ORUs)

Format

multimedia-air-optimize threshold { **video** *video* | **voice** *voice* } *

undo multimedia-air-optimize threshold

Parameters

Parameter	Description	Value
video *video*	Specifies the video packet threshold.	The value is an integer that ranges from 10 to 1000.
voice *voice*	Specifies the voice packet threshold.	The value is an integer that ranges from 10 to 1000.

Usage Guidelines

Usage Scenario

After the intelligent multimedia scheduling algorithm is enabled, the system uses algorithms to dynamically adjust EDCA parameters and ACK policies based on the number of access users, improving user experience of voice and video applications.

Prerequisites

The intelligent multimedia scheduling algorithm has been enabled using the **undo multimedia-air-optimize disable** command.

Example

Set the user packet thresholds for voice and video services in the intelligent multimedia scheduling algorithm.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name p1
[HUAWEI-wlan-rrm-prof-p1] multimedia-air-optimize threshold video 100 voice 30
```

11.7.16 priority-map downstream dot1p

Function

The **priority-map downstream dot1p** command configures mapping from 802.1p priorities of 802.3 packets to user priorities of 802.11 packets when packets are sent to an AP from upper-layer devices.

The **undo priority-map downstream dot1p** command restores the default mapping from 802.1p priorities of 802.3 packets to user priorities of 802.11 packets when packets are sent to an AP from upper-layer devices.

By default, 802.1p priority 0 of 802.3 packets maps to user priority 0 of 802.11 packets, 802.1p priority 1 to user priority 1, and similarly, 802.1p priority 7 to user priority 7.

Format

priority-map downstream dot1p { *dot1p-value1* [**to** *dot1p-value2*] } &<1-7> **dot11e** *dot11e-value*

undo priority-map downstream dot1p

Parameters

Parameter	Description	Value
dot1p *dot1p-value1*	Specifies the 802.1p priority in an 802.3 packet.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.
to *dot1p-value2*	Specifies the 802.1p priority in an 802.3 packet.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority. *dot1p-value2* must be greater than *dot1p-value1*.
dot11e *dot11e-value*	Specifies the user priority of 802.11 packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

802.3 and 802.11 data packets use different fields to identify their priorities. 802.11 packets sent from a WMM-capable STA carry the user priority (also called the User Priority field), and VLAN tagged-802.3 packets transmitted on the Ethernet contain 802.1p priorities (also called the CoS field). When data packets are forwarded from the AC or upper-layer network to an AP, the AP needs to convert the 802.3 packets to 802.11 packets and map the 802.1p priority carried in the 802.3 packet header to the user priority of 802.11 packets. You can use the **priority-map downstream dot1p** command to configure mapping from 802.1p priorities of 802.3 packets to user priorities of 802.11 packets.

Example

Configure the mapping from 802.1p priorities of 802.3 packets to user priorities of 802.11 packets in traffic profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] priority-map downstream dot1p 0 dot11e 2
```

11.7.17 priority-map downstream dscp

Function

The **priority-map downstream dscp** command configures mapping from the DSCP priority of 802.3 packets to the user priority of 802.11 packets when packets are sent to an AP from upper-layer devices.

The **undo priority-map downstream dscp** command restores the default mapping from the DSCP priority of 802.3 packets to the user priority of 802.11 packets when packets are sent to an AP from upper-layer devices.

Table 11-172 describes the default mapping from the DSCP priority of 802.3 packets to the user priority of 802.11 packets.

Table 11-172 Default mapping from the DSCP priority of 802.3 packets to the user priority of 802.11 packets

DSCP	UP
0-7	0
8-15	1
16-23	2
24-31	3
32-39	4
40-47	5
48-55	6
56-63	7

Format

priority-map downstream dscp { *dscp-value1* [**to** *dscp-value2*] } &<1-10> **dot11e** *dot11e-value*

undo priority-map downstream dscp

Parameters

Parameter	Description	Value
dscp *dscp-value1*	Specifies the DSCP priority of 802.3 packets.	The value is an integer that ranges from 0 to 63. A larger value indicates a higher priority.
to *dscp-value2*	Specifies the DSCP priority of 802.3 packets.	The value is an integer that ranges from 0 to 63. A larger value indicates a higher priority. *dscp-value2* must be greater than *dscp-value1*.
dot11e *dot11e-value*	Specifies the user priority of 802.11 packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

802.3 and 802.11 data packets use different fields to identify their priorities. 802.11 packets sent from a WMM-capable STA carry the user priority (also called the User Priority field), and IP packets transmitted on an Ethernet carry the DSCP priority (also called the ToS field). When data packets are forwarded from the central AP or upper-layer network to an RU, the RU needs to convert the 802.3 packets to 802.11 packets and map the ToS field in the IP packet header to the UP field of 802.11 packets. You can use the **priority-map downstream dscp** command to configure mapping from the DSCP priority of 802.3 packets to the user priority of 802.11 packets.

Example

Configure mapping from the DSCP priority of 802.3 packets in traffic profile **p1** to the user priority of 802.11 packets.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] priority-map downstream dscp 0 to 6 dot11e 0
```

11.7.18 priority-map downstream trust

Function

The **priority-map downstream trust** command configures a trusted priority type used in mapping from 802.3 packets to 802.11 packets when packets are sent to an AP from upper-layer devices.

The **undo priority-map downstream trust** command restores the default trusted priority type used in mapping from 802.3 packets to 802.11 packets when packets are sent to an AP from upper-layer devices.

By default, the DSCP priority is used in mapping from 802.3 packets to 802.11 packets when packets are sent to an AP from upper-layer devices.

Format

priority-map downstream trust { **dot1p** | **dscp** }

undo priority-map downstream trust

Parameters

Parameter	Description	Value
dot1p	Specifies the 802.1p priority as the trusted priority type used in mapping from 802.3 packets to 802.11 packets.	-
dscp	Specifies the DSCP priority as the trusted priority type used in mapping from 802.3 packets to 802.11 packets.	-

Views

Traffic profile view

2: Configuration level

Usage Guidelines

802.3 and 802.11 data packets use different fields to identify their priorities. 802.11 packets sent from a WMM-capable STA carry the user priority (also called the User Priority field). On a wired network, VLAN packets carry the 802.1p priority and IP packets carry the DSCP priority. When data packets are forwarded from the AC or other upper-layer devices to an AP, the packets must be converted from 802.3 packets to 802.11 packets.

You can run the **priority-map downstream trust** command to configure a trusted priority type used in mapping from 802.3 packets to 802.11 packets when packets are sent to an AP from upper-layer devices.

Example

In traffic profile **p1**, configure the 802.1p priority as the trusted priority type used in mapping from 802.3 packets to 802.11 packets when packets are sent to an AP from upper-layer devices.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] priority-map downstream trust dot1p
```

11.7.19 priority-map tunnel-upstream dot11e dscp

Function

The **priority-map tunnel-upstream dot11e dscp** command configures mapping from the user priority of 802.11 packets to the DSCP priority of tunnel packets when packets are sent to the AC from an AP.

The **undo priority-map tunnel-upstream dot11e dscp** command restores the default mapping from the user priority of 802.11 packets to the DSCP priority of tunnel packets when packets are sent to the AC from an AP.

Table 11-173 describes the default mapping from the user priority of 802.11 packets to the DSCP priority of tunnel packets.

NOTE

The CAPWAP header refers to the tunnel header.

Table 11-173 Default mapping from user priorities of 802.11 packets to DSCP priorities in CAPWAP headers

User Priority of 802.11 Packets	DSCP Priority in the CAPWAP Header
0	0
1	8
2	16
3	24
4	32
5	40
6	48
7	56

Format

priority-map tunnel-upstream dot11e { *dot11e-value1* [**to** *dot11e-value2*] } &<1-7> **dscp** *dscp-value*

undo priority-map tunnel-upstream dot11e to dscp

Parameters

Parameter	Description	Value
dot11e *dot11e-value1*	Specifies the user priority of 802.11 packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.
to *dot11e-value2*	Specifies the user priority of 802.11 packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority. *dot11e-value2* must be greater than *dot11e-value1*.
dscp *dscp-value*	Specifies the DSCP priority of tunnel packets.	The value is an integer that ranges from 0 to 63. A larger value indicates a higher priority.

2: Configuration level

Usage Guidelines

Usage Scenario

To provide QoS guarantee for data packets of different users when packets are transmitted over a tunnel, configure a specific tunnel priority or priority mapping.

802.11 packets sent from a WMM-capable STA carry the user priority (Layer 2) or DSCP priority (Layer 3), and tunnel packets carry the 802.1p priority (Layer 2) or tunnel DSCP priority (Layer 3). 802.11 packets sent to the AC from an AP must be converted into tunnel packets.

You can run the **priority-map tunnel-upstream dot11e dscp** command to configure mapping from the user priority of 802.11 packets to the DSCP priority of tunnel packets when packets are sent to the AC from an AP.

Precautions

The tunnel priority mapping is applicable to scenarios where data packets are sent in tunnel forwarding mode.

Example

In traffic profile **p1**, configure mapping from user priority 6 of 802.11 packets to DSCP priority 1 of tunnel packets when packets are sent to the AC from an AP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] priority-map tunnel-upstream dot11e 6 dscp 1
```

11.7.20 priority-map tunnel-upstream dot11e dot1p

Function

The **priority-map tunnel-upstream dot11e dot1p** command configures mapping from user priorities of 802.11 packets to 802.1p priorities of tunnel packets when packets are sent to the AC from an AP.

The **undo priority-map tunnel-upstream dot11e dot1p** command restores the default mapping from user priorities of 802.11 packets to 802.1p priorities of tunnel packets when packets are sent to the AC from an AP.

By default, user priority 0 of 802.11 packets maps to 802.1p priority 0 of tunnel packets, user priority 1 to 802.1p priority 1, and similarly, user priority 7 to 802.1p priority 7.

Format

priority-map tunnel-upstream dot11e { *dot11e-value1* [**to** *dot11e-value2*] } &<1-7> **dot1p** *dot1p-value*

undo priority-map tunnel-upstream dot11e to dot1p

Parameters

Parameter	Description	Value
dot11e *dot11e-value1*	Specifies the user priority of 802.11 packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.

Parameter	Description	Value
to *dot11e-value2*	Specifies the user priority of 802.11 packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority. *dot11e-value2* must be greater than *dot11e-value1*.
dot1p *dot1p-value*	Specifies the 802.1p priority of tunnel packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.

Usage Guidelines

Usage Scenario

To provide QoS guarantee for data packets of different users when packets are transmitted over a tunnel, configure a specific tunnel priority or priority mapping.

802.11 packets sent from a WMM-capable STA carry user priorities (Layer 2 priorities) or DSCP priorities (Layer 3 priorities). Tunnel packets carry 802.1p priorities (Layer 2 priorities) or DSCP priorities (Layer 3 priorities). When data packets are sent from APs to the AC, 802.11 packets need to be converted to tunnel packets.

You can run the **priority-map tunnel-upstream dscp dot1p** command to configure mapping from DSCP priorities of 802.11 packets to 802.1p priorities of tunnel packets when packets are sent to the AC from an AP.

Precautions

The tunnel priority mapping is applicable to scenarios where data packets are sent in tunnel forwarding mode.

Example

In traffic profile **p1**, map DSCP priorities 0 to 7 of 802.11 packets to 802.1p priority 1 of tunnel packets when data is sent from APs to the AC.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] priority-map tunnel-upstream dscp 0 to 7 dot1p 1
```

11.7.22 priority-map tunnel-upstream dscp tunnel-dscp

Function

The **priority-map tunnel-upstream dscp tunnel-dscp** command configures mapping from the DSCP priority of 802.11 packets to the DSCP priority of tunnel packets when packets are sent to the AC from an AP.

The **undo priority-map tunnel-upstream dscp tunnel-dscp** command restores the default mapping from the DSCP priority of 802.11 packets to the DSCP priority of tunnel packets when packets are sent to the AC from an AP.

By default, DSCP priority **1** of 802.11 packets maps DSCP priority **1** of tunnel packets, DSCP priority **2** of 802.11 packets maps DSCP priority **2** of tunnel packets, and so on. DSCP priority **63** of 802.11 packets maps DSCP priority **63** of tunnel packets.

Format

priority-map tunnel-upstream dscp { *dscp-value* [**to** *dscp-value1*] } &<1-10> **tunnel-dscp** *dscp-value2*

undo priority-map tunnel-upstream dscp to tunnel-dscp

Parameters

Parameter	Description	Value
dscp *dscp-value*	Specifies the DSCP priority of 802.11 packets.	The value is an integer that ranges from 0 to 63. A larger value indicates a higher priority.

Parameter	Description	Value
to *dscp-value1*	Specifies the DSCP priority of 802.11 packets.	The value is an integer that ranges from 0 to 63. A larger value indicates a higher priority. *dscp-value1* must be greater than *dscp-value*.
tunnel-dscp *dscp-value2*	Specifies the DSCP priority of tunnel packets.	The value is an integer that ranges from 0 to 63. A larger value indicates a higher priority.

To provide QoS guarantee for data packets of different users when packets are transmitted over a tunnel, configure a specific tunnel priority or priority mapping.

802.11 packets sent from a WMM-capable STA carry the user priority (Layer 2) or DSCP priority (Layer 3), and tunnel packets carry the 802.1p priority (Layer 2) or tunnel DSCP priority (Layer 3). 802.11 packets sent to the AC from an AP must be converted into tunnel packets.

You can run the **priority-map tunnel-upstream trust** command to configure a trusted priority type used in mapping from 802.11 packets to tunnel packets when packets are sent to the AC from an AP.

Precautions

The tunnel priority mapping is applicable to scenarios where data packets are sent in tunnel forwarding mode.

Example

In traffic profile **p1**, configure the DSCP priority as the trusted priority type used in mapping from 802.11 packets to tunnel packets when packets are sent to the AC from an AP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] priority-map tunnel-upstream trust dscp
```

11.7.24 priority-map upstream trust

Function

The **priority-map upstream trust** command configures the priority mapping mode from 802.11 packets to 802.3 packets when packets are sent from an AP to upper-layer devices.

The **undo priority-map upstream trust** command restores the default priority mapping mode from 802.11 packets to 802.3 packets when packets are sent from an AP to upper-layer devices.

By default, the 802.11e priority is mapped from 802.11 packets to 802.3 packets when packets are sent from an AP to upper-layer devices.

Format

priority-map upstream trust { **dot11e** | **dscp** }

undo priority-map upstream trust

Parameters

Parameter	Description	Value
dot11e	Specifies the mapping from the user priority of 802.11 packets to the DSCP and 802.1p priorities of 802.3 packets.	-
dscp	Specifies the DSCP priority mapping from 802.11 packets to 802.3 packets.	-

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

802.3 and 802.11 data packets use different fields to identify their priorities. 802.11 packets sent from a WMM-capable STA carry the user priority (also called the User Priority field), and IP packets transmitted on an Ethernet carry the DSCP priority (also called the ToS field). When data packets are forwarded from an AP to an AC or the upper-layer network, 802.3 packets need to be converted into 802.11 packets. During the conversion, the user priority of 802.11 packets is mapped to the ToS field in the IP packet header.

Currently, the priority mappings are fixed and described in the following table.

Table 11-175 Mapping between the DSCP and 802.1p priorities

DSCP Priority of 802.11 Packets	802.1p Priority of 802.3 Packets
0-7	0
8-15	1
16-23	2
24-31	3
32-39	4
40-47	5
48-55	6
56-63	7

Table 11-176 Mapping from the user priority to the 802.1p and DSCP priorities

User Priority of 802.11 Packets	DSCP Priority of 802.3 Packets	802.1p Priority of 802.3 Packets
0	0	0
1	8	1
2	16	2
3	24	3
4	32	4

User Priority of 802.11 Packets	DSCP Priority of 802.3 Packets	802.1p Priority of 802.3 Packets
5	40	5
6	48	6
7	56	7

Example

Configure the DSCP priority mapping from 802.11 packets to 802.3 packets in the traffic profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] priority-map upstream trust dscp
```

11.7.25 qos car (SSID profile view)

Function

The **qos car** command configures QoS CAR parameters.

The **undo qos car** command deletes the configured QoS CAR parameters.

By default, no QoS CAR parameters are configured in an SSID profile.

Format

qos car inbound cir *cir-value* [**cbs** *cbs-value* [**pbs** *pbs-value*] | **pir** *pir-value* [**cbs** *cbs-value* **pbs** *pbs-value*]]

undo qos car inbound

Parameters

Parameter	Description	Value
inbound	Applies a QoS CAR profile to the inbound direction of an interface.	-
cir *cir-value*	Specifies the committed information rate (CIR), which is the average rate of traffic that can pass through.	The value is an integer that ranges from 64 to 4294967295, in kbit/s.

Parameter	Description	Value
pir *pir-value*	Specifies the peak information rate (PIR), which is the maximum rate of traffic that can pass through.	The value is an integer that ranges from 64 to 4294967295, in kbit/s. The PIR value must be greater than or equal to the CIR value.
cbs *cbs-value*	Specifies the committed burst size (CBS), which is the average volume of burst traffic that can pass through an interface.	The value is an integer that ranges from 1500 to 4294967295, in bytes. By default: ● If the PIR value is not set, the CBS value is 188 times the CIR value. If the value 188 times the CIR exceeds the maximum value (4294967295) of the CBS, 4294967295 is used. ● If the PIR is set, the CBS is 125 times the CIR. If the value 125 times the CIR exceeds the maximum value (4294967295) of the CBS, 4294967295 is used.
pbs *pbs-value*	Specifies the peak burst size (PBS), which is the maximum volume of burst traffic that can pass through an interface.	The value is an integer that ranges from 1500 to 4294967295, in bytes. By default, if the PIR is set, the PBS is 125 times the PIR. If the value 125 times the PIR exceeds the maximum value (4294967295) of the PBS, 4294967295 is used.

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Traffic policing discards excess traffic to limit incoming and outgoing traffic within a proper range and to protect network resources.

When traffic is transmitted from a high-speed link to a low-speed link, the inbound interface of the low-speed link is prone to severe data loss. The data traffic rate needs to be limited. To solve this problem, configure traffic policing for outgoing traffic on the interface of the high-speed link. The interface then discards the packets whose rate exceeds the traffic policing rate, limiting the outgoing traffic rate in a proper range. You can also configure traffic policing for incoming traffic on the interface of the low-speed link. The interface then discards the received packets whose rate exceeds the traffic policing rate.

The packet color is determined by parameters **cbs** *cbs-value* and **pbs** *pbs-value* of this command.

- When the size of a packet is less than the CBS value, the packet is colored green.
- When the size of a packet is greater than or equal to the CBS value but less than the PBS value, the packet is colored yellow.
- When the size of a packet is greater than or equal to the PBS value, the packet is colored red.

QoS CAR parameters can be configured in an SSID profile to implement traffic policing on user traffic on all VAPs to which the user profile is applied. These VAPs share a token bucket, and more VAPs indicate fewer network resources that each VAP can occupy.

Precautions

QoS CAR parameters configured in an SSID profile are valid only when the service data forwarding mode is set to tunnel forwarding. In tunnel forwarding mode, this function does not take effect when Layer 2 STAs associated with the same AP communicate with each other.

When the traffic policing rate is greater than the maximum rate of an interface, traffic policing does not take effect on the interface. Set the value of *cir-value* smaller than the rate of the interface.

When the CBS value is smaller than the number of bytes in a packet, packets of this type are discarded.

To ensure that the device correctly identifies packet colors, you are advised to set the PBS value greater than the CBS value.

When a user is configured as a VIP user, the QoS CAR configured in the SSID profile does not take effect.

Example

Configure traffic policing parameters for incoming packets.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name p1
[HUAWEI-wlan-ssid-prof-p1] qos car inbound cir 64 cbs 9000 pbs 18000
```

11.7.26 rate-limit

Function

The **rate-limit** command configures the rate limit for upstream and downstream packets of all STAs or each STA on a VAP.

The **undo rate-limit** command restores the default rate limit for upstream and downstream packets of all STAs or each STA on a VAP.

By default, the rate limit for upstream and downstream packets of all STAs on a VAP is 4294967295 kbit/s, and that of each STA is 4294967295 kbit/s.

Format

rate-limit { **client** | **vap** } { **up** | **down** } *rate-value*

undo rate-limit { **client** | **vap** } { **up** | **down** }

Parameters

Parameter	Description	Value
client	Specifies a STA on a VAP.	-
vap	Specifies all STAs on a VAP.	-
up	Specifies the rate limit for upstream packets on a VAP.	-
down	Specifies the rate limit for downstream packets on a VAP.	-
rate-value	Specifies the rate limit of packets.	The value is an integer that ranges from 64 to 4294967295, in kbit/s. The value **4294967295** indicates that the rate is not limited.

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **rate-limit** command to limit the rate of upstream and downstream packets for all STAs or each STA on a VAP to protect network bandwidth resources.

Precautions

The limited rate does not take effect for STAs that go online before the **rate-limit** command is configured. To make this configuration take effect for a STA, enable the STA to go online again.

The rate limit configured for each STA on a VAP does not take effect for multicast packets.

When the NP fast forwarding function is disabled, neither the **rate-limit vap** nor **rate-limit client** command configuration takes effect for VIP users. When the NP fast forwarding function is enabled, the **rate-limit vap** command configuration takes effect for VIP users, but the **rate-limit client** command configuration does not take effect for VIP users.

Example

Set the rate limit of upstream packets to 4294967295 kbit/s for all STAs on a VAP in the traffic profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] rate-limit vap up 4294967295
```

11.7.27 rate-limit client dynamic

Function

The **rate-limit client dynamic** command sets the dynamic rate limit threshold for a single STA in a VAP.

The **undo rate-limit client dynamic** command restores the default dynamic rate limit threshold for a single STA in a VAP.

By default, the dynamic rate limit threshold for a single STA in a VAP is 16 Mbit/s.

NOTE

Dynamic rate limiting for STAs is not supported by the following models:

- AirEngine X760 series APs
- AirEngine X761 series APs
- AirEngine X762 series APs
- AirEngine X771 series APs
- AirEngine 9700D-S (including matching ORUs)

Format

rate-limit client dynamic *rate-value*

undo rate-limit client dynamic

Parameters

Parameter	Description	Value
rate-value	Specifies the rate limit of packets.	The value is an enumerated value, which can be 8, 16, or 32, in Mbit/s. The default value is 16 Mbit/s.

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a STA downloads or uploads large files on the live network, network access of other STAs may be affected.

After dynamic rate limiting is enabled, the device determines whether to perform three-phase rate limiting for wireless users depending on whether the air interface is congested. This improves network experience of wireless users.

Precautions

If static rate limiting has been enabled, static rate limiting takes precedence over dynamic rate limiting.

When the NP fast forwarding function is disabled, neither the **rate-limit vap** nor **rate-limit client** command configuration takes effect for VIP users. When the NP fast forwarding function is enabled, the **rate-limit vap** command configuration takes effect for VIP users, but the **rate-limit client** command configuration does not take effect for VIP users.

Example

Set the dynamic rate limit threshold for a single STA in a VAP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] undo rate-limit client dynamic disable
[HUAWEI-wlan-traffic-prof-p1] rate-limit client dynamic 32
```

11.7.28 rate-limit client dynamic disable

Function

The **rate-limit client dynamic disable** command disables dynamic rate limiting for a single STA in a VAP.

The **undo rate-limit client dynamic disable** command enables dynamic rate limiting for a single STA in a VAP.

By default, dynamic rate limiting is enabled for a single STA in a VAP.

NOTE

Dynamic rate limiting for STAs is not supported by the following models:

- AirEngine X760 series APs
- AirEngine X761 series APs
- AirEngine X762 series APs
- AirEngine X771 series APs
- AirEngine 9700D-S (including matching ORUs)

Format

rate-limit client dynamic disable

undo rate-limit client dynamic disable

Parameters

None

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a STA downloads or uploads large files on the live network, network access of other STAs may be affected.

After dynamic rate limiting is enabled, the device determines whether to perform three-phase rate limiting for wireless users depending on whether the air interface is congested. This improves network experience of wireless users.

Precautions

If static rate limiting has been enabled, static rate limiting takes precedence over dynamic rate limiting.

When the NP fast forwarding function is disabled, neither the **rate-limit vap** nor **rate-limit client** command configuration takes effect for VIP users. When the NP fast forwarding function is enabled, the **rate-limit vap** command configuration takes effect for VIP users, but the **rate-limit client** command configuration does not take effect for VIP users.

Example

Enable dynamic rate limiting for a single STA in a VAP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] undo rate-limit client dynamic disable
```

11.7.29 rate-limit client time-range

Function

The **rate-limit client time-range** command sets a rate limit for upstream or downstream packets of each STA on a VAP in a specified time range.

The **undo rate-limit client time-range** command restores the default rate limit of upstream or downstream packets of each STA on a VAP in a specified time range.

By default, no rate limit is set for upstream or downstream packets of each STA on a VAP in a specified time range.

Format

rate-limit client { **up** | **down** } *rate-value* **time-range** *time-range-name*

undo rate-limit client { **up** | **down** } **time-range** *time-range-name*

Parameters

Parameter	Description	Value
client	Specifies each STA on a VAP.	-
up	Specifies the rate limit for upstream packets of each STA on a VAP.	-
down	Specifies the rate limit for downstream packets of each STA on a VAP.	-

Parameter	Description	Value
rate-value	Specifies the rate limit of packets.	The value is an integer that ranges from 64 to 4294967295, in kbit/s. The value **4294967295** indicates that the packet rate is not limited.
time-range-name	Specifies the name of a time range during which the rate of packets is limited.	The value is a string of 1 to 32 characters and must begin with a letter. To avoid confusion, do not use **all** as the name of a time range.

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **rate-limit client time-range** command to set a rate limit for upstream or downstream packets of each STA on a VAP in a specified time range.

Precautions

The limited rate does not take effect for STAs that go online before the **rate-limit** command is configured. To make this configuration take effect for a STA, enable the STA to go online again.

The rate limit configured for each STA on a VAP does not take effect for multicast packets.

When the NP fast forwarding function is disabled, neither the **rate-limit vap** nor **rate-limit client** command configuration takes effect for VIP users. When the NP fast forwarding function is enabled, the **rate-limit vap** command configuration takes effect for VIP users, but the **rate-limit client** command configuration does not take effect for VIP users.

A maximum of eight time range–based rate limiting policies can be configured in the same direction (upstream or downstream). By default, the device has a default policy (determined by the **rate-limit client** { **up** | **down** } *rate-value* command configuration). A configured time range–based rate limiting policy takes precedence over the default policy. If multiple time range–based rate limiting policies are configured, the minimum rate limit value takes effect.

You need to run the **time-range** command in the system view to configure a time range.

Example

Set the rate limit for upstream packets of each STA on a VAP to 1000 kbit/s in the time range named **time**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] rate-limit client up 1000 time-range time
Warning: The specified time-range does not exist. You can create it later. Continue?[Y/N]y
```

11.7.30 rate-limit dynamic interval

Function

The **rate-limit dynamic interval** command sets the detection interval and threshold for dynamic rate limiting of a single STA on a VAP.

The **undo rate-limit dynamic** command restores the default detection interval and threshold for dynamic rate limiting of a single STA on a VAP.

The default detection interval and threshold for dynamic rate limiting of a single STA on a VAP are 5 and 80%, respectively.

Format

rate-limit dynamic interval *interval* **threshold** *threshold*

undo rate-limit dynamic

Parameters

Parameter	Description	Value
interval	Specifies the detection interval for dynamic rate limiting.	The value is an integer that ranges from 1 to 30.
threshold *threshold*	Specifies the detection threshold for dynamic rate limiting.	The value is an integer that ranges from 1 to 100.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to adjust the time when dynamic rate limiting takes effect.

If the channel utilization is higher than *threshold*% for a consecutive number of times specified by *interval* (that is, a period of time specified by *interval* x 2 seconds), the air interface congestion is determined.

Example

Configure the detection interval and threshold for dynamic rate limiting of a single STA on a VAP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name p1
[HUAWEI-wlan-rrm-prof-p1] rate-limit dynamic interval interval 10 threshold 60
```

11.7.31 svp-voice enable

Function

The **svp-voice enable** command enables the Spectralink Voice Priority (SVP) voice traffic optimization function.

The **undo svp-voice enable** command disables the SVP voice traffic optimization function.

By default, the SVP voice traffic optimization function is disabled.

Format

svp-voice enable

undo svp-voice enable

Parameters

None

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

SpectraLink Voice is a voice protocol defined by Spectralink (a Wi-Fi phone company). To ensure SpectraLink voice transmission quality on WLANs, SpectraLink defines SpectraLink Voice Priority (SVP) to describe the requirements of SpectraLink Voice on WLANs.

On a WLAN with STAs supporting the SpectraLink Voice protocol, you are advised to enable the SVP voice traffic optimization function.

Example

Enable the SVP voice traffic optimization function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] svp-voice enable
```

11.7.32 service-experience-analysis enable

Function

The **service-experience-analysis enable** command enables the service experience analysis (SEA) function.

The **undo service-experience-analysis enable** command disables the service experience analysis (SEA) function.

By default, the SEA function is disabled.

NOTE

This command is not supported by the following models:

- AirEngine series central APs
- AirEngine 5761-10W, AirEngine 5761-10WD, and AirEngine 5761S-10W
- AirEngine X762 series APs

Format

service-experience-analysis enable

undo service-experience-analysis enable

Parameters

None

Usage Guidelines

Usage Scenario

When the SIP (eSpace) service runs on a WLAN, you can enable the SEA function so that the device reports performance statistics about SIP traffic (such as IP addresses and port numbers of calling and called parties, and call quality data) to iMaster NCE-CampusInsight. In this manner, iMaster NCE-CampusInsight can analyze network performance and locate faults.

Follow-up Procedure

Run the **service-experience-analysis sip-snooping port** command to set the port number for identifying SIP packets.

Example

Enable the SEA function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name example
[HUAWEI-wlan-vap-prof-example] service-experience-analysis enable
```

11.7.33 service-experience-analysis monitor interval

Function

The **service-experience-analysis monitor interval** command configures the sampling interval for SEA-based application monitoring.

The **undo service-experience-analysis monitor interval** command restores the default sampling interval for SEA-based application monitoring.

By default, the sampling interval for SEA-based application monitoring is 10 seconds.

NOTE

This command is not supported by the following models:

- AirEngine series central APs
- AirEngine 5761-10W, AirEngine 5761-10WD, and AirEngine 5761S-10W
- AirEngine X762 series APs

Format

service-experience-analysis monitor interval *interval*

undo service-experience-analysis monitor interval

Parameters

Parameter	Description	Value
interval	Specifies the sampling interval for SEA-based application monitoring.	The value is an integer that ranges from 2 to 30, in seconds.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to configure the sampling interval for SEA-based application monitoring.

Example

Set the sampling interval for SEA-based application monitoring to 2 seconds.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name apsys
[HUAWEI-wlan-ap-system-prof-apsys] service-experience-analysis monitor interval 2
```

11.7.34 service-experience-analysis monitor application

Function

The **service-experience-analysis monitor application** command configures an application to be monitored based on SEA.

The **undo service-experience-analysis monitor application** command deletes an application monitored based on SEA.

By default, no application is monitored based on SEA.

NOTE

This command is not supported by the following models:

- AirEngine series central APs
- AirEngine 5761-10W, AirEngine 5761-10WD, and AirEngine 5761S-10W
- AirEngine X762 series APs

Format

service-experience-analysis monitor application *appname*

undo service-experience-analysis monitor application *appname*

Parameters

Parameter	Description	Value
appname	Specifies an application to be monitored based on SEA.	Currently, applications that use the TCP and RTP protocols can be monitored based on SEA. RTP-based applications include: ● skype_voip ● sip ● rtp ● whatsapp ● espace_voip ● hangouts ● slack_voip ● welink_videocall ● microsoftteams ● webex_voip ● xiaoyuyilian ● huaweimeeting

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to configure application-based traffic quality monitoring. After the configuration is complete, the AC delivers the configuration to APs that will monitor the specified application.

Prerequisites

The security engine has been enabled using the **defence engine enable** command.

Precautions

You can configure a maximum of 16 applications to be monitored based on SEA.

For some voice and video applications, if the application control packets use TCP and the data packets use UDP, the device can monitor only the quality of application control packets (TCP).

Among user-defined applications (created using the **user-defined-application** command), SEA can monitor only user-defined TCP applications (specified by the **protocol tcp** parameter) but not user-defined UDP applications (specified by the **protocol udp** parameter).

SEA does not monitor fragmented packets.

Example

Configure an application to be monitored based on SEA.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap-profile1
[HUAWEI-wlan-vap-prof-vap-profile1] service-experience-analysis monitor application WeLink
```

11.7.35 service-experience-analysis monitor ucl-group

Function

The **service-experience-analysis monitor ucl-group** command specifies a UCL group or a "UCL group + application" combination monitored based on SEA.

The **undo service-experience-analysis monitor ucl-group** command deletes a UCL group or a "UCL group + application" combination monitored based on SEA.

By default, no UCL group is monitored based on SEA.

NOTE

This command is not supported by the following models:

- AirEngine series central APs
- AirEngine 5761-10W, AirEngine 5761-10WD, and AirEngine 5761S-10W
- AirEngine X762 series APs

Format

service-experience-analysis monitor ucl-group { *group-index* | **name** *group-name* } [**application** *application-name* & <1-16>]

undo service-experience-analysis monitor ucl-group { *group-index* | **name** *group-name* } [**application** *application-name* &<1-16>]

Parameters

Parameter	Description	Value
group-index	Specifies the index of a UCL group.	The value is an integer that ranges from 1 to 64000.
name *group-name*	Specifies the name of a UCL group.	The UCL group must exist.

Parameter	Description	Value
application *application-name*	Specifies an application to be monitored based on SEA.	The application must exist. A maximum of 16 applications can be specified.

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to specify a UCL group or a "UCL group + application" combination to be monitored based on SEA.

You can specify a UCL group so that the device can monitor the quality of applications of users in the specified UCL group. You can also specify a "UCL group + application" combination, so that the device can monitor the quality of the specified application of users in the specified UCL group.

Precautions

A maximum of 128 applications, UCL groups, and "UCL group + application" combinations (including 16 applications at most) can be monitored based on SEA.

Example

Specify the application **WeLink** in the UCL group **test** to be monitored based on SEA.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap-profile1
[HUAWEI-wlan-vap-prof-vap-profile1] service-experience-analysis monitor ucl-group test application
WeLink
```

11.7.36 service-experience-analysis sip-snooping port

Function

The **service-experience-analysis sip-snooping port** command sets the port number for identifying SIP packets.

The **undo service-experience-analysis sip-snooping port** command restores the default port number for identifying SIP packets.

The default port number for identifying SIP packets is 5060.

NOTE

This command is not supported by the following models:
- AirEngine series central APs
- AirEngine 5761-10W, AirEngine 5761-10WD, and AirEngine 5761S-10W
- AirEngine X762 series APs

Format

service-experience-analysis sip-snooping port *port-number*

undo service-experience-analysis sip-snooping port

Parameters

Parameter	Description	Value
port-number	Specifies the port number for identifying SIP packets.	The value is an integer that ranges from 1 to 65535.

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

When the SIP (eSpace) service runs on a WLAN, you can enable the SEA function so that the device reports performance statistics about SIP traffic (such as IP addresses and port numbers of calling and called parties, and call quality data) to iMaster NCE-CampusInsight. In this manner, iMaster NCE-CampusInsight can analyze network performance and locate faults.

You can run this command to configure the port number for identifying SIP packets.

Before specifying the port number for identifying SIP packets, enable the SEA function using the **service-experience-analysis enable** command.

Example

Set the port number for identifying SIP packets.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name example
[HUAWEI-wlan-vap-prof-example] service-experience-analysis sip-snooping port 5080
```

11.7.37 traffic-filter (traffic profile view)

Function

The **traffic-filter** command configures ACL-based packet filtering in a traffic profile.

The **undo traffic-filter** command cancels the configuration of ACL-based packet filtering in a traffic profile.

By default, ACL-based packet filtering is not configured in a traffic profile.

Format

traffic-filter { **inbound** | **outbound** } { **ipv4** | **ipv6** | **l2** } **acl** { *acl-number* | **name** *acl-name* }

traffic-filter { **inbound** | **outbound** } **ipv4 acl** { *acl-number* | **name** *acl-name* } **l2 acl** { *acl-number* | **name** *acl-name* }

undo traffic-filter { **inbound** | **outbound** } { **ipv4** | **ipv6** | **l2** } **acl** { *acl-number* | **name** *acl-name* }

undo traffic-filter { **inbound** | **outbound** } **ipv4 acl** { *acl-number* | **name** *acl-name* } **l2 acl** { *acl-number* | **name** *acl-name* }

Parameters

Parameter	Description	Value
inbound	Configures ACL-based packet filtering in the inbound direction.	-
outbound	Configures ACL-based packet filtering in the outbound direction.	-
ipv4	Configures ACL-based IPv4 packet filtering.	-
ipv6	Configures ACL-based IPv6 packet filtering.	-
l2	Configures ACL-based Layer 2 packet filtering.	-

Parameter	Description	Value
acl *acl-number*	Specifies the number of an ACL.	The value is an integer that ranges from 3000 to 3031 and from 6000 to 6031 for an IPv4 ACL, from 3000 to 3031 and 6000 to 6031 for an IPv6 ACL, and from 4000 to 4031 for a Layer 2 ACL. ● 3000 to 3031: advanced ACLs ● 6000 to 6031: user ACLs ● 4000 to 4031: Layer 2 ACLs
name *acl-name*	Filters packets based on a specified named ACL. *acl-name* specifies the name of an ACL.	The value is a string of 1 to 65 case-sensitive characters without spaces and must begin with a letter. The value range of *acl-number* corresponding to *acl-name* is 3000 to 3031, and 6000 to 6031.

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a wireless network, administrators want to provide differentiated services for wireless users. The services may include, but are not limited to the following:

- Deny or permit access of specified wireless users to specified LAN devices.
- Deny access of specified wireless users to specified invalid IP addresses.

You can configure ACL-based packet filtering in a traffic profile for providing differentiated services to wireless users based on ACL rules.

When the **traffic-filter** command is configured in the traffic profile view, the device first matches packets against ACLs and then performs the action according to the matched policy.

When multiple **traffic-filter** commands are configured for ACL-based packet filtering in the same direction in the same traffic profile, packets are matched against the next rule in the sequence in which the commands are configured. If packets match a rule, the device executes the specified policy and stops the matching process. Otherwise, the device continues to match packets against the next rule. If no rule is matched, the packets are allowed to pass through.

If an ACL contains multiple rules, packets match against the rules in the ascending order of rule IDs. If packets match a rule, the device considers that the ACL is matched and stops the matching process. Otherwise, the device continues to match packets against the next rule. If no rule is matched, the device considers that this ACL is not matched. To improve match efficiency, you are advised to configure an ACL rule with a high match probability first and set a small ID for the rule. This will reduce the number of times ACL rules are matched and save resources.

Prerequisites

An ACL rule has been created before this command is run.

- **acl (system view)**
- **acl name**

The device has been enabled to process STA IPv6 services of STAs using the **sta-ipv6-service enable** command.

Precautions

The **traffic-filter** command can reference a numbered ACL rule that is not configured. You can configure the referenced ACL rule after running this command.

You can only configure a maximum of eight ACL rules in the same direction. The sequence in which ACL rules takes effect follows the sequence in which the rules are configured. To change the current packet filtering rules, delete all the related configurations and reconfigure the ACL-based packet filtering.

Example

Create the traffic profile **p1** and configure packet filtering in the inbound direction based on the ACL that permits packets with the source IPv4 address 192.168.0.2/32.

```
<HUAWEI> system-view
[HUAWEI] acl 3000
[HUAWEI-acl-adv-3000] rule 5 permit ip source 192.168.0.2 0
[HUAWEI-acl-adv-3000] quit
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] traffic-filter inbound ipv4 acl 3000
```

11.7.38 traffic-profile (WLAN view)

Function

The **traffic-profile** command creates a traffic profile and displays the traffic profile view, or displays the view of an existing traffic profile.

The **undo traffic-profile** command deletes a traffic profile.

By default, the system provides the traffic profile **default**.

Format

traffic-profile name *profile-name*

undo traffic-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a traffic profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all traffic profiles.	–

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

- The **traffic-profile** command applies to the following situations:
  - To apply priority mapping and traffic suppression functions to a VAP, create a traffic profile and bind the traffic profile to the VAP profile.
  - To change priority mapping and traffic suppression functions of a VAP, enter the traffic profile view of the VAP to modify the required parameters. When a traffic profile is not required, delete it.
- After a traffic profile is created, parameters in the profile use default values.

NOTE

- The profile name is mandatory when you create a profile.
- The traffic profile referenced by a VAP profile cannot be deleted. To delete the traffic profile, unbind it from the VAP profile first.

Example

Create traffic profile **p1** and display the traffic profile view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1]
```

11.7.39 traffic-profile (VAP profile view)

Function

The **traffic-profile** command binds a traffic profile to a VAP profile.

The **undo traffic-profile** command unbinds a traffic profile from a VAP profile.

By default, the traffic profile **default** is bound to a VAP profile.

Format

traffic-profile *profile-name*

undo traffic-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a traffic profile.	The traffic profile must exist.

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can use the **traffic-profile** command to bind a traffic profile to a VAP profile. The traffic profile applies to all users using the VAP profile.

Prerequisites

The traffic profile has been created using the **traffic-profile (WLAN view)** command.

Example

Create VAP profile **p1** and bind traffic profile **u1** to the VAP profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name p1
[HUAWEI-wlan-vap-prof-p1] traffic-profile u1
```

11.7.40 traffic-remark (traffic profile view)

Function

The **traffic-remark** command configures ACL-based priority re-marking in a traffic profile.

The **undo traffic-remark** command cancels ACL-based priority re-marking in a traffic profile.

By default, ACL-based priority re-marking is not configured in a traffic profile.

Format

traffic-remark { **inbound** | **outbound** } { **ipv4** | **ipv6** | **l2** } **acl** { *acl-number* | **name** *acl-name* } { **dot11e** *dot11e-value* | **dscp** *dscp-value* }

traffic-remark { **inbound** | **outbound** } **ipv4 acl** { *acl-number* | **name** *acl-name* } **l2 acl** { *acl-number* | **name** *acl-name* } { **dot11e** *dot11e-value* | **dscp** *dscp-value* }

undo traffic-remark { **inbound** | **outbound** } { **ipv4** | **ipv6** | **l2** } **acl** { *acl-number* | **name** *acl-name* }

undo traffic-remark { **inbound** | **outbound** } **ipv4 acl** { *acl-number* | **name** *acl-name* } **l2 acl** { *acl-number* | **name** *acl-name* }

Parameters

Parameter	Description	Value
inbound	Configures ACL-based priority re-marking in the inbound direction.	-
outbound	Configures ACL-based priority re-marking in the outbound direction.	-
ipv4	Configures priority re-marking for IPv4 packets.	-
ipv6	Configures priority re-marking for IPv6 packets.	-
l2	Configures priority re-marking for Layer 2 packets.	-

Parameter	Description	Value
acl *acl-number*	Specifies the number of an ACL.	The value is an integer that ranges from 3000 to 3031 and from 6000 to 6031 for IPv4 ACLs, from 3000 to 3031 and 6000 to 6031 for an IPv6 ACLs, and from 4000 to 4031 for Layer 2 ACLs. ● 3000 to 3031: advanced ACLs ● 6000 to 6031: user ACLs ● 4000 to 4031: Layer 2 ACLs
name *acl-name*	Re-marks packet priorities based on a specified named ACL. *acl-name* specifies the name of an ACL.	The value is a string of 1 to 32 case-sensitive characters without spaces and must begin with a letter. The value range of *acl-number* corresponding to *acl-name* is 3000 to 3031, and 6000 to 6031.
dot11e *dot11e-value*	Re-marks the 802.11e priority of packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.
dscp *dscp-value*	Re-marks the DSCP priorities of packets.	The value is an integer that ranges from 0 to 63. A larger value indicates a higher priority.

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The user wants to re-mark packet priorities based on ACLs to provide differentiated services. The **traffic-remark** command can be used to configure ACL-based priority re-marking.

Prerequisites

An ACL rule has been created before this command is run.

- **acl (system view)**
- **acl name**

The device has been enabled to process IPv6 services of STAs using the **sta-ipv6-service enable** command.

Precautions

The **traffic-remark** command can reference a numbered ACL rule that is not configured. You can configure the referenced ACL rule after running this command.

You can only configure a maximum of eight ACL-based packet re-marking rules in the same direction. The sequence in which ACL rules takes effect follows the rule configuration sequence. To change the current packet re-marking rules, delete all the related configurations and reconfigure the ACL-based packet re-marking.

When the **traffic-remark** command and the **traffic-filter (traffic profile view)** command are used simultaneously and the same ACL rule is associated:

- If the **deny** action is configured in the ACL rule, the **traffic-remark** command does not take effect.
- If the **permit** action is configured in the ACL rule, the command that is executed first takes effect.

Example

Create the traffic profile **p1** and configure ACL-based 802.11e priority re-marking for IPv4 packets in the inbound direction.

```
<HUAWEI> system-view
[HUAWEI] acl 3000
[HUAWEI-acl-adv-3000] rule 5 permit ip source 192.168.0.2 0
[HUAWEI-acl-adv-3000] quit
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] traffic-remark inbound ipv4 acl 3000 dot11e 7
```

11.7.41 ucc-profile (system view)

Function

The **ucc-profile** command creates a UCC profile and displays the UCC profile view, or displays the view of an existing UCC profile.

The **undo ucc-profile** command deletes a UCC profile.

By default, no UCC profile is created.

Format

ucc-profile name *profile-name*

undo ucc-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a UCC profile.	The value is a string of 1 to 31 case-sensitive characters without spaces. The string must start with a letter.
all	Indicates all UCC profiles.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Microsoft Lync is a set of communication software that provides voice, video, desktop sharing, and file transfer functions. To ensure QoS guarantee for Lync packets and improve user experience, set the priority of Lync packets in the UCC profile.

Follow-up Procedure

Configure priorities of Lync voice, video, desktop sharing, and file transfer packets in the UCC profile and bind the UCC profile to a VAP profile.

Precautions

The UCC profile that has been bound to a VAP profile cannot be deleted. To delete the UCC profile, unbind the UCC profile from the VAP profile.

Example

Create a UCC profile named **test** and enter the UCC profile view.

```
<HUAWEI> system-view
[HUAWEI] ucc-profile name test
[HUAWEI-ucc-prof-test]
```

11.7.42 ucc-profile (VAP profile view)

Function

The **ucc-profile** command binds a UCC profile to a VAP profile.

The **undo ucc-profile** command unbinds a UCC profile from a VAP profile.

By default, no UCC profile is bound to a VAP profile.

Format

ucc-profile *profile-name*

undo ucc-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a UCC profile.	The UCC profile name must exist.

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

After a UCC profile is created, run the **ucc-profile** command to bind the UCC profile to a VAP profile so that the actions in the UCC profile take effect.

Example

Create a UCC profile named **test** and bind the UCC profile to the VAP profile **vap1**.

```
<HUAWEI> system-view
[HUAWEI] ucc-profile name test
[HUAWEI-ucc-prof-test] quit
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] ucc-profile test
```

11.7.43 user-isolate (traffic profile view)

Function

The **user-isolate** command enables user isolation.

The **undo user-isolate** command disables user isolation.

By default, user isolation is disabled in a traffic profile.

Format

user-isolate l2

undo user-isolate

Parameters

Parameter	Description	Value
l2	Indicates user isolation at Layer 2 and communication at Layer 3.	-

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a traffic profile, user isolation prevents packets of users on a VAP from being forwarded to each other. That is, users on the same VAP cannot communicate with each other after user isolation is enabled. This improves user communication security and enables the gateway to centrally forward user traffic, facilitating user management.

- In tunnel forwarding mode, user isolation in the traffic profile implements Layer 2 isolation for all users on a VAP.
- In direct forwarding mode, when enabling user isolation in the traffic profile, it is recommended that port isolation be deployed on the access switch port connected to the AP.

Example

Configure Layer 2 isolation and Layer 3 communication in the traffic profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] user-isolate l2
Warning: Enabling user isolation may interrupt services. Are you sure you want to continue? [Y/N]:y
```

11.7.44 video remark

Function

The **video remark** command sets a priority for Lync video packets.

The **undo video remark** command deletes the priority of Lync video packets.

By default, the priority of Lync video packets is not set.

Format

video remark { **8021p** *8021p-value* | **dscp** { *dscp-value* | *dscp-name* } | **local-precedence** { *local-precedence-value* | *local-precedence-name* } }

undo video remark { **8021p** | **dscp** | **local-precedence** }

Parameters

Parameter	Description	Value
8021p *8021p-value*	Specifies the 802.1p priority.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.

Parameter	Description	Value
dscp { *dscp-value* | *dscp-name* }	Specifies the DSCP priority.	The value is a Diff-Serv code that is an integer ranging from 0 to 63, or a DSCP service type that can be af11, af12, af13, af21, af22, af23, af31, af32, af33, af41, af42, af43, cs1 to cs7, default, or ef. The values of service types are as follows: ● af11: 10 ● af12: 12 ● af13: 14 ● af21: 18 ● af22: 20 ● af23: 22 ● af31: 26 ● af32: 28 ● af33: 30 ● af41: 34 ● af42: 36 ● af43: 38 ● cs1: 8 ● cs2: 16 ● cs3: 24 ● cs4: 32 ● cs5: 40 ● cs6: 48 ● cs7: 56 ● default: 0 ● ef: 46

Parameter	Description	Value
local-precedence { *local-precedence-value* | *local-precedence-name* }	Specifies the local priority.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority. Or, the value is a service type that can be af1, af2, af3, af4, be, cs6, cs7, or ef. The values of service types are as follows: ● af1: 1 ● af2: 2 ● af3: 3 ● af4: 4 ● be: 0 ● cs6: 6 ● cs7: 7 ● ef: 5

Views

UCC profile view

Default Level

2: Configuration level

Usage Guidelines

Application Scenarios

Microsoft Lync is a set of communication software that provides voice, video, desktop sharing, and file transfer functions. You can run the **video remark** command to change the priority of Lync video packets.

Precautions

The 802.1p priority and local priority cannot be set for the Lync video packets of one Lync session.

If you run the **video remark** command in the same UCC profile view multiple times to set the 802.1p priority, DSCP priority, or local priority of Lync video packets, only the latest configuration takes effect.

Example

Set the DSCP priority of Lync video packets to 1 in the UCC profile **test**.

```
<HUAWEI> system-view
[HUAWEI] ucc-profile name test
[HUAWEI-ucc-prof-test] video remark dscp 1
```

11.7.45 voice remark

Function

The **voice remark** command sets a priority for Lync voice packets.

The **undo voice remark** command deletes the priority of Lync voice packets.

By default, the priority of Lync voice packets is not set.

Format

voice remark { **8021p** *8021p-value* | **dscp** { *dscp-value* | *dscp-name* } | **local-precedence** { *local-precedence-value* | *local-precedence-name* } }

undo voice remark { **8021p** | **dscp** | **local-precedence** }

Parameters

Parameter	Description	Value
8021p *8021p-value*	Specifies the 802.1p priority.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.

Parameter	Description	Value
dscp { *dscp-value* | *dscp-name* }	Specifies the DSCP priority.	The value is a Diff-Serv code that is an integer ranging from 0 to 63, or a DSCP service type that can be af11, af12, af13, af21, af22, af23, af31, af32, af33, af41, af42, af43, cs1 to cs7, default, or ef. The values of service types are as follows: ● af11: 10 ● af12: 12 ● af13: 14 ● af21: 18 ● af22: 20 ● af23: 22 ● af31: 26 ● af32: 28 ● af33: 30 ● af41: 34 ● af42: 36 ● af43: 38 ● cs1: 8 ● cs2: 16 ● cs3: 24 ● cs4: 32 ● cs5: 40 ● cs6: 48 ● cs7: 56 ● default: 0 ● ef: 46

Parameter	Description	Value
local-precedence { *local-precedence-value* | *local-precedence-name* }	Specifies the local priority.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority. Or, the value is a service type that can be af1, af2, af3, af4, be, cs6, cs7, or ef. The values of service types are as follows: ● af1: 1 ● af2: 2 ● af3: 3 ● af4: 4 ● be: 0 ● cs6: 6 ● cs7: 7 ● ef: 5

Microsoft Lync is a set of communication software that provides voice, video, desktop sharing, and file transfer functions. You can run the **voice remark** command to change the priority of Lync voice packets.

Precautions

The 802.1p priority and local priority cannot be set for the Lync voice packets of one Lync session.

If you run the **voice remark** command in the same UCC profile view multiple times to set the 802.1p priority, DSCP priority, or local priority of Lync voice packets, only the latest configuration takes effect.

Example

Set the DSCP priority of Lync voice packets to 1 in the UCC profile **test**.

```
<HUAWEI> system-view
[HUAWEI] ucc-profile name test
[HUAWEI-ucc-prof-test] voice remark dscp 1
```

11.7.46 wlan-slice high-reliability enable

Function

The **wlan-slice high-reliability enable** command enables WLAN high-reliability slicing.

The **undo wlan-slice high-reliability enable** command disables WLAN high-reliability slicing.

By default, the WLAN high-reliability slicing function is disabled.

NOTE

Air interface slicing is supported only by the following models:

- AirEngine X760 series APs
- AirEngine 9700D-S (including matching ORUs)

Format

wlan-slice high-reliability enable

undo wlan-slice high-reliability enable

Parameters

None

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In industrial and healthcare scenarios, some latency-sensitive services exist. In this case, you can run the **wlan-slice high-reliability enable** command to enable the WLAN high-reliability slicing function. After this function is enabled, the AP allocates a period of time in the time domain to latency-sensitive services based on the air interface slicing configuration (expected RTT and slicing time proportion) to meet latency requirements of these services.

Precautions

- To ensure optimal air interface slicing, ensure that channel design, device selection, capacity planning, and position design comply with network planning and design requirements.

- In WLAN high-reliability slicing scenarios, if channels are manually planned, ensure that neighboring APs of any AP in the same frequency domain are invisible to each other, that is, no co-channel interference exists between the APs. For example, there are three APs in the same frequency domain: AP1 (neighbor of AP2), AP2 (neighbor of AP1 and AP3), and AP3 (neighbor of AP2). In this case, ensure that no co-channel interference exists between AP1 and AP3.
- When the WLAN high-reliability slicing function is enabled, terminal services may be interrupted.
- The WLAN high-reliability slicing function is mutually exclusive with the air scan function. After the WLAN high-reliability slicing function is enabled, AP radios do not support air scan, and scanning-dependent services, such as smart roaming, band steering, and load balancing, are unavailable.
- If the WLAN high-reliability slicing function is enabled on an AP, port isolation cannot be configured on the switch port connected to the AP.
- WLAN high-reliability slicing and interference visualization are not supported in Mesh scenarios.
- After WLAN high-reliability slicing is enabled in an RRM profile, the profile can be bound only to a 5 GHz radio profile. Each 5 GHz radio bound to this 5 GHz radio profile supports **a maximum of two VAPs**. As WLAN high-reliability slicing uses the VAP with the WLAN ID of 15, do not configure the WLAN ID of 15 for a service VAP.
- After WLAN high-reliability slicing is enabled, CoSR, MU-MIMO, and OFDMA do not take effect on the 2.4 GHz and 5 GHz radios.
- If the WLAN high-reliability slicing function is enabled but there are no low-latency services, high-priority slices cannot be properly utilized. As a result, spectral efficiency and performance deteriorate.
- To allow terminals connected to a Wi-Fi CPE to quickly go online, ensure that multicast traffic is not suppressed during deployment. After the deployment is complete, to ensure the delay of terminals connected to the Wi-Fi CPE, configure multicast traffic suppression on the AC's uplink interface (connected to an application server) and set the rate limit to 8 pps.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1 /////Assume that GE0/0/1 is the AC's uplink interface.
[HUAWEI-GigabitEthernet0/0/1] multicast-suppression packets 8
```

- CPEs need to stay in stationary state to ensure that air interface slicing reaches the optimal state.
- Do not deliver instructions to Wi-Fi CPEs in batches when air interface slicing is enabled.

Example

Enable WLAN high-reliability slicing.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name p1
[HUAWEI-wlan-rrm-prof-p1] wlan-slice high-reliability enable
Warning: This operation will cause online STAs on the radio to go offline. Radios enabled with high-
reliability air interface slicing can provide access only to CPEs with slicing capabilities. It is recommended
that only one or two SSIDs be broadcast on a radio enabled with high-reliability air interface slicing.
Because WLAN ID 15 of the radio is used for air interface slicing, specify other WLAN IDs as required.
Continue? [Y/N] y
```

11.7.47 wlan-slice high-reliability frer-enhance

Function

The **wlan-slice high-reliability frer-enhance** command enables the enhanced dual fed and selective receiving function for WLAN high-reliability slicing scenarios.

The **undo wlan-slice high-reliability frer-enhance** command disables the enhanced dual fed and selective receiving function for WLAN high-reliability slicing scenarios.

By default, the enhanced dual fed and selective receiving function for WLAN high-reliability slicing scenarios is disabled.

NOTE

Air interface slicing is supported only by the following models:

- AirEngine X760 series APs
- AirEngine 9700D-S (including matching ORUs)

Format

wlan-slice high-reliability frer-enhance

undo wlan-slice high-reliability frer-enhance

Parameters

Usage Guidelines

Usage Scenario

Table 11-177 describes the recommended application scenarios of the enhanced dual fed and selective receiving function for WLAN high-reliability slicing.

Table 11-177 Application scenarios of the enhanced dual fed and selective receiving function for WLAN high-reliability slicing

Scenario	Enhanced Dual Fed and Selective Receiving Function for WLAN High-Reliability Slicing
There are a large number of STAs, and 2.4 GHz radios are heavily loaded. Only the performance indicator of 99.999% @ 20 ms is required.	Disabled
There are a small number of STAs, and high performance requirements are imposed. The performance indicator of higher than 99.999% @ 20 ms is required.	Enabled

NOTE

To achieve 99.999% @ 20 ms, the system must ensure that the RTT of only 1 in 100,000 packets exceeds 20 ms.

Prerequisites

The WLAN high-reliability slicing function has been enabled.

Example

Enable the enhanced dual fed and selective receiving function for WLAN high-reliability slicing scenarios.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name p1
[HUAWEI-wlan-view] wlan-slice high-reliability enable
Warning: This operation will cause online STAs on the radio to go offline. Radios enabled with high-
reliability air interface slicing can provide access only to CPEs with slicing capabilities. It is recommended
that only one or two SSIDs be broadcast on a radio enabled with high-reliability air interface slicing.
Because WLAN ID 15 of the radio is used for air interface slicing, specify other WLAN IDs as required.
Continue? [Y/N] y
[HUAWEI-wlan-rrm-prof-p1] wlan-slice high-reliability frer-enhance
```

11.7.48 wlan-slice high-reliability rtt

Function

The **wlan-slice high-reliability rtt** command configures the expected round-trip time (RTT) of WLAN high-reliability slicing.

The **undo wlan-slice high-reliability rtt** command restores the default expected RTT of WLAN high-reliability slicing.

By default, the expected RTT of WLAN high-reliability slicing is 20 ms.

NOTE

Air interface slicing is supported only by the following models:

- AirEngine X760 series APs
- AirEngine 9700D-S (including matching ORUs)

Format

wlan-slice high-reliability rtt *rtt-value*

undo wlan-slice high-reliability rtt

Parameters

Parameter	Description	Value
rtt-value	Specifies the expected RTT value.	The value is an integer that ranges from 10 to 1000, in milliseconds.

Views

RRM profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After this function is enabled, the AP allocates a period of time in the time domain to latency-sensitive services based on the air interface slicing configuration (expected RTT and slicing time proportion) to meet latency requirements of these services.

Example

Set the expected RTT of WLAN high-reliability slicing to 100 ms.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name p1
[HUAWEI-wlan-rrm-prof-p1] wlan-slice high-reliability rtt 100
```

11.7.49 wlan-slice high-reliability time-ratio

Function

The **wlan-slice high-reliability time-ratio** command configures the time proportion for WLAN high-reliability slicing.

The **undo wlan-slice high-reliability time-ratio** command restores the default time proportion for WLAN high-reliability slicing.

The default time proportion for WLAN high-reliability slicing is 80%.

NOTE

Air interface slicing is supported only by the following models:

- AirEngine X760 series APs
- AirEngine 9700D-S (including matching ORUs)

Format

wlan-slice high-reliability time-ratio *time-ratio*

undo wlan-slice high-reliability time-ratio

Parameters

Parameter	Description	Value
time-ratio	Specifies the slicing time proportion.	The value is an integer that ranges from 0 to 80, in percentage.

Views

RRM profile view

2: Configuration level

Usage Guidelines

Usage Scenario

After this function is enabled, the AP allocates a period of time in the time domain to latency-sensitive services based on the air interface slicing configuration (expected RTT and slicing time proportion) to meet latency requirements of these services.

Example

Set the time proportion for WLAN high-reliability slicing to 60%.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rrm-profile name p1
[HUAWEI-wlan-rrm-prof-p1] wlan-slice high-reliability time-ratio 60
```

11.7.50 wlan-slice high-reliability acl

Function

The **wlan-slice high-reliability acl** command specifies an ACL for air interface slicing.

The **undo wlan-slice high-reliability acl** command deletes an ACL for air interface slicing.

By default, no ACL for air interface slicing is configured.

NOTE

Air interface slicing is supported only by the following models:

- AirEngine X760 series APs
- AirEngine 9700D-S (including matching ORUs)

Format

wlan-slice high-reliability { **ipv4** | **ipv6** | **l2** } **acl** *acl-number*

undo wlan-slice high-reliability { **ipv4** | **ipv6** | **l2** } **acl** *acl-number*

Parameters

Parameter	Description	Value
ipv4	Enables air interface slicing for IPv4 packets.	-
ipv6	Enables air interface slicing for IPv6 packets.	-
l2	Enables air interface slicing for Layer 2 packets.	-

Parameter	Description	Value
acl *acl-number*	Specifies the number of an ACL.	For IPv4 and IPv6 ACLs, the value is an integer that ranges from 3000 to 3031 and 6000 to 6031 in the traffic profile. For Layer 2 ACLs, the value is an integer that ranges from 4000 to 4031. ● 3000 to 3031: advanced ACLs ● 6000 to 6031: user ACLs ● 4000 to 4031: Layer 2 ACLs

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To implement QoS for multiple low-latency services in a more refined manner, you can enable the air interface slicing function for specific traffic. You can specify an ACL to filter traffic so that air interface slicing takes effect only for traffic that matches the ACL.

Air interface slicing identifies service traffic using access control lists (ACLs).

- Common terminal: Run the **wlan-slice high-reliability acl** command in the traffic profile to configure an ACL for air interface slicing. The device performs robust scheduling on the service traffic that matches the ACL.

Precautions

An ACL rule has been created before this command is run.

- **acl (system view)**
- **acl ipv6 (system view)**
- **acl name**
- **acl ipv6 name**

Example

Specify an ACL for air interface slicing in a traffic profile.

```
<HUAWEI> system-view
[HUAWEI] acl 3000
```

```
[HUAWEI-acl-adv-3000] rule 5 permit ip source 192.168.0.2 0
[HUAWEI-acl-adv-3000] quit
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] wlan-slice high-reliability ipv4 acl 3000
```

11.7.51 wmm edca-ap

Function

The **wmm edca-ap** command sets EDCA parameters and ACK policies for an AP.

The **undo wmm edca-ap** command restores the default EDCA parameters and ACK policies for an AP.

Table 11-178 lists the default EDCA parameter settings and ACK policies for APs.

Table 11-178 Default EDCA parameter settings and ACK policies for APs

Packet Type	ECWmax	ECWmin	AIFSN	TXOPLimit	ACK Policy
AC_VO	3	2	1	47	normal
AC_VI	4	3	1	94	normal
AC_BE	6	4	3	0	normal
AC_BK	10	4	7	0	normal

Format

wmm edca-ap { **ac-vo** | **ac-vi** | **ac-be** | **ac-bk** } { **aifsn** *aifsn-value* | **ecw ecwmin** *ecwmin-value* **ecwmax** *ecwmax-value* | **txoplimit** *txoplimit-value* | **ack-policy** { **normal** | **noack** } } *

undo wmm edca-ap

Parameters

Parameter	Description	Value
ac-vo	Indicates AC_VO packets.	-
ac-vi	Indicates AC_VI packets.	-
ac-be	Indicates AC_BE packets.	-
ac-bk	Indicates AC_BK packets.	-
aifsn *aifsn-value*	Specifies the AIFSN, which determines the channel idle time.	The value is an integer that ranges from 1 to 15.

Parameter	Description	Value
ecwmin *ecwmin-value*	Specifies the *ecwmin-value*. *ecwmin-value* and *ecwmax-value* determine the average backoff time.	The value is an integer that ranges from 0 to 15 and must be less than or equal to the *ecwmax-value* value.
ecwmax *ecwmax-value*	Specifies the *ecwmax-value*. *ecwmax-value* and *ecwmin-value* determine the average backoff time.	The value is an integer that ranges from 0 to 15 and must be greater than or equal to the *ecwmin-value* value.
txoplimit *txoplimit-value*	Specifies the TXOPLimit, which determines the maximum duration in which an AP or a STA can occupy a channel. A larger *txoplimit-value* value indicates a longer duration to occupy a channel.	The value is an integer that ranges from 0 to 255. The unit is 32 microseconds. **NOTE** If the *txoplimit-value* value is 0, the STA can send only one data frame every time it occupies a channel.
ack-policy { **normal** | **noack** }	Specifies an ACK policy. ● **normal**: During 802.11 packet exchange, the receiver must return an ACK packet each time it receives a packet from the sender. ● **noack**: The receiver does not need to send an ACK message when it receives a packet from the sender. Configure this parameter only in the good air interface environment. Otherwise, severe packet loss occurs.	-

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

WMM classifies data packets into the following access categories (ACs): AC_VO, AC_VI, AC_BE, and AC_BK. A set of EDCA parameters is set for each AC queue. These parameters determine the capabilities of a queue to occupy a channel. You can set EDCA parameters for packets of different ACs to provide different priorities for the packets. In this way, APs provide different capabilities to compete for channels, achieving differentiated services.

Precautions

- The EDCA parameters configured for the four AC queues take effect only after the WMM function is enabled. By default, the WMM function is enabled in a 2G or 5G radio profile.
- By default, queues of AC_VO, AC_VI, AC_BE, and AC_BK are in descending order of priority. Priorities of the four queues are determined by their EDCA parameters.
- EDCA parameters must be configured properly. The scenarios for the reference EDCA parameter settings and ACK policies are as follows:
  a. Table 11-179 lists the reference EDCA parameter settings and ACK policies for APs in voice scenarios.

Table 11-179 Reference EDCA parameter settings and ACK policies in voice scenarios

Packet Type	ECWmax	ECWmin	AIFSN	TXOPLimit	ACK Policy
AC_VO	4	2	2	0	normal
AC_VI	5	3	5	0	normal
AC_BE	10	6	5	0	normal
AC_BK	10	8	12	0	normal

  b. Table 11-180 lists the reference EDCA parameter settings and ACK policies for APs in voice and video scenarios.

Table 11-180 Reference EDCA parameter settings and ACK policies in voice and video scenarios

Packet Type	ECWmax	ECWmin	AIFSN	TXOPLimit	ACK Policy
AC_VO	4	2	2	0	normal
AC_VI	5	3	5	0	normal
AC_BE	10	6	12	0	normal
AC_BK	10	8	12	0	normal

c. In high-density scenarios, it is recommended that you run the **dynamic-edca enable** command to enable dynamic EDCA parameter adjustment.

d. For other scenarios, the default settings are recommended.

Example

Set EDCA parameters and ACK policies for AC_VO packets in 5G radio profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-5g-profile name default
[HUAWEI-wlan-radio-5g-prof-default] wmm edca-ap ac-vo aifsn 7 ecw ecwmin 4 ecwmax 10 txoplimit
0 ack-policy normal
```

11.7.52 wmm edca-client (SSID profile view)

Function

The **wmm edca-client** command configures EDCA parameters for STAs.

The **undo wmm edca-client** command restores the default EDCA parameter settings of STAs.

Table 11-181 lists the default EDCA parameter settings for STAs.

Table 11-181 Default EDCA parameter settings for STAs

Packet Type	ECWmax	ECWmin	AIFSN	TXOPLimit
AC_VO	3	2	2	47
AC_VI	4	3	2	94
AC_BE	10	4	3	0
AC_BK	10	4	7	0

Format

wmm edca-client { **ac-vo** | **ac-vi** | **ac-be** | **ac-bk** } { **aifsn** *aifsn-value* | **ecw ecwmin** *ecwmin-value* **ecwmax** *ecwmax-value* | **txoplimit** *txoplimit-value* } *

undo wmm edca-client

Parameters

Parameter	Description	Value
ac-vo	Indicates AC_VO packets.	-
ac-vi	Indicates AC_VI packets.	-
ac-be	Indicates AC_BE packets.	-

Parameter	Description	Value
ac-bk	Indicates AC_BK packets.	-
aifsn *aifsn-value*	Specifies the arbitration inter frame spacing number (AIFSN), which determines the channel idle time.	The value is an integer that ranges from 12 to 15.
ecwmin *ecwmin-value*	Specifies the exponent form of the minimum contention window. *ecwmin-value* and *ecwmax-value* determine the average backoff time.	The value is an integer that ranges from 0 to 15 and must be less than or equal to the *ecwmax-value* value.
ecwmax *ecwmax-value*	Specifies the exponent form of the maximum contention window. *ecwmin-value* and *ecwmax-value* determine the average backoff time.	The value is an integer that ranges from 0 to 15 and must be greater than or equal to the *ecwmin-value* value.
txoplimit *txoplimit-value*	Specifies the transmission opportunity limit (TXOPLimit), which determines the maximum duration in which a STA can occupy a channel. A larger TXOPLimit value indicates a longer duration to occupy a channel.	The value is an integer that ranges from 0 to 255. The unit is 32 microseconds. **NOTE** If the TXOPLimit value is 0, the STA can send only one data frame every time it occupies a channel.

2: Configuration level

Usage Guidelines

Usage Scenario

WMM classifies data packets into the following access categories (ACs): AC_VO, AC_VI, AC_BE, and AC_BK. A set of EDCA parameters is set for each AC queue.

These parameters determine the capabilities of a queue to occupy a channel. You can set EDCA parameters for packets of different ACs to provide differentiated priorities to the packets and different capabilities to compete for channels. In this way, differentiated services are implemented.

Table 11-182 describes the EDCA parameters.

Table 11-182 EDCA parameter description

Parameter	Meaning
Arbitration Interframe Spacing Number (AIFSN)	The DIFS has a fixed value. WMM provides different DIFS values for different ACs. A large AIFSN value means that the STA must wait for a long time and has a low priority.
Exponent form of CWmin (ECWmin) and exponent form of CWmax (ECWmax)	ECWmin specifies the minimum backoff time, and ECWmax specifies the maximum backoff time. Together, they determine the average backoff time. Large ECWmin and ECWmax values mean a long average backoff time for the STA and a low STA priority.
Transmission Opportunity Limit (TXOPLimit)	After preempting a channel, the STA can occupy the channel within the period of TXOPLimit. A large TXOPLimit value means that the STA can occupy the channel for a long time. If the TXOPLimit value is 0, the STA can only send one data frame every time it preempts a channel.

Precautions

- The EDCA parameters configured for the four AC queues take effect only after the WMM function is enabled using the **undo wmm disable** command.
- By default, queues of AC_VO, AC_VI, AC_BE, and AC_BK are in descending order of priority. Priorities of the four queues are determined by their EDCA parameters.
- EDCA parameters must be configured properly. The scenarios for the reference EDCA parameter settings and ACK policies are as follows:
  a. **Table 11-183** lists the reference EDCA parameter settings and ACK policies for APs in voice scenarios.

Table 11-183 Reference EDCA parameter settings and ACK policies in voice scenarios

Packet Type	ECWmax	ECWmin	AIFSN	TXOPLimit	ACK Policy
AC_VO	4	2	2	0	normal

Packet Type	ECWmax	ECWmin	AIFSN	TXOPLimit	ACK Policy
AC_VI	5	3	5	0	normal
AC_BE	10	6	5	0	normal
AC_BK	10	8	12	0	normal

b. Table 11-184 lists the reference EDCA parameter settings and ACK policies for APs in voice and video scenarios.

Table 11-184 Reference EDCA parameter settings and ACK policies in voice and video scenarios

Packet Type	ECWmax	ECWmin	AIFSN	TXOPLimit	ACK Policy
AC_VO	4	2	2	0	normal
AC_VI	5	3	5	0	normal
AC_BE	10	6	12	0	normal
AC_BK	10	8	12	0	normal

c. In high-density scenarios, it is recommended that you run the **dynamic-edca enable** command to enable dynamic EDCA parameter adjustment.

d. For other scenarios, the default settings are recommended.

Example

Set EDCA parameters for AC_VO packets of STAs in SSID profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name p1
[HUAWEI-wlan-ssid-prof-p1] wmm edca-client ac-vo aifsn 7 ecw ecwmin 4 ecwmax 10 txoplimit 0
```

11.7.53 wmm mu-edca-client (SSID profile view)

Function

The **wmm mu-edca-client** command configures MU EDCA parameters for STAs.

The **undo wmm mu-edca-client** command restores the default MU EDCA parameter settings of STAs.

Table 11-185 lists the default MU EDCA parameter settings for STAs.

Table 11-185 Default MU EDCA parameter settings for STAs

Packet Type	ECWmax	ECWmin	AIFSN	MUEDCATimer
AC_VO	3	2	2	1
AC_VI	4	3	2	1
AC_BE	10	4	3	1
AC_BK	10	4	7	1

Format

wmm mu-edca-client { **ac-vo** | **ac-vi** | **ac-be** | **ac-bk** } { **aifsn** *aifsn-value* | **ecw ecwmin** *ecwmin-value* **ecwmax** *ecwmax-value* | **muedcatimer** *muedcatimer-value* } *

undo wmm mu-edca-client

Parameters

Parameter	Description	Value
ac-vo	Indicates AC_VO packets.	-
ac-vi	Indicates AC_VI packets.	-
ac-be	Indicates AC_BE packets.	-
ac-bk	Indicates AC_BK packets.	-
aifsn *aifsn-value*	Specifies the arbitration inter frame spacing number (AIFSN), which determines the channel idle time.	The value is an integer that ranges from 2 to 15.
ecwmin *ecwmin-value*	Specifies the exponent form of the minimum contention window. *ecwmin-value* and *ecwmax-value* determine the average backoff time.	The value is an integer that ranges from 0 to 15 and must be less than or equal to *ecwmax-value*.
ecwmax *ecwmax-value*	Specifies the exponent form of the maximum contention window. *ecwmax-value* and *ecwmin-value* determine the average backoff time.	The value is an integer that ranges from 0 to 15 and must be greater than or equal to *ecwmin-value*.

Parameter	Description	Value
muedcatimer *muedcatimer-value*	Specifies the MU EDCA timer, indicating the validity duration of MU EDCA parameters. When the timer is 0, the conventional EDCA parameters take effect.	The value is an integer that ranges from 1 to 255, in the unit of 8 TUs (1 TU = 1024 us).

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

STAs in compliance with 802.11ax or later standards (Wi-Fi 6/7 STAs) support two transmission modes: EDCA-based contention transmission and Trigger frame-based uplink transmission. In this way, Wi-Fi 6/7 STAs have more channel access opportunities than legacy STAs. To ensure channel access fairness, the MU EDCA mechanism is introduced. After being triggered by the AP to send data, Wi-Fi 6/7 STAs switch to the MU EDCA parameter set. The MU EDCA parameter set has a longer contention waiting time and a larger backoff window, and therefore has a lower priority compared with the conventional EDCA parameter set.

If Wi-Fi 6/7 STAs do not schedule Trigger frames for a long time, the STAs exit the MU EDCA mechanism and switch back to conventional EDCA parameters.

Precautions

Improper settings for MU EDCA parameters may cause poor uplink user experience.

In most scenarios, the default configurations are recommended. In MU scenarios, the recommended configurations are described in the following table.

Table 11-186 Recommended MU EDCA parameter settings for STAs in MU scenarios

Packet Type	ECWmax	ECWmin	AIFSN	MUEDCATimer
AC_VO	3	2	3	1
AC_VI	4	3	3	1
AC_BE	10	4	4	1

Packet Type	ECWmax	ECWmin	AIFSN	MUEDCATimer
AC_BK	10	4	8	1

Example

Set MU EDCA parameters for AC_VO packets of STAs in the SSID profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name p1
[HUAWEI-wlan-ssid-prof-p1] wmm mu-edca-client ac-vo aifsn 7 ecw ecwmin 4 ecwmax 10
muedcatimer 1
```

11.7.54 wmm disable (radio profile view)

Function

The **wmm disable** command disables the Wi-Fi Multimedia (WMM) function in a 2G or 5G radio profile.

The **undo wmm disable** command enables the WMM function in a 2G or 5G radio profile.

By default, the WMM function is enabled in a 2G or 5G radio profile.

Format

wmm disable

undo wmm disable

Parameters

None

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

802.11be, 802.11ax, 802.11ac and 802.11n STAs must support WMM. If the WMM function is disabled on a radio, 802.11be, 802.11ax, 802.11ac and 802.11n cannot work and STAs can access the network only in 802.11a/b/g mode.

If the WMM function is disabled, the access of non-HT STAs fails to be denied.

After the WMM function is enabled in a 2G or 5G radio profile, the AP radio to which the 2G or 5G radio profile is applied can use the WMM parameters.

Example

Enable the WMM function in 5G radio profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-5g-profile name default
[HUAWEI-wlan-radio-5g-prof-default] undo wmm disable
```

11.7.55 wmm mandatory enable

Function

The **wmm mandatory enable** disables STAs that do not support WMM from connecting to a WMM-enabled AP.

The **undo wmm mandatory enable** allows STAs that do not support WMM to connect to a WMM-enabled AP.

By default, STAs that do not support WMM are allowed to connect to a WMM-enabled AP.

Format

wmm mandatory enable

undo wmm mandatory enable

Parameters

None

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

On a WLAN, wireless channels are open and all STAs have the same chance to occupy a channel. You can configure WMM to distinguish high-priority packets and enable the high-priority packets to preempt channels. You can also disable STAs that do not support WMM from connecting to a WMM-enabled AP, which prevents those STAs from preempting channels of WMM-capable STAs.

Example

Disable STAs that do not support WMM to connect to a WMM-enabled AP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] wmm mandatory enable
```

11.8 DFI Configuration Commands

11.8.1 Command Support

WLAN-AC commands are supported only by the following models: S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.

NOTE

The DFI function is supported only by the following models:

- AirEngine X760 series APs
- AirEngine X761 series APs (excluding the AirEngine 5761-10W, AirEngine 5761S-10W, and AirEngine 5761-10WD)
- AirEngine X762 series APs running V200R021C10 or later
- AirEngine X771 series APs
- AirEngine 9700D-S (including matching ORUs)

11.8.2 dynamic flow inspection

Function

The **dynamic flow inspection** command enables or disables DFI on a VAP.

The **undo dynamic flow inspection** command restores the default DFI state on a VAP.

By default, DFI is disabled on AirEngine 5762S series models and enabled on other AP models.

Format

dynamic flow inspection { **enable** | **disable** }

undo dynamic flow inspection

Parameters

Parameter	Description	Value
enable	Enables the DFI function.	-
disable	Disables the DFI function.	-

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the DFI function is enabled on a VAP, the device identifies the traffic on this VAP and preferentially guarantees the downlink traffic of gaming and VoIP services on the air interface based on the identification result.

Precautions

Disabling the DFI function may cause the game turbo function to become invalid.

Example

Enable the DFI function on a VAP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name default
[HUAWEI-wlan-vap-prof-default] dynamic flow inspection enable
```

11.9 Application Identification Configuration Commands

11.9.1 Command Support

WLAN-AC commands are supported only by the following models: S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.

11.9.2 application-group car (SAC profile view)

Function

The **application-group car** command enables rate limiting on a specified application group or a specified application in the group.

The **undo application-group car** command disables rate limiting on a specified application group or a specified application in the group.

By default, rate limiting is not configured for packets of any application in an application group.

Format

application-group *group-name* **app-protocol** { *app-protocol-name* | **all** } **car** *cir-value*

undo application-group *group-name* **app-protocol** { *app-protocol-name* | **all** } **car**

Parameters

Parameter	Description	Value
application-group *group-name*	Specifies the name of an application group.	The specified application group name must exist in the SAC signature file.
app-protocol *app-protocol-name*	Specifies the name of an application.	The specified application must exist.
all	Specifies all applications in the group.	-
car *cir-value*	Specifies the committed information rate (CIR).	The value is an integer that ranges from 64 to 10000000, in kbit/s.

Views

SAC profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to enable rate limiting on all applications in a group or the specified application in the group.

Precautions

If **application-group remark (SAC profile view)** or **application-group car (SAC profile view)** and **application-group deny (SAC profile view)** are both configured for an application, the rate limit and priority modification policy do not take effect for the application protocol packets, and the packets are discarded.

Prerequisites

Example

Set the CIR value to 100 kbit/s of the application in the application group in the SAC profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sac-profile name p1
[HUAWEI-wlan-sac-prof-p1] application-group  app-protocol  car 100
```

11.9.3 application-group deny (SAC profile view)

Function

The **application-group deny** command enables the device to discard packets of all applications in an application group or a specific application in the group.

The **undo application-group deny** command disables the device from discarding packets of all applications in an application group or a specific application in the group.

By default, the device does not discard packets of any application in an application group.

Format

application-group *group-name* **app-protocol** { *app-protocol-name* | **all** } **deny**

undo application-group *group-name* **app-protocol** { *app-protocol-name* | **all** } **deny**

Parameters

Parameter	Description	Value
application-group *group-name*	Specifies the name of an application group.	The specified application group name must exist in the SAC signature file.
app-protocol *app-protocol-name*	Specifies the name of an application.	The specified application must exist.
all	Specifies all applications in the group.	-

Views

SAC profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A WLAN transmits traffic of varied applications. The network administrator needs to know traffic usage of the applications to plan network capacity and locate problems on the network. In this situation, you can take application traffic control measures. If packets of a specified application need to be discarded, run the **application-group deny** command. You can also use the command to discard packets of a specified protocol type or a protocol type in a specified application group.

Precautions

If **application-group remark (SAC profile view)** or **application-group car (SAC profile view)** and **application-group deny (SAC profile view)** are both configured for an application, the rate limit and priority modification policy do not take effect for the application protocol packets, and the packets are discarded.

Prerequisites

Example

Configure the device to discard packets of the application in the SAC profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sac-profile name p1
[HUAWEI-wlan-sac-prof-p1] application-group  app-protocol  deny
```

11.9.4 application-group remark (SAC profile view)

Function

The **application-group remark** command re-marks packet priorities based on a specific application group or a specific application in the group.

The **undo application-group remark** command cancels packet priority remarking based on a specific application group or a specific application in the group.

By default, an action of re-marking packet priorities based on a specific application group or a specific application in the group is not configured in an SAC profile view.

Format

application-group *group-name* **app-protocol** { *app-protocol-name* | **all** } **remark** { **dscp** *dscp-value* | **dot1p** *dot1p-value* }

undo application-group *group-name* **app-protocol** { *app-protocol-name* | **all** } **remark** { **dscp** | **dot1p** }

Parameters

Parameter	Description	Value
application-group *group-name*	Specifies the name of an application group.	The specified application group name must exist in the SAC signature file.
app-protocol *app-protocol-name*	Specifies the name of an application.	The specified application must exist.
all	Re-marks priorities of packets of all applications in the group.	-
dscp *dscp-value*	Specifies the DSCP priority.	The value is an integer that ranges from 0 to 63. A larger value indicates a higher priority.
dot1p *dot1p-value*	Specifies the 802.1p priority.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.

Views

SAC profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **application-group remark** command to re-mark packet priorities based on a specific application group or a specific application in the group. In this way, different user packets are granted the same priority, facilitating flexible user management.

Precautions

If **application-group remark (SAC profile view)** or **application-group car (SAC profile view)** and **application-group deny (SAC profile view)** are both configured for an application, the rate limit and priority modification policy do not take effect for the application protocol packets, and the packets are discarded.

Before running this command, ensure that the mode of mapping 802.3 packets (sent by upper-layer devices to APs) to 802.11 packets is the same as the packet priority re-marking type you want to configure. Specifically:

- Run the **priority-map downstream trust dot1p** command if you want to specify the parameter **dot1p** *dot1p-value*.
- Run the **priority-map downstream trust dscp** command (default) if you want to specify the parameter **dscp** *dscp-value*.

Prerequisites

Example

Re-mark DSCP priorities of packets of the application in the SAC profile **p1** as 30.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sac-profile name p1
[HUAWEI-wlan-sac-prof-p1] application-group  app-protocol  remark dscp 30
```

11.9.5 category sub-category (AP user-defined application view)

Function

The **category sub-category** command configures the category and subcategory of an AP user-defined application.

The **undo category** command restores the default category and subcategory of an AP user-defined application.

The default category and subcategory of an AP user-defined application are **General** and **Other**, respectively.

Format

category *category* **sub-category** *sub-category*

undo category

Parameters

Parameter	Description	Value
category	Specifies the category of an application.	The specified category must be supported by the device.
sub-category	Specifies the subcategory of an application.	The specified subcategory must be supported by the device.

Views

AP user-defined application view

Default Level

2: Configuration level

Usage Guidelines

One category contains multiple subcategories, but one subcategory belongs to only one category.

During the configuration, you can enter a question mark (?) to display the supported categories and subcategories.

Example

Set the category and subcategory of the AP user-defined application **UD_abc** to **Business_Systems** and **Database**, respectively.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan] user-defined-application id 65000 name UD_abc
[HUAWEI-wlan-user-def-app-UD_adc] category Business_Systems sub-category Database
```

11.9.6 defence engine enable ap-group

Function

The **defence engine enable ap-group** command enables the security engine for AP groups.

The **undo defence engine enable ap-group** command disables the security engine for AP groups.

By default, the security engine is disabled for an AP group.

Format

defence engine enable ap-group { **all** | **name** *ap-group-name* }

undo defence engine enable ap-group { **all** | **name** *ap-group-name* }

Parameters

Parameter	Description	Value
all	Enables or disables the security engine for all AP groups.	-
name *ap-group-name*	Enables or disables the security engine for the AP group with a specified name.	The AP group must exist.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a WLAN, if you need to monitor applications in real time, collect application traffic statistics, or perform QoS scheduling, run the **defence engine enable ap-group** command to enable the security engine for AP groups.

Precautions

After the **defence engine enable ap-group all** command is run to enable the security engine for all AP groups, you cannot disable the security engine for only a specified AP group. Instead, you can only run the **undo defence engine enable ap-group all** command to disable the security engine for all AP groups.

Example

Enable the security engine for the AP group **default**.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable ap-group name default
```

11.9.7 description (AP user-defined application rule view)

Function

The **description** command configures the description for an AP user-defined application rule.

The **undo description** command deletes the description of an AP user-defined application rule.

By default, no description is configured for a new AP user-defined application rule.

Format

description *description*

undo description

Parameters

Parameter	Description	Value
description	Specifies the description of an AP user-defined application rule.	The value is a string of 1 to 128 case-sensitive characters, spaces supported.

Views

AP user-defined application rule view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to configure the description for an AP user-defined application rule.

Example

Configure the description **test** for the AP user-defined application rule **rule1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan] user-defined-application id 65000 name UD_abc
[HUAWEI-wlan-user-def-app-UD_adc] rule name rule1
[HUAWEI-wlan-user-def-app-UD_abc-rule-rule1] description test
```

11.9.8 description (AP user-defined application view)

Function

The **description** command configures the description for an AP user-defined application.

The **undo description** command deletes the description of an AP user-defined application.

By default, no description is configured for a new AP user-defined application.

Format

description *description*

undo description

Parameters

Parameter	Description	Value
description	Specifies the description of an AP user-defined application.	The value is a string of 1 to 128 case-sensitive characters, spaces supported.

Views

AP user-defined application view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to configure the description for an AP user-defined application.

Example

Configure the description **test** for the AP user-defined application **UD_abc**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan] user-defined-application id 65000 name UD_abc
[HUAWEI-wlan-user-def-app-UD_adc] description test
```

11.9.9 destination-port (AP user-defined application rule view)

Function

The **destination-port** command configures a port number for an AP user-defined application rule.

The **undo destination-port** command deletes the port number of an AP user-defined application rule.

By default, no port number is configured for a new AP user-defined application rule.

Format

destination-port *port*

undo destination-port

Parameters

Parameter	Description	Value
port	Specifies the port number for an AP user-defined application rule.	The value is an integer that ranges from 1 to 65535.

Views

AP user-defined application rule view

Default Level

2: Configuration level

Usage Guidelines

After a port number is configured using this command, the service awareness (SA) engine will match network packets based on the configured port number as well as the transport-layer protocol and IP address (that is, 3-tuple information). If destination 3-tuple information about the traffic to be identified is determined, you can configure user-defined 3-tuple information to accelerate identification. For example, you can configure a 3-tuple user-defined rule based on the IP address, port number, and transport-layer protocol of a server, so that the rule can identify all the traffic accessing this server. A triplet rule must contain at least either one IP address or one port number. Note that only the destination port number can be specified in this command configuration.

Example

Configure the port number **80** for the AP user-defined application rule **rule1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan] user-defined-application id 65000 name UD_abc
[HUAWEI-wlan-user-def-app-UD_adc] rule name rule1
[HUAWEI-wlan-user-def-app-UD_abc-rule-rule1] destination-port 80
```

11.9.10 display ap application

Function

The **display ap application** command displays information about applications on APs.

Format

display ap application

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run this command to view information about all applications on APs.

Prerequisites

The security engine has been enabled for the specified AP group using the **defence engine enable ap-group** command.

Example

Display information about applications on APs.

```
<HUAWEI> display ap application
---------------------------------------------------------------------------------------------------------------

 AppID   Name                              Sub-category
---------------------------------------------------------------------------------------------------------------
 1       bt                             fileshare_p2p
 3       thunder                           fileshare_p2p
 5       ftp                            infrastructure
 6       ftps                           infrastructure
 9       qqlive                          peercasting
 15      kugoo                             peercasting
 41      qq_voip                           voip
 45      qq_im                             instant_message
......
---------------------------------------------------------------------------------------------------------------
 Total: 188
```

11.9.11 display ap application-group

Function

The **display ap application-group** command displays information about application groups on APs.

Format

display ap application-group [*group-name*]

Parameters

Parameter	Description	Value
group-name	Displays information about a specified application group. If this parameter is not specified, information about all application groups on APs is displayed.	The specified application group name must be supported by the application identification signature database file.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run this command to view information about all application groups or a specified application list on APs.

Prerequisites

The security engine has been enabled for the specified AP group using the **defence engine enable ap-group** command.

Example

Display information about all application groups on APs.

```
<HUAWEI> display ap application-group
----------------------------------------
  Index       GroupName
----------------------------------------
  1           auth_service
  2           finance
  3           data_backup
  4           database
  5           email
  6           enterprise_application
  7           internet_conferencing
  8           remote_access
  9           game
  10           instant_messaging
-----------------------------------------
 Total: 10
```

Display information about the application group **email**.

```
<HUAWEI> display ap application-group email
-----------------------------------
```

```
  Index    Application name

11.9.12 display apsa-sdb

Function

The **display apsa-sdb** command displays information about the AP application identification signature database.

Format

display apsa-sdb { **version** | **update information** }

Parameters

Parameter	Description	Value
version	Displays the version of the application identification signature database.	-
update information	Displays update information about the application identification signature database.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

Before and after updating the application identification signature database, you can run the **display apsa-sdb** { **version** | **update information** } command to view the version and update information of the signature database and check whether the update is successful.

Prerequisites

The security engine has been enabled for the specified AP group using the **defence engine enable ap-group** command.

Example

Display the version of the AP application identification signature database.

```
<HUAWEI> display apsa-sdb version
----------------------------------------------------------------
Current Version:
  Signature Database Version:2021032403
  Signature Database Size(byte):132897
  Update Time:2021-06-22 06:16:42
  Issue Time of the Update File:2021-03-24 10:11:23
----------------------------------------------------------------
```

Table 11-189 Description of the **display apsa-sdb version** command output

Item	Description
Current Version	The current signature database version is displayed in the following information.
Signature Database Version	Signature database version.
Signature Database Size(byte)	Signature database size.
Update Time	Update time of the signature database, that is, the installation time of the update package.
Issue Time of the Update File	Issue time of the update file, showing whether the update package is the latest.

Display update information about the AP application identification signature database.

```
<HUAWEI> display apsa-sdb update information
Current Update Status:  Idle.
--------------------------------------------------------
  Latest update finish time : 2021-06-22006:16:42
  Latest update result : success
 -------------------------------------------------------
```

Table 11-190 Description of the **display apsa-sdb update information** command output

Item	Description
Current Update Status	Current status of the update server. - Idle: No signature database is being updated. - Version Loading: The version is being loaded. - Live Updating: The online update is in progress. - Local Updating: The local update is in progress. - Version Rollbacking: The version is being rolled back. - Stop Updating: The update is being canceled. - Version Applying: The version is being downloaded and installed. - Version Restoring: The default version is being restored. - Version Uninstalling: The version is being uninstalled. - Update check: The update is being checked. - Engine start loading: The security engine is being loaded.
Latest update finish time	Last update finish time of the signature database.
Latest update result	Last update result of the signature database.

11.9.13 display defence engine configuration

Function

The **display defence engine configuration** command displays whether the security engine is enabled for APs.

Format

display defence engine configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After running the **defence engine enable ap-group** command to enable the security engine for AP groups, you can run this command to check whether the security engine is enabled for APs.

Example

Display whether the security engine is enabled for APs.

```
<HUAWEI> display defence engine configuration
AP group engine state : all
------------------------------------------------------------
Group name                    State
------------------------------------------------------------
default                       Disable
------------------------------------------------------------
Total items displayed: 1
```

Table 11-191 Description of the **display defence engine configuration** command output

Item	Description
AP group engine state	Security engine state of AP groups. This field is displayed as **all** only when the security engine is enabled for all AP groups. Otherwise, no information is displayed for this field.
Group name	AP group name.
State	Whether the security engine is enabled for an AP group. - Enable: The security engine is enabled. - Disabled: The security engine is disabled.

11.9.14 display references sac-profile

Function

The **display references sac-profile** command displays the reference information of an SAC profile.

Format

display references sac-profile name *profile-name*

Parameters

Parameter	Description	Value
name *profile-name*	Displays the reference information of a specified SAC profile.	The SAC profile must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check the profiles by which a specified SAC profile is referenced.

Example

Display the reference information of the SAC profile **p1**.

```
<HUAWEI> display references sac-profile name p1
----------------------------------------------------
Reference type     Reference name
----------------------------------------------------
VAP profile        wlan-vap
----------------------------------------------------
Total: 1
```

Table 11-192 Description of the **display references sac-profile** command output

Item	Description
Reference type	Type of the profile that references an SAC profile.
Reference name	Name of the profile that references an SAC profile.

11.9.15 display wlan sac-profile

Function

The **display wlan sac-profile** command displays configuration and reference information about SAC profiles.

Format

display wlan sac-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays information about all SAC profiles.	-
name *profile-name*	Displays information about the SAC profile with a specified name.	The SAC profile name must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display sac-profile** command to view the configuration and reference information about SAC profiles.

Example

Display information about all SAC profiles.

```
<HUAWEI> display wlan sac-profile all
----------------------------------------------------------
Profile name                    Reference
----------------------------------------------------------
u1                           0
----------------------------------------------------------
Total: 1
```

Table 11-193 Description of the **display wlan sac-profile all** command output

Item	Description
Profile name	Name of an SAC profile.
Reference	Number of times an SAC profile is referenced.

Display information about the SAC profile **u1**.

```
<HUAWEI> display wlan sac-profile name u1
--------------------------------------------------------------------------------
SAC Profile name                      : u1
```

```
User statistic                 : disable
VAP statistic                  : disable
SAC Policy
--------------------------------------------------------------------------------
```

Table 11-194 Description of the **display wlan sac-profile name** command output

Item	Description
SAC Profile name	Name of an SAC profile. To configure this parameter, run the **sac-profile** command.
User statistic	User protocol statistics collection function. To configure this parameter, run the **user-protocol-statistic enable** command.
VAP statistic	Protocol statistics collection function on VAPs. To configure this parameter, run the **vap-protocol-statistic enable** command.
SAC Policy	SAC policy based on the protocol application or protocol application groups. To configure this parameter, run the **application-group car (SAC profile view)**, **application-group deny (SAC profile view)**, or **application-group remark (SAC profile view)** command.

11.9.16 display sac application user-defined

Function

The **display sac application user-defined** command displays user-defined applications deployed on an AP.

Format

display sac application user-defined { **id** *application-id* | **name** *name* | **all** }

Parameters

Parameter	Description	Value
id *application-id*	Specifies the ID of an AP user-defined application.	The value is an integer that ranges from 65000 to 65031.
name *name*	Specifies the name of an AP user-defined application.	The value is a string of case-sensitive characters, and must start with **UD_**. If the name does not contain spaces, the value is a string of 4 to 32 characters. If the name contains spaces, the value is a string of 6 to 34 characters and must be enclosed with double quotation marks (""), for example, **"UD_user for test"**. The name cannot contain question marks (?), commas (,), or hyphens (-). If the name does not contain any space, it also cannot contain double quotation marks (").
all	Displays all AP user-defined applications.	-

Views

Diagnostic view

Default Level

3: Management level

Usage Guidelines

You can run this command to view the configuration of user-defined applications deployed on an AP.

Example

Display all AP user-defined applications.

```
<HUAWEI> display sac application user-defined all
------------------------------------------------------------------------------------------------------------
AppID Name                          Category                        Sub-category
------------------------------------------------------------------------------------------------------------
65000 UD_abc                        general                         other
------------------------------------------------------------------------------------------------------------
Total: 1
```

Table 11-195 Description of the **display sac application user-defined all** command output

Item	Description
AppID	ID of an AP user-defined application.
Name	Name of an AP user-defined application.
Category	Category of an AP user-defined application.
Sub-category	Subcategory of an AP user-defined application.

Display the configuration of the AP user-defined application **UD_abc**.

```
<HUAWEI> display sac application user-defined name UD_abc
------------------------------------------------------------------------------
User-defined application configuration:
Name             : UD_abc
ID               : 65000
Category         : general
Sub-category     : other

Rule configuration:
Rule number      : 1
Rule name        : rule1
Rule id          : 0
Rule state       : success
    IP address               : 0.0.0.0/0
    Destination port         : 0
    Protocol                 : tcp
    Signature type           : packet
    Signature direction      : both
    Signature plain-string   : abcdf
------------------------------------------------------------------------------
```

Table 11-196 Description of the **display sac application user-defined** command output

Item	Description
User-defined application configuration	
Name	Name of the AP user-defined application.
ID	ID of the AP user-defined application.
Category	Category of the AP user-defined application.
Sub-category	Subcategory of the AP user-defined application.
Description	Description of the AP user-defined application.

Item	Description
Rule configuration	
Rule number	Number of AP user-defined application rules.
Rule name	Name of an AP user-defined application rule.
Rule id	ID of an AP user-defined application rule.
Rule state	Rule delivery result. ● success: The rule is delivered successfully. ● failed: The rule delivery fails. ● committing: The rule is being delivered.
IP address	IPv4 address and subnet mask of an AP user-defined application rule.
Destination port	Port number of an AP user-defined application rule.
Protocol	Transport-layer protocol type of an AP user-defined application rule.
Signature type	Detection scope: ● packet
Signature direction	Detection direction: ● both: both request and response directions ● request: request direction ● response: response direction
Signature plain-string	Configured keyword.

11.9.17 ip-address (AP user-defined application rule view)

Function

The **ip-address** command configures an IPv4 address for an AP user-defined application rule.

The **undo ip-address** command deletes the IPv4 address of an AP user-defined application rule.

By default, no IPv4 address is configured for a new AP user-defined application rule.

Format

ip-address *ip-address* [*mask* | *mask-length*]

undo ip-address

Parameters

Parameter	Description	Value
ip-address	Specifies an IPv4 address.	The value is in dotted decimal notation.
mask	Specifies the subnet mask.	The value is in dotted decimal notation.
mask-length	Specifies the mask length.	The value is an integer in the range from 1 to 32.

Views

AP user-defined application rule view

Default Level

2: Configuration level

Usage Guidelines

You can configure a single IPv4 address for a user-defined application rule, or configure a network segment by specifying the subnet mask or mask length.

After an IPv4 address is configured using this command, the service awareness (SA) engine will match network packets based on the configured IPv4 address as well as the transport-layer protocol and port number (that is, 3-tuple information). If destination 3-tuple information about the traffic to be identified is determined, you can configure user-defined 3-tuple information to accelerate identification. For example, you can configure a 3-tuple user-defined rule based on the IP address, port number, and transport-layer protocol of a server, so that the rule can identify all the traffic accessing this server. A triplet rule must contain at least either one IP address or one port number. Note that only the destination IPv4 address can be specified in this command configuration.

Example

Configure the IPv4 address **10.1.1.1** for the user-defined application rule **rule1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan] user-defined-application id 65000 name UD_abc
[HUAWEI-wlan-user-def-app-UD_adc] rule name rule1
[HUAWEI-wlan-user-def-app-UD_abc-rule-rule1] ip-address 10.1.1.1
```

11.9.18 priority-remark-default

Function

The **priority-remark-default** command enables the device to restore the default priorities of SAC applications.

The **undo priority-remark-default** command disables the device from restoring the default priorities of SAC applications.

By default, the device restores the default priorities of SAC applications.

Format

priority-remark-default

undo priority-remark-default

Parameters

None

Views

SAC profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The SAC function allows you to modify the priorities of application packets as required. However, defining the priorities of applications one by one is not user-friendly.

After this command is executed, the default priorities of all applications identified by SAC are restored based on the identification result. This ensures that applications that require high real-timeness and reliability have higher priorities when SAC is enabled.

To check the default priorities of different applications, run the **display sac default-priority** command.

Example

Enable the device to restore the default priorities of SAC applications.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sac-profile name p1
[HUAWEI--wlan-sac-prof-p1] priority-remark-default
```

11.9.19 protocol (AP user-defined application rule view)

Function

The **protocol** command configures the transport-layer protocol for an AP user-defined application rule.

The **undo protocol** command restores the default transport-layer protocol of an AP user-defined application rule.

By default, the transport-layer protocol of an AP user-defined application rule is any, that is, the rule takes effect for both TCP and UDP packets.

Format

protocol { **tcp** | **udp** }

undo protocol

Parameters

Parameter	Description	Value
tcp	Specifies the TCP protocol.	-
udp	Specifies the UDP protocol.	-

Views

AP user-defined application rule view

Default Level

2: Configuration level

Usage Guidelines

You can use this command to configure the transport-layer protocol for an AP user-defined application rule. To make the rule take effect, however, you also need to specify other configuration items.

Example

Configure TCP as the transport-layer protocol of an AP user-defined application rule.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan] user-defined-application id 65000 name UD_abc
[HUAWEI-wlan-user-def-app-UD_adc] rule name rule1
[HUAWEI-wlan-user-def-app-UD_abc-rule-rule1] protocol tcp
```

11.9.20 rule name (AP user-defined application view)

Function

The **rule name** command configures a rule for an AP user-defined application and displays the rule view.

The **undo rule** command deletes rules of an AP user-defined application.

By default, no rule is configured for a new AP user-defined application.

Format

rule name *name*

undo rule { **name** *name* | **all** }

Parameters

Parameter	Description	Value
name *name*	Specifies the rule name.	The name is a string of case-sensitive characters. If the name does not contain spaces, the value is a string of 1 to 32 characters. If the name contains spaces, the value is a string of 3 to 34 characters and must be enclosed with double quotation marks (""), for example, **"user for test"**. The name cannot contain question marks (?), commas (,), or hyphens (-). If the name does not contain any space, it also cannot contain double quotation marks ("). The name cannot be **any** or **all**.
all	Deletes all AP user-defined application rules.	-

Views

AP user-defined application view

Default Level

2: Configuration level

Usage Guidelines

If the specified rule name of an AP user-defined application does not exist, a new rule is created for the AP user-defined application and the rule view is displayed. If the specified rule name of the AP user-defined application already exists, the rule view is directly displayed.

A rule can be created based on 3-tuple information, keywords, or both 3-tuple information and keywords. The 3-tuple information refers to the server IP address, protocol type, and destination port number. The keywords are signatures of data packets or data flows corresponding to an application and uniquely identify the application.

- You can run the **ip-address (AP user-defined application rule view)**, **destination-port (AP user-defined application rule view)**, and **protocol (AP user-defined application rule view)** commands to specify 3-tuple information for an application.
- You can run the **signature (AP user-defined application rule view)** command to specify keywords for an application.

Multiple rules can be configured for one AP user-defined application. These rules are logically ORed. Data flows or packets belong to the application once they match one of the rules.

If the number of user-defined application rules on an AP reaches the maximum but the number of user-defined applications does not reach the maximum, you can continue to configure user-defined applications but cannot configure new rules for these applications.

Example

Create the rule **rule1** for the AP user-defined application **UD_abc** and display the rule view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan] user-defined-application id 65000 name UD_abc
[HUAWEI-wlan-user-def-app-UD_adc] rule name rule1
[HUAWEI-wlan-user-def-app-UD_abc-rule-rule1]
```

11.9.21 sac-profile

Function

The **sac-profile** command creates an SAC profile and displays the SAC profile view, or displays the view of an existing SAC profile.

The **undo sac-profile** command deletes an SAC profile. To delete a bound SAC profile, unbind the profile first.

By default, no SAC profile is available in the system.

Format

sac-profile name *profile-name*

undo sac-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of an SAC profile.	The value is a string of 1 to 35 case-insensitive characters. It cannot contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all SAC profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

You can run the **sac-profile** command to create an SAC profile. In the profile, you can perform the following configurations: discarding traffic of specified applications, setting priorities for packets of specified applications, and limiting packet rate of specified applications.

Example

Create the SAC profile **p1** and enter the SAC profile view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sac-profile name p1
[HUAWEI-wlan-sac-prof-p1]
```

11.9.22 signature (AP user-defined application rule view)

Function

The **signature** command configures the signature for an AP user-defined application.

The **undo signature** command deletes the signature of an AP user-defined application.

By default, no signature is configured for an AP user-defined application.

Format

signature context packet direction { **request** | **response** | **both** } **plain-string** *plain-string*

undo signature

Parameters

Parameter	Description	Value
context	Specifies the context with which the signature to be configured matches.	-
packet	Indicates the packet-based matching mode.	-
request	Indicates the request detection direction.	-
response	Indicates the response detection direction.	-
both	Indicates that the detection direction is both request and response directions.	-
plain-string *plain-string*	Indicates a plain-text string.	The value is a string of 3 to 128 case-sensitive characters. If the string contains spaces and question marks (?), the value is a string of 5 to 130 characters and must be enclosed with double quotation marks (""), for example, **"GET w?"**. If the string contains a double quotation mark ("), the double quotation mark needs to be escaped into **\x22**. For example, if the string is **abc"d**, you need to enter **abc\x22d**.

Views

AP user-defined application rule view

Default Level

2: Configuration level

Usage Guidelines

Only one signature can be configured for an AP user-defined application rule.

If you run this command multiple times, only the latest configuration takes effect.

Example

Configure the signature **abcde** for the AP user-defined application rule **rule1**, configure the packet-based matching mode, and set the detection direction to the request direction.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan] user-defined-application id 65000 name UD_abc
[HUAWEI-wlan-user-def-app-UD_adc] rule name rule1
[HUAWEI-wlan-user-def-app-UD_abc-rule-rule1] protocol tcp
[HUAWEI-wlan-user-def-app-UD_abc-rule-rule1] signature context packet direction request plain-string
abcde
```

11.9.23 sac-profile (VAP profile view)

Function

The **sac-profile** command binds an SAC profile to a VAP profile.

The **undo sac-profile** command unbinds an SAC profile to a VAP profile.

By default, no SAC profile is bound to a VAP profile.

Format

sac-profile *profile-name*

undo sac-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of an SAC profile.	The SAC profile must exist.

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

You can use this command to bind an SAC profile to a VAP profile. The SAC profile then applies to all users using this VAP profile.

Example

Bind the SAC profile **p1** to the VAP profile **vap1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sac-profile name p1
[HUAWEI-wlan-sac-prof-p1] quit
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] sac-profile p1
```

11.9.24 upgrade local apsa-sdb

Function

The **upgrade local apsa-sdb** command manually updates the local application signature database for APs.

Format

upgrade local apsa-sdb file *filename*

Parameters

Parameter	Description	Value
file *filename*	Specifies the update file, in .zip format. You need to upload the file to the flash directory of the storage device through FTP or SFTP in advance.	The value is a string of 1 to 64 characters without spaces.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To update the signature database, download the update file from Huawei security center isecurity.huawei.com to the PC, upload the file to the flash directory of the storage device through FTP or SFTP, and then run this command to update the signature database.

Prerequisites

The security engine has been enabled for the specified AP group using the **defence engine enable ap-group** command.

Precautions

The update file must be placed in the flash directory, because this command does not support the file path setting.

This command cannot be used to load the signature database for APs running V200R019C00 or earlier.

Example

Manually update the local application signature database for APs using the signature file **APSA_H30071006_2021053106.zip**.

```
<HUAWEI> system-view
[HUAWEI] upgrade local apsa-sdb file APSA_H30071006_2021053106.zip
Warning: This operation will upgrade the AP signature database file. Continue? [Y/N]:y
It will take several seconds to update the AP signature database file, please wait...............
Info: The AP signature database file is successfully upgraded.
```

11.9.25 user-defined-application (WLAN view)

Function

The **user-defined-application** command creates an AP user-defined application and displays the AP user-defined application view.

The **undo user-defined-application** command deletes AP user-defined applications.

By default, no AP user-defined application is configured.

Format

user-defined-application id *application-id* [**name** *name*]

undo user-defined-application { **id** *application-id* | **name** *name* | **all** }

Parameters

Parameter	Description	Value
id *application-id*	Specifies the ID of an AP user-defined application.	The value is an integer that ranges from 65000 to 65031.

Parameter	Description	Value
name *name*	Specifies the name of an AP user-defined application.	The value is a string of case-sensitive characters, and must start with **UD_**. If the name does not contain spaces, the value is a string of 4 to 32 characters. If the name contains spaces, the value is a string of 6 to 34 characters and must be enclosed with double quotation marks (""), for example, **"UD_user for test"**. The name cannot contain question marks (?), commas (,), or hyphens (-). If the name does not contain any space, it also cannot contain double quotation marks (").
all	Deletes all AP user-defined applications.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

If the specified AP user-defined application name does not exist, a new AP user-defined application is created and the AP user-defined application view is displayed. If the specified AP user-defined application name exists, the AP user-defined application view is directly displayed. If the **name** parameter is not specified, the user-defined application named **UD_id** is created by default.

Example

Create the AP user-defined application **UD_abc**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan] user-defined-application id 65000 name UD_abc
[HUAWEI-wlan-user-def-app-UD_adc]
```

11.9.26 user-protocol-statistic enable

Function

The **user-protocol-statistic enable** command enables the user protocol statistics collection function.

The **undo user-protocol-statistic enable** command disables the user protocol statistics collection function.

By default, the user protocol statistics collection function is disabled.

Format

user-protocol-statistic enable

undo user-protocol-statistic enable

Parameters

None

Views

SAC profile view

Default Level

2: Configuration level

Usage Guidelines

After going online on an AP, users start various applications on STAs to access the network. By analyzing packets sent by STAs, the collects information about network usage by applications of each user and reports the collected information (including the IP and MAC addresses of STAs and the application types) to the network management system (NMS). The NMS then displays and stores the information, which the administrator can view at any time. To identify user-based applications, run the **user-protocol-statistic enable** command.

NOTE

This function takes effect only for STAs who go online after the **user-protocol-statistic enable** command is successfully executed.

Example

Enable the user protocol statistics collection function in the SAC profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sac-profile name p1
[HUAWEI-wlan-sac-prof-p1] user-protocol-statistic enable
```

11.9.27 vap-protocol-statistic enable

Function

The **vap-protocol-statistic enable** command enables the protocol statistics collection function in a VAP.

The **undo vap-protocol-statistic enable** command disables the protocol statistics collection function in a VAP.

By default, the protocol statistics collection function is disabled in a VAP.

Format

vap-protocol-statistic enable

undo vap-protocol-statistic enable

Parameters

None

Views

SAC profile view

Default Level

2: Configuration level

Usage Guidelines

After going online on an AP, users start various applications on STAs to access the network. By analyzing packets sent by STAs, the collects information about network usage by applications of each user and reports the collected information (including the IP and MAC addresses of STAs and the application types) to the network management system (NMS). The NMS then displays and stores the information, which the administrator can view at any time. To identify applications in a VAP, run the **vap-protocol-statistic enable** command.

Example

Enable the protocol statistics collection function for VAPs in SAC profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sac-profile name p1
[HUAWEI-wlan-sac-prof-p1] vap-protocol-statistic enable
```

11.10 WLAN Location Configuration Commands

11.10.1 Command Support

- WLAN-AC commands are supported only by the following models: S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.
- The AeroScout MU location function is not supported by the following models:
  - AirEngine X760 series APs running V200R022C00 or earlier
  - AirEngine X761 series APs running V200R022C00 or earlier
  - AirEngine X762 series APs running V200R022C00 or earlier (In V200R022C10 and later versions, these APs support only single AP-based AeroScout MU location but do not support three-point location.)
  - AirEngine series central APs (including matching RUs) running V200R022C00 or earlier

  - AirEngine 9700D-S (including matching ORUs)
- The Wi-Fi tag location function is not supported by the following models:
  - AirEngine X760 series APs: do not support Ekahau tag location, and do not support AeroScout tag location in V200R022C00 or earlier.
  - AirEngine X761 series APs: do not support Ekahau tag location, and do not support AeroScout tag location in V200R022C00 or earlier.
  - AirEngine X771 series APs: do not support Ekahau tag location.
  - AirEngine X762 series APs
  - AirEngine series central APs (including matching RUs): do not support Ekahau tag location, and do not support AeroScout tag location in V200R022C00 or earlier.
  - AirEngine 9700D-S (including matching ORUs)
- Only the following models support Bluetooth terminal location, Bluetooth tag location, and Bluetooth data transparent transmission:
  - AirEngine X760 series APs
  - AirEngine X761 series APs (excluding the AirEngine 5761-10W, AirEngine 5761S-10W, AirEngine 5761-10WD, and AirEngine 5761-11EI)
  - AirEngine X771 series APs
  - AirEngine 5762-12 and AirEngine 5762S-12 running V200R022C10 or later
- The Bluetooth broadcast function is supported only by the following models:
  - AirEngine X760 series APs
  - AirEngine X761 series APs (excluding the AirEngine 5761-10W, AirEngine 5761S-10W, AirEngine 5761-10WD, and AirEngine 5761-11EI)
  - AirEngine X771 series APs
  - AirEngine 5762-12 and AirEngine 5762S-12 running V200R022C10 or later

11.10.2 aeroscout compound-time

Function

The **aeroscout compound-time** command configures the aggregation time of AeroScout tag and mobile unit (MU) packets on the AC.

The **undo aeroscout compound-time** command restores the default aggregation time of AeroScout tag and MU packets.

The default aggregation time of AeroScout tag and MU packets is 6553.5s on the AC.

Format

aeroscout compound-time *time-value*

undo aeroscout compound-time

Parameters

Parameter	Description	Value
time-value	Specifies the packet aggregation time.	The value is an integer that ranges from 0 to 65535. The unit is in 0.1s. If *time-value* is set to 0, the AP does not aggregate packets but reports the packets in real time.

Views

Location profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During AeroScout location, the AP does not report the received tag packets immediately to the upstream device but aggregates the packets. After a specified time, the AP reports the aggregated packets.

The AeroScout location server delivers an aggregation time of 6553.5s to the APs. The AC delivers the aggregation time to the APs using the **aeroscout compound-time** command. The AP selects a smaller aggregation time. By default, the aggregation time on the APs is 6553.5s.

If the packet aggregation time is set to a large value on the AeroScout location system, it takes a long time for the AP to report the aggregated packets, resulting in poor real-time performance and a large delay in the transmission of location packets. You can run the **aeroscout compound-time** command to set a small aggregation time to reduce the delay in location packet transmission.

Precautions

When the size of aggregated packets on an AP reaches 1k bytes, the AP immediately reports the aggregated packets.

Example

Set the aggregation time to 10s.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] location-profile name example
[HUAWEI-wlan-location-prof-example] aeroscout compound-time 100
```

11.10.3 aeroscout local

Function

The **aeroscout local** command configures a local IP address used by the AC to receive packets from a location server.

The **undo aeroscout local** command deletes the configured local IP address used by the AC to receive packets from a location server.

By default, no local IP address is configured for the AC to receive packets from a location server.

Format

aeroscout local ip-address *ip-address*

undo aeroscout local

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies a local IPv4 address used by the AC to receive packets from a location server.	The value is in dotted decimal notation.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **aeroscout server port** *port-num* **via-ac ac-port** *ac-port-num* command is executed to configure location data to be reported through the AC, run the **aeroscout local ip-address** *ip-address* command to configure a local IP address used by the AC to receive packets from a location server. The AC can receive packets from the location server only using this IP address.

Precautions

You need to run the **source ip-address** *ip-address* command to configure the source IP address used by the AC to send packets to the location server.

Example

Configure 10.1.1.1 as the local IP address used by the AC to receive packets from a location server.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] aeroscout local ip-address 10.1.1.1
```

11.10.4 aeroscout mu-enable

Function

The **aeroscout mu-enable** command enables WLAN location of AeroScout mobile units (MUs).

The **undo aeroscout mu-enable** command disables WLAN location of AeroScout MUs.

By default, WLAN location of AeroScout MUs is disabled.

Format

aeroscout mu-enable

undo aeroscout mu-enable

Parameters

None

Views

Location profile view

Default Level

2: Configuration level

Usage Guidelines

You can run the **aeroscout mu-enable** command to enable WLAN location of AeroScout MUs.

Example

Enable WLAN location of AeroScout MUs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] location-profile name example
[HUAWEI-wlan-location-prof-example] aeroscout mu-enable
```

11.10.5 aeroscout server

Function

The **aeroscout server** command sets the port number for APs to report location packets of AeroScout tags and Mobile Units (MUs).

The **undo aeroscout server** command deletes the configured port number for APs to report location packets of AeroScout tags and MUs.

By default, no port number is configured for APs to report location packets of AeroScout tags and MUs.

Format

aeroscout server port *port-num* [**via-ac ac-port** *ac-port-num*]

undo aeroscout server

Parameters

Parameter	Description	Value
port *port-num*	Specifies a port number through which APs report location packets of AeroScout tags and MUs when APs are configured to directly report data. Specifies a port number through which the AC reports location packets of AeroScout tags and MUs when the AC is configured to forward data.	The value is an integer that ranges from 1025 to 65535.
via-ac	Indicates that the AC forwards location packets of AeroScout tags and MUs reported by APs to the AeroScout server. **NOTE** If the APs report the received tag packets and MU packets directly to the AeroScout location server, the **display wlan location statistics aeroscout** command cannot collect statistics about AeroScout tag locations and MU locations, and the **display wlan location config-info aeroscout** command cannot display the configuration delivered by the AeroScout location server to APs.	-
ac-port *ac-port-num*	Specifies the destination port number on the AC to which APs report location packets of AeroScout tags and MUs.	The value is an integer that ranges from 1025 to 65535.

Views

Location profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Location packets of AeroScout tags and MUs received by APs can be reported to the AeroScout location server directly or through the AC.

Precautions

You cannot configure a port number that has been occupied by other services. Otherwise, the destination port configuration fails.

For the same location method, via-ac can be configured only in one profile. If **via-ac** has been specified in the current location profile for a specific location method, it cannot be specified in other profiles for the same location method.

NOTE

An AeroScout server proactively establishes connections with APs. Therefore, manually add the APs and specify their MAC addresses, port numbers, and IP addresses on the AeroScout server. If the AC is configured to forward location data, you only need to specify the AC IP address. You do not need to specify the IP address of the AeroScout server on the AC.

Follow-up Procedure

If the AC is configured to forward location packets to the location server, run the **source ip-address** *ip-address* command to configure the source IP address for the AC to send packets to the location server and run the **aeroscout local ip-address** *ip-address* command to configure a local IP address for the AC to receive packets from the location server.

Example

Set the port number for APs to report location packets of AeroScout tags and MUs to 1144.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] location-profile name example
[HUAWEI-wlan-location-prof-example] aeroscout server port 1144
```

11.10.6 aeroscout tag-enable

Function

The **aeroscout tag-enable** command enables WLAN location of AeroScout tags.

The **undo aeroscout tag-enable** command disables WLAN location of AeroScout tags.

By default, WLAN location of AeroScout tags is disabled.

Format

aeroscout tag-enable

undo aeroscout tag-enable

Parameters

None

Views

Location profile view

Default Level

2: Configuration level

Usage Guidelines

You can run the **aeroscout tag-enable** command to enable WLAN location of AeroScout tags.

Example

Enable WLAN location of AeroScout tags.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] location-profile name example
[HUAWEI-wlan-location-prof-example] aeroscout tag-enable
```

11.10.7 ble low-power-threshold

Function

The **ble low-power-threshold** command sets a low power alarm threshold for BLE devices or Bluetooth tags.

The **undo ble low-power-threshold** command restores the low power alarm threshold of BLE devices or Bluetooth tags to the default value.

By default, the low power alarm threshold of BLE devices or Bluetooth tags is 20%.

Format

ble low-power-threshold *low-power-threshold*

undo ble low-power-threshold

Parameters

Parameter	Description	Value
low-power-threshold	Specifies the low power alarm threshold of BLE devices or Bluetooth tags.	The value is an enumerated type. The options are as follows: • 0: 0% • 20: 20% • 40: 40% • 60: 60% • 80: 80%

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

After the **sniffer enable** command is executed to enable the Bluetooth monitoring or Bluetooth tag location function of an AP's built-in Bluetooth module, the built-in Bluetooth module will scan and obtain information about surrounding BLE devices or Bluetooth tags. The information includes battery power of BLE devices or Bluetooth tags. When the obtained battery power of a BLE device or Bluetooth tag is lower than the low power alarm threshold, the AC generates an alarm indicating that the BLE device or Bluetooth tag has low battery power.

Example

Set the low power alarm threshold for BLE devices or Bluetooth tags to 40%.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ble low-power-threshold 40
```

11.10.8 ble monitoring-list

Function

The **ble monitoring-list** command adds specified Bluetooth devices to the Bluetooth device monitoring list.

The **undo ble monitoring-list** command deletes specified Bluetooth devices from the Bluetooth device monitoring list.

By default, no Bluetooth devices are added to the monitoring list.

Format

ble monitoring-list { **all** | **mac** *mac-address1* [**to** *mac-address2*] }

undo ble monitoring-list { **all** | **mac** *mac-address1* [**to** *mac-address2*] }

Parameters

Parameter	Description	Value
mac *mac-address1*	Specifies the MAC address of a Bluetooth device to be monitored.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.
to *mac-address2*	Specifies the end MAC address of a Bluetooth device when Bluetooth devices are added to or deleted from the monitoring list in batches. The *mac-address2* value must be greater than or equal to the *mac-address1* value. *mac-address1* and *mac-address2* together specify a range of MAC addresses.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.
all	Indicates all Bluetooth devices.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the Bluetooth monitoring, Bluetooth tag location, or Bluetooth data transparent transmission function is enabled using the **sniffer enable** command, no Bluetooth device is monitored when no Bluetooth device (BLE device, Bluetooth tag, or Bluetooth client) is added to the monitoring list. After Bluetooth devices are added to the monitoring list, only the Bluetooth devices in the list are monitored. When a Bluetooth device in the monitoring list is offline or has insufficient battery power, an alarm is triggered on the device accordingly. Bluetooth clients do not support low battery power alarms.

Precautions

After the Bluetooth monitoring, Bluetooth tag location, or Bluetooth data transparent transmission function is disabled using the **undo sniffer enable** command, an alarm is triggered on the device, indicating that Bluetooth devices are offline.

Bluetooth devices with all-0 or all-F MAC addresses cannot be added to the monitoring list.

Example

Add the Bluetooth device with the MAC address 00e0-fc12-3456 to the monitoring list.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ble monitoring-list mac 00e0-fc12-3456
```

Add the Bluetooth devices with MAC addresses from 00e0-fc12-3456 to 00e0-fc12-3458 to the monitoring list.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ble monitoring-list mac 00e0-fc12-3456 to 00e0-fc12-3458
```

Disable the device from monitoring Bluetooth devices.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] undo ble monitoring-list all
Warning: This operation will delete all the manually configured Bluetooth monitoring lists. Continue? [Y/
N]:y
```

11.10.9 ble report interval

Function

The **ble report interval** command sets an interval at which an AP reports Bluetooth device information.

The **undo ble report interval** command restores the default interval at which an AP reports Bluetooth device information.

By default, an AP reports Bluetooth device information at an interval of 10 minutes.

Format

ble report interval *interval-value*

undo ble report interval

Parameters

Parameter	Description	Value
interval-value	Specifies the interval at which an AP reports Bluetooth device information.	The value is an integer that ranges from 1 to 60, in minutes.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an AP collects information about 255 Bluetooth devices, the AP stops collecting information about more Bluetooth devices. When the aging time of Bluetooth device information collected by an AP expires, the AP clears aged device information and scans for new Bluetooth device information. The aging time of Bluetooth device information cannot be configured. The default aging time is 10 minutes. When the interval at which an AP reports Bluetooth device information times out, the AP reports Bluetooth device information to an AC. Bluetooth device information includes types, RSSIs, and whether Bluetooth tags are disconnected.

Example

Set the interval at which an AP reports Bluetooth device information to 20 minutes.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ble report interval 20
```

11.10.10 ble source

Function

The **ble source** command configures a global source IP address in packets sent by an AC to a location server.

The **undo ble source** command deletes a global source IP address from packets sent by an AC to a location server.

By default, the source IP address is not configured in packets sent by an AC to a location server, and the IP address of the route outbound interface is used as the source IP address.

Format

ble source ip-address *ip-address*

undo ble source

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies a source IPv4 address in packets sent by an AC to a location server.	The value is in dotted decimal notation.

Usage Guidelines

Usage Scenario

In Bluetooth location scenarios, you can run the **ble source** command to configure a source IP address in packets sent by an AC to a location server.

Run the **ble source** command to configure different source IP addresses for the active and standby ACs.

When source IP addresses are configured on an AC using the **ble source** and **source** commands at the same time, the source IP address configured using the **source** command takes effect.

Precautions

- Ensure that the AC IP address manually configured on the location server is the same as that configured using the **ble source** command.
- The source IP address must exist on the AC; otherwise, the configuration does not take effect.

Example

Configure 10.102.25.23 as the source IP address of the packets sent from the AC to the location server.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ble source ip-address 10.102.25.23
```

11.10.11 ble-profile (AP group view and AP view)

Function

The **ble-profile** command binds a BLE profile to an AP group or AP.

The **undo ble-profile** command unbinds a BLE profile from an AP group or AP.

By default, no BLE profile is bound to an AP group or AP.

Format

ble-profile *profile-name*

undo ble-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a BLE profile.	The BLE profile name must exist.

Views

AP group view, AP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After creating a BLE profile using the **ble-profile (WLAN view)** command, you need to bind the profile in the AP view or AP group view to make the settings in the profile take effect.

Precautions

After you bind a BLE profile in the AP view or AP group view, parameter settings in the BLE profile take effect for all APs using this profile.

Example

Create BLE profile **example** and bind the profile to AP group **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ble-profile name example
[HUAWEI-wlan-ble-prof-example] quit
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] ble-profile example
```

11.10.12 ble-profile (WLAN view)

Function

The **ble-profile** command creates a BLE profile or displays the BLE profile view.

The **undo ble-profile** command deletes a BLE profile.

By default, no BLE profile is created.

Format

ble-profile name *profile-name*

undo ble-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a BLE profile, which must be unique and identifies a profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all BLE profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to create or delete a BLE profile or enter the BLE profile view to configure the profile. If the specified profile name does not exist, this command creates a new BLE profile and displays the configuration view of this profile. All parameters in this profile use default values. You can also change values of these parameters.

Follow-up Procedure

After creating a BLE profile, you need to run the **ble-profile (AP group view and AP view)** command in the AP view or AP group view to bind the profile to make the settings in the profile take effect.

Precautions

A BLE profile bound to an AP or AP group cannot be deleted. To delete a BLE profile, unbind it in the AP view or AP group view.

Example

Create BLE profile **example** and enter its view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ble-profile name example
[HUAWEI-wlan-ble-prof-example]
```

11.10.13 broadcaster enable

Function

The **broadcaster enable** command enables the Bluetooth broadcast function of an AP's built-in Bluetooth module.

The **undo broadcaster enable** command disables the Bluetooth broadcast function of an AP's built-in Bluetooth module.

By default, the Bluetooth broadcast function of an AP's built-in Bluetooth module is disabled.

NOTE

The Bluetooth broadcast function is supported only by the following models:

- AirEngine X760 series APs
- AirEngine X761 series APs (excluding the AirEngine 5761-10W, AirEngine 5761S-10W, AirEngine 5761-10WD, and AirEngine 5761-11EI)
- AirEngine X771 series APs
- AirEngine 5762-12 and AirEngine 5762S-12 running V200R022C10 or later

Format

broadcaster enable

undo broadcaster enable

Parameters

None

Views

BLE profile view

Default Level

2: Configuration level

Usage Guidelines

When an AP's built-in Bluetooth module is used as a BLE device, you can run this command to enable the Bluetooth broadcast function. After this function is enabled, the built-in Bluetooth module sends BLE broadcast frames to surrounding devices. The frame content complies with the iBeacon protocol.

Enabling both the Bluetooth scanning and broadcast functions of an AP affects the efficiency for the AP's Bluetooth module to scan surrounding BLE devices. When an AP does not serve as a Bluetooth base station, it is recommended that the broadcast function of the AP be disabled.

Example

Enable the Bluetooth broadcast function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ble-profile name example
[HUAWEI-wlan-ble-prof-example] broadcaster enable
```

11.10.14 broadcasting-content

Function

The **broadcasting-content** command configures the content of a BLE broadcast frame sent by an AP's built-in Bluetooth module.

The **undo broadcasting-content** command restores the default content of a BLE broadcast frame sent by an AP's built-in Bluetooth module.

By default, the UUID, Major, and Minor fields in a BLE broadcast frame sent by an AP's built-in Bluetooth module are null, and the RSSI calibration value is –65 dBm.

NOTE

The Bluetooth broadcast function is supported only by the following models:

- AirEngine X760 series APs
- AirEngine X761 series APs (excluding the AirEngine 5761-10W, AirEngine 5761S-10W, AirEngine 5761-10WD, and AirEngine 5761-11EI)
- AirEngine X771 series APs
- AirEngine 5762-12 and AirEngine 5762S-12 running V200R022C10 or later

Format

broadcasting-content { **uuid** { **uuid-character-string** *uuid-value* | **uuid-hex** *uuid-value* } | **major** { **major-character-string** *major-value* | **major-hex** *major-value* | **major-decimal** *major-value* } | **minor** { **minor-character-string** *minor-value* | **minor-hex** *minor-value* | **minor-decimal** *minor-value* } | **reference-rssi** *reference-rssi-value* }*

undo broadcasting-content [**uuid** | **major** | **minor** | **reference-rssi**]

Parameters

Parameter	Description	Value
uuid uuid-character-string *uuid-value*	Specifies the UUID field in a BLE broadcast frame. UUID is the universally unique identifier of a BLE device.	The value is a string of 1 to 16 characters. The default value is null.
uuid uuid-hex *uuid-value*	Specifies the UUID field in a BLE broadcast frame. UUID is the universally unique identifier of a BLE device.	The value is in hexadecimal notation. The value length ranges from 1 to 32 bytes. The default value is null.
major major-character-string *major-value*	Specifies the Major field in a BLE broadcast frame. This field specifies a major group and is combined with the Minor field to define information about a BLE device, for example, location of a BLE device.	The value is a string of 1 or 2 characters. The default value is null.
major major-hex *major-value*	Specifies the Major field in a BLE broadcast frame. This field specifies a major group and is combined with the Minor field to define information about a BLE device, for example, location of a BLE device.	The value is in hexadecimal notation. The value length ranges from 1 to 4 bytes. The default value is null.
major major-decimal *major-value*	Specifies the Major field in a BLE broadcast frame. This field specifies a major group and is combined with the Minor field to define information about a BLE device, for example, location of a BLE device.	The value is an integer that ranges from 0 to 65535. The default value is null.
minor minor-character-string *minor-value*	Specifies the Minor field in a BLE broadcast frame. This field specifies a minor group and is combined with the Major field to define information about a BLE device, for example, location of a BLE device.	The value is a string of 1 or 2 characters. The default value is null.

Parameter	Description	Value
minor minor-hex *minor-value*	Specifies the Minor field in a BLE broadcast frame. This field specifies a minor group and is combined with the Major field to define information about a BLE device, for example, location of a BLE device.	The value is in hexadecimal notation. The value length ranges from 1 to 4 bytes. The default value is null.
minor minor-decimal *minor-value*	Specifies the Minor field in a BLE broadcast frame. This field specifies a minor group and is combined with the Major field to define information about a BLE device, for example, location of a BLE device.	The value is an integer that ranges from 0 to 65535. The default value is null.
reference-rssi *reference-rssi-value*	Specifies the RSSI calibration value of a BLE device. RSSI calibration value indicates the RSSI value of a BLE device measured at a distance of 1 m. It is used to estimate the distance between the BLE device and Bluetooth terminals.	The value is an integer that ranges from –97 to –50, in dBm. The default value is -65 that is measured when the transmit power of an APs' built-in Bluetooth module is 0 dBm.

Views

BLE profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After enabling the broadcast function of an AP's built-in Bluetooth module using the **broadcaster enable** command, you can run this command to configure the content of BLE broadcast frames sent by the module.

Precautions

The RSSI calibration value in a BLE broadcast frame is set based on the actual measurement result.

After changing the transmit power of a built-in Bluetooth module using the **tx-power (BLE profile view)** command, you need to measure and configure the RSSI calibration value again. Therefore, you are advised to run the **tx-power (BLE profile view)** command to configure the transmit power of a built-in Bluetooth module before configuring the RSSI calibration value.

Example

Configure the content of a BLE broadcast frame sent by an AP's built-in Bluetooth module. Set **UUID uuid-hex** to **12345678123456789**, **Major major-hex** to **A22**, **Minor minor-hex** to **011**, and **reference-rssi** to **-70**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ble-profile name example
[HUAWEI-wlan-ble-prof-example] broadcasting-content uuid uuid-hex 12345678123456789 major
major-hex A22 minor minor-hex 011 reference-rssi -70
```

Configure the content of a BLE broadcast frame sent by an AP's built-in Bluetooth module. Set **LocalName** to **name1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ble-profile name example
[HUAWEI-wlan-ble-prof-example] broadcasting-content local-name name1
```

11.10.15 broadcasting-content (AP group view)

Function

The **broadcasting-content** command configures the content of a BLE broadcast frame sent by an AP's built-in Bluetooth module.

The **undo broadcasting-content** command restores the default content of a BLE broadcast frame sent by an AP's built-in Bluetooth module.

By default, the UUID of the BLE broadcast frames sent by an AP's built-in Bluetooth module is null.

NOTE

The Bluetooth broadcast function is supported only by the following models:

- AirEngine X760 series APs
- AirEngine X761 series APs (excluding the AirEngine 5761-10W, AirEngine 5761S-10W, AirEngine 5761-10WD, and AirEngine 5761-11EI)
- AirEngine X771 series APs
- AirEngine 5762-12 and AirEngine 5762S-12 running V200R022C10 or later

Format

broadcasting-content uuid { **uuid-character-string** *uuid-value* | **uuid-hex** *uuid-value* }

undo broadcasting-content uuid

Parameters

Parameter	Description	Value
uuid uuid-character-string *uuid-value*	Specifies the UUID field of BLE broadcast frames, which is a string of characters and used to identity devices.	The value is a string of 1 to 16 characters.
uuid uuid-hex *uuid-value*	Specifies the UUID field of BLE broadcast frames, which is in hexadecimal notation and used to identity devices.	The value is a string of 1 to 32 hexadecimal characters.

Usage Guidelines

Usage Scenario

After enabling the broadcast function of an AP's built-in Bluetooth module using the **broadcaster enable** command, you can run this command to configure the UUID of BLE broadcast frames sent by the module.

Precautions

The UUIDs set in the AP view, BLE profile bound to the AP view, AP group view, and BLE profile bound to the AP group take effect in the following order:

1. UUID set in the AP view
2. UUID set in the BLE profile bound to the AP view
3. UUID set in the AP group view
4. UUID set in the BLE profile bound to the AP group view

Example

Set the UUID of the BLE broadcast frames sent by an AP's Bluetooth module in the AP group view to **12345678123456789** in hexadecimal notation.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name mygroup
[HUAWEI-wlan-ap-group-mygroup] broadcasting-content uuid uuid-hex 12345678123456789
```

11.10.16 broadcasting-content (AP view)

Function

The **broadcasting-content** command configures the content of a BLE broadcast frame sent by an AP's built-in Bluetooth module.

The **undo broadcasting-content** command restores the default content of a BLE broadcast frame sent by an AP's built-in Bluetooth module.

By default, the UUID, Major, Minor, and RSSI calibration fields in a BLE broadcast frame sent by an AP's built-in Bluetooth module are null.

NOTE

The Bluetooth broadcast function is supported only by the following models:

- AirEngine X760 series APs
- AirEngine X761 series APs (excluding the AirEngine 5761-10W, AirEngine 5761S-10W, AirEngine 5761-10WD, and AirEngine 5761-11EI)
- AirEngine X771 series APs
- AirEngine 5762-12 and AirEngine 5762S-12 running V200R022C10 or later

Format

broadcasting-content { **uuid** { **uuid-character-string** *uuid-value* | **uuid-hex** *uuid-value* } | **major** { **major-character-string** *major-value* | **major-hex** *major-value* | **major-decimal** *major-value* } | **minor** { **minor-character-string** *minor-value* | **minor-hex** *minor-value* | **minor-decimal** *minor-value* } | **reference-rssi** *reference-rssi-value* }*

undo broadcasting-content [**uuid** | **major** | **minor** | **reference-rssi**]

Parameters

Parameter	Description	Value
uuid uuid-character-string *uuid-value*	Specifies the UUID field of BLE broadcast frames, which is a string of characters and used to identity devices.	The value is a string of 1 to 16 characters.
uuid uuid-hex *uuid-value*	Specifies the UUID field of BLE broadcast frames, which is in hexadecimal notation and used to identity devices.	The value is a string of 1 to 32 hexadecimal characters.
major major-character-string *major-value*	Specifies the Major field in a BLE broadcast frame. This field specifies a major group and is combined with the Minor field to define information about a BLE device, for example, location of a BLE device.	The value is a string of 1 or 2 characters. The default value is null.

Parameter	Description	Value
major major-hex *major-value*	Specifies the Major field in a BLE broadcast frame. This field specifies a major group and is combined with the Minor field to define information about a BLE device, for example, location of a BLE device.	The value is in hexadecimal notation. The value length ranges from 1 to 4 bytes. The default value is null.
major major-decimal *major-value*	Specifies the Major field in a BLE broadcast frame. This field specifies a major group and is combined with the Minor field to define information about a BLE device, for example, location of a BLE device.	The value is an integer that ranges from 0 to 65535. The default value is null.
minor minor-character-string *minor-value*	Specifies the Minor field in a BLE broadcast frame. This field specifies a minor group and is combined with the Major field to define information about a BLE device, for example, location of a BLE device.	The value is a string of 1 or 2 characters. The default value is null.
minor minor-hex *minor-value*	Specifies the Minor field in a BLE broadcast frame. This field specifies a minor group and is combined with the Major field to define information about a BLE device, for example, location of a BLE device.	The value is in hexadecimal notation. The value length ranges from 1 to 4 bytes. The default value is null.
minor minor-decimal *minor-value*	Specifies the Minor field in a BLE broadcast frame. This field specifies a minor group and is combined with the Major field to define information about a BLE device, for example, location of a BLE device.	The value is an integer that ranges from 0 to 65535. The default value is null.
reference-rssi *reference-rssi-value*	Specifies the RSSI calibration value of a BLE device. RSSI calibration value indicates the RSSI value of a BLE device measured at a distance of 1 m. It is used to estimate the distance between the BLE device and Bluetooth terminals.	The value is an integer that ranges from –97 to –50, in dBm. The default value is null.

Usage Guidelines

Usage Scenario

After enabling the broadcast function of an AP's built-in Bluetooth module using the **broadcaster enable** command, you can run this command to configure the content of BLE broadcast frames sent by the module.

Precautions

The contents set in the AP view, BLE profile bound to the AP view, AP group view, and BLE profile bound to the AP group take effect in the following order:

1. Contents set in the AP view
2. Contents set in the BLE profile bound to the AP view
3. Contents set in the AP group view
4. Contents set in the BLE profile bound to the AP group view

Example

Set the UUID of the BLE broadcast frames sent by an AP's Bluetooth module in the AP view to **12345678123456789** in hexadecimal notation.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 0
[HUAWEI-wlan-ap-0] broadcasting-content uuid uuid-hex 12345678123456789
```

11.10.17 broadcasting-interval

Function

The **broadcasting-interval** command configures the interval for an AP's built-in Bluetooth module to send BLE broadcast frames.

The **undo broadcasting-interval** command restores the default interval for an AP's built-in Bluetooth module to send BLE broadcast frames.

By default, the built-in Bluetooth module of an AP sends BLE broadcast frames at an interval of 500 ms.

NOTE

The Bluetooth broadcast function is supported only by the following models:

- AirEngine X760 series APs
- AirEngine X761 series APs (excluding the AirEngine 5761-10W, AirEngine 5761S-10W, AirEngine 5761-10WD, and AirEngine 5761-11EI)
- AirEngine X771 series APs
- AirEngine 5762-12 and AirEngine 5762S-12 running V200R022C10 or later

Format

broadcasting-interval *broadcasting-interval-value*

undo broadcasting-interval

Parameters

Parameter	Description	Value
broadcasting-interval-value	Specifies the interval for an AP's built-in Bluetooth module to send BLE broadcast frames.	The value is an integer that ranges from 100 to 10240, in milliseconds.

Table 11-198 Description of the **display ble-profile name** *profile-name* command output

Item	Description
Broadcaster switch	Whether the Bluetooth broadcast function is enabled. ● enable ● disable To configure this parameter, run the **broadcaster enable** command.
Broadcaster interval(ms)	Interval at which BLE broadcast frames are sent. To configure this parameter, run the **broadcasting-interval** command.
Broadcaster content	Content of a BLE broadcast frame. To configure this parameter, run the **broadcasting-content** command.
UUID	UUID field in a BLE broadcast frame. UUID refers to the universally unique identifier of a Bluetooth device.
Major	Major field in a BLE broadcast frame. This field specifies a major group and is combined with the Minor field to define information about a BLE device, for example, location of the BLE device.
Minor	Minor field in a BLE broadcast frame. This field specifies a minor group and is combined with the Major field to define information about a BLE device, for example, location of the BLE device.

Item	Description
Reference RSSI	RSSI calibration value. This value refers to the RSSI of a BLE device measured at a distance of 1 m. It is used to calculate the distance between a BLE device and a BLE terminal or tag.
MQTT Server	MQTT server configuration. To configure this parameter, run the **mqtt-server** command.
Transmit power	Transmit power of an AP's built-in Bluetooth module. To configure this parameter, run the **tx-power (BLE profile view)** command.
Sniffer switch	Whether the Bluetooth function is enabled. ● enable ● disable To configure this parameter, run the **sniffer enable** command.
Sniffer mode	Bluetooth working mode. To configure this parameter, run the **sniffer enable** command.
Source IP address	Source IP address used to report Bluetooth packets. To configure this parameter, run the **source (BLE profile view)** command.
Report switch	Whether Bluetooth packets are reported. ● enable ● disable To configure this parameter, run the **report enable** command.
Report mode	Mode in which an AP reports Bluetooth packets. To configure this parameter, run the **report-mode** command.
Report interval(s)	Interval at which an AP reports Bluetooth packets. To configure this parameter, run the **report-mode** command.

Item	Description
Report server	IP address of a Bluetooth server. To configure this parameter, run the **report-to-server** command.
Report server port	Port number of a Bluetooth server. To configure this parameter, run the **report-to-server** command.
Report via-AC	Whether Bluetooth packets are reported to a server through the AC. ● enable: Bluetooth packets are reported through the AC. ● disable: Bluetooth packets are reported not through the AC. To configure this parameter, run the **report-to-server** command.
Report via-AC port	Port number used by the AC to report Bluetooth packets. To configure this parameter, run the **report-to-server** command.

11.10.19 display location-profile

Function

The **display location-profile** command displays configuration information about a location profile.

Format

display location-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Specifies all location profiles.	-
name *profile-name*	Specifies a location profile.	The location profile name must exist.

Views

Aeroscout-tag	Whether WLAN location of AeroScout tags is enabled. To configure this parameter, run the **aeroscout tag-enable** command.
Aeroscout-mu	Whether WLAN location of AeroScout MUs is enabled. To configure this parameter, run the **aeroscout mu-enable** command.
Aeroscout ae-port	Port number used by APs to report location packets. To configure this parameter, run the **aeroscout server** command.
Aeroscout compound-time	Aggregation time of AeroScout location packets. To configure this parameter, run the **aeroscout compound-time** command.
Aeroscout via-AC	Whether AeroScout location packets are reported to the location server through an AC. ● enable: The AeroScout location packets are reported to the location server through an AC. ● disable: The AeroScout location packets are not reported to the location server through an AC. To configure this parameter, run the **aeroscout server** command.
Aeroscout via-AC port	Port number used by an AC to report AeroScout location packets. To configure this parameter, run the **aeroscout server** command.
Ekahau-tag	Whether WLAN location of Ekahau tags is enabled. To configure this parameter, run the **ekahau tag-enable** command.
Ekahau erc IP-address	IP address of the Ekahau location server. To configure this parameter, run the **ekahau server** command.

Item	Description
Ekahau erc port	Port number of the Ekahau location server. To configure this parameter, run the **ekahau server** command.
Ekahau via-AC	Whether Ekahau location packets are reported to the location server through an AC. - enable: The Ekahau location packets are reported to the location server through an AC. - disable: The Ekahau location packets are not reported to the location server through an AC. To configure this parameter, run the **ekahau server** command.
Ekahau via-AC port	Port number used by an AC to report Ekahau location packets. To configure this parameter, run the **ekahau server** command.
Source IP-address	Source IP address used by an AC to report location packets. To configure this parameter, run the **source (location profile view)** command.
private mu	Whether terminal location is enabled. To configure this parameter, run the **private mu-enable** command.
private server	IP address of the terminal location server. To configure this parameter, run the **private server** command.
private server domain	Domain name of the terminal location server. To configure this parameter, run the **private server** command.
private server port	Port number of the terminal location server. To configure this parameter, run the **private server** command.

Item	Description
private via-AC	Whether terminal location packets are reported to the location server through an AC. - enable: The terminal location packets are reported to the location server through an AC. - disable: The terminal location packets are not reported to the location server through an AC. To configure this parameter, run the **private server** command.
private via-AC port	Port number used by an AC to report terminal location packets. To configure this parameter, run the **private server** command.
private report-frequency(ms)	Interval at which an AP reports terminal location packets. To configure this parameter, run the **private report-frequency** command.
private report-protocol	Protocol used by an AP to report information. To configure this parameter, run the **private report-protocol** command.
private ssl-policy name	SSL policy used when the terminal location protocol is HTTPS. To configure this parameter, run the **private report-protocol** command.
private mu protocol-version	Terminal location protocol version. To configure this parameter, run the **private mu protocol-version** command.
collect location data	Whether the device is enabled to collect wireless device location data. To configure this parameter, run the **collect-location-data enable** command.
collect location data RSSI threshold(dBm)	RSSI threshold for wireless device location data. To configure this parameter, run the **collect-location-data rssi-threshold** command.

11.10.20 display references ble-profile

Function

The **display references ble-profile** command displays reference information about a BLE profile.

Format

display references ble-profile name *profile-name*

Parameters

Parameter	Description	Value
name *profile-name*	Displays reference information about a specified BLE profile.	The BLE profile name must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view reference information about a BLE profile.

Example

Display reference information about BLE profile **example**.

```
<HUAWEI> display references ble-profile name example
------------------------------------------------------------------------
Reference type              Reference name
------------------------------------------------------------------------
AP group                   default
------------------------------------------------------------------------
Total: 1
```

Table 11-201 Description of the **display references ble-profile** command output

Item	Description
Reference type	Type of the profile that references a BLE profile.
Reference name	Name of the profile that references a BLE profile.

11.10.21 display wlan ble global configuration

Function

The **display wlan ble global configuration** command displays global configurations of Bluetooth devices.

Format

display wlan ble global configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view global configurations of Bluetooth devices and know the configuration about the Bluetooth device information report function.

Example

Display global configurations of Bluetooth devices.

```
<HUAWEI> display wlan ble global configuration
--------------------------------------------------------------------------------
BLE report interval(min)       :10
BLE low power threshold(%)     :20
BLE source IP address          :0.0.0.0
--------------------------------------------------------------------------------
```

Table 11-202 Description of the **display wlan ble global configuration** command output

Item	Description
BLE report interval(min)	Interval at which an AP reports Bluetooth device information.
BLE low power threshold(%)	Low power alarm threshold of Bluetooth devices.
BLE source IP address	A global source IP address in packets sent by an AC to a location server.

11.10.22 display wlan ble monitoring-list

Function

The **display wlan ble monitoring-list** command displays the BLE device monitoring list.

Format

display wlan ble monitoring-list

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After running the **ble monitoring-list mac** command to add BLE devices to the monitoring list, you can run the **display wlan ble monitoring-list** command to check BLE devices in the monitoring list.

If you run the **ble monitoring-list all** command to monitor all BLE devices, you can run the **display wlan ble monitoring-list** command to check BLE devices scanned by APs.

Example

Display the BLE device monitoring list.

```
<HUAWEI> display wlan ble monitoring-list
--------------------------------------------------------------------------------
Index        MAC
--------------------------------------------------------------------------------
0           00e0-fc34-0000
1           00e0-fc34-7777
--------------------------------------------------------------------------------
Total: 2
```

Table 11-203 Description of the **display wlan ble monitoring-list** command output

Item	Description
Index	Index.
MAC	MAC address of a BLE device.

11.10.23 display wlan ble site-info

Function

The **display wlan ble site-info** command displays information about Bluetooth devices that are scanned by an AP's built-in Bluetooth module.

Format

display wlan ble site-info { **all** | **mac-address** *mac-address* | **host-ap** { **valid** | **host-ap-id** *ap-id* | **host-ap-name** *ap-name* } }

Parameters

Parameter	Description	Value
all	Displays information about all Bluetooth devices.	-
mac-address *mac-address*	Displays information about a specified Bluetooth device.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.
host-ap valid	Displays information about APs' built-in Bluetooth modules among all Bluetooth device information.	-
host-ap host-ap-id *ap-id*	Displays information about the Bluetooth module built in an AP with the specified ID.	The AP ID must exist.
host-ap host-ap-name *ap-name*	Displays information about the Bluetooth module built in an AP with the specified name.	The AP name must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After you enable the Bluetooth monitoring function using the **sniffer enable** command, an AP's built-in Bluetooth module scans surrounding Bluetooth devices and obtains their information. You can then run this command to view obtained information about Bluetooth devices scanned by the built-in Bluetooth module.

After the Bluetooth broadcast function is enabled for an AP with the built-in Bluetooth module, the Bluetooth module works as a Bluetooth station, whose information can be found in Bluetooth device information. If the Bluetooth MAC address label of an AP is lost, it is time-consuming to locate the mapping between the AP and built-in Bluetooth module. In this case, configure the **host-ap** parameter to filter out information about the AP's built-in Bluetooth module among all Bluetooth device information.

Example

Display information about all Bluetooth devices.

```
<HUAWEI> display wlan ble site-info all
------------------------------------------------------------------------------------------------------------------------------------------
---------------------
Index  MAC            Host AP ID Host AP name RSSI  Power Type       DetachedFlag Aging-Timeout(m)
Broadcast count Advertisement data
------------------------------------------------------------------------------------------------------------------------------------------
---------------------
0      0000-0101-0202  4         AP4          -30   50%   asset-tag  N          57              10
02-02-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-fa
------------------------------------------------------------------------------------------------------------------------------------------
---------------------
Total: 1
```

Table 11-204 Description of the **display wlan ble site-info** command output

Item	Description
Index	Index.
MAC	MAC address of a Bluetooth device.
Host AP ID	ID of the AP to which a Bluetooth device belongs. The display of **--** indicates that Bluetooth device information does not belong to the built-in Bluetooth module of the AP.
Host AP name	Name of the AP to which a Bluetooth device belongs. The display of **--** indicates that Bluetooth device information does not belong to the built-in Bluetooth module of the AP.
RSSI	Signal strength of a Bluetooth device received by an AP's built-in Bluetooth module.
Power	Battery power of a Bluetooth device. If no information about battery power is obtained, this item is displayed as **--**.

Item	Description
Type	Bluetooth device type. The options are as follows: - ibeacon: Bluetooth terminal - asset-tag: Bluetooth tag - sensor-tag: Bluetooth client
DetachedFlag	Whether a Bluetooth device is disconnected. The options are as follows: - Y: The Bluetooth device is disconnected. - N: The Bluetooth device is connected. **NOTE** Bluetooth device disconnection check is not supported in Bluetooth monitoring or transparent transmission mode. This parameter is valid only when the Bluetooth device type is **asset-tag**.
Aging-Timeout(m)	Remaining aging time of a Bluetooth device. The maximum value is 60 minutes.
Broadcast count	Number of broadcast packets sent by a Bluetooth device.
Advertisement data	Content of data carried in a broadcast frame sent by a Bluetooth device. The maximum length of a displayed broadcast frame is 21 bytes.

11.10.24 display wlan location config-info aeroscout

Function

The **display wlan location config-info aeroscout** command displays configurations delivered to APs from the AeroScout location server.

Format

display wlan location config-info aeroscout { **ap-id** *ap-id* | **ap-name** *ap-name* }

Parameters

Parameter	Description	Value
ap-id *ap-id*	Displays the LBS configuration of the AP with a specified AP ID.	The AP ID must already exist.
ap-name *ap-name*	Displays the LBS configuration of the AP with a specified AP name.	The AP name must already exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run this command to check configurations delivered to APs from the AeroScout location server.

Prerequisites

The AeroScout location function has been enabled using the **aeroscout tag-enable** or **aeroscout mu-enable** command, the AC has been enabled to forward location packets of AeroScout tags and MUs reported by APs to the AeroScout location server, and the AeroScout location server has delivered configuration information to the APs.

If the prerequisites are not met, for example, APs directly report packets of AeroScout tags and MUs to the AeroScout location server, a hyphen (-) is displayed after this command is run.

Example

Display AeroScout location configuration on the AP named **ap_4**.

```
<HUAWEI> display wlan location config-info aeroscout ap-name ap_4
----------------------------------------------------------------------
AP ID                            : 4
AP name                          : ap_4
AP MAC address                   : 00e0-fc54-5a80
Response IP address              : 10.3.3.3
Response port                    : 1144
AP tag mode                      : start
AP MU mode                       : start
Dilution factor                  : 100
Dilution timeout(s)              : 5
Tags multicast address           : 010c-cc00-0000
Compounded message timeout(0.1s) : 12
```

Table 11-205 Description of the **display wlan location config-info aeroscout** command output

Item	Description
AP ID	AP ID.
AP name	AP name.
AP MAC address	AP's MAC address.
Response IP address	IP address of the location server used to receive the Response packets from the AP.
Response port	Port number used by APs to report location information.
AP tag mode	Tag detection status on the AP: ● start: The AP starts tag detection. ● stop: The AP stops tag detection. **NOTE** **AP tag mode** is displayed as **start** only when **aeroscout tag-enable** is configured on the AC and tag location is configured on the AeroScout location server.
AP MU mode	MU detection status on the AP: ● start: The AP starts MU detection. ● stop: The AP stops MU detection. **NOTE** **AP MU mode** is displayed as **start** only when **aeroscout mu-enable** is configured on the AC and MU location is configured on the AeroScout location server.
Dilution factor	Count-based packet dilution. For example, the value 100 indicates that one out of 100 packets is reported.
Dilution timeout(s)	Time-based packet dilution. For example, the value 1 indicates that at least one packet is reported every second.
Tags multicast address	Multicast MAC address of the tag.
Compounded message timeout(0.1s)	Maximum time during which the AP caches tag, in the unit of 100 milliseconds.

11.10.25 display wlan location device-info tag

Function

The **display wlan location device-info tag** command displays tag location information about APs.

Format

display wlan location device-info tag { **all** | **ap-id** *ap-id* | **ap-name** *ap-name* }

Parameters

Parameter	Description	Value
all	Displays tag location information about all APs.	-
ap-id *ap-id*	Displays tag location information about a specified AP ID.	The AP ID must exist.
ap-name *ap-name*	Displays tag location information about a specified AP name.	The AP name must already exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view tag location information about APs, facilitating tag location statistics collection.

Example

Display tag location information about all APs.

```
<HUAWEI> display wlan location device-info tag all
AP ID   AP name     Tag type        Tag MAC          Channel     RSSI
------------------------------------------------------------------------------
0       ap1         AeroScout       00e0-fc76-e360    11          -50
1       ap3         Ekahau         00e0-fc76-e380    11          -50
------------------------------------------------------------------------------
Total: 2
```

Table 11-206 Description of the display wlan location device-info tag command output

Item	Description
AP ID	AP ID.
AP name	AP name.
Tag type	Type of the tag. The value is of the enumerated type. ● Ekahau: Ekahau tag ● AeroScout: AeroScout tag
Tag MAC	MAC address of the located tag.
Channel	Working channel of the located tag.
RSSI	RSSI of the located tag, in dBm.

11.10.26 display wlan location global configuration

Function

The **display wlan location global configuration** command displays global configurations of Wi-Fi location.

Format

display wlan location global configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view global configurations of Wi-Fi location to learn about the configuration of reporting Wi-Fi location information.

Example

Display global configurations of Wi-Fi location.

```
<HUAWEI> display wlan location global configuration
------------------------------------------------------------------------------
Location source IP address     :0.0.0.0
Aeroscout local IP address     :-
------------------------------------------------------------------------------
```

Table 11-207 Description of the **display wlan location global configuration** command output

Item	Description
Location source IP address	Source IP address in location packets forwarded by the AC to the location server.
Aeroscout local IP address	Local IP address used by the AC to receive packets from the location server.

11.10.27 ekahau server

Function

The **ekahau server** command sets the destination IP address and port number for APs to report Ekahau tag location packets.

The **undo ekahau server** command deletes the configured destination IP address and port number for APs to report Ekahau tag location packets.

By default, no destination IP address or port number is configured for APs to report Ekahau tag location packets.

Format

ekahau server ip-address *ip-address* **port** *port-num* [**via-ac ac-port** *ac-port-num*]

undo ekahau server

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies the IPv4 address of the Ekahau location server.	The value is in dotted decimal notation.

Parameter	Description	Value
port *port-num*	Specifies the destination port number on the Ekahau location server to which APs directly report Ekahau tag location packets. Specifies the destination port number on the Ekahau location server to which APs report Ekahau tag location packets through an AC.	The value is an integer that ranges from 1025 to 65535.
via-ac	Specifies that the Ekahau tag location packets received by APs are reported to the Ekahau location server through an AC.	-
ac-port *ac-port-num*	Specifies the destination port number on the AC to which APs report Ekahau tag location packets.	The value is an integer that ranges from 1025 to 65535.

Views

Location profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The Ekahau tag location packets received by APs can be reported to the Ekahau location server directly or through an AC.

Precautions

You cannot configure a port number that has been occupied by other services; otherwise, the port configuration fails.

For the same location method, via-ac can be configured only in one profile. If **via-ac** has been specified in the current location profile for a specific location method, it cannot be specified in other profiles for the same location method.

Example

Set the destination IP address and port number on the location server to which APs report Ekahau tag location packets to **192.168.1.2** and **8569**, respectively.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] location-profile name example
[HUAWEI-wlan-location-prof-example] ekahau server ip-address 192.168.1.2 port 8569
```

11.10.28 ekahau tag-enable

Function

The **ekahau tag-enable** command enables WLAN location of Ekahau tags.

The **undo ekahau tag-enable** command disables WLAN location of Ekahau tags.

By default, WLAN location of Ekahau tags is disabled.

Format

ekahau tag-enable

undo ekahau tag-enable

Parameters

None

Views

Location profile view

Default Level

2: Configuration level

Usage Guidelines

You can run the **ekahau tag-enable** command to enable WLAN location of Ekahau tags.

Example

Enable WLAN location of Ekahau tags.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] location-profile name example
[HUAWEI-wlan-location-prof-example] ekahau tag-enable
```

11.10.29 location source

Function

The **location source** command configures a global source IP address in packets sent by an AC to a location server.

The **undo location source** command deletes a global source IP address from packets sent by an AC to a location server.

By default, the source IP address is not configured in packets sent by an AC to a location server.

Format

location source ip-address *ip-address*

undo location source

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies a source IPv4 address in packets sent by an AC to a location server.	The value is in dotted decimal notation.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **location source** command to configure a source IP address in UDP packets sent by an AC to a location server.

Run the **location source** command to configure different source IP addresses for the active and standby ACs.

When source IP addresses are configured on an AC using the **location source** and **source** commands at the same time, the source IP address configured using the **source** command takes effect.

Precautions

- Ensure that the AC IP address manually configured on the location server is the same as that configured using the **location source** command.
- The source IP address must exist on the AC; otherwise, the configuration does not take effect.
- The source IP address in packets sent by an AC to a location server can be a global source IP address in the WLAN view and the source IP address in the location profile. The source IP address in the location profile takes precedence over the global source IP address in the WLAN view. If the source IP address in packets sent by an AC to a location server is not configured or the source IP address version is different from the IP address version of the location server, the AC's default IP address used for communicating with the location server is used as the source IP address.

Example

Configure 10.102.25.23 as the source IP address of the UDP packets sent from the AC to the location server.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] location source ip-address 10.102.25.23
```

11.10.30 location-profile

Function

The **location-profile** command binds a location profile to an AP radio.

The **undo location-profile** command unbinds a location profile from an AP radio.

By default, no location profile is bound to a radio.

Format

location-profile *profile-name* **radio** { *radio-id* | **all** }

undo location-profile radio { *radio-id* | **all** }

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a location profile.	The location profile name must already exist.

Parameter	Description	Value
radio *radio-id*	Specifies the ID of the radio to which the location profile is bound.	The value is an integer that ranges from 0 to 2. Three radios are available only on the following models: ● AirEngine 8760-X1-PRO, AirEngine 8760R-X1E, AirEngine 6760-X1, AirEngine 6760-X1E, AirEngine 5760-51 ● AirEngine 6761-21T, AirEngine 6761S-21T, AirEngine 6761-22T ● AirEngine 8771-X1T
all	Binds the location profile to all radios.	-

Views

AP group view, AP view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to bind a location profile to an AP group radio or AP radio. After the binding, the parameters of the location profile will be applied to the AP group radio or AP radio.

Example

Bind the location profile **default** to radio 0 of the AP group **ap-group1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name ap-group1
[HUAWEI-wlan-ap-group-ap-group1] location-profile default radio 0
```

11.10.31 location-profile (WLAN view)

Function

The **location-profile** command creates a location profile or displays the location profile view.

The **undo location-profile** command deletes a location profile.

By default, no location profile is created.

Format

location-profile name *profile-name*

undo location-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a location profile, which uniquely identifies a location profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all location profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

This command creates or deletes a location profile, or displays the location profile view in which you can configure the profile. If the specified profile name does not exist, the command creates a location profile and displays the view of this location profile, and all parameters in the location profile use default values. You can also change values of these parameters.

Example

Create the location profile **test**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] location-profile name test
[HUAWEI-wlan-location-prof-test]
```

11.10.32 private mu protocol-version

Function

The **private mu protocol-version** command sets the terminal location protocol version.

The **undo private mu protocol-version** command restores the default terminal location protocol version.

The default terminal location protocol version is v3.

Format

private mu protocol-version { **v3** | **v5** }

undo private mu protocol-version

Parameters

Parameter	Description	Value
v3	Sets the protocol version to v3.	-
v5	Sets the protocol version to v5.	-

Views

Location profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the terminal location protocol version is v5, APs report more information to the location server, such as the timestamp (the time when APs scan STAs). The location server obtains the information to improve location accuracy.

Precautions

The terminal location protocol version must be the supported by the location server.

Example

Set the terminal location protocol version to v5.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] location-profile name example
[HUAWEI-wlan-location-prof-example] private mu protocol-version v5
```

11.10.33 private mu-enable

Function

The **private mu-enable** command enables terminal location of APs.

The **undo private mu-enable** command disables terminal location of APs.

By default, terminal location of APs is disabled.

Format

private mu-enable

undo private mu-enable

Parameters

None

Views

Location profile view

Default Level

2: Configuration level

Usage Guidelines

You can run the **private mu-enable** command to enable terminal location of APs.

Example

Enable terminal location of APs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] location-profile name example
[HUAWEI-wlan-location-prof-example] private mu-enable
```

11.10.34 private report-frequency

Function

The **private report-frequency** command sets the interval at which an AP reports channel scan information.

The **undo private report-frequency** command restores the default interval at which an AP reports channel scan information.

By default, an AP reports channel scan information every 20000 ms.

Format

private report-frequency *time*

undo private report-frequency

Parameters

Parameter	Description	Value
time	Specifies the interval at which an AP reports channel scan information.	The value is an integer that ranges from 500 ms to 60000 ms.

Views

Location profile view

Default Level

2: Configuration level

Usage Guidelines

During terminal location, an AP periodically scans channels to collect data. The collected data is buffered and updated on the AP, then reported to the location server at specified intervals.

Example

Set the interval at which an AP reports channel scan information to 30000 ms.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] location-profile name example
[HUAWEI-wlan-location-prof-example] private report-frequency 30000
```

11.10.35 private report-protocol

Function

The **private report-protocol** command sets a protocol type for APs to report information.

The **undo private report-protocol** command restores the default protocol type used by APs to report information.

By default, an AP uses UDP to reports information.

Format

private report-protocol { **udp** | **http** | **https ssl-policy** *ssl-policy* }

undo private report-protocol

Parameters

Parameter	Description	Value
udp	Sets the protocol type to UDP.	-
http	Sets the protocol type to HTTP.	-
https	Sets the protocol type to HTTPS.	-
ssl-policy *ssl-policy*	Specifies the name of an SSL policy.	The value is a string of 1 to 31 case-sensitive characters without spaces or question marks (**?**).

Views

Location profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If APs are used to report location data to a server, the protocol type can be set only to UDP.

If location data is reported to a server through the AC, the protocol type can be set to HTTP or UDP. If higher security is required, HTTPS is applicable.

Prerequisites

When the protocol type is set to HTTPS, an SSL policy must have been created and the AP has been configured to report terminal location information through an AC.

Example

Set the protocol type to HTTP for APs to report information.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] location-profile name example
[HUAWEI-wlan-location-prof-example] private report-protocol http
```

Set the protocol type to HTTPS for APs to report information.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] location-profile name example
[HUAWEI-wlan-location-prof-example] private report-protocol https ssl-policy policy1
```

11.10.36 private server

Function

The **private server** command configures the destination IP address and port number for APs to report STA location data.

The **undo private server** command restores the default destination IP address and port number for APs to report STA location data.

By default, no destination IP address or port number is configured for APs to report STA location data.

Format

private server { **ip-address** *ip-address* | **domain** *domain* } **port** *port-num* [**via-ac ac-port** *ac-port-num*]

undo private server

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies the server's IPv4 address to which APs report STA location data.	The value is in dotted decimal notation.
domain *domain*	Specifies the domain name to which APs report STA location data.	The value is a string of 1 to 255 characters.
port *port-num*	Specifies the destination port number on the location server to which APs directly report terminal location data. Specifies the destination port number on the location server to which APs report terminal location data through an AC.	The value is an integer that ranges from 1 to 65535.
via-ac	Indicates that STA location data is reported to the location server through an AC	-

Parameter	Description	Value
ac-port *ac-port-num*	Specifies the destination port number on the AC to which APs report STA location data.	The value is an integer that ranges from 5000 to 65535.

Views

Location profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After an AP completes channel scan, the AP can report the collected data to the location server in the following two methods.

- The AP directly reports the data to the location server.
- The AP reports the data to the location server through an AC.

When the AP and the location server are located on different LANs, the AP must report the data to the AC first. The AC must identify information about authorized and unauthorized STAs based on the location data and report the information to the location server.

If the route between the AP and location server is reachable, and the AC is not required to identify information about authorized and unauthorized STAs, configure the AP to send data to the location server directly, preventing adverse impact of the location function on AC performance and WLAN services.

Precautions

You cannot configure a port number that has been occupied by other services; otherwise, the port configuration fails.

For the same location method, via-ac can be configured only in one profile. If **via-ac** has been specified in the current location profile for a specific location method, it cannot be specified in other profiles for the same location method.

To set the protocol type to HTTP for APs to report information, specify **via-ac ac-port** *ac-port-num* in the command. If the UDP protocol is used and the domain name is specified, the parameter **via-ac ac-port** *ac-port-num* cannot be configured.

Example

Configure APs to report STA location data directly to the location server, and set the server's IP address and port number to **192.168.1.2** and **32180**, respectively.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] location-profile name example
[HUAWEI-wlan-location-prof-example] private server ip-address 192.168.1.2 port 32180
```

11.10.37 report enable

Function

The **report enable** command enables APs to send Bluetooth packets.

The **undo report enable** command disables APs from sending Bluetooth packets.

By default, an AP is disabled from sending Bluetooth packets.

Format

report enable

undo report enable

Parameters

None

Views

BLE profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the Bluetooth tag location or Bluetooth data transparent transmission function is configured on an AP, run this command to enable the AP to send the Bluetooth packets to a location server or an AC.

Example

Enable APs to send Bluetooth packets.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ble-profile name example
[HUAWEI-wlan-ble-prof-example] report enable
```

11.10.38 report-mode

Function

The **report-mode** command sets the mode and interval for APs to send Bluetooth packets.

The **undo report-mode** command cancels the configured mode and interval for APs to send Bluetooth packets.

By default, an AP sends Bluetooth packets at an interval of 10 seconds.

Format

report-mode { **immediate** | **periodic** [**interval** *interval*] }

undo report-mode

Parameters

Parameter	Description	Value
immediate	Enables APs to send Bluetooth packets immediately.	-
periodic	Enables APs to send Bluetooth packets periodically.	-
interval *interval*	Specifies an interval at which Bluetooth packets are sent.	The value is an integer that ranges from 1 to 600, in seconds.

Views

BLE profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After an AP is enabled to report Bluetooth packet information, the AP reports Bluetooth packet information to the AC or location server. When APs are enabled to send Bluetooth packets immediately, the location accuracy is high but AP performance may be affected. When APs are enabled to send Bluetooth packets periodically, the location accuracy is low but AP performance is not affected.

Precautions

When APs are enabled to send Bluetooth packets periodically, set a proper interval at which Bluetooth packets are sent. Otherwise, location results may be inaccurate.

Example

Enable APs to send Bluetooth packets immediately.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ble-profile name example
[HUAWEI-wlan-ble-prof-example] report-mode immediate
```

11.10.39 report-to-server

Function

The **report-to-server** command configures the destination server and port number to which APs report Bluetooth packets.

The **undo report-to-server** command restores the default destination server and port number to which APs report Bluetooth packets.

By default, no destination IP address or port number is configured for APs to report Bluetooth packets.

Format

report-to-server ip-address *ip-address* **port** *port-num* [**via-ac ac-port** *ac-port-num*]

report-to-server domain *domain* **port** *port-num*

undo report-to-server

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies the IPv4 address of the location server to which APs report Bluetooth packets.	The value is in dotted decimal notation.
domain *domain*	Specifies the domain name of the location server to which APs report Bluetooth packets.	The value is a string of 1 to 255 characters.
port *port-num*	Specifies the destination UDP port number on the location server to which APs directly report Bluetooth packets. Specifies the destination UDP port number on the location server to which APs report Bluetooth packets through an AC.	The value is an integer that ranges from 1 to 65535.
via-ac	Specifies that Bluetooth packets are reported to a location server through an AC.	-

Parameter	Description	Value
ac-port *ac-port-num*	Specifies the destination UDP port number on the AC to which APs report Bluetooth packets.	The value is an integer that ranges from 5000 to 65535.

Views

BLE profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the Bluetooth function is enabled, APs need to report collected Bluetooth data to a server. APs report the data using either of the following two methods:

- Reporting the data directly to the server
- Reporting the data to the server through an AC

Precautions

When configuring a port number, ensure that the port is not occupied by other services. If the port is occupied by other services, the port fails to be created.

For the same Bluetooth location function, Bluetooth data reporting through an AC can be configured only in one BLE profile. If Bluetooth data reporting through an AC has been configured in the current BLE profile for a Bluetooth location mode, the forwarding mode cannot be configured in other BLE profiles for the same Bluetooth location function.

Example

Enable APs to report Bluetooth packets to the server with destination IP address **192.168.1.2** and port number **8569**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ble-profile name example
[HUAWEI-wlan-ble-prof-example] report-to-server ip-address 192.168.1.2 port 8569
```

11.10.40 reset wlan ble site-info

Function

The **reset wlan ble site-info** command deletes information about BLE devices stored on an AC.

Format

reset wlan ble site-info { **all** | **mac-address** *mac-address* }

Parameters

Parameter	Description	Value
all	Deletes information about all BLE devices.	-
mac-address *mac-address*	Deletes information about the BLE device with the specified MAC address from the device list on the AC.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When the remaining aging time of BLE devices is long and some BLE devices are not in the current WLAN coverage area, but entries on the AC still exist, you can run this command to delete information about these BLE devices.

Precautions

Deleted information about BLE devices cannot be recovered. If the aging time of a BLE device is zero, information about the BLE device is automatically deleted from the device list on the AC.

Example

Delete information about all BLE devices from the AC.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] reset wlan ble site-info all
```

11.10.41 reset wlan location device-info tag

Function

The **reset wlan location device-info tag** command clears tag information received by APs on the AC.

Format

reset wlan location device-info tag { **all** | **ap-id** *ap-id* | **ap-name** *ap-name* }

Parameters

Parameter	Description	Value
all	Clears tag information received by all APs.	-
ap-id *ap-id*	Clears tag information received by a specified AP ID.	The AP ID must exist.
ap-name *ap-name*	Clears tag information received by a specified AP name.	The AP name must already exist.

Views

All views

Default Level

3: Management level

Usage Guidelines

When tag information is too much, you can run this command to clear tag information received by APs on the AC. Cleared information cannot be recovered.

Example

Clear tag information received by all APs.

```
<HUAWEI> reset wlan location device-info tag all
```

11.10.42 sniffer enable

Function

The **sniffer enable** command enables and configures the working mode of an AP's built-in Bluetooth module.

The **undo sniffer enable** command disables the Bluetooth function of an AP's built-in Bluetooth module.

By default, the Bluetooth function of an AP's built-in Bluetooth module is disabled.

Format

sniffer enable { **ibeacon-mode** | **tag-mode** | **transparent-mode** }

undo sniffer enable

Parameters

Parameter	Description	Value
ibeacon-mode	Enables the Bluetooth monitoring function of an AP's built-in Bluetooth module.	-
tag-mode	Enables the Bluetooth tag location function of an AP's built-in Bluetooth module.	-
transparent-mode	Enables the Bluetooth data transparent transmission function of an AP's built-in Bluetooth module.	-

Views

BLE profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the Bluetooth monitoring or Bluetooth tag location function is enabled, the built-in Bluetooth module of an AP will scan and obtain information about surrounding BLE devices or Bluetooth tags. The built-in Bluetooth module then reports the obtained information such as MAC addresses, RSSIs, BLE broadcast frame contents, and battery power.

After the Bluetooth monitoring function is enabled, an AP obtains battery power information about surrounding BLE devices at WLAN service off-peak hours, for example, from 2:00 a.m. to 2:30 a.m. (system time), and then reports the obtained information to the AC. Precisely configure the system time of an AC to ensure that WLAN services are not affected when the AC obtains battery power of BLE devices.

After the Bluetooth data transparent transmission function is enabled, the built-in Bluetooth module of an AP scans surrounding Bluetooth clients, and reports information about the scanned Bluetooth clients, such as packet data, MAC addresses, and RSSIs. For BLE devices or Bluetooth terminals of some vendors, scan response frames can carry battery power information. The Bluetooth module also supports the query for battery level information. An AP periodically (at 2:00 am of the system time) sends scan request frames to surrounding BLE devices or Bluetooth terminals. After receiving the scan request frames, the BLE devices or Bluetooth terminals send scan response frames carrying battery power information. After receiving the scan response frames, the AP transparently transmits the frames to the AC or server.

The Bluetooth broadcast and Bluetooth monitoring functions can be enabled simultaneously for an AP's built-in Bluetooth module. When the two functions are both enabled, the AP's built-in Bluetooth module is also monitored.

After you run the **undo sniffer enable** command to disable the BLE monitoring or Bluetooth tag location function, the AC will trigger an alarm indicating that BLE devices or Bluetooth tags are offline.

Precautions

Enabling both the Bluetooth scanning and broadcast functions of an AP affects the efficiency for the AP's Bluetooth module to scan surrounding BLE devices. When an AP does not serve as a Bluetooth base station, it is recommended that the broadcast function of the AP be disabled.

Example

Enable the Bluetooth monitoring function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ble-profile name example
[HUAWEI-wlan-ble-prof-example] sniffer enable ibeacon-mode
Warning: Modifying the monitoring mode may cause BLE devices in the original monitoring mode to go
offline and age.
```

11.10.43 source (location profile view)

Function

The **source** command sets the source IP address used by the AC to send packets to a location server.

The **undo source** command deletes the configured source IP address.

By default, the source IP address used by the AC to send packets to a location server is not configured.

Format

source ip-address *ip-address*

undo source

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies the source IPv4 address used by the AC to send packets to a location server.	The value is in dotted decimal notation.

Views

Location profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the source IP address used by the AC to send packets to a location server is configured using the **source** command, the UDP packet sent from the AC to a location server carries this IP address as its source IP address.

Precautions

- Ensure that the AC IP address manually configured on a location server is the same as that configured using the **source** command.
- The source IP address must be a valid IP address existing on the device; otherwise, the configuration does not take effect.
- The source IP address in packets sent by an AC to a location server can be a global source IP address in the WLAN view and the source IP address in the location profile. The source IP address in the location profile takes precedence over the global source IP address in the WLAN view. If the source IP address in packets sent by an AC to a location server is not configured or the source IP address version is different from the IP address version of the location server, the AC's default IP address used for communicating with the location server is used as the source IP address.

Example

Configure the source IP address of the UDP packets sent from the AC to a location server as 10.102.25.23.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] location-profile name example
[HUAWEI-wlan-location-prof-example] source ip-address 10.102.25.23
```

11.10.44 source (BLE profile view)

Function

The **source** command sets the source IP address used by the AC to send packets to a location server.

The **undo source** command deletes the configured source IP address.

By default, the source IP address used by the AC to send packets to a location server is not configured, and the IP address of the route outbound interface is used as the source IP address.

Format

source ip-address *ip-address*

undo source

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies the source IPv4 address used by the AC to send packets to a location server.	The value is in dotted decimal notation.

Views

BLE profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In Bluetooth location scenarios, after the source IP address used by the AC to send packets to a location server is configured using the **source** command, the packet sent from the AC to a location server carries this IP address as its source IP address.

Precautions

- Ensure that the AC IP address manually configured on a location server is the same as that configured using the **source** command.
- The source IP address must be a valid IP address existing on the device; otherwise, the configuration does not take effect.
- When the **source (BLE profile view)** and **ble source** commands are both executed, the function configured using the **source (BLE profile view)** command takes effect.

Example

Configure the source IP address of UDP packets sent from the AC to a location server as 10.102.25.23.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ble-profile name example
[HUAWEI-wlan-ble-prof-example] source ip-address 10.102.25.23
```

11.10.45 tx-power (BLE profile view)

Function

The **tx-power** command configures the transmit power of an AP's built-in Bluetooth module.

The **undo tx-power** command restores the default transmit power of an AP's built-in Bluetooth module.

The default transmit power of an AP's built-in Bluetooth module is 0 dBm.

Format

tx-power *tx-power-value*

undo tx-power

Parameters

Parameter	Description	Value
tx-power-value	Specifies the transmit power of an AP's built-in Bluetooth module.	The value is of the enumerated type. The options are –21, –18, –15, –12, –9, –6, –3, 0, 1, 2, 3, 4, and 5, in dBm.

Views

BLE profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to change the transmit power of an AP's built-in Bluetooth module. Increasing the transmit power can improve Bluetooth signal transmission quality but causes more severe interference to other wireless devices. Reducing the transmit power can reduce interference to other wireless devices but affects Bluetooth signal transmission quality. Configure the transmit power of an AP's built-in Bluetooth module properly based on site requirements.

Precautions

After changing the transmit power of an AP's built-in Bluetooth module, you need to run the **broadcasting-content** command to reconfigure the RSSI calibration value in BLE broadcast frames.

Example

Set the transmit power of an AP's built-in Bluetooth module to 2 dBm.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ble-profile name example
[HUAWEI-wlan-ble-prof-example] tx-power 2
```

11.11 WLAN Security Configuration Commands

11.11.1 Command Support

WLAN-AC commands are supported only by the following models: S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.

11.11.2 anti-attack flood blacklist enable

Function

The **anti-attack flood blacklist enable** command enables the flood blacklist function.

The **undo anti-attack flood blacklist enable** command disables the flood blacklist function.

By default, the flood blacklist function is disabled.

Format

anti-attack flood { **arp** | **dhcp** | **dhcpv6** | **igmp** | **mdns** | **nd** | **other-broadcast** | **other-multicast** } **blacklist enable**

undo anti-attack flood { **arp** | **dhcp** | **dhcpv6** | **igmp** | **mdns** | **nd** | **other-broadcast** | **other-multicast** } **blacklist enable**

Parameters

Parameter	Description	Value
arp	Indicates whether to enable the ARP flood blacklist function.	-
dhcp	Indicates whether to enable the DHCP flood blacklist function.	-
dhcpv6	Indicates whether to enable the DHCPv6 flood blacklist function.	-
igmp	Indicates whether to enable the IGMP flood blacklist function.	-
mdns	Indicates whether to enable the mDNS flood blacklist function.	-

Parameter	Description	Value
nd	Indicates whether to enable the ND flood blacklist function.	-
other-broadcast	Indicates whether to enable the flood blacklist function for broadcast packets other than ARP, DHCP, DHCPv6, and ND packets.	-
other-multicast	Indicates whether to enable the flood blacklist function for multicast packets other than IGMP and mDNS packets.	-

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the protocol-based flood blacklist function is enabled, the device considers traffic of a specified protocol (such as DHCP or ARP) with a rate higher than that specified in **anti-attack flood sta-rate-threshold** a flood attack and adds the STA to the blacklist.

Prerequisites

The flood prevention function has been enabled using the **undo anti-attack flood disable** command.

Example

Enable the DHCP flood blacklist function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name profile1
[HUAWEI-wlan-vap-prof-profile1] anti-attack flood dhcp blacklist enable
```

11.11.3 anti-attack flood disable

Function

The **anti-attack flood disable** disables the flood prevention function.

The **undo anti-attack flood disable** command enables the flood prevention function.

By default, the flood prevention function is enabled.

Format

anti-attack flood { **all** | **arp** | **dhcp** | **dhcpv6** | **igmp** | **mdns** | **nd** | **other-broadcast** | **other-multicast** } **disable**

undo anti-attack flood { **all** | **arp** | **dhcp** | **dhcpv6** | **igmp** | **mdns** | **nd** | **other-broadcast** | **other-multicast** } **disable**

Parameters

Parameter	Description	Value
all	Indicates whether to enable the flood prevention function for ARP, DHCP, DHCPv6, IGMP, mDNS, and ND multicast, broadcast, and unicast packets.	-
arp	Indicates whether to enable the ARP flood prevention function.	-
dhcp	Indicates whether to enable the DHCP flood prevention function.	-
dhcpv6	Indicates whether to enable the DHCPv6 flood prevention function.	-
igmp	Indicates whether to enable the IGMP flood prevention function.	-
mdns	Indicates whether to enable the mDNS flood prevention function.	-
nd	Indicates whether to enable the ND flood prevention function.	-

Parameter	Description	Value
other-broadcast	Indicates whether to enable the flood prevention function for broadcast packets other than ARP, DHCP, DHCPv6, and ND packets.	-
other-multicast	Indicates whether to enable the flood prevention function for multicast packets other than IGMP and mDNS packets.	-

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a large number of packets are sent to a device in a short time, the device becomes busy processing the packets and cannot process normal services. To prevent flood attacks, you can configure protocol-based flood prevention.

Precautions

The flood prevention function takes effect only for incoming traffic on an AP's wired interface.

Example

Disable the DHCP flood prevention function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name profile1
[HUAWEI-vap-prof-profile1] anti-attack flood dhcp disable
```

11.11.4 anti-attack flood sta-rate-threshold

Function

The **anti-attack flood sta-rate-threshold** command sets the flood threshold.

The **undo anti-attack flood sta-rate-threshold** command restores the default flood threshold.

The default flood threshold is 4 pps for ARP, DHCP, DHCPv6, IGMP, and mDNS packets, 8 pps for ND packets, 10 pps for broadcast packets other than ARP, DHCP, DHCPv6, and ND packets, and 10 pps for multicast packets other than IGMP and mDNS packets.

Format

anti-attack flood { **arp** | **dhcp** | **dhcpv6** | **igmp** | **mdns** | **nd** | **other-broadcast** | **other-multicast** } **sta-rate-threshold** *sta-rate-threshold*

undo anti-attack flood { **arp** | **dhcp** | **dhcpv6** | **igmp** | **mdns** | **nd** | **other-broadcast** | **other-multicast** } **sta-rate-threshold**

Parameters

Parameter	Description	Value
arp	Specifies ARP packets.	-
dhcp	Specifies DHCP packets.	-
dhcpv6	Specifies DHCPv6 packets.	-
igmp	Specifies IGMP packets.	-
mdns	Specifies mDNS packets.	-
nd	Specifies ND packets.	-
other-broadcast	Specifies broadcast packets other than ARP, DHCP, DHCPv6, and ND packets.	-
other-multicast	Specifies multicast packets other than IGMP and mDNS packets.	-
sta-rate-threshold	Specifies the rate threshold of broadcast traffic from STAs.	For **arp**, **dhcp**, **dhcpv6**, and **nd**, the value is an integer that ranges from 1 to 5000, in pps. For **igmp**, **mdns**, **other-broadcast**, and **other-multicast**, the value is an integer that ranges from 0 to 5000, in pps.

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the flood prevention function is enabled, you can run this command to set the broadcast traffic threshold.

When the traffic rate exceeds the threshold, the device considers a flood attack from the STA and discards the traffic. This prevents the upper-layer network from being affected by the flood.

If the flood blacklist function is enabled using the **anti-attack flood blacklist enable** command, the device adds flood STAs to the blacklist.

Prerequisites

The flood prevention function has been enabled using the **undo anti-attack flood disable** command.

Precautions

The flood prevention function takes effect only for incoming traffic on an AP's wired interface.

Example

Set the DHCP flood threshold to 100 pps.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name profile1
[HUAWEI-vap-prof-profile1] anti-attack flood dhcp sta-rate-threshold 100
```

11.11.5 arp anti-attack check user-bind enable

Function

The **arp anti-attack check user-bind enable** command enables dynamic ARP inspection (DAI).

The **undo arp anti-attack check user-bind enable** command disables DAI.

By default, DAI is disabled.

Format

arp anti-attack check user-bind enable

undo arp anti-attack check user-bind enable

Parameters

None

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

DAI allows an AP to detect the ARP Request and Reply packets transmitted on the VAPs of the AP, to discard invalid and attack ARP packets, and to send an alarm to the connected AC. This function prevents ARP packets of unauthorized users from accessing the external network through the AP, protecting authorized users against interference or spoofing, and protecting the AP.

- Invalid ARP packets: The source IP and MAC addresses of ARP Request and Reply packets do not match.
- Attack ARP packets: When an AP receives a large number of consecutive ARP packets and the number of ARP packets exceeds the ARP attack alarm threshold, an ARP attack occurs.

Example

Enable DAI.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] arp anti-attack check user-bind enable
```

11.11.6 attack-device trap enable

Function

The **attack-device trap enable** command enables the alarm function for attack detection.

The **undo attack-device trap enable** command disables the alarm function for attack detection.

By default, the alarm function for attack detection is disabled.

Format

attack-device trap enable

undo attack-device trap enable

Parameters

None

Views

WIDS profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After this command is executed, an alarm is triggered immediately when the device detects an attack.

Prerequisites

The attack detection function has been enabled by using the **wids attack detect** command.

Precautions

If a large number of attack devices exist, enabling this function will trigger a large number of alarms and generate a large number of logs. Therefore, you are advised to use this function together with a log server.

Example

Enable the alarm function for attack detection.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wids-profile name default
[HUAWEI-wlan-wids-prof-default] attack-device trap enable
```

11.11.7 brute-force-detect interval

Function

The **brute-force-detect interval** command sets the interval for brute force key cracking detection.

The **undo brute-force-detect interval** command restores the default interval for brute force key cracking detection.

By default, the interval for brute force key cracking detection is 60 seconds.

Format

brute-force-detect interval *interval*

undo brute-force-detect interval

Parameters

Parameter	Description	Value
interval *interval*	Specifies the interval for brute force key cracking detection.	The value is an integer that ranges from 10 to 120, in seconds.

Views

WIDS profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a brute force key cracking attack, an attacker tries all possible key combinations one by one to obtain the correct password. To improve password security, enable defense against brute force key cracking to prolong the time used to crack passwords.

An AP checks whether the number of key negotiation failures during WPA/WPA2-PSK, WAPI-PSK, or WEP-Share-Key authentication of a user exceeds the threshold configured using the **brute-force-detect threshold** command. If so, the AP considers that the user is using the brute force method to crack the password and reports an alarm to the AC. If the dynamic blacklist function is enabled, the AP adds the user to the dynamic blacklist and discards all the packets from the user until the dynamic blacklist entry ages out.

Follow-up Procedure

Run the **undo dynamic-blacklist disable** command to enable the dynamic blacklist function.

Example

Set the interval for brute force key cracking detection to 100 seconds.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] radio 0
[HUAWEI-wlan-group-radio-default/0] wids attack detect wpa-psk enable
[HUAWEI-wlan-group-radio-default/0] quit
[HUAWEI-wlan-ap-group-default] quit
[HUAWEI-wlan-view] wids-profile name default
[HUAWEI-wlan-wids-prof-default] brute-force-detect interval 100
```

11.11.8 brute-force-detect quiet-time

Function

The **brute-force-detect quiet-time** command sets the quiet time for an AP to report brute force key attacks to an AC.

The **undo brute-force-detect quiet-time** command restores the default quiet time for an AP to report brute force key attacks to an AC.

By default, the quiet time for an AP to report brute force key attacks to an AC is 600 seconds.

Format

brute-force-detect quiet-time *quiet-time-value*

undo brute-force-detect quiet-time

Parameters

Parameter	Description	Value
quiet-time-value	Specifies the quiet time for an AP to report brute force key attacks to an AC.	The value is an integer that ranges from 60 to 36000, in seconds.

Views

WIDS profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After attack detection is enabled on an AP, the AP reports alarms upon attack detection. If an attack source launches attacks repeatedly, a large number of repeated alarms are generated. To prevent this situation, configure the quiet time function for attack detection. When detecting attack sources of the same MAC address, the AP does not report alarms in the quiet time. However, if the AP still detects attacks from the attack source after the quiet time expires, the AP reports alarms. You can set the quiet time based on attack types.

To obtain attack information in a timely manner, set the quiet time to a small value. If attack detection is enabled on many APs, and attacks are frequently detected, set the quiet time to a large value to prevent frequent alarm reports.

Follow-up Procedure

Run the **undo dynamic-blacklist disable** command to enable the dynamic blacklist function.

Example

Set the quiet time for an AP to report brute force key attacks to an AC to 300 seconds.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] radio 0
[HUAWEI-wlan-group-radio-default/0] wids attack detect wpa-psk enable
[HUAWEI-wlan-group-radio-default/0] quit
[HUAWEI-wlan-ap-group-default] quit
[HUAWEI-wlan-view] wids-profile name default
[HUAWEI-wlan-wids-prof-default] brute-force-detect quiet-time 300
```

11.11.9 brute-force-detect threshold

Function

The **brute-force-detect threshold** command sets the maximum number of key negotiation failures allowed within a brute force key cracking attack detection period.

The **undo brute-force-detect threshold** command restores the default maximum number of key negotiation failures allowed within a brute force key cracking attack detection period.

By default, an AP allows a maximum of 20 key negotiation failures within a brute force key cracking attack detection period.

Format

brute-force-detect threshold *threshold*

undo brute-force-detect threshold

Parameters

Parameter	Description	Value
threshold *threshold*	Specifies the number of key negotiation failures within a detection period.	The value is an integer that ranges from 1 to 100.

Views

WIDS profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a brute force key cracking attack, an attacker tries all possible key combinations one by one to obtain the correct password. To improve password security, enable defense against brute force key cracking to prolong the time used to crack passwords.

An AP checks whether the number of key negotiation failures during WPA/WPA2-PSK, WAPI-PSK, or WEP-Share-Key authentication of a user exceeds the threshold configured using the **brute-force-detect threshold** command. If so, the AP considers that the user is using the brute force method to crack the password and reports an alarm to the AC. If the dynamic blacklist function is enabled, the AP adds the user to the dynamic blacklist and discards all the packets from the user until the dynamic blacklist entry ages out. If the threshold is set to a small value, the AP may incorrectly add authorized users to the dynamic blacklist, causing the users unable to go online.

Follow-up Procedure

Run the **undo dynamic-blacklist disable** command to enable the dynamic blacklist function.

Example

Set the maximum number of key negotiation failures allowed within a brute force key cracking attack detection period to 60.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] radio 0
[HUAWEI-wlan-group-radio-default/0] wids attack detect wpa-psk enable
[HUAWEI-wlan-group-radio-default/0] quit
[HUAWEI-wlan-ap-group-default] quit
[HUAWEI-wlan-view] wids-profile name default
[HUAWEI-wlan-wids-prof-default] brute-force-detect threshold 60
```

11.11.10 contain

Function

The **contain** command enables containment of rogue and interfering devices based on the RSSI and number of associated STAs on the devices.

The **undo contain** command disables containment of rogue and interfering devices based on the RSSI and number of associated STAs on the devices.

By default, containment of rogue and interfering devices based on the RSSI and number of associated STAs on the devices is disabled.

Format

contain { **min-rssi** *min-rssi* | **min-sta-num** *min-sta-num* }

undo contain { **min-rssi** | **min-sta-num** }

Parameters

Parameter	Description	Value
min-rssi *min-rssi*	Specifies the minimum RSSI value.	The value is an integer that ranges from -95 to -50.
min-sta-num *min-sta-num*	Specifies the minimum number of associated STAs.	The value is an integer that ranges from 1 to 10.

Views

WIDS profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After RSSI-based containment is enabled, if the RSSIs of detected rogue and interfering devices are no more than the specified minimum RSSI value, the devices are not contained. They are contained only when their RSSIs exceed the specified minimum RSSI value.

After containment based on the number of associated STAs is enabled, if the number of STAs associated with detected rogue and interfering devices is smaller than the specified minimum value, the devices are not contained. They are contained only when the number of STAs associated with them reaches the specified minimum value.

Prerequisites

Detection and containment of rogue and interfering devices have been enabled.

Precautions

This function is not supported in manual containment mode.

Example

Enable containment of rogue and interfering APs with spoofing SSIDs and set the number of associated STAs that triggers containment to 5.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] radio 0
[HUAWEI-wlan-group-radio-default/0] wids contain enable
[HUAWEI-wlan-group-radio-default/0] quit
[HUAWEI-wlan-ap-group-default] quit
[HUAWEI-wlan-view] wids-profile name default
```

```
[HUAWEI-wlan-wids-prof-default] contain-mode spoof-ssid-ap
[HUAWEI-wlan-wids-prof-default] contain min-sta-num 5
```

11.11.11 contain-mode

Function

The **contain-mode** command sets the containment mode against rogue or interference devices.

The **undo contain-mode** command deletes the containment mode against rogue or interference devices.

By default, no containment mode against rogue or interference devices is set.

Format

contain-mode { **open-ap** | **spoof-ssid-ap** | **client** [**protect sta-whitelist-profile** *profile-name*] | **adhoc** }

undo contain-mode { **open-ap** | **spoof-ssid-ap** | **client** [**protect**] | **adhoc** }

Parameters

Parameter	Description	Value
open-ap	Sets the containment mode against open-authentication rogue or interference APs.	-
spoof-ssid-ap	Sets the containment mode against rogue or interference APs using spoofing SSIDs.	-
client	Sets the containment mode against unauthorized STAs or interference STAs.	-
protect sta-whitelist-profile *profile-name*	Protects STAs based on the STA whitelist. Authorized STAs in the whitelist are protected from connecting to rogue or interference APs.	-
adhoc	Sets the containment mode against Ad-hoc devices.	-

Views

WIDS profile view

Default Level

2: Configuration level

Usage Guidelines

Rogue or interference devices pose serious security threats to enterprise networks.

After the containment mode is set against rogue or interference APs, the monitor AP uses the identity of the rogue or interference AP to broadcast deauthentication frames to forcibly disconnect STAs. To prevent the STAs from connecting to the rogue or interference AP again, the monitor AP will periodically and continuously send deauthentication frames.

After the containment mode is set against rogue STAs, interference STAs or Ad-hoc devices, the monitor AP uses the MAC address of a rogue device to continuously send unicast deauthentication frames.

Example

Counter rogue and interference APs with spoofing SSIDs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] radio 0
[HUAWEI-wlan-group-radio-default/0] wids contain enable
[HUAWEI-wlan-group-radio-default/0] quit
[HUAWEI-wlan-ap-group-default] quit
[HUAWEI-wlan-view] wids-profile name default
[HUAWEI-wlan-wids-prof-default] contain-mode spoof-ssid-ap
```

11.11.12 device report-interval

Function

The **device report-interval** command sets the interval at which an AP reports incremental wireless device information.

The **undo device report-interval** command restores the default interval at which an AP reports incremental wireless device information.

By default, an AP reports incremental wireless device information to an AC at an interval of 300 seconds.

Format

device report-interval *interval*

undo device report-interval

Parameters

Parameter	Description	Value
interval	Specifies the interval at which an AP reports incremental wireless device information.	The value is an integer that ranges from 60 to 3600, in seconds.

Views

WIDS profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The monitoring AP buffers information about detected wireless devices at the interval set using the **device report-interval** command. When the interval is reached, the monitoring AP reports the information to the AC and then clears the reported information.

Prerequisites

The device detection function has been enabled using the **wids device detect enable** command for the AP.

Example

Set the interval at which an AP reports incremental wireless device information to 120 seconds.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] radio 0
[HUAWEI-wlan-group-radio-default/0] wids device detect enable
[HUAWEI-wlan-group-radio-default/0] quit
[HUAWEI-wlan-ap-group-default] quit
[HUAWEI-wlan-view] wids-profile name default
[HUAWEI-wlan-wids-prof-default] device report-interval 120
```

11.11.13 dhcp trust port

Function

The **dhcp trust port** command configures a DHCP trusted interface on an AP.

The **undo dhcp trust port** command cancels the configuration.

By default, the DHCP trusted interface is enabled on the AP's uplink interface in the AP wired port profile view.

Format

dhcp trust port

undo dhcp trust port

Parameters

None

Views

AP wired port profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before WLAN services are delivered to an AP, run the **dhcp trust port** command in the AP wired port profile view. After the command is run, the AP receives the DHCP OFFER, ACK, and NAK packets sent by the authorized DHCP server and forwards the packets to STAs so that the STAs can obtain valid IP addresses and go online.

The **undo dhcp trust port** command configured in the AP wired port profile view takes effect only in direct forwarding mode, but not in tunnel forwarding mode.

Precautions

When executed in the AP wired port view, this command takes effect only on uplink interfaces of an AP. To configure a downlink wired interface on an AP as a DHCP trusted interface, you only need to run the **learn-client-address enable (AP wired port profile view)** command to enable STA address learning, but do not need to run the **dhcp trust port** command.

Example

Create an AP wired port profile named **wire1**, and enable a DHCP trusted interface on an AP in this profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wired-port-profile name wire1
[HUAWEI-wlan-wired-port-wire1] dhcp trust port
```

11.11.14 display ap radio-environment

Function

The **display ap radio-environment** command displays air interface environment information about AP radios.

Format

display ap radio-environment { **ap-name** *ap-name* | **ap-id** *ap-id* } [**radio** *radio-id*]

Parameters

Parameter	Description	Value
ap-name *ap-name*	Displays air interface environment information about radios of the AP with a specified name.	The AP name must exist.
ap-id *ap-id*	Displays air interface environment information about radios of the AP with a specified ID.	The AP ID must exist.
radio *radio-id*	Displays air interface environment information about the AP radio with a specified ID.	The radio ID must exist.

Views

All views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When WLAN access experience is poor, you can run this command to view air interface environment information and Wi-Fi interference sources. The interference can be determined based on the noise floor, signal to interference plus noise ratio (SINR), co-channel interference, and adjacent-channel interference. After this command is executed, radio scanning of the AP is automatically enabled, and the AP starts to scan the air interface environment of radios. You can run this command again to view air interface environment scanning results.

Precautions

When you run this command for the first time, no air interface environment scanning result is displayed. To view air interface environment scanning results, run this command again.

After AP radio scanning is enabled using this command, the air interface performance of an AP is affected. If this command is not executed again after five minutes, AP radio scanning is automatically disabled.

If the **radio** *radio-id* parameter is not specified, air interface environment information about all radios of the AP is displayed.

NOTE

In the scanning result, the channel utilization, co-channel interference, and adjacent-channel interference are calculated with the impact of non-Wi-Fi interference. However, non-Wi-Fi interference devices are not displayed in the interference source list.

Example

Display air interface environment information about radio 0 of AP 1.

```
<HUAWEI> display ap radio-environment ap-id 1 radio 0
Warning: This operation will enable scanning for the specified radio, affecting AP's air interface
performance. Scanning will be automatically disabled 5 minutes after this command is run. Continue? [Y/
N]y
Info: This operation may take a few seconds. Please wait for a moment.done.

```

Table 11-208 Description of the **display ap radio-environment** { **ap-name** *ap-name* | **ap-id** *ap-id* } [**radio** *radio-id*] command output

Item	Description
Radio	Radio on which the air interface environment is scanned.
ScanChannel	Scanning channel.
WorkChannel	Working channel of the AP.
ScanCycle	Scanning count.
Ch	Channel that has scanned a device.
NF	Noise floor.
CU(%)	Channel utilization.
CommIf(%)	Co-channel interference.
AdjaceIf(%)	Adjacent-channel interference.
#Neighbors	Number of scanned radio neighbors.
SINR	Signal to interference plus noise ratio (SINR).

Item	Description
MAC	MAC address of the scanned device.
Type	Type of the scanned interference device. ● i: WIDS device ● p: Non-WIDS device
RSSI	RSSI of the scanned device.
SSID	SSID to which the scanned device is connected.

NOTE

If an AP detects that a channel has a high co-channel interference (higher than 50%), another Wi-Fi device is using this channel and affects the local AP. In this case, it is recommended that the AP channel be switched using radio calibration or other methods.

11.11.15 display references wids-whitelist-profile

Function

The **display references wids-whitelist-profile** command displays reference information about a WIDS whitelist profile.

Format

display references wids-whitelist-profile name *profile-name*

Parameters

Parameter	Description	Value
name *profile-name*	Displays reference information about a specified WIDS whitelist profile.	The WIDS whitelist profile must already exist.

Table 11-215 Description of the **display wids-profile name** command output

Item	Description
Device report interval(s)	Interval at which an AP reports the detected incremental wireless device information. To configure this parameter, run the **device report-interval** command.
Brute force detect interval(s)	Interval for brute force key cracking detection. To configure this parameter, run the **brute-force-detect interval** command.
Brute force detect threshold	Maximum number of key negotiation failures allowed within a brute force key cracking detection period. To configure this parameter, run the **brute-force-detect threshold** command.
Brute force quiet time(s)	Quiet time for an AP to report the detected brute force attacks to the AC. To configure this parameter, run the **brute-force-detect quiet-time** command.
Flood detect interval(s)	Flood attack detection interval. To configure this parameter, run the **flood-detect interval** command.
Flood detect threshold	Flood attack detection threshold. To configure this parameter, run the **flood-detect threshold** command.
Flood quiet time(s)	Quiet time for an AP to report the detected flood attacks to the AC. To configure this parameter, run the **flood-detect quiet-time** command.
Weak IV quiet time(s)	Quiet time for an AP to report the detected weak IV attacks to the AC. To configure this parameter, run the **weak-iv-detect quiet-time** command.
Spoof quiet time(s)	Quiet time for an AP to report the detected spoofing attacks to the AC. To configure this parameter, run the **spoof-detect quiet-time** command.

Item	Description
Dynamic blacklist	Whether the dynamic blacklist function is enabled. To configure this parameter, run the **dynamic-blacklist disable** command.
Contain rogue mode	Containment mode against rogue devices. To configure this parameter, run the **contain-mode** command.
Contain minimum RSSI(dBm)	Minimum RSSI value for containing rogue and interfering devices based on the RSSI of the devices. To configure this parameter, run the **contain** command.
Contain minimum sta number	Minimum number of associated STAs for containing rogue and interfering devices based on the number of STAs associated with the devices. To configure this parameter, run the **contain** command.
Attack device trap switch	Whether the alarm function for attack detection is enabled. To configure this parameter, run the **attack-device trap enable** command.
STA whitelist profile	STA protection based on a STA whitelist. To configure this parameter, run the **contain-mode** command.
WIDS spoof profile	WIDS spoof SSID profile bound to the WIDS profile. To configure this parameter, run the **wids-spoof-profile (WIDS profile view)** command.
WIDS whitelist profile	WIDS whitelist profile bound to the WIDS profile. To configure this parameter, run the **wids-whitelist-profile (WIDS profile view)** command.

11.11.20 display wids-spoof-profile

Function

The **display wids-spoof-profile** command displays information about a WIDS spoof SSID profile.

Format

display wids-spoof-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays information about all WIDS spoof SSID profiles.	-
name *profile-name*	Displays information about a specified WIDS spoof SSID profile.	The WIDS spoof SSID profile must already exist.

Item	Description
Profile name	Name of a WIDS spoof SSID profile.

Item	Description
Reference	Number of times a WIDS spoof SSID profile is referenced.

Display information about the WIDS spoof SSID profile **default**.

```
<HUAWEI> display wids-spoof-profile name default
------------------------------------------------------------
ID      Pattern rule
------------------------------------------------------------
0       ^HUAWE[1l]$
------------------------------------------------------------
Total: 1
```

Table 11-217 Description of the **display wids-spoof-profile name** command output

Item	Description
ID	Index.
Pattern rule	Matching rule for spoofing SSIDs. To set the matching rule, run the **spoof-ssid** command.

11.11.21 display references security-profile

Function

The **display references security-profile** command displays reference information about a security profile.

Format

display references security-profile name *profile-name*

Parameters

Parameter	Description	Value
name *profile-name*	Displays reference information about a specified security profile.	The security profile must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the command to view reference information about a security profile.

Example

Display reference information about the security profile **security-profile1**.

```
<HUAWEI> display references security-profile name security-profile1
--------------------------------------------
Reference type          Reference name
--------------------------------------------
VAP profile             vap-profile1
--------------------------------------------
Total: 1
```

Table 11-218 Description of the **display references security-profile** command output

Item	Description
Reference type	Type of the profile that references a security profile.
Reference name	Name of the profile that references a security profile.

11.11.22 display references sta-blacklist-profile

Function

The **display references sta-blacklist-profile** command displays reference information about a STA blacklist profile.

Format

display references sta-blacklist-profile name *profile-name*

Parameters

Parameter	Description	Value
name *profile-name*	Displays reference information about a STA blacklist profile.	The STA blacklist profile must exist.

Views

Default Level

1: Monitoring level

Usage Guidelines

You can run the command to view reference information about a STA blacklist profile.

Example

Display reference information about the STA blacklist profile **sta-blacklist-profile1**.

```
<HUAWEI> display references sta-blacklist-profile name sta-blacklist-profile1
--------------------------------------------
Reference type          Reference name
--------------------------------------------
VAP profile             vap-profile1
--------------------------------------------
Total: 1
```

Table 11-219 Description of the **display references sta-blacklist-profile** command output

Item	Description
Reference type	Type of the profile that references the STA blacklist profile.
Reference name	Name of the profile that references the STA blacklist profile.

11.11.23 display references sta-whitelist-profile

Function

The **display references sta-whitelist-profile** command displays reference information about a STA whitelist profile.

Format

display references sta-whitelist-profile name *profile-name*

Parameters

Parameter	Description	Value
name *profile-name*	Displays reference information about a STA whitelist profile.	The STA whitelist profile must exist.

Reference name	Name of the profile that references the STA whitelist profile.

11.11.24 display security-profile

Function

The **display security-profile** command displays configuration and reference information about a security profile.

Format

display security-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays information about all security profiles.	-
name *profile-name*	Displays information about a specified security profile.	The security profile must exist.

```

Table 11-222 Description of the **display security-profile name** command output

Item	Description
Security policy	Security policy. The following security policies are supported: - Open system: WEP open system authentication - Share key: WEP shared key authentication - WEP 802.1x: Dynamic WEP - WPA 802.1x: WPA-802.1X - WPA2 802.1x: WPA2-802.1X - WPA-WPA2 802.1x: WPA-WPA2-802.1X - WPA PSK - WPA2 PSK - WPA-WPA2 PSK - WPA PPSK - WPA2 PPSK - WPA-WPA2 PPSK - WPA3 SAE - WPA3 802.1x: WPA3-802.1X - WPA2-WPA3 PSK-SAE - WPA2-WPA3 802.1x: WPA2-WPA3-802.1X - WAPI PSK - WAPI certificate - OWE - WPA2 RPSK - -: No security policy To configure this parameter, run the **security wep**, **security dot1x**, **security psk**, **security wpa2-wpa3 psk-sae**, **security wpa3 sae**, **security wpa3 dot1x**, **security enhanced-open aes**, or **security wapi** command.

Item	Description
Encryption	Encryption mode. The following encryption modes are supported: GCMP-256, TKIP, AES, AES-TKIP, WEP-40, WEP-104, WEP-128, and SMS4. The WAPI encryption mode is fixed to SMS4, the hybrid WPA3-SAE +WPA2-WPA3 encryption mode is fixed to AES, and the WPA3-802.1X encryption mode is fixed to GCMP-256 + AES, and the OWE encryption mode is fixed to AES. To configure this parameter, run the **wep key**, **security dot1x**, **security wpa2-wpa3 psk-sae**, **security wpa3 sae**, **security wpa3 dot1x**, **security enhanced-open aes**, **security wpa2-wpa3 dot1x**, or **security psk** command.
PMF	Whether the Protected Management Frame (PMF) function of a VAP is enabled. ● **disable**: This function is disabled. ● **optional**: This function is enabled in optional mode. ● **mandatory**: This function is forcibly enabled. This line is displayed in the command output only when the authentication and encryption mode is WPA2-AES/WPA3/OWE. To configure this parameter when the authentication mode is WPA2-AES, run the **pmf** command. When the authentication mode is WPA3, this parameter is unconfigurable. The value of this parameter is fixed at **mandatory** when the authentication mode is WPA3-SAE or WPA3-802.1X and **optional** when the authentication mode is WPA2-WPA3. When the authentication mode is OWE or its transition mode, the value of this parameter is fixed at **mandatory**.
Key *key-id*	Key ID. To configure this parameter, run the **wep key** command.

Item	Description
Default key ID	Default key ID. To configure this parameter, run the **wep default-key** command.
PTK update	Whether to enable periodic PTK update in WPA, WPA2, or WPA-WPA2 authentication and encryption. ● enable: This function is enabled. ● disable: This function is disabled. To configure this parameter, run the **wpa ptk-update enable** command.
PTK update interval(s)	The interval for updating PTKs in WPA, WPA2, or WPA-WPA2 authentication and encryption. The value is an integer in seconds. To configure this parameter, run the **wpa ptk-update ptk-update-interval** command.
CA certificate filename	CA certificate file name. To configure this parameter, run the **wapi import certificate** command.
ASU certificate filename	File name of the authentication server unit (ASU) certificate. To configure this parameter, run the **wapi import certificate** command.
AC certificate filename	AC certificate file name. To configure this parameter, run the **wapi import certificate** command.
AC private key filename	AC private key file name. To configure this parameter, run the **wapi import private-key** command.
AC local key pair name	Name of the local ECC key pair on the AC. To configure this parameter, run the **wapi import private-key** command.
WAPI source interface	WAPI source interface. To configure this parameter, run the **wapi source interface** command.
Authentication server IP	IP address of the ASU certificate server. To configure this parameter, run the **wapi asu** command.

Item	Description
WAI timeout(s)	Timeout period of an association. To configure this parameter, run the **wapi sa-timeout** command.
BK update interval(s)	Interval for updating the base key (BK). To configure this parameter, run the **wapi bk** command.
BK lifetime threshold(%)	Threshold for triggering BK update. To configure this parameter, run the **wapi bk** command.
USK update method	Whether the USK is updated based on a time interval or a packet count. To configure this parameter, run the **wapi key-update** command.
USK update interval(s)	Interval for updating the unicast session key (USK). To configure this parameter, run the **wapi usk** command.
MSK update method	Whether the MSK is updated based on a time interval or a packet count. To configure this parameter, run the **wapi key-update** command.
MSK update interval(s)	Interval for updating the MBMS service key (MSK). To configure this parameter, run the **wapi msk** command.
Cert auth retrans count	Number of retransmissions of certificate authentication packets. To configure this parameter, run the **wapi cert-retrans-count** command.
USK negotiate retrans count	Number of retransmissions of USK negotiation packets. To configure this parameter, run the **wapi usk** command.
MSK negotiate retrans count	Number of retransmissions of MSK negotiation packets. To configure this parameter, run the **wapi msk** command.

11.11.25 display sta-blacklist-profile

Function

The **display sta-blacklist-profile** command displays configuration and reference information about a STA blacklist profile.

Format

display sta-blacklist-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays information about all STA blacklist profiles.	-
name *profile-name*	Displays information about a specified STA blacklist profile.	The STA blacklist profile must exist.

Views

All views

1: Monitoring level

Usage Guidelines

After configuring STA blacklists on a device, you can run this command to check whether a MAC address is in the blacklists.

Example

Display reference information about all STA blacklist profiles.

```
<HUAWEI> display sta-blacklist-profile all
------------------------------------------------------------
Profile name                          Reference
------------------------------------------------------------
sta-blacklist-profile1                 1
------------------------------------------------------------
Total: 1
```

Table 11-223 Description of the **display sta-blacklist-profile all** command output

Item	Description
Profile name	Name of a STA blacklist profile.

Item	Description
Reference	Number of times a STA blacklist profile is referenced.

Display information about the STA blacklist profile **sta-blacklist-profile1**.

```
<HUAWEI> display sta-blacklist-profile name sta-blacklist-profile1
-------------------------------------------------------------
Index      MAC               Description
-------------------------------------------------------------
0          00e0-fc11-2222
-------------------------------------------------------------
Total: 1
```

Table 11-224 Description of the **display sta-blacklist-profile name** command output

Item	Description
Index	Blacklist index.
MAC	MAC address of a STA in the blacklist. To configure the parameter, run the **sta-mac** command.
Description	Description of a MAC address in the blacklist.

11.11.26 display station dynamic-blacklist

Function

The **display station dynamic-blacklist** command displays the dynamic blacklist on an AP.

Format

display station dynamic-blacklist { **ap-id** *ap-id* | **ap-name** *ap-name* }

Parameters

Parameter	Description	Value
ap-id *ap-id*	Displays information about STAs that are denied access on the AP with a specified ID.	The AP ID must exist.

Parameter	Description	Value
ap-name *ap-name*	Displays information about STAs that are denied access on the AP with a specified name.	The AP name must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

There is a STA dynamic blacklist on an AP. The blacklist helps control access of STAs, for example, forbidding STAs with bogus IP addresses to go online. If a STA is not allowed to go online, the STA is added to the dynamic blacklist. Before the dynamic blacklist entry ages out, the STA cannot associate with the AP. After the aging time of a dynamic blacklist entry is reached, the dynamic blacklist entry is automatically deleted. During this period, if the STA on an entry is added to the blacklist again, the aging time of the entry is updated and recalculated.

The administrator can run this command to check STAs in the blacklist and the reasons for adding the STAs to the blacklist.

Example

Display the dynamic blacklist on AP.

```
<HUAWEI> display station dynamic-blacklist ap-name example
Total: 1
------------------------------------------------------------------------------
STA MAC          Time left(s)   Reason
------------------------------------------------------------------------------
00e0-fc12-3456    160           WIDS attack
------------------------------------------------------------------------------
```

Table 11-225 Description of the **display station dynamic-blacklist** command output

Item	Description
STA MAC	MAC address of a STA.
Time left(s)	Remaining aging period, in seconds. To configure the parameter, run the **dynamic-blacklist aging-time** command.

Item	Description
Reason	Reason why a STA is added to the dynamic blacklist. ● static IP: The AP is configured to deny access of STAs with bogus IP addresses, and the STA has a static IP address configured. ● ARP flood: The AP is configured to detect and defend against ARP flood attacks, and the STA initiates an ARP flood attack. ● IGMP flood: The AP is configured to detect and defend against IGMP flood attacks, and the STA initiates an IGMP flood attack. ● ND flood: The AP is configured to detect and defend against ND flood attacks, and the STA initiates an ND flood attack. ● DHCP flood: The AP is configured to detect and defend against DHCP flood attacks, and the STA initiates a DHCP flood attack. ● DHCPv6 flood: The AP is configured to detect and defend against DHCPv6 flood attacks, and the STA initiates a DHCPv6 flood attack. ● MDNS flood: The AP is configured to detect and defend against mDNS flood attacks, and the STA initiates an mDNS flood attack. ● other multicast flood: The AP is configured to detect and defend against flood attacks through multicast packets other than IGMP, and mDNS multicast packets, and the STA initiates such an attack. ● other broadcast flood: The AP is configured to detect and defend against flood attacks through broadcast packets other than ARP, DHCP, DHCPv6, and ND multicast packets, and the STA initiates such an attack. ● WIDS attack: The AP is configured to detect attacks on a WLAN. ● MESH key fail: Key negotiation fails during mesh link setup.

	● other: Other reason

11.11.27 display sta-whitelist-profile

Function

The **display sta-whitelist-profile** command displays configuration and reference information about a STA whitelist profile.

Format

display sta-whitelist-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays information about all STA whitelist profiles.	-
name *profile-name*	Displays information about a specified STA whitelist profile.	The STA whitelist profile must exist.

Views

0         00e0-fc11-2222
-------------------------------------------------------------
Total: 1
-------------------------------------------------------------
Index      OUI                 Description
-------------------------------------------------------------
0         00-00-01
-------------------------------------------------------------
Total: 1
```

Table 11-227 Description of the **display sta-whitelist-profile name** command output

Item	Description
Index	Whitelist index.
MAC	MAC address of a STA in the whitelist. To configure the parameter, run the **sta-mac** command.
OUI	OUI of a STA in the whitelist. To configure the parameter, run the **oui** command.
Description	Description of a MAC address in the whitelist.

11.11.28 display wlan ids attack-detected

Function

The **display wlan ids attack-detected** command displays information about the detected attacking devices.

Format

display wlan ids attack-detected { **all** | **flood** | **spoof** | **wapi-psk** | **weak-iv** | **wep-share-key** | **wpa-psk** | **wpa2-psk** | **mac-address** *mac-address* }

Parameters

Parameter	Description	Value
all	Displays information about all types of attacking devices.	-
flood	Displays information about devices launching flood attacks.	-
spoof	Displays information about devices launching spoofing attacks.	-
wapi-psk	Displays information about devices that perform brute force cracking in WAPI-PSK authentication mode.	-
weak-iv	Displays information about devices launching weak IV attacks.	-
wep-share-key	Displays information about devices that perform brute force cracking in WEP-SK authentication mode.	-
wpa-psk	Displays information about devices that perform brute force cracking in WPA-PSK authentication mode.	-
wpa2-psk	Displays information about devices that perform brute force cracking in WPA2-PSK authentication mode.	-
mac-address *mac-address*	Displays information about the detected attacking devices with specified MAC addresses.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.

Table 11-229 Description of the **display wlan ids attack-detected mac-address** *mac-address* command output

Item	Description
MAC address	● For spoofing attacks, this parameter indicates the basic service set identifier (BSSID) that forges the MAC address of an AP. ● For other types of attacks, this parameter indicates the MAC address of the device launching attacks.
Number of detected APs	Number of APs which detect this attack.
Channel	Channel in which the last attack is detected.
RSSI(dBm)	Average received signal strength indicator (RSSI) of the attack frames detected.

Item	Description
Reported AP	Information of the AP which detects the attack.
AP name	Name of the AP which detects the attack.
Flood attack type	Flood attacks detected by the AP.
Spoof attack type	Spoofing attacks detected by the AP.
First detected time	First time when an attack is detected by an AP.

11.11.29 display wlan ids attack-detected statistics

Function

The **display wlan ids attack-detected statistics** command displays the number of attacks detected.

Format

display wlan ids attack-detected statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After attack detection is enabled, you can run the **display wlan ids attack-detected statistics** command to view the total number of all types of attacks.

Prerequisites

The attack detection functions of all types have been enabled using the **wids attack detect enable** command.

Example

Display the number of attacks detected.

```
<HUAWEI> display wlan ids attack-detected statistics
Attack tracking since: 2015-01-27/12:02:11
--------------------------------------------------------------------------------
Type                                                          Total
--------------------------------------------------------------------------------
Probe request frame flood attack                    : 0
Authentication request frame flood attack           : 0
Deauthentication frame flood attack                 : 0
Association request frame flood attack              : 0
Disassociation request frame flood attack           : 0
Reassociation request frame flood attack            : 0
Action frame flood attack                           : 0
EAPOL start frame flood attack                      : 0
EAPOL logoff frame flood attack                     : 0
Weak IVs detected                                   : 0
Spoofed deauthentication frame attack               : 0
Spoofed disassociation frame attack                 : 0
Other types of spoofing frame attack                : 0
WEP share-key attack                                : 0
WPA attack                                          : 0
WPA2 attack                                         : 0
WAPI attack                                         : 0
--------------------------------------------------------------------------------
```

Table 11-230 Description of the **display wlan ids attack-detected statistics** command output

Item	Description
Type	Attack type: ● Probe request frame flood attack ● Authentication request frame flood attack ● Deauthentication frame flood attack ● Association request frame flood attack ● Disassociation request frame flood attack ● Reassociation request frame flood attack ● Action frame flood attack ● EAPOL start frame flood attack ● EAPOL logoff frame flood attack ● Weak IVs detected ● Spoofed deauthentication frame attack ● Spoofed disassociation frame attack ● Other types of spoofing frame attack ● WEP share-key attack: brute force cracking attack in WEP-SK authentication mode ● WPA attack: brute force cracking attack in WPA-PSK authentication mode ● WPA2 attack: brute force cracking attack in WPA2-PSK authentication mode ● WAPI attack: brute force cracking attack in WAPI authentication mode
Total	Total number of attacks detected.

11.11.30 display wlan ids attack-history

Function

The **display wlan ids attack-history** command displays historical records about the attacking devices detected.

Format

display wlan ids attack-history { **all** | **flood** | **spoof** | **wapi-psk** | **weak-iv** | **wep-share-key** | **wpa-psk** | **wpa2-psk** | **mac-address** *mac-address* }

Parameters

Parameter	Description	Value
all	Displays historical records about all types of attacking devices.	-
flood	Displays historical records about devices launching flood attacks.	-
spoof	Displays historical records about devices launching spoofing attacks.	-
wapi-psk	Displays historical records about devices that perform brute force cracking in WAPI-PSK authentication mode.	-
weak-iv	Displays historical records about devices launching weak IV attacks.	-
wep-share-key	Displays historical records about devices that perform brute force cracking in WEP-SK authentication mode.	-
wpa-psk	Displays historical records about devices that perform brute force cracking in WPA-PSK authentication mode.	-
wpa2-psk	Displays information about devices that perform brute force cracking in WPA2-PSK authentication mode.	-
mac-address *mac-address*	Displays historical records about detected devices launching attacks with specified MAC addresses.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.

Usage Guidelines

Usage Scenario

After attack detection is enabled, information about the detected attacking devices is saved in the attacking device list. If an attacking device no longer launches an attack, the device is removed from the attacking device list and saved to the historical attacking device list. You can run the **display wlan ids attack-history** command to check historical records about the attacking devices detected.

Prerequisites

The attack detection functions of all types have been enabled using the **wids attack detect enable** command.

Example

Display historical records of all attacking devices.

```
<HUAWEI> display wlan ids attack-history all
act: Action frame            asr: Association request
aur: Authentication request  daf: Deauthentication frame
dar: Disassociation request  wiv: Weak IV detected
pbr: Probe request           rar: Reassociation request
eaps: EAPOL start frame      eapl: EAPOL logoff frame
saf: Spoofed disassociation frame
sdf: Spoofed deauthentication frame
otsf: Other types of spoofing frames
AP: Name of the monitor AP that has detected the device
AT: Attack type              CH: Channel number
-------------------------------------------------------------------------------
MAC address     AT     CH   RSSI(dBm)  Last detected time    AP
-------------------------------------------------------------------------------
00e0-fc12-37ec  pbr    165  -86        2014-11-20/15:51:43   ap-13
00e0-fc12-171d  pbr    165  -88        2014-11-20/15:41:43   ap-13
00e0-fc12-0bf4  pbr    165  -81        2014-11-20/15:41:53   ap-13
-------------------------------------------------------------------------------
Total: 3, printed: 3
```

Table 11-231 Description of the **display wlan ids attack-history all** command output

Item	Description
MAC address	- For spoofing attacks, this parameter indicates the basic service set identifier (BSSID) that forges the MAC address of an AP. - For other types of attacks, this parameter indicates the MAC address of the device launching attacks.
AT	Acronym of the attack type.
CH	Channel in which the last attack is detected.
RSSI(dBm)	Average received signal strength indicator (RSSI) of the attack frames detected.
Last detected time	Last time at which an attack is detected.
AP	Name of the monitor AP.

11.11.31 display wlan ids contain

Function

The **display wlan ids contain** command displays information about contained devices.

Format

display wlan ids contain { **all** | **ap** | **adhoc** | **client** | **ssid** | **mac-address** *mac-address* | **monitor-ap** { **ap-name** *ap-name* | **ap-id** *ap-id* } [**radio** *radio-id*] }

Parameters

Parameter	Description	Value
all	Displays information about all contained devices.	-
ap	Displays information about contained APs.	-
adhoc	Displays information about contained ad-hoc devices.	-
client	Displays information about contained STAs.	-
ssid	Displays information about contained SSIDs.	-
mac-address *mac-address*	Displays information about the contained device with a specified MAC address.	The MAC address must exist.
monitor-ap ap-name *ap-name*	Displays information about contained devices that are detected by the AP with a specified name.	The AP name must exist.
monitor-ap ap-id *ap-id*	Displays information about contained devices that are detected by the AP with a specified ID.	The AP ID must exist.
monitor-ap { **ap-name** *ap-name* | **ap-id** *ap-id* } **radio** *radio-id*	Displays information about contained devices that are detected by the radio with a specified ID on a specified AP.	The radio ID must exist on the AP.

Views

1: Monitoring level

Usage Guidelines

After WIDS or WIPS is enabled, you can run this command to view information about contained devices.

Example

Display the list of all contained devices.

```
<HUAWEI> display wlan ids contain all
#Rf: Number of monitor radios that have contained the device
CH: Channel number
--------------------------------------------------------------------------------
MAC address      CH  Authentication   Last detected time   #Rf   Reason   SSID
--------------------------------------------------------------------------------
00e0-fc12-3456   11  open            2014-11-20/16:16:57  1     manual     -
--------------------------------------------------------------------------------
Total: 1, printed: 1
```

Table 11-232 Description of the **display wlan ids contain all** command output

Item	Description
MAC address	MAC address of the contained device.
CH	Channel on which the monitor AP detected the contained device for the last time.
Authentication	Authentication mode of the contained device.
Last detected time	Last time at which the monitor AP detected the contained device.
#Rf	Number of monitor radios that have contained the device.
Reason	Reason for the device to be contained. The priorities of containment reasons are in descending order as follows: manual > open-encrypt > spoof-ap > protect-client > client > adhoc.
SSID	SSID of the contained device.

Display information about contained SSIDs.

```
<HUAWEI> display wlan ids contain ssid
#Dev: Number of devices using SSID
----------------------------------------------------------------------
 SSID                            #Dev     Last detected time
----------------------------------------------------------------------
 CMCC                              2        2012-07-27/16:41:55

Reason	Reason for the device to be contained. The priorities of containment reasons are in descending order as follows: manual > open-encrypt > spoof-ap > protect-client > client > adhoc.

11.11.32 display wlan ids device-detected

Function

The **display wlan ids device-detected** command displays various wireless devices detected on the WLAN.

Format

display wlan ids device-detected { **all** | [**interference** | **rogue**] **ap** | [**rogue**] **bridge** | [**rogue**] **client** [**bssid** *bssid*] | **adhoc** | [**rogue**] **ssid** | **mac-address** *mac-address* | **monitor-ap** { **ap-name** *ap-name* | **ap-id** *ap-id* } [**radio** *radio-id*] }

Parameters

Parameter	Description	Value
all	Displays all wireless devices detected on the WLAN.	-
interference	Displays interfering devices detected on the WLAN.	-
rogue	Displays rogue devices detected on the WLAN.	-
ap	Displays APs detected on the WLAN.	-
bridge	Displays bridge devices detected on the WLAN.	-
client	Displays user terminals detected on the WLAN.	-
bssid *bssid*	Displays detailed information about devices with the specified BSSID detected on the WLAN.	The format is H-H-H. An H is a hexadecimal number of 4 digits.
adhoc	Displays detected user terminals that belong to the ad-hoc network on the WLAN.	-
ssid	Displays detailed information about devices with the specified SSID detected on the WLAN.	-
mac-address *mac-address*	Displays detailed information about the device with a specified MAC address detected on the WLAN.	The MAC address must exist.
monitor-ap ap-name *ap-name*	Displays detailed information about devices detected by the monitor AP with a specified name on the WLAN.	The AP name must exist.
monitor-ap ap-id *ap-id*	Displays detailed information about devices detected by the monitor AP with a specified ID on the WLAN.	The AP ID must exist.

Parameter	Description	Value
monitor-ap { **ap-name** *ap-name* | **ap-id** *ap-id* } **radio** *radio-id*	Displays detailed information about devices detected by the radio with a specified ID on a specified AP on the WLAN.	The radio ID must exist on the AP.

Usage Guidelines

Usage Scenario

To ensure the WLAN reliability, all the wireless devices on the current WLAN must be monitored. You can run the **display wlan ids detected** command to view information about the wireless devices detected.

Prerequisites

The device detection function has been enabled on the AP using the **wids device detect enable** command.

Example

Display all wireless devices detected on the WLAN.

```
<HUAWEI> display wlan ids device-detected all
Flags: r: rogue, p: permit, i: interference, a: adhoc, w: AP, b: wireless-bridge, c: client
#Rf: Number of monitor radios that have detected the device
CH: Channel number
RSSI(dBm): Maximum RSSI of detected device
StaNum: Number of detected STAs associated with the device
-------------------------------------------------------------------------------------------------
MAC address     Type    CH  RSSI(dBm) StaNum  Authentication   Last detected time   #Rf   SSID
-------------------------------------------------------------------------------------------------
00e0-fc20-de2b  i/w     1   -60       5       open             2014-11-20/11:03:44  1     -
-------------------------------------------------------------------------------------------------
Total: 1, printed: 1
```

Table 11-236 Description of the **display wlan ids device-detected all** command output

Item	Description
MAC address	MAC address of the detected device.

Item	Description
Type	Type of the detected device: - r: rogue device - p: authorized device - i: interfering device - a: user terminal on the ad-hoc network - w: AP - b: bridge device - c: user terminal
CH	Channel on which the device was detected for the last time.
RSSI(dBm)	RSSI of the detected device.
StaNum	Number of STAs associated with the detected device.
Authentication	Authentication mode of the detected device.
Last detected time	Last time when the device was detected.
#Rf	Number of radios that detect the device.
SSID	SSID of the detected device.

Display information about APs detected on the WLAN.

```
<HUAWEI> display wlan ids device-detected ap
Flags: r: rogue, p: permit, i: interference
#Rf: Number of monitor radios that have detected the device

```

Table 11-239 Description of the **display wlan ids device-detected mac-address** command output

Item	Description
MAC address	MAC address of the detected device.
BSSID	BSSID of the detected device.
Type	Type of the detected device.
SSID	SSID of the detected device.
Authentication	Authentication mode of the detected device.
Number of monitor radios that have detected the device	Number of radios that detect the device. If WIDS is enabled on multiple APs, the type of the device may be detected by these APs' radios.
Last detected channel	Channel of the detected device.
Maximum RSSI(dBm)	Maximum RSSI of the detected device.
Beacon interval(TUs)	Interval at which the detected device sends Beacon frames.
First detected time	First time at which the device was detected.
Reported AP 1	Information about the monitor AP which reports detection information.
AP name	Name of the monitor AP.
Radio ID	Radio ID of the monitor AP.
MAC address	MAC address of the monitor AP.
Radio type	Radio type of the monitor AP.
Channel	Channel of the monitor AP.
RSSI(dBm)	RSSI of the monitor AP.
Last detected time	Last time when the device was detected.
Counter measure	Whether the device is contained.

Item	Description
Counter measure reason	Reason why the device is contained. - open-encrypt: The authentication mode of the device is open. - spoof-ssid-ap: The device is a rogue AP or interference AP with a spoofing SSID. - protect-client: The device is a STA in the STA whitelist and is contained to prevent it from accessing a rogue AP. - client: The device is a rogue STA or interference STA. - adhoc: The device is an ad-hoc device. - manual: The device is manually contained.

11.11.33 display wlan ids device-detected statistics

Function

The **display wlan ids device-detected statistics** command displays statistics on all wireless devices detected on a WLAN.

Format

display wlan ids device-detected statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display wlan ids device-detected statistics** command to view statistics on all wireless devices detected on a WLAN.

Example

Display statistics on wireless devices detected on a WLAN.

```
<HUAWEI> display wlan ids device-detected statistics
------------------------------------------------------------------------------------------------

Rogue Adhoc          : 0
Contain Adhoc        : 0
Rogue AP             : 0
Permit AP            : 0
Interference AP      : 0
Contain AP           : 0
Rogue client         : 2
Permit client        : 0
Interference Client  : 0
Contain client       : 2
Permit Bridge        : 2
Rogue Bridge         : 0
Interference Bridge  : 0
------------------------------------------------------------------------------------------------
```

Table 11-240 Description of the **display wlan ids device-detected statistics** command output

Item	Description
Rogue Adhoc	Number of rogue ad-hoc devices.
Contain Adhoc	Number of contained ad-hoc devices.
Rogue AP	Number of rogue APs.
Permit AP	Number of authorized APs.
Interference AP	Number of interfering APs.
Contain AP	Number of contained APs.
Rogue Client	Number of rogue terminal devices.
Permit Client	Number of authorized terminal devices.
Interference Client	Number of interfering terminal devices.
Contain Client	Number of contained terminal devices.
Permit Bridge	Number of authorized bridge devices.
Rogue Bridge	Number of unauthorized bridge devices.
Interference Bridge	Number of interfering bridge devices.

11.11.34 display wlan dynamic-blacklist

Function

The **display wlan dynamic-blacklist** command displays information about devices in the dynamic blacklist.

Format

display wlan dynamic-blacklist { **all** | **ap-id** *ap-id* | **ap-name** *ap-name* | **mac-address** *mac-address* }

Parameters

Parameter	Description	Value
all	Displays information about all devices in the dynamic blacklist.	-
ap-id *ap-id*	Displays information about attacking devices detected by the AP with a specified ID.	The AP ID must exist.
ap-name *ap-name*	Displays information about attacking devices detected by the AP with a specified name.	The AP name must exist.
mac-address *mac-address*	Displays information about attack devices with a specified MAC address.	The MAC address must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

An AP uses attack detection and dynamic blacklist functions to add a detected attack device to the dynamic blacklist, and rejects packets sent from this device until the device entry in the dynamic blacklist ages. You can run this command to view information about devices in the dynamic blacklist.

Example

Display information about all devices in the dynamic blacklist.

```
<HUAWEI> display wlan dynamic-blacklist all
#AP: Number of monitor APs that have detected the device
```

```
LAT: Left aging time(s)
act: Action frame            asr: Association request

11.11.35 display wlan ids rogue-history

Function

The **display wlan ids rogue-history** command displays historical records of rogue devices.

Format

display wlan ids rogue-history { **all** | **ap** | **bridge** | **client** | **adhoc** | **ssid** | **mac-address** *mac-address* }

Parameters

Parameter	Description	Value
all	Displays historical records of all rogue devices.	-
ap	Displays historical records of rogue APs.	-

Parameter	Description	Value
bridge	Displays historical records of rogue bridge devices.	-
client	Displays historical records of rogue user terminals.	-
adhoc	Displays historical records of rogue ad-hoc devices.	-
ssid	Displays historical records of contained devices with unauthorized SSIDs.	-
mac-address *mac-address*	Displays historical records of devices with specified MAC addresses.	The MAC addresses must exist.

Views

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run the **display wlan ids rogue-history** command to view the historical records of rogue devices.

Prerequisites

The device detection function has been enabled on the AP using the **wids device detect enable** command.

Example

Display historical records of all rogue devices.

```
<HUAWEI> display wlan ids rogue-history all
Flags: a: adhoc, w: AP, b: wireless-bridge, c: client
CH: Channel number
--------------------------------------------------------------------------------
MAC address     Type  CH  Authentication   Last detected time   SSID
--------------------------------------------------------------------------------
00e0-fc12-3456  w     11  open             2014-11-20/11:20:37  wlan
00e0-fc12-3457  c     11  -                2014-11-20/11:16:07  -
--------------------------------------------------------------------------------
Total: 2, printed: 2
```

Table 11-243 Description of the **display wlan ids rogue-history all** command output

Item	Description
MAC address	MAC address of the rogue device listed in the historical record list.
Type	Type of the rogue device listed in the historical record list: ● a: user terminal on the ad-hoc network ● w: AP ● b: bridge device ● c: user terminal
CH	Channel in which the device is detected for the last time.
Authentication	Authentication mode of the rogue device listed in the historical record list.
Last detected time	Last time when the device is detected.
SSID	SSID of the detected device.

Display historical records of rogue APs.

```
<HUAWEI> display wlan ids rogue-history ap
CH: channel number
------------------------------------------------------------------------------
MAC address     CH  Authentication   Last detected time   SSID
------------------------------------------------------------------------------
00e0-fc12-3458  11  open             2014-11-20/11:20:37  wlan
00e0-fc12-3459  11  open             2014-11-20/11:20:44  -
------------------------------------------------------------------------------
Total: 2, printed: 2
```

Display historical records of SSIDs.

```
<HUAWEI> display wlan ids rogue-history ssid
#Dev: number of devices using SSID
------------------------------------------------------------------------------
SSID                             #Dev  Last detected time

Item	Description
MAC address	MAC address of the detected device.
Type	Type of the detected device.
SSID	SSID of an ESS.
Authentication	Authentication mode of the detected device.
Last detected time	Last time when the device is detected.

11.11.36 display wlan ids spoof-ssid fuzzy-match

Function

The **display wlan ids spoof-ssid fuzzy-match** command displays fuzzy matching rules for spoofing SSIDs.

Format

display wlan ids spoof-ssid fuzzy-match regex *regex-value*

Parameters

Parameter	Description	Value
regex *regex-value*	Specifies the matching rules for spoofing SSIDs and displays spoofing SSIDs that match the rules.	The rules must exist. The value is in text format and can contain 1 to 48 case-sensitive characters. It supports Chinese characters or mixture of Chinese and English characters. **NOTE** You can only use a command editor of the UTF-8 encoding format to edit Chinese characters.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view SSIDs that match a specific rule, run the **display wlan ids spoof-ssid fuzzy-match regex** *regex-value* command.

Example

Display SSIDs that match a specific rule.

```
<HUAWEI> display wlan ids spoof-ssid fuzzy-match regex ^HUAWE[1l]$
#Dev: Number of devices using SSID
--------------------------------------------------------------------------------
Match SSID                       #Dev  Last detected time   WIDS spoof profile
--------------------------------------------------------------------------------

Total: 2
```

Table 11-246 Description of the **display wlan ids spoof-ssid fuzzy-match regex** command output

Item	Description
Match SSID	SSID matching a specific rule.
#Dev	Number of APs using the matching SSID.
Last detected time	Latest time when the SSID is detected.
WIDS spoof profile	WIDS spoof profile to which the rules belong.

11.11.37 display wlan wapi certificate

Function

The **display wlan wapi certificate** command displays the content of a certificate file.

Format

display wlan wapi certificate file-name *file-name*

Parameters

Parameter	Description	Value
file-name *file-name*	Specifies a certificate file name.	The value is a string of 1 to 255 characters. It cannot contain question marks (?) and cannot start or end with double quotation marks (" ") or spaces.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view content of certificate files imported to the device.

In the command, *file-name* must specify the complete path of a certificate file. For example, if the certificate file **as.cer** is saved in the flash memory, run **display wlan wapi certificate file-name flash:/as.cer** command.

Example

Display content of certificate file **as.cer**.

```
<HUAWEI> display wlan wapi certificate file-name flash:/as.cer
Certificate:
Data:
  Version: V3
  Serial number:
      50 FA CF CA
  Signature algorithm: sha256ECDSA192
  Issuer:
      C = CN
      O = 0003
      OU = CUCC
      CN = as_test_1@ASU
  Validity:
    Not before: 2013-01-19 16:54:34 UTC
    Not after : 2033-01-19 16:54:34 UTC
  Subject:
      C = CN
      O = 0003
      OU = CUCC
      CN = as_test_1@ASU
  Subject public key information:
    Public key algorithm: ECC

      5E 82 C1 42 2D A9 42 C3 CE 91 98 7F 21 83 7C 71
      3A
```

Table 11-247 Description of the **display wlan wapi certificate** command output

Item	Description
Version	Version of the X.509 certificate.
Serial number	Serial number of the certificate.
Signature algorithm	Signature algorithm used by the certificate.
Issuer	Certificate issuer.
Validity	Valid period of the certificate, specified by the start date and end date.
Subject	Subject of the certificate.
Subject public key information	Information about the public key of the certificate.

11.11.38 dynamic-blacklist aging-time

Function

The **dynamic-blacklist aging-time** command sets an aging time for a dynamic blacklist.

The **undo dynamic-blacklist aging-time** command restores the aging time of a dynamic blacklist to the default value.

By default, the aging time of a dynamic blacklist is 300 seconds.

Format

dynamic-blacklist aging-time *time*

undo dynamic-blacklist aging-time

Parameters

Parameter	Description	Value
time	Specifies the aging time at the expiry of which a specified MAC address is removed from the dynamic blacklist.	The value is an integer that ranges from 180 to 3600, in seconds.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

When detecting attacks from a STA, an AP reports the STA to the AC, forbids the STA to go online, and rejects any packets sent from the STA. As long as the STA is blacklisted, it cannot go online again even if it no longer launches attacks. To avoid that, you can run the **dynamic-blacklist aging-time** command to configure an aging time for the dynamic blacklist. If the configured aging time expires and the AP detects no attack from the STA, the STA is once again allowed to go online.

Example

Set the aging time of the dynamic blacklist to 200 seconds.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name example
[HUAWEI-wlan-ap-system-prof-example] dynamic-blacklist aging-time 200
```

11.11.39 dynamic-blacklist disable

Function

The **dynamic-blacklist disable** command disables the dynamic blacklist function.

The **undo dynamic-blacklist disable** command enables the dynamic blacklist function.

By default, the dynamic blacklist function is enabled.

Format

dynamic-blacklist disable

undo dynamic-blacklist disable

Parameters

None

Views

WIDS profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Attack detection is enabled to detect flood attacks, weak IV attacks, spoofing attacks, and brute force key cracking attacks. When detecting attacks initiated by a device, an AP reports an alarm to the AC. In addition, you can run the **undo dynamic-blacklist disable** command to enable the dynamic blacklist function on the AC for handling flood attacks and brute force key cracking attacks. The AC then automatically adds the attacking device to a dynamic blacklist and discards packets sent from the attacking device till the dynamic blacklist ages out.

An AP can use the dynamic blacklist to filter out the blacklisted wireless devices to avoid malicious attacks.

Follow-up Procedure

Run the **dynamic-blacklist aging-time** command to set an aging time for the dynamic blacklist.

Example

Enable the dynamic blacklist function.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] wids-profile name default
[HUAWEI-wlan-wids-prof-default] undo dynamic-blacklist disable
```

11.11.40 flood-detect interval

Function

The **flood-detect interval** command sets the flood attack detection interval.

The **undo flood-detect interval** command restores the default flood attack detection interval.

By default, the flood attack detection interval is 10 seconds.

Format

flood-detect interval *interval*

undo flood-detect interval

Parameters

Parameter	Description	Value
interval *interval*	Specifies the interval for flood attack detection.	The value is an integer that ranges from 10 to 120, in seconds.

Views

WIDS profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A flood attack occurs when an AP receives a large number of packets of the same type within a short period. As a result, the AP is flooded by too many attack packets to process service packets from authorized wireless terminals.

After the flood attack detection function is enabled, an AP counts the number of packets of the same type that it receives from a user at regular intervals. When the number exceeds a specified threshold, the AP considers that the user launches a flood attack. If the dynamic blacklist function is enabled, the user will be added to a dynamic blacklist.

Follow-up Procedure

Run the **undo dynamic-blacklist disable** command to enable the dynamic blacklist function.

Example

Set the flood attack detection interval to 120s.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] radio 0
[HUAWEI-wlan-group-radio-default/0] wids attack detect flood enable
[HUAWEI-wlan-group-radio-default/0] quit
[HUAWEI-wlan-ap-group-default] quit
[HUAWEI-wlan-view] wids-profile name default
[HUAWEI-wlan-wids-prof-default] flood-detect interval 120
```

11.11.41 flood-detect quiet-time

Function

The **flood-detect quiet-time** command sets the quiet time for an AP to report the detected flood attacks to the AC.

The **undo flood-detect quiet-time** command restores the quiet time for an AP to report the detected flood attacks to the AC.

By default, the quiet time is 600 seconds for an AP to report the detected flood attacks to the AC.

Format

flood-detect quiet-time *quiet-time-value*

undo flood-detect quiet-time

Parameters

Parameter	Description	Value
quiet-time-value	Specifies the quiet time for an AP to report the detected flood attacks to the AC.	The value is an integer that ranges from 60 to 36000, in seconds.

Views

WIDS profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After attack detection is enabled on an AP, the AP reports alarms upon attack detection. If an attack source launches attacks repeatedly, a large number of repeated alarms are generated. To prevent this situation, configure the quiet time for an AP to report alarms. When detecting attack sources of the same MAC address, the AP does not report alarms in the quiet time. However, if the AP still detects attacks from the attack source after the quiet time expires, the AP reports alarms. You can set the quiet time based on attack types.

To obtain attack information in a timely manner, set the quiet time to a small value. If attack detection is enabled on many APs, and attacks are frequently detected, set the quiet time to a large value to prevent frequent alarm reports.

Follow-up Procedure

Run the **undo dynamic-blacklist disable** command to enable the dynamic blacklist function.

Example

Set the quiet time to 300 seconds for an AP to report the detected flood attacks to the AC.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] radio 0
[HUAWEI-wlan-group-radio-default/0] wids attack detect flood enable
[HUAWEI-wlan-group-radio-default/0] quit
[HUAWEI-wlan-ap-group-default] quit
[HUAWEI-wlan-view] wids-profile name default
[HUAWEI-wlan-wids-prof-default] flood-detect quiet-time 300
```

11.11.42 flood-detect threshold

Function

The **flood-detect threshold** command sets the flood attack detection threshold. A flood attack occurs when an AP receives a large number of packets of the same type within a short period.

The **undo flood-detect threshold** command restores the default flood attack detection threshold.

By default, the flood attack detection threshold is 500.

Format

flood-detect threshold *threshold*

undo flood-detect threshold

Parameters

Parameter	Description	Value
threshold *threshold*	Specifies the flood attack detection threshold.	The value is an integer that ranges from 1 to 1000.

Views

WIDS profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A flood attack occurs when a device receives a large number of packets of the same type within a short period. As a result, the device is flooded by too many attack packets to process service packets from authorized wireless terminals.

After the flood attack detection function is enabled, a device counts the number of packets of the same type that it receives from a user at regular intervals. When the number exceeds a specified threshold, the device considers that the user launches a flood attack. If the dynamic blacklist function is enabled, the user will be added to a dynamic blacklist. If the threshold is set to a small value, the device may incorrectly add authorized users to the dynamic blacklist, causing the users unable to go online.

Follow-up Procedure

Run the **undo dynamic-blacklist disable** command to enable the dynamic blacklist function.

Example

Set the flood attack detection threshold to 350.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] radio 0
[HUAWEI-wlan-group-radio-default/0] wids attack detect flood enable
[HUAWEI-wlan-group-radio-default/0] quit
[HUAWEI-wlan-ap-group-default] quit
[HUAWEI-wlan-view] wids-profile name default
[HUAWEI-wlan-wids-prof-default] flood-detect threshold 350
```

11.11.43 ip source check user-bind enable

Function

The **ip source check user-bind enable** command enables IP source guard (IPSG) on APs.

The **undo ip source check user-bind enable** command disables IPSG on APs.

By default, IPSG is disabled on APs.

Format

ip source check user-bind enable

undo ip source check user-bind enable

Parameters

None

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Users can configure static IP addresses for their clients and connect to the Internet after passing 802.1X authentication. To defend against source IP address spoofing attacks, you need to enable IPSG on APs.

To prevent IP packets of unauthorized users from entering external networks through an AP, enable IPSG in a VAP profile and bind the VAP profile to an AP or AP group. The IPSG function can filter incoming packets on an AP radio interface, preventing unauthorized packets from passing through the AP.

Example

Enable IPSG on APs.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] ip source check user-bind enable
```

11.11.44 learn-client-address dhcp-strict

Function

The **learn-client-address dhcp-strict** command enables strict STA IP address learning through DHCP.

The **undo learn-client-address dhcp-strict** command disables strict STA IP address learning through DHCP.

By default, strict STA IP address learning through DHCP is disabled.

Format

learn-client-address dhcp-strict [**blacklist enable**]

undo learn-client-address dhcp-strict

Parameters

Parameter	Description	Value
blacklist enable	Adds STAs with bogus IP addresses to a blacklist. By default, STAs with bogus IP addresses are not added to a blacklist.	-

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a STA associates with an AP, the following situation occurs after strict STA IP address learning through DHCP is enabled:

- If the STA obtains an IP address through DHCP, the AP will automatically report the IP address to the AC. The STA IP address can be used to maintain the mapping between STA IP addresses and MAC addresses.
- For a STA using a static IP address:
  - If **blacklist enable** is specified, the STA will be added to a dynamic blacklist of the AP and cannot associate with the AP before the blacklist entry ages.
  - If **blacklist enable** is not specified, the STA can associate with the AP but the AP does not learn the IP address of the STA.

Prerequisites

STA address learning has been enabled using the **undo learn-client-address ipv4 disable** command.

Precautions

After strict STA IP address learning is enabled, it is recommended that you run the **ip source check user-bind enable** and **arp anti-attack check user-bind enable** commands to enable IPSG and DAI so that STAs can communicate with the network only after obtaining an IP address through DHCP.

If this function is disabled, you can manually configure a static IP address. However, if a STA obtains an IP address dynamically using DHCP, goes online, and then is assigned a static IP address, the administrator cannot detect the IP address change of this STA.

Example

Enable strict STA IP address learning through DHCP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] learn-client-address dhcp-strict
```

11.11.45 learn-client-address { dhcpv6-strict | dhcpv6-slaac }

Function

The **learn-client-address { dhcpv6-strict | dhcpv6-slaac }** command enables strict STA IPv6 address learning.

The **undo learn-client-address { dhcpv6-strict | dhcpv6-slaac }** command disables strict STA IPv6 address learning.

By default, strict STA IPv6 address learning is disabled.

Format

learn-client-address { **dhcpv6-strict** | **dhcpv6-slaac** } [**blacklist enable**]

undo learn-client-address { **dhcpv6-strict** | **dhcpv6-slaac** }

Parameters

Parameter	Description	Value
dhcpv6-strict	Enables the STA IPv6 address learning function only through DHCPv6.	-
dhcpv6-slaac	Enables the STA IPv6 address learning function only through DHCPv6 or SLAAC in DHCPv6 + SLAAC scenarios.	-
blacklist enable	Adds STAs with bogus IPv6 addresses to a blacklist. By default, STAs with bogus IPv6 addresses are not added to a blacklist.	-

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a STA associates with an AP, the following situation occurs after strict STA IPv6 address learning is enabled:

- If the STA obtains an IPv6 address through DHCPv6 or SLAAC, the AP will proactively report the STA's IPv6 address to the AC to maintain the STA's IPv6 address and MAC address binding entry.
- For a STA using a static IPv6 address:
  - If **blacklist enable** is specified, the STA will be added to a dynamic blacklist of the AP and cannot associate with the AP before the blacklist entry ages.
  - If **blacklist enable** is not specified, the STA can associate with the AP but the AP does not learn the IPv6 address of the STA.

Prerequisites

The ND trusted interface of the AP has been disabled using the **undo nd trust port** command in the VAP profile view.

STA address learning has been enabled using the **undo learn-client-address ipv6 disable** command.

Precautions

After strict STA IP address learning is enabled, it is recommended that you run the **ip source check user-bind enable** and **arp anti-attack check user-bind enable** commands to enable IPSG and DAI so that STAs can communicate with the network only after obtaining an IPv6 address.

If this function is disabled, you can manually configure a static IP address. However, if a STA obtains an IP address dynamically using DHCPv6 or SLAAC, goes online, and then is assigned a static IP address, the administrator cannot detect the IP address change of this STA.

If you run this command multiple times, only the latest configuration takes effect.

Example

Enable strict STA IPv6 address learning only through DHCPv6 or SLAAC.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] learn-client-address dhcpv6-slaac
```

11.11.46 learn-client-address disable (VAP profile view)

Function

The **learn-client-address disable** command disables STA address learning.

The **undo learn-client-address disable** command enables STA address learning.

By default, STA address learning is enabled.

Format

learn-client-address { **ipv4** | **ipv6** } **disable**

undo learn-client-address { **ipv4** | **ipv6** } **disable**

Parameters

Parameter	Description	Value
ipv4	Indicates the IPv4 address.	-
ipv6	Indicates the IPv6 address.	-

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a STA is associated with a STA address learning-enabled AP and obtains an IP address, the AP proactively reports the STA's IP address to the AC to maintain the IP address-MAC address binding entry of the STA. In addition, when a STA requests an IP address using DHCP, the AP can learn the IPv4 address of the STA gateway.

Prerequisites

- Before enabling STA address learning, ensure that the ND trusted interface of the AP for the IPv6 address has been disabled using the **undo nd trust port** command.
- Before disabling STA address learning, ensure that strict STA IPv4 address learning has been disabled using the **undo learn-client-address dhcp-strict** command and strict STA IPv6 address learning disabled using the **undo learn-client-address dhcpv6-strict** command.

Precautions

- The device enabled with STA address learning can learn only a limited number of IPv6 addresses; therefore, you are advised to configure only one IPv6 prefix for the IPv6 gateway. If you configure too many IPv6 prefixes, the number of IPv6 addresses exceeds the upper limit, and extra IPv6 addresses cannot be learned by the device. IPv6 addresses that are not learned by the device cannot be used for communication.

- If a bridging device functions as a STA to connect to an AP enabled with STA address learning, the AP cannot learn IP addresses of users connected to the bridging device; therefore, the users cannot communicate with the network. In this situation, disable STA address learning.
- Disabling STA address learning will lead to a Portal authentication failure.
- When a STA requests an IP address using DHCP, the STA address learning-enabled AP can only learn the IPv4 gateway address but cannot learn the IPv6 gateway address.
- If no STA connected to a STA address learning-enabled AP requests an IP address using DHCP, the AP cannot learn the gateway IP address.

Example

Disable STA IPv4 address learning.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] learn-client-address ipv4 disable
```

11.11.47 nd trust port

Function

The **nd trust port** command enables the ND trusted interface on an AP.

The **undo nd trust port** command cancels the configuration.

By default, the ND trusted interface is disabled on an AP

Format

nd trust port

undo nd trust port

Parameters

None

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a bogus ND server is deployed at the user side, STAs may obtain incorrect IPv6 addresses and network configuration parameters and cannot communicate properly. After the **undo nd trust port** command is executed in the VAP profile view, an AP discards the ND OFFER, ACK, and NAK packets sent by the bogus ND server and the IPv6 address of the unauthorized ND server.

Before WLAN services are delivered to an AP, run the **nd trust port** command in the AP wired port profile view. After the command is run, the AP receives the ND OFFER, ACK, and NAK packets sent by the authorized ND server and forwards the packets to STAs so that the STAs can obtain valid IPv6 addresses and go online.

Prerequisites

The function of processing STA IPv6 services has been enabled using the **sta-ipv6-service enable** command.

Before enabling the ND trusted interface, ensure that STA IPv6 address learning has been disabled using the **learn-client-address ipv6 disable** command.

Example

Create the VAP profile **vap1** and enable the ND trusted interface on the AP in the VAP profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] nd trust port
```

11.11.48 oui

Function

The **oui** command configures an organizationally unique identifier (OUI) for STAs in the whitelist.

The **undo oui** command deletes the OUI of a specified STA or all STAs in the whitelist.

By default, no OUI is configured for STAs in the whitelist.

Format

oui *oui* [**description** *description*]

undo oui { *oui* | **all** }

Parameters

Parameter	Description	Value
oui	Specifies the OUI of STAs in the whitelist.	The value is in H-H-H format. An H is a hexadecimal number of 2 digits. For example, **11-22-33** indicates a STA whose first 6 bits of the MAC address are 11-22-33.
description	Specifies the OUI description of STAs in the whitelist.	The value is a string of 1 to 80 characters.
all	Deletes the OUI of all STAs in the whitelist.	-

Views

STA whitelist profile view

Default Level

2: Configuration level

Usage Guidelines

After the whitelist function is enabled, all STAs in the whitelist can connect to the WLAN. In some scenarios, all STAs with a specified OUI need to be added to the whitelist. You can run the **oui** command to add STAs with a specified OUI to the whitelist.

Example

Configure the OUI **00-11-22** for STAs in the whitelist profile **sta-whitelist-profile1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sta-whitelist-profile name sta-whitelist-profile1
[HUAWEI-wlan-whitelist-prof-sta-whitelist-profile1] oui 00-11-22
```

11.11.49 permit-ap

Function

The **permit-ap** command configures a WIDS whitelist.

The **undo permit-ap** command deletes entries in the WIDS whitelist.

By default, no WIDS whitelist is configured.

Format

permit-ap { **mac-address** *mac-address* | **oui** *oui* | **ssid** *ssid* }

undo permit-ap { **mac-address** { *mac-address* | **all** } | **oui** { *oui* | **all** } | **ssid** { **name** *ssid* | **all** } }

Parameters

Parameter	Description	Value
mac-address *mac-address*	Adds or deletes an authorized MAC address.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits. The MAC address cannot be FFFF-FFFF-FFFF, 0000-0000-0000, or a multicast MAC address.
mac-address all	Deletes an authorized MAC address list.	-
oui *oui*	Adds or deletes an authorized OUI.	The value is in H-H-H format. An H is a hexadecimal number of 2 digits.
oui all	Deletes an authorized OUI list.	-

Parameter	Description	Value
ssid name *ssid*	Deletes an authorized SSID.	The value is a string of 1 to 32 case-sensitive characters. It supports Chinese characters or Chinese + English characters, without tab characters. To start an SSID with a space, you need to encompass the SSID with double quotation marks (" "), for example, **" hello"**. The double quotation marks occupy two characters. To start an SSID with a double quotation mark, you need to add a backslash (\) before the double quotation mark, for example, **\"hello**. The backslash occupies one character.

Parameter	Description	Value
ssid *ssid*	Adds an authorized SSID.	The value is a string of 1 to 32 case-sensitive characters. It supports Chinese characters or Chinese + English characters, without tab characters. To start an SSID with a space, you need to encompass the SSID with double quotation marks (" "), for example, **" hello"**. The double quotation marks occupy two characters. To start an SSID with a double quotation mark, you need to add a backslash (\) before the double quotation mark, for example, **\"hello**. The backslash occupies one character.
ssid all	Deletes an authorized SSID list.	-

2: Configuration level

Usage Guidelines

Usage Scenario

After WIDS/WIPS is enabled, rogue APs can be detected and contained. However, there may be APs of other vendors or other networks working in the existing signal coverage areas. If these APs are contained, their services will be affected. To prevent this situation, configure an authorized AP list, including an authorized MAC address list, OUI list, and SSID list. If a rogue AP is detected but matches the authorized AP list, the AP is considered an authorized AP and will not be contained.

For example, APs of other vendors are deployed on the existing WLAN to expand network capacity. To prevent the APs from being contained, add OUIs of the vendors to a whitelist and add SSIDs of these APs to a whitelist. In this way, the device will consider the APs as authorized APs.

The device determines whether a detected AP is authorized as follows:

1. Check whether the AP's MAC address is in the authorized MAC address list.
   - If so, the AP is an authorized AP.
   - If not, go to step 2.
2. Check whether the AP's OUI and SSID are in the OUI and SSID lists.
   - If only the SSID is configured, check whether the AP's SSID is in the authorized SSID list.
     - If so, the AP is an authorized AP.
     - If not, the AP is a rogue AP.
   - If only the OUI is configured, check whether the AP's OUI is in the authorized OUI list.
     - If so, the AP is an authorized AP.
     - If not, the AP is a rogue AP.
   - If OUI and SSID of an AP are configured and both of them are matched, check whether the AP's OUI and SSID are in the authorized OUI and SSID lists.
     - If so, the AP is an authorized AP.
     - If neither or only one of them is in the list, the AP is a rogue AP.
   - If both OUI and SSID of an AP are configured and either of them can be matched, check whether either of AP's OUI and SSID are in the authorized OUI list or SSID list.
     - If both or one of them is in the list, the AP is an authorized AP.
     - If neither of them is in the list, the AP is a rogue AP.

Precautions

If you add or delete an entry, the device will re-check the validity of the rogue APs. If a rogue AP becomes authorized, the device stops containing it. If an authorized AP becomes rogue, the device starts to contain it.

Example

Add an MAC address, an OUI, and an SSID to the WIDS whitelist.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wids-whitelist-profile name default
[HUAWEI-wlan-wids-whitelist-default] permit-ap mac-address 00e0-fc12-3456
```

```
[HUAWEI-wlan-wids-whitelist-default] permit-ap oui 00-11-22
[HUAWEI-wlan-wids-whitelist-default] permit-ap ssid example
```

11.11.50 permit-ap oui-ssid-match

Function

The **permit-ap oui-ssid-match** command configures an OUI and SSID matching policy in a WIDS whitelist.

The **undo permit-ap oui-ssid-match** command deletes the OUI and SSID matching policy in a WIDS whitelist.

By default, both OUIs and SSIDs are matched in a WIDS whitelist.

Format

permit-ap oui-ssid-match { **both** | **any** }

undo permit-ap oui-ssid-match

Parameters

Parameter	Description	Value
both	Matches both OUIs and SSIDs in a WIDS whitelist.	-
any	Matches either of OUIs and SSIDs in a WIDS whitelist.	-

Views

WIDS whitelist profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After WIDS or WIPS is enabled, you can run the **permit-ap** command to configure a WIDS whitelist, including the authorized MAC address list, authorized OUI list, and authorized SSID list. If a rogue AP is detected but matches the authorized AP list, the AP is considered an authorized AP and will not be contained.

This command is used to configure a policy for matching OUIs and SSIDs in the WIDS whitelist.

- Both: Both the OUI and SSID of an AP are matched against the authorized OUI list and authorized SSID list. If no match is found in the lists, the AP is considered a rogue AP. If only one of authorized OUI and SSID lists is configured in the WIDS whitelist, the device matches the OUI or SSID of the AP only against the configured list.

- Any: The OUI and SSID of an AP is matched against the authorized OUI list or the authorized SSID list accordingly. If a match is found in either of the lists, the AP is considered an authorized AP; if not, the AP is considered a rogue AP.

Precautions

After the OUI and SSID matching policy is modified, the device checks whether the AP is authorized. If not, the device determines the containment policy. If a rogue AP becomes authorized, the device stops containing it. If an authorized AP becomes rogue, the device starts to contain it.

Example

Set the OUI and SSID matching policy in a WIDS whitelist to **any**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wids-whitelist-profile name default
[HUAWEI-wlan-wids-whitelist-default] permit-ap oui 00-11-22
[HUAWEI-wlan-wids-whitelist-default] permit-ap ssid example
[HUAWEI-wlan-wids-whitelist-default] permit-ap oui-ssid-match any
```

11.11.51 pmf

Function

The **pmf** command enables the Protected Management Frame (PMF) function of a VAP.

The **undo pmf** command disables the PMF function for a VAP.

By default, the PMF function is disabled for a VAP.

Format

pmf { **optional** | **mandatory** }

undo pmf

Parameters

Parameter	Description	Value
optional	Indicates the optional mode, in which STAs can access the VAP regardless of whether the STAs support PMF or not, but the VAP encrypts only management frames of PMF-capable STAs.	-

Parameter	Description	Value
mandatory	Indicates the mandatory mode, in which the VAP permits access only from PMF-capable STAs.	-

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

PMF is a specification released by Wi-Fi Alliance (WFA) based on IEEE 802.11w standards. It aims to apply security measures defined in WPA2, WPA3, OWE to unicast and multicast management action frames to improve network credibility.

If management frames transmitted on WLANs are not encrypted, the following security problems may be introduced. PMF can address the problems.

- Hackers intercept management frames exchanged between the APs and users.
- Hackers pretend to be APs and send Disassociation and Deauthentication frames to disconnect users.
- Hackers pretend to be users and send Disassociation frames to APs to disconnect the users.

Precautions

The authentication and encryption mode in a security profile must be set to WPA2–AES/WPA2-WPA3/WPA3/OWE.

If the authentication mode is WPA3, this command does not take effect. If the authentication mode is WPA3-SAE or WPA3-802.1X, the PMF mode is fixed at **mandatory**. If the authentication mode is WPA2-WPA3, the PMF mode is fixed at **optional**.

If the authentication mode is OWE or its transition mode, this command does not take effect, and the PMF mode is fixed at **mandatory**.

Modifying configuration in the security profile will disconnect all users on the VAP that uses the security profile. The users need to reassociate with the VAP to go online.

The PMF function cannot be deployed on Mesh networks.

Example

Enable the PMF function in optional mode.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] security wpa2 psk pass-phrase abcdfffffg aes
[HUAWEI-wlan-sec-prof-p1] pmf optional
```

11.11.52 reset wlan ids attack-detected

Function

The **reset wlan ids attack-detected** command deletes information about the attacking devices detected.

Format

reset wlan ids attack-detected { **all** | **flood** | **spoof** | **wapi-psk** | **weak-iv** | **wep-share-key** | **wpa-psk** | **wpa2-psk** | **mac-address** *mac-address* }

Parameters

Parameter	Description	Value
all	Deletes information about all types of attacking devices.	-
flood	Deletes information about devices launching flood attacks.	-
spoof	Deletes information about devices launching spoofing attacks.	-
wapi-psk	Deletes information about devices that perform brute force cracking in WAPI-PSK authentication mode.	-
weak-iv	Deletes information about devices launching weak IV attacks.	-
wep-share-key	Deletes information about devices that perform brute force cracking in WEP-SK authentication mode.	-
wpa-psk	Deletes information about devices that perform brute force cracking in WPA-PSK authentication mode.	-
wpa2-psk	Deletes information about devices that perform brute force cracking in WPA2-PSK authentication mode.	-
mac-address *mac-address*	Deletes information about detected devices launching attacks with specified MAC addresses.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.

3: Management level

Usage Guidelines

After attack detection is enabled, information about attacking devices detected is recorded. When there is excessive information recorded or the recorded information is useless, you can run the **reset wlan ids attack-detected** command to delete the information.

Example

Delete information about all the current attacking devices.

```
<HUAWEI> reset wlan ids attack-detected all
```

11.11.53 reset wlan ids attack-detected statistics

Function

The **reset wlan ids attack-detected statistics** command deletes the number of attacks detected.

Format

reset wlan ids attack-detected statistics

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

After attack detection is enabled, the number of attacks detected is recorded. When there is excessive information recorded or the recorded information is useless, you can run the **reset wlan ids attack-detected statistics** command to delete the information.

Example

Delete the number of attacks detected.

```
<HUAWEI> reset wlan ids attack-detected statistics
```

11.11.54 reset wlan ids attack-history

Function

The **reset wlan ids attack-history** command deletes historical records about the attacking devices detected.

Format

reset wlan ids attack-history { **all** | **flood** | **spoof** | **wapi-psk** | **weak-iv** | **wep-share-key** | **wpa-psk** | **wpa2-psk** | **mac-address** *mac-address* }

Parameters

Parameter	Description	Value
all	Deletes historical records about all types of attacking devices.	-
flood	Deletes historical records about devices launching flood attacks.	-
spoof	Deletes historical records about devices launching spoofing attacks.	-
wapi-psk	Deletes historical records about devices that perform brute force cracking in WAPI-PSK authentication mode.	-
weak-iv	Deletes historical records about devices launching weak IV attacks.	-
wep-share-key	Deletes historical records about devices that perform brute force cracking in WEP-SK authentication mode.	-
wpa-psk	Deletes historical records about devices that perform brute force cracking in WPA-PSK authentication mode.	-
wpa2-psk	Deletes historical records about devices that perform brute force cracking in WPA2-PSK authentication mode.	-
mac-address *mac-address*	Deletes historical records about detected devices launching attacks with specified MAC addresses.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.

Usage Guidelines

After attack detection is enabled, historical records about attacking devices detected are recorded. When there is excessive information recorded or the recorded information is useless, you can run the **reset wlan ids attack-history** command to delete the information.

Example

Delete historical records about all the current attacking devices.

```
<HUAWEI> reset wlan ids attack-history all
```

11.11.55 reset wlan dynamic-blacklist

Function

The **reset wlan dynamic-blacklist** command deletes information about devices in the dynamic blacklist.

Format

reset wlan dynamic-blacklist { **ap-id** *ap-id* | **ap-name** *ap-name* | **mac-address** *mac-address* | **all** }

Parameters

Parameter	Description	Value
ap-id *ap-id*	Deletes the dynamic blacklist information reported by the AP with a specified ID.	The AP ID must exist.
ap-name *ap-name*	Deletes the dynamic blacklist information reported by the AP with a specified name.	The AP name must exist.
mac-address *mac-address*	Deletes the device with a specified MAC address from the dynamic blacklist.	The MAC address must exist.
all	Deletes all information in the dynamic blacklist.	-

Views

All views

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The **reset wlan dynamic-blacklist** command is applicable to the following scenarios:

- To re-collect the dynamic blacklist information, run the **reset wlan dynamic-blacklist all** command to delete all information in the dynamic blacklist. After that, the AC re-collects the information.
- To remove an authorized device from the dynamic blacklist, run the **reset wlan dynamic-blacklist mac-address** command to remove the MAC address of the device from the dynamic blacklist. After that, information sent from the device is not rejected.

Precautions

Running the **reset wlan dynamic-blacklist** command affects packet receiving of APs. Exercise caution when running this command.

Example

Delete the device with the MAC address 00E0-FC12-3456 from the dynamic blacklist.

```
<HUAWEI> reset wlan dynamic-blacklist mac-address 00e0-fc12-3456
```

11.11.56 reset wlan ids rogue-history

Function

The **reset wlan ids rogue-history** command deletes historical records of rogue devices.

Format

reset wlan ids rogue-history { **all** | **ap** | **bridge** | **client** | **adhoc** | **ssid** [*ssid*] | **mac-address** *mac-address* }

Parameters

Parameter	Description	Value
all	Deletes historical records of all rogue devices.	-
ap	Deletes historical records of rogue APs.	-
bridge	Deletes historical records of rogue bridge devices.	-

Parameter	Description	Value
client	Deletes historical records of rogue user terminals.	-
adhoc	Deletes historical records of rogue ad-hoc devices.	-
ssid [*ssid*]	Deletes historical records of devices with specified SSIDs.	The SSID must exist. To specify an SSID starting with a space, include the SSID with double quotation marks (" "). For example, in the SSID **" hello"**, the double quotation marks at the start and end of the SSID occupy two characters. To specify an SSID starting with a double quotation mark ("), enter an escape character (\) before the double quotation mark. For example, in the SSID **\"hello**, the escape character (\) occupies one character.
mac-address *mac-address*	Deletes historical records of devices with specified MAC addresses.	The value must be an existing MAC address.

Views

All views

Default Level

3: Management level

Usage Guidelines

When there are excessive historical records of rogue devices or their historical records are useless, you can run the **reset wlan ids rogue-history** command to delete the historical records.

Example

Delete all detected historical records of the rogue devices.

```
<HUAWEI> reset wlan ids rogue-history all
```

11.11.57 rogue-device log enable

Function

The **rogue-device log enable** command enables the function of recording rogue device information in the log.

The **undo rogue-device log enable** command disables the function of recording rogue device information in the log.

By default, the function of recording rogue device information in the log is disabled.

Format

rogue-device log enable

undo rogue-device log enable

Parameters

None

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a rogue device is detected after this function is enabled, information about the device is recorded in the log.

Example

Enable the function of recording rogue device information in the log.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] rogue-device log enable
```

11.11.58 security dot1x

Function

The **security dot1x** command configures 802.1X authentication and encryption for WPA and WPA2.

The **undo security** command restores the default security policy.

By default, no security policy is configured.

Format

security { **wpa** | **wpa2** | **wpa-wpa2** } **dot1x** { **aes** | **tkip** | **aes-tkip** }

security wpa-wpa2 dot1x tkip aes

undo security

Parameters

Parameter	Description	Value
wpa	Configures WPA authentication.	-
wpa2	Configures WPA2 authentication.	-
wpa-wpa2	Configures WPA-WPA2 authentication. STAs can be authenticated using WPA or WPA2.	-
aes	Configures AES encryption.	-
tkip	Configures TKIP encryption.	-
aes-tkip	Configures AES-TKIP encryption. After successful authentication, STAs can use the AES or TKIP algorithm for data encryption.	-

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

There are two types of WPA/WPA2 authentication: WPA/WPA2-PSK authentication (also called WPA/WPA2-Personal) and WPA/WPA2-802.1X authentication (also called WPA/WPA2-Enterprise). 802.1X authentication is of high security and is applicable to enterprise networks.

To access a WLAN device using WPA or WPA2 802.1X authentication, run the **security dot1x** command. If multiple types of STAs connect to the network and they support different authentication and encryption modes, you can configure hybrid encryption and authentication modes.

The **security wpa-wpa2 dot1x tkip aes** command indicates that WPA and WPA2 use TKIP and AES for data encryption, respectively.

Precautions

TKIP and AES-TKIP are insecure encryption algorithms. For data encryption, AES is recommended.

The following STAs do not support the WPA2 802.1X authentication and cannot access the AP. You must configure other security policies for the STAs.

- Nokia: N8
- HP: Pre 3

The authentication type in the security profile and authentication profile must both be set to 802.1X authentication. You can run the **display wlan config-errors** command to check whether error messages are generated for authentication type mismatch between the security profile and authentication profile.

The system displays the message only when the security profile has been bound to the other profiles.

If 802.1X authentication and TKIP or AES-TKIP encryption for WPA/WPA2 are configured, the access of non-HT STAs fails to be denied.

The offline management VAP does not support 802.1X authentication and encryption modes. Therefore, if the offline management VAP is enabled for a VAP profile, the VAP profile cannot be bound to a security profile with WPA/WPA2 802.1X authentication and encryption configured. If the VAP profile has been bound to a security profile, the authentication and encryption modes of the security profile cannot be changed to WPA/WPA2 802.1X.

Example

Configure WPA (802.1X authentication and TKIP encryption).

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] security wpa dot1x tkip
```

Configure WPA2 (802.1X authentication and TKIP encryption).

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] security wpa2 dot1x tkip
```

Configure WPA-WPA2 (802.1X authentication and TKIP-AES encryption).

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] security wpa-wpa2 dot1x aes-tkip
```

11.11.59 security enhanced-open

Function

The **security enhanced-open** command configures Opportunistic Wireless Encryption (OWE) authentication or authentication and encryption in OWE transition mode.

The **undo security** command restores the default security policy.

By default, no security policy is configured.

Format

security enhanced-open aes [**transition-ssid** *ssid*]

undo security

Parameters

Parameter	Description	Value
aes	Configures AES encryption.	-
transition-ssid *ssid*	Specifies an SSID to use open authentication in OWE transition mode. ● If this parameter is not specified, OWE authentication is used. ● If this parameter is specified, the OWE transition mode is used. **NOTE** In OWE transition mode, you need to configure two VAP profiles on the same radio and set their authentication modes to OWE and open, respectively. Ensure that the parameter **transition-ssid** is set the same as the SSID in the VAP profile using the open security policy but different from the SSID in the VAP profile using OWE authentication. The OWE transition mode takes effect only when a VAP profile on the same radio uses the same SSID as **transition-ssid** and the open security policy, and the corresponding VAP is enabled. If such effective conditions are not met, the device uses OWE authentication.	The value is a string of 1 to 32 case-sensitive characters without spaces. If spaces are contained in the SSID, enclose the string using double quotation marks ("). For example, if an SSID is **a bc**, enter **"a bc"** when specifying this parameter. In this case, the string can contain a maximum of 30 characters. If the first character of an SSID is a double quotation mark ("), add a backslash (\) to the SSID as the prefix. For example, if an SSID is **"abc**, enter **\"abc** when specifying this parameter. In this case, the string can contain a maximum of 31 characters.

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

OWE is a Wi-Fi Enhanced Open authentication mode that allows users to access the network without entering the password. In OWE authentication mode, the device uses the AES encryption algorithm to encrypt data on the network, thereby protecting data exchange between STAs and the Wi-Fi network. The OWE transition mode provides backward compatibility with STAs that do not support OWE authentication. That is, these STAs access the network in open-system authentication mode, while OWE-capable STAs access the network in OWE authentication mode.

Precautions

- OWE authentication or its transition mode automatically enables the PMF function in mandatory mode. That is, the **pmf** { **optional** | **mandatory** } command configuration does not take effect in OWE authentication or its transition mode.
- OWE authentication depends on the PMF function, but 802.11n APs do not support the PMF function. Therefore, 802.11n APs do not support OWE authentication.
- OWE authentication and 802.11r cannot be enabled at the same time.
- OWE authentication is not supported in WDS and Mesh scenarios.
- If the security profile is bound to another profile, running this command may interrupt services.
- Some STAs may fail to access the network in OWE or OWE transition mode due to compatibility issues.
- Some OWE-capable STAs may still access the network through open system authentication in OWE transition mode due to compatibility issues.

Example

Set the authentication mode to the OWE transition mode and the SSID using the open-system authentication mode to **wlan-net**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] security enhanced-open aes transition-ssid wlan-net
```

11.11.60 security open

Function

The **security open** command configures open-system authentication.

The **undo security** command restores the default security policy.

By default, no security policy is configured.

Format

security open

undo security

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Open-system authentication is applicable to public venues where users move frequently and do not need to be authenticated, such as airports and stations. That is, users can access the network without authentication and encryption.

Precautions

It is not secure to use open system authentication independently. Any wireless terminals can access the network without authentication. You are advised to configure open system authentication together with Portal authentication or MAC address authentication.

Example

Configure open-system authentication.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] security open
```

11.11.61 security psk

Function

The **security psk** command configures WPA/WPA2 PSK authentication and encryption.

The **undo security** command restores the default security policy.

By default, no security policy is configured.

Format

security { **wpa** | **wpa2** | **wpa-wpa2** } **psk** { **pass-phrase** | **hex** } *key-value* { **aes** | **tkip** | **aes-tkip** }

security wpa-wpa2 psk { **pass-phrase** | **hex** } *key-value* **tkip aes**

undo security

Parameters

Parameter	Description	Value
wpa	Configures WPA authentication.	-
wpa2	Configures WPA2 authentication.	-
wpa-wpa2	Configures WPA-WPA2 authentication. STAs can be authenticated using WPA or WPA2.	-
psk	Configures PSK authentication.	-
pass-phrase	Specifies the key phrase.	-
hex	Specifies a hexadecimal number. The password of **hex** does not have enough complexity, so **pass-phrase** is recommended.	-

Parameter	Description	Value
key-value	Specifies a password in cipher text.	The value is of 8 to 63 ASCII characters in plain text, 64 hexadecimal characters in plain text, or 48 or 68 or 88 or 108 characters in cipher text. The question mark (?) is supported, which you can enter by pressing **Ctrl+T**. A password cannot contain the space and double quotation mark (") at the same time. When the password contains a space, add the double quotation mark (") to the beginning and end of the string when entering the password. For example, if the password is **YsHsjx 202206**, enter **"YsHsjx 202206"**. **NOTE** For security purposes, you are advised to configure a key that contains at least two of the following: digits, lowercase letters, uppercase letters, and special characters.
aes	Configures AES encryption.	-
tkip	Configures TKIP encryption.	-
aes-tkip	Configures AES-TKIP encryption. After successful authentication, STAs can use the AES or TKIP algorithm for data encryption.	-

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

There are two types of WPA/WPA2 authentication: WPA/WPA2-PSK authentication (also called WPA/WPA2-Personal) and WPA/WPA2 802.1X authentication (also called WPA/WPA2-Enterprise). 802.1X authentication is of high security and is applicable to enterprise networks.

To access a WLAN device using WPA or WPA2 PSK authentication, run the **security psk** command. If multiple types of STAs are available, you can configure the WPA-WPA2 and AES-TKIP security policy for authentication and data encryption.

The **security wpa-wpa2 psk** { **pass-phrase** | **hex** } *key-value* **tkip aes** command indicates that WPA and WPA2 use TKIP and AES for data encryption, respectively.

Precautions

TKIP and AES-TKIP are insecure encryption algorithms. For data encryption, AES is recommended.

If the key is in hexadecimal notation, you can enter hexadecimal characters without entering 0x.

If a security profile is bound to multiple VAP profiles, it will take a few minutes to configure WPA/WPA2 PSK authentication and encryption in the security profile.

The system displays the message only when the security profile has been bound to the other profiles.

If PSK authentication and TKIP or AES-TKIP encryption for WPA/WPA2 is configured, the access of non-HT STAs fails to be denied.

If the password is changed to one starting or ending with a space (for example, **YsHsjx_202206**) on the device, some STAs (such as STAs running Windows 7) may filter out the space when you change the password on the STAs. This will lead to an association failure. Therefore, it is not recommended that a password starting or ending with a space be set on the device. If such a password has been configured on the device, delete the existing WLAN configuration on a STA, reassociate the STA with the SSID, and enter the password. For detailed terminal types, refer to the *Test Report on Terminal Compatibility*.

Example

Configure WPA-PSK authentication and the authentication key.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] security wpa psk pass-phrase YsHsjx_202206 aes
```

Configure WPA2-PSK authentication and the authentication key.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] security wpa2 psk pass-phrase YsHsjx_202206 aes
```

Configure WPA-WPA2 hybrid encryption and PSK authentication.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] security wpa-wpa2 psk pass-phrase YsHsjx_202206 aes-tkip
```

11.11.62 security wapi

Function

The **security wapi** command configures the WAPI authentication mode.

The **undo security** command restores the default security policy.

By default, no security policy is configured.

Format

security wapi psk { **pass-phrase** | **hex** } *key-value*

security wapi certificate

undo security

Parameters

Parameter	Description	Value
certificate	Configures WAPI certificate authentication.	-
psk	Configures WAPI pre-shared key authentication.	-
pass-phrase	Specifies the key phrase.	-
hex	Specifies a hexadecimal number. The password of **hex** does not have enough complexity, so **pass-phrase** is recommended.	-

Parameter	Description	Value
key-value	Specifies a password in cipher text.	In pass-phrase mode, the key is a string of 8 to 63 characters in plaintext, or 48 or 68 or 88 or 108 characters in ciphertext. In hex mode, the key is a string of 8 to 32 hexadecimal numbers, in which the length of the string must be an even, or a string of 48 or 68 characters in ciphertext. A password cannot contain the space and double quotation mark (") at the same time. When the password contains a space, add the double quotation mark (") to the beginning and end of the string when entering the password. For example, if the password is **YsHsjx 202206**, enter **"YsHsjx 202206"**. **NOTE** For security purposes, you are advised to configure a key that contains at least two of the following: digits, lowercase letters, uppercase letters, and special characters.

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

WAPI supports two authentication modes: certificate authentication and pre-shared key authentication. When pre-shared key authentication is used, a pre-shared key must be configured.

- If WAPI authentication is specified as a security policy in a security profile, you can run the **wapi authentication-method** command to configure the WAPI authentication mode.
- The **wapi authentication-method** command determines the WAPI authentication and key management mode. When certificate authentication and key management are configured, authentication involves identity authentication and key negotiation, and the authentication server and certificate need to be configured. When pre-shared key authentication is configured, a pre-shared key needs to be configured, and STAs also need to know the pre-shared key. In this situation, authentication just involves key negotiation.

Precautions

The system displays the message only when the security profile has been bound to the other profiles.

Example

Set the WAPI authentication mode to pre-shared key authentication and specify the key.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] security wapi psk pass-phrase YsHsjx_202206
```

11.11.63 security wep

Function

The **security wep** command configures the WEP authentication mode.

The **undo security** command restores the default security policy.

By default, no security policy is configured.

Format

security wep [**share-key** | **dynamic**]

undo security

Parameters

Parameter	Description	Value
security wep	Sets the WEP authentication mode to open-system and encrypts service packets using WEP.	-
security wep share-key	When the WEP authentication mode is set to shared-key authentication: ● If the parameter is present, WEP uses the configured shared key to authenticate wireless terminals and encrypt service packets. ● If the parameter is not present, WEP only uses the configured shared key to encrypt the service packets. A shared key is configured on the wireless terminals regardless of whether the parameter is present.	-
security wep dynamic	Sets the WEP authentication mode to dynamic WEP.	-

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can select security policies on a WLAN based on the security level. WEP is a security policy used earlier and has security risks. It can be used in open scenarios that do not require high security.

Table 11-248 Comparing authentication modes

Configuration	Link Authentication Mode	Encryption Mode	Advantage	Disadvantage
security open	open	Not encrypted	Wireless devices can connect to a network without authentication.	STA identities are not checked, bringing security risks. Service data is not WEP-encrypted.
security wep	open	Static WEP encryption	Service data is WEP-encrypted.	STA identities are not checked, bringing security risks.
security wep share-key	Shared key authentication	Static WEP encryption	A shared key is used to enhance security. Service data is WEP-encrypted.	● A long key string must be configured on each device and is difficult to expand. ● A static key is used, which is easy to decipher.
security wep dynamic	open	Dynamic WEP encryption	Dynamic WEP encryption for service data provides higher security.	802.1X authentication is also required. The configuration is complex.

Precautions

- If the **security wep** [**share-key**] command is executed, you can run the **wep key** command to configure the pre-shared key. Otherwise, the default pre-shared key is used.
- If the **security wep dynamic** command is executed to configure dynamic WEP, you also need to configure 802.1X authentication. Otherwise, dynamic WEP does not take effect.
- Each AP can have at most four key indexes configured. The key indexes used by different VAPs cannot be the same.

- The system displays the message only when the security profile has been bound to the other profiles.
- If WEP authentication is configured, the function of denying access of non-HT STAs fails to take effect.
- Mobile phones do not support dynamic WEP.
- RUs do not support dynamic WEP.
- The WEP encryption algorithm is insecure. WPA2 or WPA3 is recommended in scenarios that have high security requirements.

Example

Create security profile **p1** and set the authentication mode to **share-key**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] security wep share-key
```

11.11.64 security wpa2-wpa3 psk-sae

Function

The **security wpa2-wpa3 psk-sae** command configures WPA2-WPA3-SAE authentication and encryption.

The **undo security** command restores the default security policy.

By default, no security policy is configured.

Format

security wpa2-wpa3 psk-sae pass-phrase *key-value* **aes**

undo security

Parameters

Parameter	Description	Value
pass-phrase *key-value*	Specifies the password for WPA2-WPA3-SAE authentication.	The value is of 8 to 63 ASCII characters in plain text, 64 hexadecimal characters in plain text, or 48 or 68 or 88 or 108 characters in cipher text. A password cannot contain the space and double quotation mark (") at the same time. When the password contains a space, add the double quotation mark (") to the beginning and end of the string when entering the password. For example, if the password is **YsHsjx 202206**, enter **"YsHsjx 202206"**. **NOTE** For security purposes, you are advised to configure a key that contains at least two of the following: digits, lowercase letters, uppercase letters, and special characters.
aes	Configures AES encryption.	-

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

WPA2 is still widely used. To allow STAs that do not support WPA3 to access the WPA3 network, the device supports the WPA3-Personal transition mode, that is, WPA2-WPA3-SAE authentication.

WPA3-Personal supports hybrid authentication, allowing for only WPA2-WPA3 authentication and AES encryption.

Precautions

- WPA2-WPA3 hybrid authentication automatically enables the PMF function in optional mode. That is, configuring the **pmf** { **optional** | **mandatory** } command does not take effect in WPA2-WPA3 hybrid authentication scenarios.
- If the security profile is bound to another profile, running this command may interrupt services.

Example

Configure WPA2-WPA3-SAE authentication and set the user password to **YsHsjx_202206**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] security wpa2-wpa3 psk-sae pass-phrase YsHsjx_202206 aes
```

11.11.65 security wpa2-wpa3 dot1x

Function

The **security wpa2-wpa3 dot1x** command configures WPA2-WPA3-802.1X authentication and encryption.

The **undo security** command restores the default security policy.

By default, no security policy is configured.

Format

security wpa2-wpa3 dot1x aes

undo security

Parameters

Parameter	Description	Value
aes	Configures AES encryption.	-

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

WPA2 is still widely used. To allow STAs that do not support WPA3 to access the WPA3 network, the device supports the WPA3-Enterprise transition mode, that is, WPA2-WPA3-802.1X authentication.

WPA3-Enterprise supports hybrid authentication, allowing for only WPA2-WPA3 authentication and AES encryption.

Precautions

- WPA2-WPA3 hybrid authentication automatically enables the PMF function in optional mode. That is, configuring the **pmf** { **optional** | **mandatory** } command does not take effect in WPA2-WPA3 hybrid authentication scenarios.

- If the security profile is bound to another profile, running this command may interrupt services.

Example

Configure WPA2-WPA3-802.1X authentication.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] security wpa2-wpa3 dot1x aes
```

11.11.66 security wpa3 dot1x

Function

The **security wpa3 dot1x** command configures WPA3-802.1X authentication and encryption.

The **undo security** command restores the default security policy.

By default, no security policy is configured.

Format

security wpa3 dot1x { **gcmp256** | **aes** }

undo security

Parameters

Parameter	Description	Value
gcmp256	Indicates the AES-GCM encryption algorithm using a 256-bit key.	-
aes	Configures AES encryption.	-

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

WPA3 authentication is classified into the enterprise edition and personal edition, that is, WPA3-802.1X authentication and WPA3-SAE authentication.

Compared with WPA2-802.1X authentication, WPA3-802.1X authentication enhances the algorithm strength by increasing the key length to 192 bits (WPA2 uses a 128-bit encryption key). WPA3-802.1X authentication is applicable to scenarios with high security requirements, such as governments and large enterprises.

WPA3-802.1X authentication has specific requirements on terminals and servers. To deploy WPA3-802.1X authentication, you may need to upgrade related hardware.

Precautions

- WPA3 authentication automatically enables the PMF function in mandatory mode. That is, configuring the **pmf** { **optional** | **mandatory** } command does not take effect in WPA3 authentication scenarios.
- WPA3-802.1X authentication is supported only by APs in compliance with 802.11ac Wave 2 or higher standards.
- WPA3 and 802.11r cannot be used at the same time.
- WPA3 authentication is not supported in WDS and mesh scenarios.
- If the security profile is bound to another profile, running this command may interrupt services.

Example

Configure the WPA3-802.1X authentication mode.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] security wpa3 dot1x gcmp256
```

11.11.67 security wpa3 sae

Function

The **security wpa3 sae** command configures WPA3-SAE authentication and encryption.

The **undo security** command restores the default security policy.

By default, no security policy is configured.

Format

security wpa3 sae pass-phrase *key-value* **aes**

undo security

Parameters

Parameter	Description	Value
pass-phrase *key-value*	Specifies the password for WPA3-SAE authentication.	The value is of 8 to 63 ASCII characters in plain text, 64 hexadecimal characters in plain text, or 48 or 68 or 88 or 108 characters in cipher text. A password cannot contain the space and double quotation mark (") at the same time. When the password contains a space, add the double quotation mark (") to the beginning and end of the string when entering the password. For example, if the password is **YsHsjx 202206**, enter **"YsHsjx 202206"**. **NOTE** For security purposes, you are advised to configure a key that contains at least two of the following: digits, lowercase letters, uppercase letters, and special characters.
aes	Configures AES encryption.	-

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

WPA3 authentication is classified into the enterprise edition and personal edition, that is, WPA3-802.1X authentication and WPA3-SAE authentication.

Similar to WPA/WPA2-PSK authentication, WPA3-SAE authentication applies to small office networks that do not require high network security or authentication server deployment. However, WPA3-SAE introduces the SAE handshake protocol. Compared with WPA/WPA2-PSK authentication, WPA3-SAE can effectively defend against offline dictionary attacks and increase the difficulty of brute force cracking. In addition, the SAE handshake protocol provides forward secrecy. Even if an attacker knows the password on the network, the attacker cannot decrypt or obtain traffic, greatly improving the security of the WPA3 personal network.

Precautions

- WPA3 authentication automatically enables the PMF function in mandatory mode. That is, configuring the **pmf** { **optional** | **mandatory** } command does not take effect in WPA3 authentication scenarios.
- WPA3-SAE authentication depends on the PMF function, but 802.11n APs do not support the PMF function. Therefore, 802.11n APs do not support WPA3-SAE authentication.
- WPA3-SAE does not support PPSK authentication.
- WPA3 and 802.11r cannot be used at the same time.
- WPA3 authentication is not supported in WDS and mesh scenarios.
- If the security profile is bound to another profile, running this command may interrupt services.

Example

Configure WPA3-SAE authentication and set the user password to **YsHsjx_202206**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] security wpa3 sae pass-phrase YsHsjx_202206 aes
```

11.11.68 security-profile (WLAN view)

Function

The **security-profile** command creates a security profile or enters the security profile view.

The **undo security-profile** command deletes a security profile according to the ID or name.

By default, security profiles **default**, **default-wds** and **default-mesh** are available in the system.

Format

security-profile name *profile-name*

undo security-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a security profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").

Parameter	Description	Value
all	Deletes all security profiles. **NOTE** Security profiles **default**, **default-wds** and **default-mesh** cannot be deleted.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to configure access security. A security profile must be configured before you specify an authentication mode in the profile. To delete a security profile, run the **undo security-profile** command.

The system configures the new profile, the default value is no authentication and no encryption.

Example

Configure a security profile named **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1]
```

11.11.69 security-profile (VAP profile view)

Function

The **security-profile** command binds a security profile to a VAP profile.

The **undo security-profile** command unbinds a security profile from a VAP profile.

By default, the security profile **default** is bound to a VAP profile.

Format

security-profile *profile-name*

undo security-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a security profile.	The security profile must exist.

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

You can use this command to bind a security profile to a VAP profile. The security profile then applies to all users using this VAP profile.

By default, no security policy is configured in a security profile. A VAP can be created on a radio only after a security policy is configured.

Example

Create VAP profile **ChinaNet** and bind security profile **security-profile1** to the VAP profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name ChinaNet
[HUAWEI-wlan-vap-prof-ChinaNet] security-profile security-profile1
```

11.11.70 spoof-detect quiet-time

Function

The **spoof-detect quiet-time** command sets the quiet time for an AP to report the detected spoofing attacks to the AC.

The **undo spoof-detect quiet-time** command restores the default quiet time for an AP to report the detected spoofing attacks to the AC.

By default, the quiet time is 600 seconds for an AP to report the detected spoofing attacks to the AC.

Format

spoof-detect quiet-time *quiet-time-value*

undo spoof-detect quiet-time

Parameters

Parameter	Description	Value
quiet-time-value	Specifies the quiet time for an AP to report the detected spoofing attacks to the AC.	The value is an integer that ranges from 60 to 36000, in seconds.

Views

WIDS profile view

Default Level

2: Configuration level

Usage Guidelines

After attack detection is enabled on an AP, the AP reports alarms upon attack detection. If an attack source launches attacks repeatedly, a large number of repeated alarms are generated. To prevent this situation, configure the quiet time for an AP to report alarms. When detecting attack sources of the same MAC address, the AP does not report alarms in the quiet time. However, if the AP still detects attacks from the attack source after the quiet time expires, the AP reports alarms. You can set the quiet time based on attack types.

To obtain attack information in a timely manner, set the quiet time to a small value. If attack detection is enabled on many APs, and attacks are frequently detected, set the quiet time to a large value to prevent frequent alarm reports.

Example

Set the quiet time to 300 seconds for an AP to report the detected spoofing attacks to the AC.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] radio 0
[HUAWEI-wlan-group-radio-default/0] wids attack detect spoof enable
[HUAWEI-wlan-group-radio-default/0] quit
[HUAWEI-wlan-ap-group-default] quit
[HUAWEI-wlan-view] wids-profile name default
[HUAWEI-wlan-wids-prof-default] spoof-detect quiet-time 300
```

11.11.71 spoof-ssid

Function

The **spoof-ssid** command configures a fuzzy matching rule for spoofing SSIDs.

The **undo spoof-ssid** command deletes a fuzzy matching rule for spoofing SSIDs.

By default, no fuzzy matching rule is configured for spoofing SSIDs.

Format

spoof-ssid fuzzy-match regex *regex-value*

undo spoof-ssid { **fuzzy-match regex** *regex-value* | **all** }

Parameters

Parameter	Description	Value
fuzzy-match	Configures a fuzzy matching rule to identify spoofing SSIDs.	-
regex *regex-value*	Specifies the regular expression for an SSID. If an SSID matches the regular expression, the SSID is considered a spoofing SSID.	The value is in text format and can contain 1 to 48 case-sensitive characters. It supports Chinese characters or mixture of Chinese and English characters. **NOTE** You can only use a command editor of the UTF-8 encoding format to edit Chinese characters.
all	Deletes all fuzzy matching rules.	-

Views

WIDS spoof SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

WLAN services are available in public places, such as banks and airports. Users can connect to the WLANs after associating with corresponding SSIDs. If a rogue AP is deployed and provides spoofing SSIDs similar to authorized SSIDs, the users may be misled and connect to the rogue AP, which brings security risks. To address this problem, configure a fuzzy matching rule to identify spoofing SSIDs. The device compares a detected SSID with the matching rule. If the SSID matches the rule, the SSID is considered a spoofing SSID. The AP using the spoofing SSID is a rogue AP. After rogue AP containment is configured, the device contains the rogue AP and disconnects users from the spoofing SSID.

Precautions

To make fuzzy matching rules for spoofing SSIDs take effect, enable device detection and rogue device containment so that the device can take countermeasures against rogue APs.

To contain all SSIDs except those on the local device, set the fuzzy matching rule to * and then run the **contain-mode** command to set the containment mode to **spoof-ssid-ap**.

Example

Configure a fuzzy matching rule using the regular expression **^TES[1l]$** to identify spoofing SSIDs **TEST1** or **TESL** similar to **TEST**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wids-spoof-profile name default
[HUAWEI-wlan-wids-spoof-default] spoof-ssid fuzzy-match regex ^TES[1l]$
```

11.11.72 sta arp-nd-proxy before-assoc

Function

The **sta arp-nd-proxy before-assoc** command enables an AP to send ARP/ND proxy packets for a STA before the STA is successfully associated.

The **undo sta arp-nd-proxy before-assoc** command disables an AP from sending ARP/ND proxy packets for a STA before the STA is successfully associated.

By default, an AP does not send ARP/ND proxy packets for a STA before the STA is successfully associated.

Format

sta arp-nd-proxy before-assoc

undo sta arp-nd-proxy before-assoc

Parameters

None

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an AP is enabled to send ARP/ND proxy packets for a STA before the STA succeeds in authentication or key negotiation, the Layer 2 switch connected to the

AP will learn the MAC address of the STA. If an attack floods thousands of STA MAC addresses, the MAC address table on the switch will be seriously corrupted, bringing security risks. To avoid this issue, you can run the **undo sta arp-nd-proxy before-assoc** command to configure the AP to send ARP/ND proxy packets for a STA after the STA succeeds in authentication or key negotiation.

In scenarios with low security requirements, you can run the **sta arp-nd-proxy before-assoc** command to configure the AP to send ARP/ND proxy packets for a STA before the STA is successfully associated to improve link update efficiency.

Precautions

After the **undo sta arp-nd-proxy before-assoc** command is run on an AP, the AP does not send ARP/ND proxy packets for a STA that goes online in open or WEP mode.

Example

Configure an AP to send ARP/ND proxy packets for a STA before the STA is successfully associated.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] sta arp-nd-proxy before-assoc
```

11.11.73 sta-access-mode

Function

The **sta-access-mode** command binds STA blacklist and STA whitelist profiles to VAP profiles or AP system profiles.

The **undo sta-access-mode** command unbinds STA blacklist and STA whitelist profiles from VAP profiles or AP system profiles.

By default, no STA blacklist and STA whitelist profiles are bound to a VAP profile and an AP system profile.

Format

sta-access-mode { **blacklist** | **whitelist** } *profile-name*

undo sta-access-mode

Parameters

Parameter	Description	Value
blacklist	Specifies a STA blacklist profile.	-
whitelist	Specifies a STA whitelist profile.	-
profile-name	Specifies the names of STA blacklist and whitelist profiles.	The STA blacklist and whitelist profiles must exist.

Views

VAP profile view, AP system profile view

Default Level

2: Configuration level

Usage Guidelines

STA blacklists and whitelists configured by using the **sta-mac** command take effect only after the STA blacklist and whitelist profiles are bound to VAP profiles or AP system profiles using the **sta-access-mode** command.

When STA blacklist and whitelist profiles are bound to different profiles, the effective scope of the STA blacklists and whitelists differs.

- VAP profile: The STA blacklist and whitelist take effect on the corresponding VAP.
- AP system profile: The STA blacklist and whitelist take effect on the corresponding AP.
- VAP profile and AP system profile: A STA cannot go online if it cannot meet any of access requirements.

If a STA blacklist or whitelist profile is bound to a VAP profile or an AP system profile, only one STA blacklist or whitelist profile takes effect in the VAP profile or AP system profile.

Example

Bind the STA blacklist profile **sta-blacklist-profile1** to the VAP profile **vap-profile1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap-profile1
[HUAWEI-wlan-vap-prof-vap-profile1] sta-access-mode blacklist sta-blacklist-profile1
```

11.11.74 sta-blacklist-profile

Function

The **sta-blacklist-profile** command creates a STA blacklist profile or displays the STA blacklist profile view.

The **undo sta-blacklist-profile** command deletes one or more STA blacklist profiles.

By default, no STA blacklist profile is created.

Format

sta-blacklist-profile name *profile-name*

undo sta-blacklist-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a STA blacklist profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all STA blacklist profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the MAC address of a STA is in the blacklist, the STA cannot go online. If the STA blacklist profile is not referenced or the MAC address of a STA is not in the blacklist, the STA is allowed to go online.

The configured blacklist takes effect only after the STA blacklist profile is bound to a VAP profile or an AP system profile using the **sta-access-mode** command.

If a STA is added to the blacklist, the system automatically disconnects the STA.

Precautions

If STA blacklist profiles are bound to a VAP profile and an AP system profile, a STA cannot go online when the MAC address of the STA is in either of the STA blacklist profile.

Example

Create the STA blacklist profile **sta-blacklist-profile1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sta-blacklist-profile name sta-blacklist-profile1
[HUAWEI-wlan-blacklist-prof-sta-blacklist-profile1]
```

11.11.75 sta-mac

Function

The **sta-mac** command adds the MAC addresses of a STA to the blacklist or whitelist.

The **undo sta-mac** command deletes a specified STA MAC address or all STA MAC addresses from the blacklist or whitelist.

By default, the MAC address of a STA is not added to the blacklist or whitelist.

Format

sta-mac *mac-address* [**description** *description*]

undo sta-mac { *mac-address* | **all** }

Parameters

Parameter	Description	Value
mac-address	Adds a MAC address to the blacklist or whitelist.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.
description	Adds MAC address description to a blacklist or whitelist.	The value is a string of 1 to 80 case-insensitive characters that can include Chinese or Chinese+English characters. **NOTE** You can only use a command editor of the UTF-8 encoding format to edit Chinese characters.
all	Deletes all MAC addresses from the blacklist or whitelist.	-

Views

STA blacklist profile view, STA whitelist profile view

Default Level

2: Configuration level

Usage Guidelines

If the blacklist function is enabled, all STAs in the blacklist cannot connect to the WLAN.

If the whitelist function is enabled, only STAs in the whitelist can connect to the WLAN.

If a STA is added to the blacklist, the system automatically disconnects the STA.

STAs that have gone online before a whitelist is configured are not forced to go offline even if they are not on the whitelist.

Example

Add the MAC address 00e0-fc12-3456 of a STA to the blacklist profile **sta-blacklist-profile1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sta-blacklist-profile name sta-blacklist-profile1
[HUAWEI-wlan-blacklist-prof-sta-blacklist-profile1] sta-mac 00e0-FC12-3456
```

11.11.76 sta-whitelist-profile

Function

The **sta-whitelist-profile** command creates a STA whitelist profile or displays the STA whitelist profile view.

The **undo sta-whitelist-profile** command deletes one or more STA whitelist profiles.

By default, no STA whitelist profile is created.

Format

sta-whitelist-profile name *profile-name*

undo sta-whitelist-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a STA whitelist profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").

Parameter	Description	Value
all	Deletes all STA whitelist profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

The configured whitelist takes effect only after the STA whitelist profile is bound to a VAP profile or an AP system profile using the **sta-access-mode** command.

If the configured whitelist takes effect, only STAs in the whitelist can access the WLAN.

STAs that have gone online before a whitelist is configured are not forced to go offline even if they are not on the whitelist.

Example

Create the STA whitelist profile **sta-whitelist-profile1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] sta-whitelist-profile name sta-whitelist-profile1
[HUAWEI-wlan-whitelist-prof-sta-whitelist-profile1]
```

11.11.77 wapi asu

Function

The **wapi asu** command specifies an IP address for an authentication server unit (ASU) server.

The **undo wapi asu** command deletes the IP address of the ASU server.

By default, no IP address is specified for the ASU server.

Format

wapi asu ip *ip-address*

undo wapi asu ip

Parameters

Parameter	Description	Value
ip-address	Specifies an IP address for the ASU server.	The value is in dotted decimal notation.

Views

Security profile view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If WAPI certificate authentication is configured, an AC sends WAPI authentication packets to the ASU server at the specified IP address.

Prerequisites

If WAPI certificate authentication is specified as a security policy in a security profile, run the **wapi asu** command to specify an IP address for the ASU server.

Precautions

The **wapi asu** command helps to determine to which ASU server WAPI packets are sent. Users must ensure the correctness of both ASU certificates and ASU servers; otherwise, they may fail in user authentication.

The system displays the message only when the security profile has been bound to the other profiles.

Example

Specify IP address 10.164.10.10 for the ASU server.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] wapi asu ip 10.164.10.10
```

11.11.78 wapi bk

Function

The **wapi bk** command sets the interval for updating a BK and the BK lifetime percentage.

The **undo wapi bk** command restores the default interval for updating a BK and the BK lifetime percentage.

By default, the interval for updating a BK is 43200s, and the BK lifetime percentage is 70%.

Format

wapi { **bk-threshold** *bk-threshold* | **bk-update-interval** *bk-update-interval* }

undo wapi { **bk-threshold** | **bk-update-interval** }

Parameters

Parameter	Description	Value
bk-threshold *bk-threshold*	Specifies the BK lifetime percentage.	The value is an integer that ranges from 1 to 100.
bk-update-interval *bk-update-interval*	Specifies the interval for updating a BK.	The value is an integer that ranges from 600 to 604800, in seconds.

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

You can set the intervals for updating a BK to ensure security.

The value obtained by multiplying the interval for updating a BK by the BK lifetime percentage should be greater than or equal to 300 seconds. If the interval for updating a BK is less than 300s, the BK may be updated before negotiation is complete due to low STA performance. In this case, some STAs may be forced offline or cannot go online.

Example

Set the interval for updating a BK to 10000s and the BK lifetime percentage to 80%.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] wapi bk-update-interval 10000
Warning: If the product of bk-update-interval and bk-threshold is smaller than 300s, users may be forced
offline. Continue? [Y/N]:y
[HUAWEI-wlan-sec-prof-p1] wapi bk-threshold 80
```

11.11.79 wapi cert-retrans-count

Function

The **wapi cert-retrans-count** command sets the number of retransmissions of certificate authentication packets.

The **undo wapi cert-retrans-count** command restores the default number of retransmissions of certificate authentication packets.

By default, the number of retransmissions is 3.

Format

wapi cert-retrans-count *cert-count*

undo wapi cert-retrans-count

Parameters

Parameter	Description	Value
cert-count	Specifies the number of retransmissions of certificate authentication packets.	The value is an integer that ranges from 1 to 10.

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

If WAPI authentication is specified as a security policy, run the **wapi cert-retrans-count** command to set the number of retransmissions of certificate authentication packets.

Example

Set the number of retransmissions of certificate authentication packets to 5.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] wapi cert-retrans-count 5
```

11.11.80 wapi import certificate

Function

The **wapi import certificate** command imports the AC certificate file, certificate of the AC certificate issuer, and ASU certificate file.

The **undo wapi certificate** command deletes the imported AC certificate file, certificate of the AC certificate issuer, or ASU certificate file.

By default, the AC certificate file, certificate of the AC certificate issuer, and ASU certificate file are not imported.

Format

wapi import certificate { **ac** | **asu** | **issuer** } **format pkcs12 file-name** *file-name* **password** *password*

wapi import certificate { **ac** | **asu** | **issuer** } **format pem file-name** *file-name*

undo wapi certificate { **ac** | **asu** | **issuer** }

Parameters

Parameter	Description	Value
ac	Specifies the AC certificate.	-
asu	Specifies the ASU certificate.	-
issuer	Specifies the certificate of a specified certificate issuer.	-
format pkcs12	Imports a certificate in P12 format.	-
format pem	Imports a certificate in PEM format.	-
file-name *file-name*	Specifies a certificate file name, which the complete path of a certificate file must be specified.	The value is a string of 1 to 255 characters. It cannot contain question marks (?) and cannot start or end with double quotation marks (" ") or spaces.

Parameter	Description	Value
password *password*	Specifies the key of the P12 certificate.	The password can be in plain text or cipher text. ● A plain text password is a string of 1 to 32 characters. ● A cipher text password is a string of 48 or 68 characters.

Views

Security profile view

Default Level

3: Management level

Usage Guidelines

- If WAPI certificate authentication is specified as a security policy in a security profile, you can run this command to specify the AC certificate, issuer certificate, and ASU certificate. STAs will fail to be authenticated if you do not run this command. The issuer certificate helps to check whether the AC certificate is modified.
- Before using this command, store the AC certificate and ASU certificate to the storage of the device, and import the certificates and private key using SFTP. Certificates must be X509 V3 certificates and comply with the WAPI standard. Otherwise, certificates cannot be imported.
- After this command is run:
  - When an issuer certificate is configured, the system checks correctness of the AC certificate.
  - If the authentication system uses only two certificates, the issuer certificate and ASU certificate have the same certificate file name and are the same certificate. If the authentication system uses three certificates, the issuer certificate and ASU certificate are different from each other and both must be imported.

NOTE

- The ASU certificate and issuer certificate must be imported.
- Certificates to be imported must be valid and correct.
- If the certificates with the same name but different contents have been imported by other security profiles, delete the earlier certificate first.

Example

Import the AC certificate.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] wapi import certificate ac format pem file-name flash:/local_ac.cer
```

11.11.81 wapi import private-key

Function

The **wapi import private-key** command imports the AC private key file.

The **undo wapi private-key** command deletes the imported AC private key file.

By default, no AC private key file is imported.

Format

wapi import private-key format pkcs12 file-name *file-name* **password** *password*

wapi import private-key format pem file-name *file-name*

undo wapi private-key

Parameters

Parameter	Description	Value
format pkcs12	Imports a private key file in P12 format.	-
format pem	Imports a private key file in PEM format.	-
file-name *file-name*	Specifies the name of a private key file.	The value is a string of 1 to 255 characters. It cannot contain question marks (?) and cannot start or end with double quotation marks (" ") or spaces.

Parameter	Description	Value
password *password*	Specifies the password in the private key file of the P12 format.	The password can be in plain text or cipher text. ● A plain text password is a string of 1 to 32 characters. ● A cipher text password is a string of 48 or 68 characters.

Views

Security profile view

Default Level

3: Management level

Usage Guidelines

- If WAPI certificate authentication is specified as a security policy in a security profile, run the **wapi import private-key** command to specify the private key file for the AC certificate.
- Before using this command, store the AC private key file to the storage medium of the device, and import the private key file using SFTP.
- After this command is used, the system obtains the private key file and establishes the mapping between the certificate and private key.

NOTE

The certificate and private key to be imported must be valid and correct.

Example

Import the AC private key file **ac_key.key**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] wapi import private-key format pem file-name flash:/ac_key.key
```

11.11.82 wapi key-update

Function

The **wapi key-update** command sets the USK and MSK update mode.

The **undo wapi key-update** command restores the default USK and MSK update mode.

By default, USKs and MSKs are updated based on time.

Format

wapi { **usk** | **msk** } **key-update** { **disable** | **time-based** }

undo wapi { **usk** | **msk** } **key-update**

Parameters

Parameter	Description	Value
usk	Indicates USK update.	-
msk	Indicates MSK update.	-
disable	Disables key update.	-
time-based	Indicates time-based update. You can run the **wapi msk** and **wapi usk** commands to respectively set the intervals for updating an MSK and a USK.	-

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

- To ensure network security, update keys in a timely manner. There are several key update modes.
- The **wapi key-update** command sets the USK and MSK update mode. If the interval for updating an MSK or a USK is too long, key security cannot be ensured.
- If **disable** is specified, keys will not be updated.

Example

Set the USK update mode to time-based update.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] wapi usk key-update time-based
```

11.11.83 wapi msk

Function

The **wapi msk** command sets the interval for updating an MSK, and number of retransmissions of MSK negotiation packets.

The **undo wapi msk** command restores the default interval for updating an MSK, and number of retransmissions of MSK negotiation packets.

By default, the interval for updating an MSK is 86400s; the number of retransmissions of MSK negotiation packets is 3.

Format

wapi { **msk-update-interval** *msk-interval* | **msk-retrans-count** *msk-count* }

undo wapi { **msk-update-interval** | **msk-retrans-count** }

Parameters

Parameter	Description	Value
msk-update-interval *msk-interval*	Specifies the interval for updating an MSK. When the MSK update mode is set to time-based update using the **wapi key-update** command, the interval for updating an MSK needs to be set.	The value is an integer that ranges from 600 to 604800, in seconds.
msk-retrans-count *msk-count*	Specifies the number of retransmissions of MSK negotiation packets.	The value is an integer that ranges from 1 to 10.

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

WAPI defines a dynamic key negotiation mechanism, but there are still security risks if a STA uses the same encryption key for a long time. Both the USK and MSK have a lifetime. The USK or MSK needs to be updated when its lifetime ends.

Example

Set the interval for updating an MSK to 10000s, and number of retransmissions of MSK negotiation packets to 5.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] wapi msk key-update time-based
[HUAWEI-wlan-sec-prof-p1] wapi msk-update-interval 10000
[HUAWEI-wlan-sec-prof-p1] wapi msk-retrans-count 5
```

11.11.84 wapi sa-timeout

Function

The **wapi sa-timeout** command sets the security association (SA) timeout period for key encryption.

The **undo wapi sa-timeout** command restores the default SA timeout period for key encryption.

The default SA timeout period for key encryption is 60s.

Format

wapi sa-timeout *sa-time*

undo wapi sa-timeout

Parameters

Parameter	Description	Value
sa-time	Specifies the SA timeout period.	The value is an integer that ranges from 1 to 255, in seconds.

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

You can prolong the WAPI timeout period to increase the authentication success ratio.

Example

Set the SA timeout period to 100s.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] wapi sa-timeout 100
```

11.11.85 wapi source interface

Function

The **wapi source interface** command configures a source interface for an AC to communicate with an ASU server.

The **undo wapi source interface** command cancels the source interface for an AC to communicate with an ASU server.

By default, no source interface is configured for an AC to communicate with an ASU server.

Format

wapi source interface { **vlanif** *vlan-id* | **loopback** *loopback-number* }

undo wapi source interface

Parameters

Parameter	Description	Value
vlanif *vlan-id*	Configures a VLANIF interface as the source interface.	The value is an integer that ranges from 1 to 4094.
loopback *loopback-number*	Configures a loopback interface as the source interface.	The value is an integer that ranges from 0 to 1023.

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In WLAN applications, to use WAPI authentication and enable socket communication between an AC and an ASU server, the AC needs a WAPI source IP address using which all packets are sent to the ASU server.

Prerequisites

An IP address has been assigned to the specified loopback or VLANIF interface.

Precautions

The IP address of the WAPI source interface on the AC must be on the same network segment as the IP address of the ASU server. If no WAPI source interface is configured, the IP address of the AC source interface is used as the source IP address for sending WAPI packets to the WAPI server by default.

Example

Configure a VLANIF interface as the source interface for the AC to communicate with the ASU server.

```
<HUAWEI> system-view
[HUAWEI] vlan 100
[HUAWEI-vlan100] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 192.168.10.1 24
[HUAWEI-Vlanif100] quit
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] wapi source interface Vlanif 100
```

11.11.86 wapi usk

Function

The **wapi usk** command sets the interval for updating a USK, and number of retransmissions of USK negotiation packets.

The **undo wapi usk** command restores the default interval for updating a USK, and number of retransmissions of USK negotiation packets.

By default, the interval for updating a USK is 86400s; the number of retransmissions of USK negotiation packets is 3.

Format

wapi { **usk-update-interval** *usk-interval* | **usk-retrans-count** *usk-count* }

undo wapi { **usk-update-interval** | **usk-retrans-count** }

Parameters

Parameter	Description	Value
usk-update-interval *usk-interval*	Specifies the interval for updating a USK. When the USK update mode is set to time-based update using the **wapi key-update** command, the interval for updating a USK needs to be set.	The value is an integer that ranges from 600 to 604800, in seconds.
usk-retrans-count *usk-count*	Specifies the number of retransmissions of USK negotiation packets.	The value is an integer that ranges from 1 to 10.

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

WAPI defines a dynamic key negotiation mechanism, but there are still security risks if a STA uses the same encryption key for a long time. Both the USK and MSK have a lifetime. The USK or MSK needs to be updated when its lifetime ends.

Example

Set the interval for updating a USK to 10000s, and number of retransmissions of USK negotiation packets to 5.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] wapi usk key-update time-based
[HUAWEI-wlan-sec-prof-p1] wapi usk-update-interval 10000
[HUAWEI-wlan-sec-prof-p1] wapi usk-retrans-count 5
```

11.11.87 weak-iv-detect quiet-time

Function

The **weak-iv-detect quiet-time** command sets the quiet time for an AP to report the detected weak IV attacks to the AC.

The **undo weak-iv-detect quiet-time** command restores the default quiet time for an AP to report the detected weak IV attacks to the AC.

By default, the quiet time is 600 seconds for an AP to report the detected weak IV attacks to the AC.

Format

weak-iv-detect quiet-time *quiet-time-value*

undo weak-iv-detect quiet-time

Parameters

Parameter	Description	Value
quiet-time-value	Specifies the quiet time for an AP to report the detected weak IV attacks to the AC.	The value is an integer that ranges from 60 to 36000, in seconds.

Views

WIDS profile view

Default Level

2: Configuration level

Usage Guidelines

After attack detection is enabled on an AP, the AP reports alarms upon attack detection. If an attack source launches attacks repeatedly, a large number of repeated alarms are generated. To prevent this situation, configure the quiet time for an AP to report alarms. When detecting attack sources of the same MAC address, the AP does not report alarms in the quiet time. However, if the AP still detects attacks from the attack source after the quiet time expires, the AP reports alarms. You can set the quiet time based on attack types.

To obtain attack information in a timely manner, set the quiet time to a small value. If attack detection is enabled on many APs, and attacks are frequently detected, set the quiet time to a large value to prevent frequent alarm reports.

Example

Set the quiet time to 300 seconds for an AP to report the detected weak IV attacks to the AC.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] radio 0
[HUAWEI-wlan-group-radio-default/0] wids attack detect weak-iv enable
[HUAWEI-wlan-group-radio-default/0] quit
[HUAWEI-wlan-ap-group-default] quit
[HUAWEI-wlan-view] wids-profile name default
[HUAWEI-wlan-wids-prof-default] weak-iv-detect quiet-time 300
```

11.11.88 wep default-key

Function

The **wep default-key** command sets the default key ID for WEP authentication or encryption.

The **undo wep default-key** command restores the default key ID for WEP authentication or encryption.

By default, key 0 is used for WEP authentication or encryption.

Format

wep default-key *key-id*

undo wep default-key

Parameters

Parameter	Description	Value
key-id	Specifies the default key ID.	The key ID must exist.

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

- A maximum of four WEP keys can be configured, and only one WEP key is used for authentication and encryption. This command specifies which key to use.
- After a key ID is specified, the specified key is used for authentication or encryption.
- Each AP can have at most four key indexes configured. The key indexes used by different VAPs cannot be the same.
- The system displays the message only when the security profile has been bound to the other profiles.

Example

Set the default key ID to 1.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] wep default-key 1
```

11.11.89 wep key

Function

The **wep key** command sets a WEP key.

The **undo wep key** command deletes the specified key.

By default, WEP-40 is used. The default username and password are available in *WLAN Default Usernames and Passwords* (**Enterprise Network** or **Carrier**). If you have not obtained the access permission of the document, see **Help** on the website to find out how to obtain it.

Format

wep key *key-id* { **wep-40** | **wep-104** | **wep-128** } { { **pass-phrase** | **hex** } *key-value* | **dot1x** }

undo wep key *key-id*

Parameters

Parameter	Description	Value
key-id	Specifies the key ID.	The value is an integer that ranges from 0 to 3.
wep-40	Configures WEP-40 authentication.	-
wep-104	Configures WEP-104 authentication.	-
wep-128	Configures WEP-128 authentication.	-
pass-phrase	Specifies the key phrase.	-
hex	Specifies a hexadecimal number.	-

Parameter	Description	Value

key-value	Specifies a password in cipher text.	The password can be in plain text or cipher text.
		- A plain text password is a string of case-sensitive characters.
		  - If WEP-40 is used, the WEP key is 10 hexadecimal characters or 5 ASCII characters.
		  - If WEP-104 is used, the WEP key is 26 hexadecimal characters or 13 ASCII characters.
		  - If WEP-128 is used, the WEP key is 32 hexadecimal characters or 16 ASCII characters.
		- A cipher text password is a string of 48 or 68 characters.
		A password cannot contain the space and double quotation mark (") at the same time. When the password contains a space, add the double quotation mark (") to the beginning and end of the string when entering the password. For example, if the password is **YsHsjx**

Parameter	Description	Value
		202206, enter **"YsHsjx 202206"**.
dot1x	Specifies dynamic WEP encryption.	-

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To connect to a WLAN device in WEP shared-key authentication mode or dynamic WEP mode, run the **wep key** command to set a WEP key.

NOTE

If the key is in hexadecimal notation, you can enter hexadecimal characters without entering 0x.

Precautions

The system displays the message only when the security profile has been bound to the other profiles.

Example

Configure a WEP key and its ID.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name p1
[HUAWEI-wlan-sec-prof-p1] wep key 1 wep-128 hex 12345678123456781234567812345678
```

11.11.90 wids attack detect

Function

(AP group radio view) The **wids attack detect enable** command enables attack detection on all specified radios in an AP group.

(AP group radio view) The **wids attack detect disable** command disables attack detection on all specified radios in an AP group.

(AP group radio view) The **undo wids attack detect enable** command restores the default attack detection configuration on all specified radios in an AP group.

(AP radio view) The **wids attack detect enable** command enables attack detection on an AP radio.

(AP radio view) The **wids attack detect disable** command disables attack detection on an AP radio.

(AP radio view) The **undo wids attack detect** command cancels the configuration of the attack detection function on an AP radio. The status of this function on the AP radio is then determined by the status of this function in the AP group radio view.

By default, attack detection is disabled on an AP radio; flood attack detection, weak IV attack detection, and spoofing attack detection are disabled on radios in the AP group; and brute force key cracking attack detection is enabled on radios in the AP group.

Format

wids attack detect { **all** | **flood** | **weak-iv** | **spoof** | **wpa-psk** | **wpa2-psk** | **wapi-psk** | **wep-share-key** } { **enable** | **disable** }

undo wids attack detect { **all** | **flood** | **weak-iv** | **spoof** | **wpa-psk** | **wpa2-psk** | **wapi-psk** | **wep-share-key** }

Parameters

Parameter	Description	Value
all	Indicates all attack detection functions.	-
flood	Indicates flood attack detection.	-
weak-iv	Indicates weak IV attack detection.	-
spoof	Indicates spoofing attack detection.	-
wpa-psk	Indicates brute force attack detection in WPA-PSK authentication.	-
wpa2-psk	Indicates brute force attack detection in WPA2-PSK authentication.	-
wapi-psk	Indicates brute force attack detection in WAPI-PSK authentication.	-
wep-share-key	Indicates brute force attack detection in shared key authentication.	-

Views

AP group radio view, AP radio view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To monitor and prevent malicious or unintentional attacks on WLANs in real time, network administrators can enable the following attack detection functions based on actual requirements:

- **flood**: indicates flood attack detection used to detect whether an AP receives a large number of packets of the same type in a short period.
- **weak-iv**: indicates weak IV attack detection used to detect whether weak IV is used for WEP encryption on a WLAN.
- **spoof**: indicates spoofing attack detection used to detect whether a potential attacker pretends to be an AP to broadcast Deauthentication and Disassociation packets.
- **wpa-psk**, **wpa2-psk**, **wapi-psk**, or **wep-share-key**: indicates brute force attack detection. If the WPA-PSK, WPA2-PSK, WAPI-PSK, or WEP-SK security policy is configured on a WLAN, brute force attack detection can be enabled to increase the time required for password cracking and improve password security.

Precautions

- The configuration in the AP radio view has a higher priority than that in the AP group radio view.
- After the attack detection function is enabled using the **wids attack detect enable** command, the detected data is stored only on the local device. To report the data to the iMaster NCE-Campus, run the **collect-item user-data enable** command in the SMI view to enable the device to report intelligent O&M data to the iMaster NCE-Campus.
- If no attack detection function is enabled in the AP radio view, the configuration in the AP group radio view is inherited. If any attack detection function is enabled in the AP radio view, the configuration in the AP group radio view does not take effect and the configuration in the AP radio view is inherited. For example, when all attack detection functions are enabled in the AP group radio view:
  - If no attack detection function is enabled in the AP radio view, the configuration in the AP group radio view takes effect. That is, all attack detection functions are enabled on the AP radio.
  - If spoofing attack detection is enabled in the AP radio view, the configuration in the AP radio view takes effect. That is, only spoofing attack detection is enabled on the AP radio.

Follow-up Procedure

Run the **undo dynamic-blacklist disable** command to enable the dynamic blacklist function.

Run the **attack-device trap enable** command to enable the alarm function for attack detection.

Example

Enable brute force attack detection in WPA-PSK authentication on radio 0 in AP group **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] radio 0
[HUAWEI-wlan-group-radio-default/0] wids attack detect wpa-psk enable
```

11.11.91 wids manual-contain

Function

The **wids manual-contain** command manually contains specified devices.

The **undo wids manual-contain** command disables containment of specified devices.

By default, no device is manually contained.

Format

wids manual-contain device-mac *device-mac*

undo wids manual-contain { **all** | **device-mac** *device-mac* }

Parameters

Parameter	Description	Value
device-mac *device-mac*	Specifies the MAC address of a device to be contained.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.
all	Contains all devices.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **wids manual-contain** command in the WLAN view to manually contain a specified device in a complicated environment.

Precautions

Wireless bridges are not contained.

Example

Contain the AP with the MAC address 00e0-fc04-0004.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wids manual-contain device-mac 00e0-fc04-0004
```

11.11.92 wids contain enable

Function

(AP group radio view) The **wids contain enable** command enables rogue or interference device containment on all specified radios in an AP group.

(AP group radio view) The **undo wids contain enable** command disables rogue or interference device containment on all specified radios in an AP group.

(AP radio view) The **wids contain enable** command enables rogue or interference device containment on an AP radio.

(AP radio view) The **undo wids contain enable** command cancels the configuration of the rogue or interference device containment function on an AP radio. The status of this function on the AP radio is then determined by the status of this function in the AP group radio view.

By default, rogue or interference device containment is disabled on AP radios.

Format

wids contain enable

undo wids contain enable

Parameters

None

Views

AP group radio view, AP radio view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Rogue or interference devices pose serious security threats to enterprise networks.

After the containment mode is set against rogue or interference APs, the monitor AP uses the identity of the rogue or interference AP to broadcast deauthentication frames to forcibly disconnect STAs. To prevent the STAs from connecting to the rogue or interference AP again, the monitor AP will periodically and continuously send deauthentication frames.

After the containment mode is set against rogue or interference STAs or ad-hoc devices, the monitor AP uses the MAC address of a rogue or interference device to continuously send unicast deauthentication frames.

Precautions

The configuration in the AP radio view has a higher priority than that in the AP group radio view.

After the **keep-service enable** command is executed, if the **wids device detect enable** and **wids contain enable** commands are configured to enable rogue or interference device detection and containment, the AP will continue providing data services after going offline. However, the AC considers the AP as a rogue or interference device and adds it to the containment list. The containment mechanism will disconnect STAs from the AP. Therefore, service holding upon CAPWAP link disconnection does not take effect in this case.

After command **keep-service enable allow new-access** is executed, if the **wids device detect enable** and **wids contain enable** commands are configured to enable rogue or interference device detection and containment, the AP will continue providing data services after going offline. However, the AC considers the AP as a rogue or interference device and adds it to the containment list. The containment mechanism will disable the AP from allowing access of new STAs. Therefore, the function of enabling an offline AP to allow access of new STAs does not take effect in this case.

Follow-up Procedure

Run the **contain-mode** command to set the rogue or interference device containment mode.

Example

Enable rogue or interference device containment on radio 0 in AP group **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] radio 0
[HUAWEI-wlan-group-radio-default/0] wids contain enable
```

11.11.93 wids device detect enable

Function

(AP group radio view) The **wids device detect enable** command enables device detection on all specified radios in an AP group.

(AP group radio view) The **undo wids device detect enable** command disables device detection on all specified radios in an AP group.

(AP radio view) The **wids device detect enable** command enables device detection on an AP radio.

(AP radio view) The **undo wids device detect enable** command cancels the configuration of the device detection function on an AP radio. The status of this function on the AP radio is then determined by the status of this function in the AP group radio view.

By default, device detection is disabled on AP radios.

Format

wids device detect enable

undo wids device detect enable

Parameters

None

Views

AP group radio view, AP radio view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the wireless device detection function is enabled, the monitoring AP detects information about wireless devices in its coverage range and reports the information to the AC. The AC determines whether unauthorized devices exist on the WLAN.

Precautions

The configuration in the AP radio view has a higher priority than that in the AP group radio view.

After the **keep-service enable** command is executed, if the **wids device detect enable** and **wids contain enable** commands are configured to enable rogue or interference device detection and containment, the AP will continue providing data services after going offline. However, the AC considers the AP as a rogue or interference device and adds it to the containment list. The containment mechanism will disconnect STAs from the AP. Therefore, service holding upon CAPWAP link disconnection does not take effect in this case.

After command **keep-service enable allow new-access** is executed, if the **wids device detect enable** and **wids contain enable** commands are configured to enable rogue or interference device detection and containment, the AP will continue providing data services after going offline. However, the AC considers the AP as a rogue or interference device and adds it to the containment list. The containment mechanism will disable the AP from allowing access of new STAs. Therefore, the function of enabling an offline AP to allow access of new STAs does not take effect in this case.

After the device detection function is enabled using this command, the detected data is stored only on the local device. To report the data to the iMaster NCE-Campus, run the **collect-item user-data enable** command in the SMI view to enable the device to report intelligent O&M data to the iMaster NCE-Campus.

Example

Enable device detection on radio 0 in AP group **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] radio 0
[HUAWEI-wlan-group-radio-default/0] wids device detect enable
```

11.11.94 wids-whitelist-profile (WLAN view)

Function

The **wids-whitelist-profile** command creates a WIDS whitelist profile and enters the WIDS whitelist profile view.

The **undo wids-whitelist-profile** command deletes a WIDS whitelist profile.

By default, the system provides the WIDS whitelist profile **default**.

Format

wids-whitelist-profile name *profile-name*

undo wids-whitelist-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a WIDS whitelist profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" "). Only the default profile **default** is supported.
all	Deletes all WIDS whitelist profiles.	The default WIDS whitelist profile **default** can be modified but cannot be deleted.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After WIDS/WIPS is enabled, rogue APs can be detected and countered. However, there may be APs of other vendors or on other networks working in the existing signal coverage areas. If these APs are countered, their services will be affected. To prevent this situation, configure an authorized AP list, including an authorized MAC address list, OUI list, and SSID list. If an unauthorized AP is detected but matches the authorized AP list, the AP is considered an authorized AP and will not be countered. After you create and a WIDS whitelist profile using the **wids-whitelist-profile** command, run the **permit-ap** command to configure an authorized AP list.

Follow-up Procedure

Run the **wids-whitelist-profile (WIDS profile view)** command to bind the WIDS whitelist profile to a WIDS profile so that the WIDS whitelist profile can take effect.

Example

Create the WIDS whitelist profile **default**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wids-whitelist-profile name default
[HUAWEI-wlan-wids-whitelist-default]
```

11.11.95 wids-profile (WLAN view)

Function

The **wids-profile** command creates a WIDS profile and enters the WIDS profile view.

The **undo wids-profile** command deletes a WIDS profile.

By default, the system provides the WIDS profile **default**.

You can run the **display wids-profile** command to view the configuration of the WIDS profile **default**.

Format

wids-profile name *profile-name*

undo wids-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a WIDS profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" "). Only the default profile **default** is supported.
all	Deletes all WIDS profiles.	The default WIDS profile **default** can be modified but cannot be deleted.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can configure the WIDS function on a device to detect and counter rogue devices on a WLAN. The WIDS function also enables the device to detect attacks and add devices launching the attacks to a dynamic blacklist. Packets sent from the blacklisted devices will be rejected to protect authorized users.

After you create and a WIDS profile using the **wids-profile** command, you can configure APs to detect and counter rogue or interference devices, and detect attacks in the profile.

Follow-up Procedure

Run the **wids-profile (AP group view and AP view)** command to bind the WIDS profile to an AP group or AP so that the WIDS profile can take effect.

Example

Create the WIDS profile **office**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wids-profile name office
[HUAWEI-wlan-wids-prof-office]
```

11.11.96 wids-spoof-profile (WLAN view)

Function

The **wids-spoof-profile** command creates a WIDS spoof SSID profile and enters the WIDS spoof SSID profile view.

The **undo wids-spoof-profile** command deletes a WIDS spoof SSID profile.

By default, the system has a default WIDS spoof SSID profile **default**.

Format

wids-spoof-profile name *profile-name*

undo wids-spoof-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a WIDS spoof SSID profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" "). Only the default profile **default** is supported.
all	Deletes all WIDS spoof SSID profiles.	The default WIDS spoof SSID profile **default** can be modified but cannot be deleted.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

WLAN services are available in public places, such as banks and airports. Users can connect to the WLANs after associating with corresponding SSIDs. If a rogue AP is deployed and provides spoofing SSIDs similar to authorized SSIDs, the users may be misled and connect to the rogue AP, which brings security risks. To address this problem, configure a fuzzy matching rule to identify spoofing SSIDs. After you create and a WIDS spoof SSID profile using the **wids-spoof-profile** command, run the **spoof-ssid** command to configure a fuzzy matching rule to identify spoofing SSIDs.

Follow-up Procedure

Run the **wids-spoof-profile (WIDS profile view)** command to bind the WIDS spoof SSID profile to a WIDS profile to make the WIDS spoof SSID profile take effect.

Example

Create the WIDS spoof SSID profile **office**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wids-spoof-profile name office
[HUAWEI-wlan-wids-spoof-office]
```

11.11.97 work-mode

Function

(AP group radio view) The **work-mode** command sets the working mode of all specified AP radios in an AP group.

(AP group radio view) The **undo work-mode** command restores the default working mode of all specified AP radios in an AP group.

(AP radio view) The **work-mode** command sets the working mode of a specified radio on an AP in an AP group.

(AP radio view) The **undo work-mode** command restores the working mode of a specified radio on an AP to the working mode configured in the AP group radio view.

By default, AP radios work in normal mode.

Format

work-mode { **monitor** [[**proxy-scan**] **dual-band-scan enable**] | **normal** }

undo work-mode

Parameters

Parameter	Description	Value
monitor	Indicates the monitor mode.	-
dual-band-scan enable	Indicates inter-band scanning.	-
proxy-scan dual-band-scan enable	Indicates proxy scanning.	-
normal	Indicates the normal mode.	-

Views

AP group radio view, AP radio view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An AP can work in two modes:

- **normal**: indicates the normal mode.
  - If air scan functions (such as WIDS, spectrum analysis, and terminal location) are disabled on a radio, the radio is used to transmit common WLAN services.
  - If air scan functions (such as WIDS, spectrum analysis, and terminal location) are enabled on a radio, the radio transmits common WLAN services and also provides the monitoring function. A transient increase in the WLAN service latency may occur, which does not affect network access. However, if any latency-sensitive service (such as videoconferencing) is running, it is recommended that a separate radio be used for air scan.
- **monitor**: indicates the monitor mode.

  In this mode, the radio can only transmit WLAN services scanned by the air interface but cannot transmit common WLAN services.

Precautions

- The change of the radio working mode can lead to service interruption. Users cannot associate with the AP when its radio works in monitor mode.
- The configuration in the AP radio view has a higher priority than that in the AP group radio view.
- In monitor mode, the working channels and power of AP radios change at any time. In this situation, the working channels and power of the AP radios display as **-**.

- Radio 1 does not support inter-band scanning.
- The switching between the proxy scanning mode and other modes may lead to an AP restart.
- If the inter-band or proxy scanning configuration is delivered to an AP that does not support these two modes, the monitor mode takes effect on the AP.

Example

Set the working mode of radio 0 in AP group **default** to **monitor**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] radio 0
[HUAWEI-wlan-group-radio-default/0] work-mode monitor
Warning: Modify the work mode may cause business interruption, continue?[y/n]
:y
```

11.11.98 wpa ptk-update enable

Function

The **wpa ptk-update enable** command enables periodic PTK update in WPA or WPA2 authentication and encryption.

The **undo wpa ptk-update enable** command disables periodic PTK update.

By default, periodic PTK update is disabled.

Format

wpa ptk-update enable

undo wpa ptk-update enable

Parameters

None

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In WPA or WPA2 authentication and encryption, a Pairwise Transient Key (PTK) is generated at the key negotiation stage to encrypt unicast radio packets. To ensure secure encryption, enable periodic PTK update so that the AP and STA use a new PTK to encrypt radio packets after a regular interval.

Precautions

When periodic PTK update is implemented, some STAs may encounter service interruptions or go offline due to individual problems.

Follow-up Procedure

Run the **wpa ptk-update ptk-update-interval** command to configure the periodic PTK update interval.

Example

Enable the periodic PTK update function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name example
[HUAWEI-wlan-sec-prof-example] wpa ptk-update enable
```

11.11.99 wpa ptk-update ptk-update-interval

Function

The **wpa ptk-update ptk-update-interval** command configures an interval for updating PTKs in WPA or WPA2 authentication and encryption.

The **undo wpa ptk-update ptk-update-interval** command restores the default PTK update interval.

By default, the interval for updating PTKs is 43200 seconds.

Format

wpa ptk-update ptk-update-interval *ptk-rekey-interval*

undo wpa ptk-update ptk-update-interval

Parameters

Parameter	Description	Value
ptk-rekey-interval	Specifies the PTK update interval.	The value is an integer ranging from 43200 to 86400, in seconds.

Views

Security profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To ensure secure encryption during WPA or WPA2 authentication, enable periodic PTK update. You can run this command to configure the PTK update interval. A smaller interval indicates faster PTK update and more secure data encryption. However, if the PTK update interval is set too small, the STA and AP implement more negotiations, affecting the throughput.

Precautions

The configured periodic PTK update interval takes effect only after you enable the periodic PTK update function using the **wpa ptk-update enable** command.

Example

Set the periodic PTK update interval to 50,000 seconds.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name example
[HUAWEI-wlan-sec-prof-example] wpa ptk-update ptk-update-interval 50000
```

11.12 WLAN WDS Configuration Commands

The WDS function is not supported by the following AP models:

- AirEngine series APs
- Central APs (including matching RUs)

11.12.1 Command Support

WLAN-AC commands are supported only by the following models: S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.

11.12.2 dhcp trust port (WDS profile view)

Function

The **dhcp trust port** command enables a DHCP trusted port in a WDS profile.

The **undo dhcp trust port** command disables a DHCP trusted port in a WDS profile.

By default, a DHCP trusted port is enabled in a WDS profile.

Format

dhcp trust port

undo dhcp trust port

Parameters

None

Views

WDS profile view

Default Level

2: Configuration level

Usage Guidelines

After a DHCP trusted port is enabled in a WDS profile and the WDS profile is applied to an AP, the AP receives the DHCP OFFER, ACK, and NAK packets sent by authorized DHCP servers and forwards the packets to STAs so that the STAs can obtain valid IP addresses and go online.

Example

Enable a DHCP trusted port in the WDS profile **test**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wds-profile name test
[HUAWEI-wlan-wds-prof-test] dhcp trust port
```

11.12.3 display references wds-profile

Function

The **display references wds-profile** command displays reference information about a WDS profile.

Format

display references wds-profile name *profile-name*

Parameters

Parameter	Description	Value
name *profile-name*	Displays reference information about a specified WDS profile.	The WDS profile must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display references wds-profile** command to check reference information about a WDS profile.

Example

Display reference information about the WDS profile **test**.

```
<HUAWEI> display references wds-profile name test
------------------------------------------------------------------------------
Reference type     Reference name                          Reference radio  WLAN ID
------------------------------------------------------------------------------
AP group          group-1                            Radio-0         13
AP group          group-1                            Radio-0         14
------------------------------------------------------------------------------
Total: 2
```

Table 11-249 Description of the **display references wds-profile name** command output

Parameter	Description
Reference type	Type of the profile to which the WDS profile is bound.
Reference name	Name of the profile to which the WDS profile is bound. ● Run the **wds-profile radio** command in the AP group view or view of the AP with a specified ID to apply a WDS profile. ● Run the **wds-profile (AP group radio view or AP radio view)** command in the AP group radio view or AP radio view to apply a WDS profile.
Reference radio	AP radio to which the WDS profile is applied.
WLAN ID	WLAN ID to which the WDS profile is bound.

11.12.4 display references wds-whitelist-profile

Function

The **display references wds-whitelist-profile** command displays reference information about a WDS whitelist profile.

Format

display references wds-whitelist-profile name *whitelist-name*

Parameters

Parameter	Description	Value
name *whitelist-name*	Displays reference information about a specified WDS whitelist profile.	The WDS whitelist profile must exist.

Views

All views

1: Monitoring level

Usage Guidelines

You can run the **display references wds-whitelist-profile** command to check reference information about a specified WDS whitelist profile.

Example

Display reference information about the WDS whitelist profile **test**.

```
<HUAWEI> display references wds-whitelist-profile name test
------------------------------------------------------------------------------
Reference type                Reference name
------------------------------------------------------------------------------
AP group                    profile-1
AP group                    profile-2
------------------------------------------------------------------------------
Total: 2
```

Table 11-250 Description of the **display references wds-whitelist-profile** command output

Parameter	Description
Reference type	Type of the profile to which the WDS whitelist profile is bound.
Reference name	Name of the profile to which the WDS whitelist profile is bound. Run the **wds-whitelist-profile (AP group radio view or AP radio view)** command in the AP group radio view or AP radio view to apply a WDS whitelist profile.

11.12.5 display wds-profile

Function

The **display wds-profile** command displays reference or configuration information about a WDS profile.

Format

display wds-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays reference information about all WDS profiles.	-
name *profile-name*	Displays information about a specified WDS profile.	The WDS profile must exist.

Table 11-252 Description of the **display wds-profile name** command output

Item	Description
WDS name	WDS name. To set a WDS name, run the **wds-name** command.
WDS work mode	WDS working mode. To set the WDS working mode, run the **wds-mode** command.
Security profile	Security profile bound to a WDS profile. To bind a security profile to a WDS profile, run the **security-profile (WDS profile view)** command.

Item	Description
DHCP trust port	Whether to enable a DHCP trusted port in a WDS profile. - enable: A DHCP trusted port is enabled. - disable: A DHCP trusted port is disabled. To enable a DHCP trusted port in a WDS profile, run the **dhcp trust port (WDS profile view)** command.
ND trust port	Whether to enable an ND trusted port in a WDS profile. - enable: An ND trusted port is enabled. - disable: An ND trusted port is disabled. To enable an ND trusted port in a Mesh profile, run the **nd trust port (WDS profile view)** command.
MU-MIMO	Whether the MU-MIMO function is enabled. To configure the parameter, run the **mu-mimo disable** command.
Tagged vlan	VLAN configured in a WDS profile. To configure a VLAN in a WDS profile, run the **vlan tagged (WDS profile view)** command.
Priority map trust	Priority mapping trusted by the WDS air interface. To configure the parameter, run the **priority-map trust (WDS profile view)** command.
Priority map mode	Mapping from DSCP priorities to 802.11e user priorities on the WDS air interface. To configure the parameter, run the **priority-map dscp (WDS profile view)** command.
Beacon 2.4G rate	Transmit rate of 2.4 GHz management frames configured in the WDS profile. To configure the parameter, run the **beacon-2g-rate** command.

Item	Description
Beacon 5G rate	Transmit rate of 5 GHz management frames configured in the WDS profile. To configure the parameter, run the **beacon-5g-rate** command.

11.12.6 display wds-whitelist-profile

Function

The **display wds-whitelist-profile** command displays reference or configuration information about a WDS whitelist profile.

Format

display wds-whitelist-profile { **all** | **name** *whitelist-name* }

Parameters

Parameter	Description	Value
all	Displays reference information about all WDS whitelist profiles.	-
name *whitelist-name*	Displays information about a specified WDS whitelist profile.	The WDS whitelist profile must exist.

Views

All views

Usage Guidelines

You can run the **display wds-whitelist-profile** command to view the number of times a WDS whitelist profile is referenced or MAC addresses added in a specified WDS whitelist profile.

Example

Display reference information about all WDS whitelist profiles.

```
<HUAWEI> display wds-whitelist-profile all
--------------------------------------------------------------------------------
```

```
Profile name                    Reference
------------------------------------------------------------------------------
default                           0
test                              2
------------------------------------------------------------------------------
Total: 2
```

Table 11-253 Description of the **display wds-whitelist-profile all** command output

Item	Description
Profile name	Name of a WDS whitelist profile. To create a WDS whitelist profile, run the **wds-whitelist-profile** command.
Reference	Number of times a WDS whitelist profile is referenced.

Display information about the WDS whitelist profile **test**.

```
<HUAWEI> display wds-whitelist-profile name test
------------------------------------------------------------------------------
WDS whitelist name: test
WDS whitelist MAC list information:
------------------------------------------------------------------------------
Index     MAC
------------------------------------------------------------------------------
0         00e0-fcb1-56a0
------------------------------------------------------------------------------
Total: 1
```

Table 11-254 Description of the **display wds-whitelist-profile name** command output

Item	Description
Index	WDS whitelist ID in a WDS whitelist profile.
MAC	MAC address on a WDS whitelist. To add a MAC address to a WDS whitelist, run the **peer-ap mac (WDS whitelist profile view)** command.

11.12.7 display wds vap

Function

The **display wds vap** command displays information about a WDS VAP.

Format

display wds vap { **ap-group** *ap-group-name* | **ap-id** *ap-id* [**radio** *radio-id*] | **ap-name** *ap-name* [**radio** *radio-id*] } [**wds-name** *wds-name*]

display wds vap { **all** | **wds-name** *wds-name* }

Parameters

Parameter	Description	Value
ap-group *ap-group-name*	Displays information about all WDS VAPs in a specified AP group.	The AP group must exist.
ap-id *ap-id*	Displays information about WDS VAPs on the AP with a specified ID.	The AP ID must exist.
ap-name *ap-name*	Displays information about WDS VAPs on the AP with a specified name.	The AP name must exist.
radio *radio-id*	Displays information about WDS VAPs of a specified AP radio.	The radio ID must exist.
wds-name *wds-name*	Displays information about WDS VAPs of a specified WDS name.	The WDS name must exist.
all	Displays information about all WDS VAPs.	-

Usage Guidelines

You can run the **display wds vap** command to display information about a WDS VAP.

Example

Display information about all WDS VAPs.

```
<HUAWEI> display wds vap all
WID : WLAN ID
--------------------------------------------------------------------------------
AP ID AP name      RfID WID        WDS name            BSSID          WDS links
--------------------------------------------------------------------------------
1     AP2           0  14          wds                 00e0-fc12-3456  0
1     AP2           0  13          wds                 00e0-fc12-3457  0
0     AP1           0  14          wds                 00e0-fc12-3467  1
0     AP1           0  13          wds                 00e0-fc12-3468  1
```

```
--------------------------------------------------------------------------------------
Total: 4
```

Table 11-255 Description of the **display wds vap** command output

Item	Description
AP ID	AP ID.
AP name	AP name.
RfID	Radio ID.
WID	WLAN ID of a VAP.
WDS name	WDS name. To set a WDS name, run the **wds-name** command.
BSSID	MAC address of a VAP.
WDS links	Number of WDS links.

11.12.8 display wlan wds link

Function

The **display wlan wds link** command displays information about a WDS link.

Format

display wlan wds link { **all** | **ap-id** *ap-id* [**radio** *radio-id*] | **ap-name** *ap-name* [**radio** *radio-id*] | **wds-profile** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays information about all WDS links.	-
ap-id *ap-id*	Displays information about WDS links on the AP with a specified ID.	The AP ID must exist.
ap-name *ap-name*	Displays information about WDS links on the AP with a specified name.	The AP name must exist.
radio *radio-id*	Displays information about WDS links of a specified AP radio.	The radio ID must exist.
wds-profile *profile-name*	Displays information about WDS links in a specified WDS profile.	The WDS profile must exist.

AP_2                  1  3    36   root    -          -72   -40   56   99   23   21/19/-/-
----------------------------------------------------------------------------------------------------
Total: 2
```

Table 11-256 Description of the **display wlan wds link** command output

Item	Description
APName	Name of the local AP.
P-APName	Name of the peer AP.
Rf	Radio ID of the local AP.
Dis	Radio coverage distance parameter of the local AP.
Ch	Working channel of a WDS link.
WDS	WDS role of the local AP.
P-Status	Status of the peer AP.
RSSI	RSSI of the peer AP.
MaxR	Maximum RSSI threshold of a WDS link.
Per	Packet error ratio of a WDS link.
Re	Packet retransmission ratio of a WDS link.

Item	Description
TSNR	Total SNR of a WDS link.
SNR(Ch0~3:dB)	SNR of each spatial stream of a WDS link.

11.12.9 nd trust port (WDS profile view)

Function

The **nd trust port** command enables an ND trusted port in a WDS profile.

The **undo nd trust port** command disables an ND trusted port in a WDS profile.

By default, an ND trusted port is enabled in a WDS profile.

Format

nd trust port

undo nd trust port

Parameters

None

Views

WDS profile view

Default Level

2: Configuration level

Usage Guidelines

After an ND trusted port is enabled in a WDS profile and the WDS profile is applied to an AP, the AP receives valid ND protocol packets and forwards the packets to STAs or peer APs so that the STAs can obtain valid IPv6 addresses and go online.

Example

Enable an ND trusted port in the WDS profile **test**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wds-profile name test
[HUAWEI-wlan-wds-prof-test] nd trust port
```

11.12.10 peer-ap mac (WDS whitelist profile view)

Function

The **peer-ap mac** command adds MAC addresses of neighboring APs that are allowed to connect to an AP to a WDS whitelist profile.

The **undo peer-ap mac** command deletes the MAC addresses of neighboring APs from a WDS whitelist profile.

By default, no MAC address of a neighboring AP is added to a WDS whitelist profile.

Format

peer-ap mac *mac-address*

undo peer-ap mac *mac-address*

Parameters

Parameter	Description	Value
mac-address	Specifies the MAC address of a neighboring AP to be added to a WDS whitelist profile.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.

Views

WDS whitelist profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a WDS whitelist profile is created, you can run the **peer-ap mac** command to add neighboring APs' MAC addresses to the profile.

If a WDS whitelist profile is bound to a WDS profile, only APs with MAC addresses in the WDS whitelist profile can access the local AP, and other APs are denied access.

Precautions

A maximum of six MAC addresses can be added to a WDS whitelist profile.

Example

Create the WDS whitelist profile **whitelist** and add the MAC address **00e0-fc01-0001** to the whitelist profile. Bind the WDS whitelist profile **whitelist** to radio **0** of APs in the AP group **group1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wds-whitelist-profile name whitelist
[HUAWEI-wlan-wds-whitelist-whitelist] peer-ap mac 00e0-fc01-0001
[HUAWEI-wlan-wds-whitelist-whitelist] quit
[HUAWEI-wlan-view] ap-group name group1
[HUAWEI-wlan-ap-group-group1] radio 0
[HUAWEI-wlan-group-radio-group1/0] wds-whitelist-profile whitelist
```

11.12.11 priority-map dscp (WDS profile view)

Function

The **priority-map dscp** command configures the mapping from DSCP priorities to 802.11e user priorities on the WDS air interface.

The **undo priority-map dscp** command restores the default mapping from DSCP priorities to 802.11e user priorities on the WDS air interface.

Table 11-257 describes the mapping from DSCP priorities to 802.11e user priorities by default.

Table 11-257 Mapping from DSCP priorities to 802.11e user priorities

DSCP Priority	802.11e User Priority
0-7	0
8-15	1
16-23	2
24-31	3
32-39	4
40-47	5
48-55	6
56-63	7

Format

priority-map dscp { *dscp-value1* [**to** *dscp-value2*] } &<1-10> **dot11e** *dot11e-value*

undo priority-map dscp

Parameters

Parameter	Description	Value
dscp *dscp-value1*	Specifies the DSCP priority of 802.3 packets.	The value is an integer that ranges from 0 to 63. A larger value indicates a higher priority.
to *dscp-value2*	Specifies the DSCP priority of 802.3 packets.	The value is an integer that ranges from 0 to 63. A larger value indicates a higher priority.
dot11e *dot11e-value*	Specifies the 802.11e user priority.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.

Views

WDS profile view

Default Level

2: Configuration level

Usage Guidelines

On a WDS network, you can run this command to configure the mapping from DSCP priorities to 802.11e user priorities on the WDS air interface of an AP.

Example

Map DSCP priorities 0-6 to 802.11e user priority 0 on the WDS air interface.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wds-profile name test
[HUAWEI-wlan-wds-prof-test] priority-map dscp 0 to 6 dot11e 0
```

11.12.12 priority-map trust (WDS profile view)

Function

The **priority-map trust** command configures the priority mapping to be trusted by the WDS air interface.

The **undo priority-map trust** command restores the default priority mapping to be trusted by the WDS air interface.

By default, the WDS air interface trusts the mapping from DSCP priorities to 802.11e user priorities.

Format

priority-map trust { **dot1p** | **dscp** }

undo priority-map trust

Parameters

Parameter	Description	Value
dot1p	Indicates that the WDS air interface trusts the mapping from 802.1p priorities to 802.11e user priorities.	-
dscp	Indicates that the WDS air interface trusts the mapping from DSCP priorities to 802.11e user priorities.	-

Views

WDS profile view

Default Level

2: Configuration level

Usage Guidelines

On a WDS network, when 802.1p or DSCP priorities in data packets need to be mapped to 802.11e user priorities and the packets are transmitted through a WDS link, run this command.

Example

Configure the WDS air interface to trust the mapping from 802.1p priorities to 802.11e user priorities.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wds-profile name test
[HUAWEI-wlan-wds-prof-test] priority-map trust dot1p
```

11.12.13 security-profile (WDS profile view)

Function

The **security-profile** command binds a security profile to a WDS profile.

The **undo security-profile** command restores the default security profile bound to a WDS profile.

By default, the security profile **default-wds** is bound to a WDS profile.

Format

security-profile *profile-name*

undo security-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of the security profile bound to a WDS profile.	The security profile must exist.

Views

WDS profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before a WDS profile is applied to an AP radio to set up WDS links, the WDS profile must have a security profile bound to ensure WDS link security.

Precautions

After a security profile is bound to a WDS profile, the authentication policy and encryption mode in the security profile cannot be changed, but the authentication key can be changed.

A WDS profile can only have one security profile bound. If you run the command multiple times in the same WDS profile view, the latest configuration overwrites the old one.

Example

Create the security profile **sec** and set the security policy to WPA2+PSK+AES. Create the WDS profile **test** and bind the security profile to the WDS profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name sec
[HUAWEI-wlan-sec-prof-sec] security wpa2 psk pass-phrase YsHsjx_202206 aes
[HUAWEI-wlan-sec-prof-sec] quit
[HUAWEI-wlan-view] wds-profile name test
[HUAWEI-wlan-wds-prof-test] security-profile sec
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.12.14 vlan tagged (WDS profile view)

Function

The **vlan tagged** command adds one or a group of VLANs to a WDS profile in tagged mode.

The **undo vlan tagged** command deletes VLANs from a WDS profile.

By default, no VLAN is configured in a WDS profile.

NOTE

Currently, VLANs can only be added to a WDS profile in tagged mode.

Format

vlan tagged { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

undo vlan tagged { { *vlan-id1* [**to** *vlan-id2*] } &<1-10> | **all** }

Parameters

Parameter	Description	Value
vlan-id1 [**to** *vlan-id2*]	Specifies the tagged VLAN ID. - *vlan-id1* specifies the first VLAN ID. - **to** *vlan-id2* specifies the last VLAN ID. The value of *vlan-id2* must be greater than or equal to the value of *vlan-id1*. The *vlan-id1* and *vlan-id2* parameters determine a VLAN range. If **to** *vlan-id2* is not specified, only the VLAN specified by *vlan-id1* is added to the WDS profile in tagged mode. You can specify a maximum of 10 VLAN ranges at a time. The entered VLAN ranges cannot overlap.	- The value of *vlan-id1* is an integer that ranges from 1 to 4094. - The value of *vlan-id2* is an integer that ranges from 1 to 4094.
all	Deletes all tagged VLANs from a WDS profile.	-

Views

WDS profile view

Default Level

2: Configuration level

Usage Guidelines

Adding VLANs to a WDS profile is equivalent to adding hybrid interfaces to a VLAN. After one or a group of VLANs is added to a WDS profile, the WDS link forwards only the packets with these VLAN IDs from STAs and peer APs.

NOTE

A maximum of 256 VLANs can be added to a WDS profile.

Example

Create the WDS profile **test** and add VLANs 3, 4, 5, 6, 10, and 12 to the WDS profile in **tagged** mode.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wds-profile name test
[HUAWEI-wlan-wds-prof-test] vlan tagged 3 to 6 10 12
```

11.12.15 wds-mode

Function

The **wds-mode** command sets the WDS mode in a WDS profile.

By default, the WDS mode in a WDS profile is **leaf**.

Format

wds-mode { **root** | **middle** | **leaf** }

Parameters

Parameter	Description	Value
root	Sets the WDS mode to root.	-
middle	Sets the WDS mode to middle.	-
leaf	Sets the WDS mode to leaf.	-

Views

WDS profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To connect an AP to an AC through WDS links, use this command to set the WDS mode for an AP radio based on the location of the AP on a WDS network.

In the downlink direction, a root node can connect to a middle or leaf node, and a middle node can connect to a leaf node. A leaf node is the termination node of a WDS link.

Precautions

After changing the WDS mode in a WDS profile, reset the APs using the profile to make the changed WDS mode take effect.

Example

Create the WDS profile **test** and set the WDS mode of the profile to **middle**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wds-profile name test
[HUAWEI-wlan-wds-prof-test] wds-mode middle
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.12.16 wds-name

Function

The **wds-name** command sets a WDS name for a WDS profile.

The **undo wds-name** command deletes the WDS name of a WDS profile.

By default, the WDS name of a WDS profile is **HUAWEI-WLAN-WDS**.

Format

wds-name *name*

undo wds-name

Parameters

Parameter	Description	Value
name	Specifies the character string that indicates the WDS name.	The value is a string of 1 to 32 case-sensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").

Views

WDS profile view

Default Level

2: Configuration level

Usage Guidelines

A WDS name is similar to an SSID. On a WDS network, an AP radio discovers WDS services provided by other APs based on the WDS name.

Each WDS profile must have a WDS name. The default WDS name of a WDS profile is **HUAWEI-WLAN-WDS**. You can run the **wds-name** command to set a WDS name for a WDS profile.

Example

Create the WDS profile **test** and set the WDS name of the profile to **bridge**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wds-profile name test
[HUAWEI-wlan-wds-prof-test] wds-name bridge
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.12.17 wds-profile

Function

The **wds-profile** command creates a WDS profile or displays the WDS profile view.

The **undo wds-profile** command deletes a WDS profile.

By default, the system provides the WDS profile **default**.

Format

wds-profile name *profile-name*

undo wds-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a WDS profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all WDS profiles. **NOTE** The WDS profile **default** cannot be deleted.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Each WDS profile must have a WDS name. The default WDS name of a WDS profile is **HUAWEI-WLAN-WDS**. You can run the **wds-name** command to set a WDS name for a WDS profile.

Example

Create the WDS profile **test** and set the WDS name of the profile to **bridge**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wds-profile name test
[HUAWEI-wlan-wds-prof-test] wds-name bridge
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.12.18 wds-profile radio

Function

The **wds-profile radio** command binds a WDS profile to an AP group or AP.

The **undo wds-profile radio** command deletes a WDS profile from an AP group or AP.

By default, no WDS profile is bound to an AP group or AP.

Format

wds-profile *profile-name* **radio** { **all** | *radio-id* }

undo wds-profile radio { **all** | *radio-id* }

Parameters

Parameter	Description	Value
profile-name	Specifies the name of the WDS profile bound to an AP or AP group.	The WDS profile must exist.
all	Binds a WDS profile to all AP radios.	-
radio-id	Binds a WDS profile to a specified AP radio.	The radio ID must exist.

Views

AP group view, AP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a WDS profile is bound to an AP or AP group, the AP radio will generate a WDS VAP to provide WDS services. The WDS VAP provides hidden SSIDs for WDS nodes to set up connections.

Prerequisites

A WDS profile has been created and configured properly.

Precautions

Among the VAPs created after a WDS profile is bound to an AP radio, the VAPs with the WLAN IDs 13 and 14 cannot be occupied.

An AP radio can only have one WDS profile bound.

Since the WLAN WDS and Mesh functions are mutually exclusive, the WDS and Mesh profiles cannot be applied to an AP radio at the same time.

Example

Bind the WDS profile **test** to radio **0** of APs in the AP group **group1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name group1
[HUAWEI-wlan-ap-group-group1] wds-profile test radio 0
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.12.19 wds-profile (AP group radio view or AP radio view)

Function

The **wds-profile** command binds a WDS profile to an AP radio.

The **undo wds-profile** command unbinds a WDS profile from an AP radio.

By default, no WDS profile is bound to an AP radio.

Format

wds-profile *profile-name*

undo wds-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of the WDS profile bound to an AP radio.	The WDS profile must exist.

Views

AP group radio view, AP radio view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a WDS profile is bound to an AP radio, the radio will generate a WDS VAP to provide WDS services. The WDS VAP provides hidden SSIDs for WDS nodes to set up connections.

Prerequisites

A WDS profile has been created and configured properly.

Precautions

Among the VAPs created after a WDS profile is bound to an AP radio, the VAPs with the WLAN IDs 13 and 14 cannot be occupied.

An AP radio can only have one WDS profile bound.

This command has the same function as the **wds-profile radio** command. You can use either of them.

Example

Bind the WDS profile **test** to radio **0** of APs in the AP group **group1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name group1
[HUAWEI-wlan-ap-group-group1] radio 0
[HUAWEI-wlan-group-radio-group1/0] wds-profile test
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.12.20 wds-whitelist-profile

Function

The **wds-whitelist-profile** command creates a WDS whitelist profile or displays the WDS whitelist profile view.

The **undo wds-whitelist-profile** command deletes a WDS whitelist profile.

By default, no WDS whitelist profile is available in the system.

Format

wds-whitelist-profile name *whitelist-name*

undo wds-whitelist-profile { **all** | **name** *whitelist-name* }

Parameters

Parameter	Description	Value
name *whitelist-name*	Specifies the name of a WDS whitelist profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all WDS whitelist profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

After a WDS whitelist profile is created using the **wds-whitelist-profile** command, you can run the **peer-ap mac (WDS whitelist profile view)** command in the WDS whitelist profile view to add MAC addresses of peer APs that are allowed to set up WDS links with the local AP to the profile.

Example

Create the WDS whitelist profile **whitelist** and add the MAC address **00e0-fc01-0001** to the whitelist profile. Bind the WDS whitelist profile **whitelist** to radio **0** of APs in the AP group **group1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wds-whitelist-profile name whitelist
[HUAWEI-wlan-wds-whitelist-whitelist] peer-ap mac 00e0-fc01-0001
[HUAWEI-wlan-wds-whitelist-whitelist] quit
[HUAWEI-wlan-view] ap-group name group1
[HUAWEI-wlan-ap-group-group1] radio 0
[HUAWEI-wlan-group-radio-group1/0] wds-whitelist-profile whitelist
```

11.12.21 wds-whitelist-profile (AP group radio view or AP radio view)

Function

The **wds-whitelist-profile** command binds a WDS whitelist profile to an AP radio.

The **undo wds-whitelist-profile** command unbinds a WDS whitelist profile from an AP radio.

By default, no WDS whitelist profile is bound to an AP radio.

Format

wds-whitelist-profile *whitelist-name*

undo wds-whitelist-profile

Parameters

Parameter	Description	Value
whitelist-name	Specifies the name of the WDS whitelist profile bound to an AP radio.	The WDS whitelist profile must exist.

Views

AP group radio view, AP radio view

Default Level

2: Configuration level

Usage Guidelines

After a WDS whitelist profile is applied to an AP radio, the AP radio can only set up WDS links with neighboring APs whose MAC addresses are in the WDS whitelist profile. If no WDS whitelist profile is bound to an AP radio, the AP radio can establish WDS links with any neighboring APs.

NOTE

On a WDS network, a root or middle node controls subnode access by MAC addresses added to the WDS whitelist profile. However, a leaf node does not require a whitelist.

An AP radio can only have one WDS whitelist profile bound. If you run the command multiple times on the same AP radio, the latest configuration overwrites the old one.

Example

Create the WDS whitelist profile **whitelist** and add the MAC address **00e0-fc01-0001** to the whitelist profile. Bind the WDS whitelist profile **whitelist** to radio **0** of APs in the AP group **group1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wds-whitelist-profile name whitelist
[HUAWEI-wlan-wds-whitelist-whitelist] peer-ap mac 00e0-fc01-0001
[HUAWEI-wlan-wds-whitelist-whitelist] quit
[HUAWEI-wlan-view] ap-group name group1
[HUAWEI-wlan-ap-group-group1] radio 0
[HUAWEI-wlan-group-radio-group1/0] wds-whitelist-profile whitelist
```

11.13 WLAN Mesh Configuration Commands

11.13.1 Command Support

WLAN-AC commands are supported only by the following models: S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.

11.13.2 dhcp trust port (Mesh profile view)

Function

The **dhcp trust port** command enables a DHCP trusted port in a Mesh profile.

The **undo dhcp trust port** command disables a DHCP trusted port in a Mesh profile.

By default, a DHCP trusted port is enabled in a Mesh profile.

Format

dhcp trust port

undo dhcp trust port

Parameters

None

Views

Mesh profile view

Default Level

2: Configuration level

Usage Guidelines

After a DHCP trusted port is enabled in a Mesh profile and the Mesh profile is applied to an AP, the AP receives the DHCP OFFER, ACK, and NAK packets sent by authorized DHCP servers and forwards the packets to STAs so that the STAs can obtain valid IP addresses and go online.

Example

Enable a DHCP trusted port in the Mesh profile **test**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-profile name test
[HUAWEI-wlan-mesh-prof-test] dhcp trust port
```

11.13.3 display mesh-profile

Function

The **display mesh-profile** command displays reference or configuration information about Mesh profiles.

Format

display mesh-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays reference information about all Mesh profiles.	-
name *profile-name*	Displays reference information about a specified Mesh profile.	The Mesh profile must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display mesh-profile** command to view the number of times a Mesh profile is referenced or configuration information of a specified Mesh profile.

Example

Display reference information about all Mesh profiles.

```
<HUAWEI> display mesh-profile all
--------------------------------------------------------------------------------
Profile name                     Reference
--------------------------------------------------------------------------------
default                          0
test                             2
--------------------------------------------------------------------------------
Total: 2
```

Table 11-258 Description of the **display mesh-profile all** command output

Item	Description

Table 11-259 Description of the **display mesh-profile name** command output

Item	Description
Mesh handover profile	Mesh handover profile bound to a Mesh profile. To configure this parameter, run the **mesh-handover-profile (Mesh profile view)** command.
Security profile	Security profile bound to a Mesh profile. To configure this parameter, run the **security-profile (Mesh profile view)** command.
Mesh ID	Mesh ID of a Mesh profile. To configure this parameter, run the **mesh-id** command.
Max link number	Maximum number of Mesh links allowed on an AP. To configure this parameter, run the **max-link-number** command.
Link RSSI threshold	RSSI threshold of a Mesh link. To configure this parameter, run the **link-rssi-threshold** command.
Link report interval	Interval for reporting Mesh link information. To configure this parameter, run the **link-report-interval** command.
Link aging timeout	Aging time of a Mesh link. To configure this parameter, run the **link-aging-time** command.

Item	Description
FWA switch	FWA status in a Mesh profile. ● enable: The FWA is enabled. ● disable: The FWA is disabled. To configure this parameter, run the **fwa enable** command.
FWA EDCA mode	EDCA mode. ● auto: indicates the automatic mode. ● manual: indicates the manual mode. To configure this parameter, run the **fwa wmm edca-mode** command.
DHCP trust port	Whether to enable a DHCP trusted port in a Mesh profile. ● enable: A DHCP trusted port is enabled. ● disable: A DHCP trusted port is disabled. To configure this parameter, run the **dhcp trust port (Mesh profile view)** command.
ND trust port	Whether to enable an ND trusted port in a Mesh profile. ● enable: An ND trusted port is enabled. ● disable: An ND trusted port is disabled. To configure this parameter, run the **nd trust port (Mesh profile view)** command.
Tagged VLAN	VLAN configured in a Mesh profile. To configure this parameter, run the **vlan tagged (Mesh profile view)** command.
Priority map trust	Priority mapping trusted by the Mesh air interface. To configure this parameter, run the **priority-map trust (Mesh profile view)** command.

Item	Description
Priority map mode	Mapping from DSCP priorities to 802.11e user priorities on the Mesh air interface. To configure this parameter, run the **priority-map dscp (Mesh profile view)** command.
Client mode	Whether to enable the Mesh client mode. - enable: The Mesh client mode is enabled. - disable: The Mesh client mode is disabled.
Beacon 2.4G rate	Transmit rate of 2.4 GHz management frames configured in the Mesh profile. To configure this parameter, run the **beacon-2g-rate** command.
Beacon 5G rate	Transmit rate of 5 GHz management frames configured in the Mesh profile. To configure this parameter, run the **beacon-5g-rate** command.
Beacon 6G rate	Transmit rate of 6 GHz management frames configured in the Mesh profile. To configure this parameter, run the **beacon-6g-rate** command.
AC_VO	AC_VO packets.
AC_VI	AC_VI packets.
AC_BE	AC_BE packets.
AC_BK	AC_BK packets.
ECWmax	Exponent form of the maximum contention window (ECWmax). ECWmin and ECWmax determine the average backoff time. To configure this parameter, run the **fwa wmm edca-client** command.
ECWmin	Exponent form of the minimum contention window (ECWmin). ECWmin and ECWmax determine the average backoff time. To configure this parameter, run the **fwa wmm edca-client** command.

Item	Description
AIFSN	Arbitration inter frame spacing number (AIFSN), which determines the channel idle time. To configure this parameter, run the **fwa wmm edca-client** command.
TXOPLimit	Transmission opportunity limit (TXOPLimit), which determines the maximum duration in which a STA can occupy a channel. A larger TXOPLimit value indicates a longer duration to occupy a channel. To configure this parameter, run the **fwa wmm edca-client** command.

11.13.4 display mesh-whitelist-profile

Function

The **display mesh-whitelist-profile** command displays reference or configuration information about a Mesh whitelist profile.

Format

display mesh-whitelist-profile { **all** | **name** *whitelist-name* }

Parameters

Parameter	Description	Value
all	Displays reference information about all Mesh whitelist profiles.	-
name *whitelist-name*	Displays information about a specified Mesh whitelist profile.	The Mesh whitelist profile must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display mesh-whitelist-profile** command to view the number of times a Mesh whitelist profile is referenced or MAC addresses added in a specified Mesh whitelist profile.

Example

Display reference information about all Mesh whitelist profiles.

```
<HUAWEI> display mesh-whitelist-profile all
--------------------------------------------------------------------------------
Profile name                          Reference
--------------------------------------------------------------------------------
default                              0
test                                 2
--------------------------------------------------------------------------------
Total: 2
```

Table 11-260 Description of the **display mesh-whitelist-profile all** command output

Item	Description
Profile name	Name of a Mesh whitelist profile. To configure this parameter, run the **mesh-whitelist-profile** command.
Reference	Number of times a Mesh whitelist profile is referenced.

Display information about the Mesh whitelist profile **test**.

```
<HUAWEI> display mesh-whitelist-profile name test
--------------------------------------------------------------------------------
Mesh whitelist name: test
Mesh whitelist MAC list information:
--------------------------------------------------------------------------------
Index     MAC
--------------------------------------------------------------------------------
0         00e0-fc76-e360
1         00e0-fc74-9640
--------------------------------------------------------------------------------
Total: 2
```

Table 11-261 Description of the **display mesh-whitelist-profile name** command output

Item	Description
Index	Mesh whitelist ID in a Mesh whitelist profile.

Item	Description
MAC	MAC address on a Mesh whitelist. To configure this parameter, run the **peer-ap mac (Mesh whitelist profile view)** command.

11.13.5 display mesh vap

Function

The **display mesh vap** command displays information about a Mesh VAP.

Format

display mesh vap { **ap-group** *ap-group-name* | **ap-id** *ap-id* [**radio** *radio-id*] | **ap-name** *ap-name* [**radio** *radio-id*] } [**mesh-id** *mesh-id*]

display mesh vap { **all** | **mesh-id** *mesh-id* }

Parameters

Parameter	Description	Value
ap-group *ap-group-name*	Displays information about all Mesh VAPs in a specified AP group.	The AP group must exist.
ap-id *ap-id*	Displays information about Mesh VAPs on the AP with a specified ID.	The AP ID must exist.
ap-name *ap-name*	Displays information about Mesh VAPs on the AP with a specified name.	The AP name must exist.
radio *radio-id*	Displays information about Mesh VAPs of a specified AP radio.	The radio ID must exist.
mesh-id *mesh-id*	Displays information about Mesh VAPs of a specified Mesh ID.	The Mesh ID must exist.
all	Displays information about all Mesh VAPs.	-

--------------------------------------------------------------------------------
Total: 1
```

Table 11-264 Description of the **display references mesh-whitelist-profile** command output

Item	Description
Reference type	Type of the profile by which a Mesh whitelist profile is referenced.
Reference name	Name of the profile by which a Mesh whitelist profile is referenced. To configure this parameter, run the **mesh-whitelist-profile (AP group radio view or AP radio view)** command in the AP group radio view or AP radio view.

11.13.8 display wlan mesh link

Function

The **display wlan mesh link** command displays information about a Mesh link.

Format

display wlan mesh link { **all** | **ap-id** *ap-id* [**radio** *radio-id*] | **ap-name** *ap-name* [**radio** *radio-id*] | **mesh-profile** *profile-name* | **peer-mac** *peer-mac* }

Parameters

Parameter	Description	Value
all	Displays information about all Mesh links.	-
ap-id *ap-id*	Displays information about Mesh links on the AP with a specified ID.	The AP ID must exist.
ap-name *ap-name*	Displays information about Mesh links on the AP with a specified name.	The AP name must exist.
radio *radio-id*	Displays information about Mesh links of a specified AP radio.	The radio ID must exist.
mesh-profile *profile-name*	Displays information about Mesh links in a specified Mesh profile.	The Mesh profile must exist.
peer-mac *peer-mac*	Displays information about the Mesh link on a specified peer MAC address.	The MAC address must exist.

1: Monitoring level

Usage Guidelines

You can run the **display wlan mesh link** command to view information about a Mesh link.

Example

Display information about all Mesh links.

```
<HUAWEI> display wlan mesh link all
Rf   : radio ID              Dis  : coverage distance(100m)
Ch   : channel               Per  : drop percent(%)

Table 11-265 Description of the **display wlan mesh link** command output

Item	Description
APName	Name of the local AP.
P-APMAC	MAC address of the peer AP.
P-APName	Name of the peer AP.
Rf	Radio ID of the local AP.
Dis	Radio coverage distance parameter of the local AP.
Ch	Working channel of a Mesh link.
Mesh	Mesh role of the local AP. ● portal: mesh-portal ● node: mesh-node ● node(leaf): mesh-node (leaf mode)
P-Status	Status of the peer AP.
RSSI	RSSI of the peer AP.
MaxR	Maximum RSSI threshold of a Mesh link.
Per	Packet error ratio of a Mesh link.
Re	Packet retransmission ratio of a Mesh link.
TSNR	Total SNR of Mesh links.
SNR(dB)	SNR of each spatial stream of a Mesh link.
Tx(Mbps)	Transmit rate.
Rx(Mbps)	Receive rate.
LinkStatus	Link status. ● active: active in Mesh handover mode ● inactive: inactive in Mesh handover mode ● -: client mode or a common Mesh network

Item	Description
IP Address	IP address of a vehicle-mounted AP. This item is displayed only when the specified MAC address indicates a vehicle-mounted Fat AP.
Link Rf	Radio used by the vehicle-mounted AP. This item is displayed only when the specified MAC address indicates a vehicle-mounted Fat AP.
Channel utilization	Channel utilization of the vehicle-mounted AP. This item is displayed only when the specified MAC address indicates a vehicle-mounted Fat AP.
Channel interference	Co-channel interference of the vehicle-mounted AP. This item is displayed only when the specified MAC address indicates a vehicle-mounted Fat AP.

11.13.9 display wlan mesh route

Function

The **display wlan mesh route** command displays AP routing information on a Mesh network.

Format

display wlan mesh route { **ap-id** *ap-id* | **ap-name** *ap-name* | **all** }

Parameters

Parameter	Description	Value
ap-id	Displays routing information of the AP with a specified ID on a Mesh network.	The AP ID must exist.
ap-name	Displays routing information of the AP with a specified name on a Mesh network.	The AP name must exist.
all	Displays all APs' routing information on a Mesh network.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use this command to view specified or all APs' routing information on a Mesh network, which helps you locate faults on the Mesh network.

Example

Display all APs' routing information on a Mesh network.

```
<HUAWEI> display wlan mesh route all
-------------------------------------------------------------------------------
AP name/MAC/Mesh role/Radio          Next-hop name/MAC/Mesh role/Radio
-------------------------------------------------------------------------------
ap1/00e0-fc74-9640/MP/0             ap2/00e0-fc76-e360/MPP/0
-------------------------------------------------------------------------------
Total: 1
```

Table 11-266 Description of the **display wlan mesh route** command output

Item	Description
AP name	Name of an AP.
MAC	MAC address of the AP.
Mesh role	Role of the AP on the Mesh network.
Radio	Radio ID of the AP.
Next-hop name	Name of the next-hop AP.

11.13.10 fwa wmm edca-client

Function

The **fwa wmm edca-client** command configures EDCA parameters used by the remote AP to negotiate with the AT.

The **undo fwa wmm edca-client** command restores the default EDCA parameters used by the remote AP to negotiate with the AT.

Table 11-267 lists the default EDCA parameter settings.

Table 11-267 Default EDCA parameter settings

Packet Type	Parameters	Description
AC_VO	ECWmax	3
	ECWmin	2
	AIFSN	2
	TXOPLimit	47
AC_VI	ECWmax	4
	ECWmin	3
	AIFSN	2
	TXOPLimit	94
AC_BE	ECWmax	10
	ECWmin	4
	AIFSN	3
	TXOPLimit	0
AC_BK	ECWmax	10
	ECWmin	4
	AIFSN	7
	TXOPLimit	0

Format

fwa wmm edca-client { **ac-vo** | **ac-vi** | **ac-be** | **ac-bk** } { **aifsn** *aifsn-value* | **ecw ecwmin** *ecwmin-value* **ecwmax** *ecwmax-value* | **txoplimit** *txoplimit-value* } *

undo fwa wmm edca-client

Parameters

Parameter	Description	Value
ac-vo	Indicates AC_VO packets.	-
ac-vi	Indicates AC_VI packets.	-
ac-be	Indicates AC_BE packets.	-
ac-bk	Indicates AC_BK packets.	-

Parameter	Description	Value
aifsn *aifsn-value*	Specifies the arbitration inter frame spacing number (AIFSN), which determines the channel idle time.	The value is an integer that ranges from 1 to 15.
ecwmin *ecwmin-value*	Specifies the exponent form of the minimum contention window. *ecwmin-value* and *ecwmax-value* determine the average backoff time.	The value is an integer that ranges from 0 to 15 and must be smaller than the *ecwmax-value* value.
ecwmax *ecwmax-value*	Specifies the exponent form of the maximum contention window. *ecwmin-value* and *ecwmax-value* determine the average backoff time.	The value is an integer that ranges from 0 to 15 and must be greater than the *ecwmin-value* value.
txoplimit *txoplimit-value*	Specifies the transmission opportunity limit (TXOPLimit), which determines the maximum duration in which a STA can occupy a channel. A larger TXOPLimit value indicates a longer duration to occupy a channel.	The value is an integer that ranges from 0 to 255. The unit is 32 microseconds. **NOTE** If the TXOPLimit value is 0, the STA can send only one data frame every time it occupies a channel.

Views

Mesh profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

WMM classifies data packets into the following access categories (ACs): AC_VO, AC_VI, AC_BE, and AC_BK. A set of EDCA parameters is set for each AC queue. These parameters determine the capabilities of a queue to occupy a channel. You can set EDCA parameters for packets of different ACs to provide differentiated priorities to the packets and different capabilities to compete for channels. In this way, differentiated services are implemented.

Table 11-268 describes the EDCA parameters.

Table 11-268 EDCA parameter description

Parameter	Meaning
Arbitration Interframe Spacing Number (AIFSN)	The DIFS has a fixed value. WMM provides different DIFS values for different ACs. A large AIFSN value means that the STA must wait for a long time and has a low priority.
Exponent form of CWmin (ECWmin) and exponent form of CWmax (ECWmax)	ECWmin specifies the minimum backoff time, and ECWmax specifies the maximum backoff time. Together, they determine the average backoff time. Large ECWmin and ECWmax values mean a long average backoff time for the STA and a low STA priority.
Transmission Opportunity Limit (TXOPLimit)	After preempting a channel, the STA can occupy the channel within the period of TXOPLimit. A large TXOPLimit value means that the STA can occupy the channel for a long time. If the TXOPLimit value is 0, the STA can only send one data frame every time it preempts a channel.

Precautions

- The EDCA parameters configured using the **fwa wmm edca-client** command take effect only after you set the EDCA mode to manual mode using the **fwa wmm edca-mode manual** command.
- By default, queues of AC_VO, AC_VI, AC_BE, and AC_BK are in descending order of priority. Priorities of the four queues are determined by their EDCA parameters.

You need to configure EDCA parameters according to actual scenarios. **Table 11-269** shows the configuration of EDCA parameters in voice scenarios, and **Table 11-270** shows the configuration in voice and video hybrid scenarios.

Table 11-269 Recommended configuration of EDCA parameters in voice scenarios

Packet Type	Parameters	Description
AC_VO	ECWmax	4
	ECWmin	2
	AIFSN	2
	TXOPLimit	0

Packet Type	Parameters	Description
AC_VI	ECWmax	5
	ECWmin	3
	AIFSN	5
	TXOPLimit	0
AC_BE	ECWmax	10
	ECWmin	6
	AIFSN	5
	TXOPLimit	0
AC_BK	ECWmax	10
	ECWmin	8
	AIFSN	12
	TXOPLimit	0

Table 11-270 Recommended configuration of EDCA parameters in voice and video hybrid scenarios

Packet Type	Parameters	Description
AC_VO	ECWmax	4
	ECWmin	2
	AIFSN	2
	TXOPLimit	0
AC_VI	ECWmax	5
	ECWmin	3
	AIFSN	5
	TXOPLimit	0
AC_BE	ECWmax	10
	ECWmin	6
	AIFSN	12
	TXOPLimit	0
AC_BK	ECWmax	10
	ECWmin	8

Packet Type	Parameters	Description
	AIFSN	12
	TXOPLimit	0

Example

Configure EDCA parameters of AC_VO packets used by the remote AP to negotiate with the AT.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-profile name test
[HUAWEI-wlan-mesh-prof-test] fwa wmm edca-mode manual
[HUAWEI-wlan-mesh-prof-test] fwa wmm edca-client ac-vo aifsn 7 ecw ecwmin 4 ecwmax 10 txoplimit
0
```

11.13.11 fwa wmm edca-mode

Function

The **fwa wmm edca-mode** command sets the Enhanced Distributed Channel Access (EDCA) mode.

By default, the automatic EDCA mode is used.

Format

fwa wmm edca-mode { **auto** | **manual** }

Parameters

Parameter	Description	Value
auto	Sets the EDCA mode to automatic. In automatic EDCA mode, ATs automatically adjust EDCA parameters based on the number of ATs connecting to the remote AP.	-

Parameter	Description	Value
manual	Sets the EDCA mode to manual. In manual mode, you can run the **fwa wmm edca-client** command to configure EDCA parameters of the AT. The remote AP negotiates with the AT according to the configured parameters.	-

Views

Mesh profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In scenarios where the AT connects to the remote AP through Mesh links, if the EDCA mode is **auto**, ATs automatically adjust EDCA parameters based on the number of ATs connecting to the remote APif the EDCA mode is **manual**, you can run the **fwa wmm edca-client** command to configure EDCA parameters of the AT. The remote AP then negotiates with the AT according to the configured parameters.

NOTE

- The **fwa wmm edca-mode** command takes effect only after the FWA mode is enabled in the Mesh profile using the **fwa enable** command.
- In automatic EDCA mode, the EDCA parameters manually configured using the **fwa wmm edca-client** command do not take effect on the AP.
- This command applies only to scenarios where the AT connects to the remote AP through Mesh links.

Example

Set the EDCA mode to auto.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-profile name test
[HUAWEI-wlan-mesh-prof-test] fwa wmm edca-mode auto
```

11.13.12 fwa enable

Function

The **fwa enable** command enables fixed wireless access (FWA) in a Mesh profile.

The **undo fwa enable** command disables FWA in a Mesh profile.

By default, FWA is disabled in a Mesh profile.

FWA is not supported by AirEngine series APs.

Format

fwa enable

undo fwa enable

Parameters

None

Views

Mesh profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An outdoor Access Terminal (AT) needs to set up a Mesh link with a remote AP to provide network access for downlink STAs connected to the AT. In this case, configure the Mesh service on the remote AP and enable FWA in the Mesh profile so that the AT can connect to the remote AP.

Configuration Impact

The FWA configuration has the following impacts:

- FWA and vehicle-ground fast link handover are mutually exclusive in a Mesh profile.
- The default value of the parameter *link-num* in the **max-link-number** *link-num* command is 32, and the value is in the range of 1 to 32.
- The default RSSI threshold of a Mesh link is fixed at –90 dBm, which cannot be changed using the **link-rssi-threshold** command.
- The Mesh service configuration can be performed without the need to bind a Mesh whitelist profile to the Mesh profile.
- A radio bound to the Mesh profile allows access from only ATs. If ATs are not used, do not enable FWA, which prevents a Mesh service configuration failure.

Example

Enable FWA for the Mesh profile named **test**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-profile name test
[HUAWEI-wlan-mesh-prof-test] fwa enable
```

Disable FWA for the Mesh profile named **test**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-profile name test
[HUAWEI-wlan-mesh-prof-test] undo fwa enable
```

11.13.13 link-aging-time

Function

The **link-aging-time** command sets the aging time of a Mesh link.

The **undo link-aging-time** command restores the default aging time of a Mesh link.

The default aging time of a Mesh link is 10 seconds.

Format

link-aging-time *aging-time*

undo link-aging-time

Parameters

Parameter	Description	Value
aging-time	Specifies the aging time of a Mesh link.	The value is an integer that ranges from 5 to 60, in seconds.

Views

Mesh profile view

Default Level

2: Configuration level

Usage Guidelines

If a Mesh node cannot receive keepalive packets from a neighboring node for a period of time greater than or equal to the aging time of a Mesh link, the Mesh node considers the Mesh link disconnected and will reselect a link.

In a fast changing radio environment, if the aging time of a Mesh link is set to a small value, Mesh links may be frequently disconnected or reselected, causing network flapping. If the aging time of a Mesh link is set to a large value, a Mesh node cannot reselect Mesh links in a timely manner, causing service interruption. Therefore, you need to configure a proper aging time for Mesh links based on actual situations.

Example

Set the aging time of a Mesh link to 10s.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-profile name test
[HUAWEI-wlan-mesh-prof-test] link-aging-time 10
```

11.13.14 link-report-interval

Function

The **link-report-interval** command sets the interval at which an MP reports Mesh link information to the AC.

The **undo link-report-interval** command restores the default interval at which an MP reports Mesh link information to the AC.

By default, an MP reports Mesh link information to the AC at an interval of 30 seconds.

Format

link-report-interval *report-interval*

undo link-report-interval

Parameters

Parameter	Description	Value
report-interval	Specifies the interval at which an MP reports Mesh link information to the AC.	The value is an integer that ranges from 5 to 3600, in seconds. The default value is 30.

Views

Mesh profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the network is unstable, an MP may frequently send Mesh link establishment or teardown information to the AC, affecting AC's processing of user services. To solve this problem, run the **link-report-interval** command to configure an MP to periodically send Mesh link information to the AC. After the command is executed, the MP sends link information to the AC only at specified intervals, ensuring normal processing of user services.

Example

Set the interval at which an MP reports Mesh link information to the AC to 20s.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-profile name test
[HUAWEI-wlan-mesh-prof-test] link-report-interval 20
```

11.13.15 link-rssi-threshold

Function

The **link-rssi-threshold** command sets the received signal strength indicator (RSSI) threshold of a mesh link.

The **undo link-rssi-threshold** command restores the default RSSI threshold of a mesh link.

By default, the RSSI threshold of a mesh link is -75 dBm. After the FWA mode is enabled in a Mesh profile, the RSSI threshold of a Mesh link is fixed as -90 dBm.

Format

link-rssi-threshold *threshold-value*

undo link-rssi-threshold

Parameters

Parameter	Description	Value
threshold-value	Specifies the RSSI threshold of a mesh link.	The value is an integer that ranges from -90 to -20, in dBm. The default value is -75. After the FWA mode is enabled in a Mesh profile, the RSSI threshold of a Mesh link is fixed as -90 dBm.

Views

Mesh profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The RSSI threshold of a mesh link indicates the minimum RSSI of the mesh link. If the RSSI of an MP that joins a WMN is lower than the RSSI threshold configured using the **link-rssi-threshold** command, the routing information table of the mesh link is updated and routing information about the MP is deleted.

The RSSI threshold of a mesh link depends on the distance between two MPs that establish the mesh link. If the two MPs are far from each other, a smaller RSSI threshold is recommended. If the two MPs are close to each other, a larger RSSI threshold is recommended.

Example

Set the RSSI threshold of mesh links to -60 dBm.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-profile name test
[HUAWEI-wlan-mesh-prof-test] link-rssi-threshold -60
```

11.13.16 max-link-number

Function

The **max-link-number** command sets the maximum number of mesh links that can be established between APs.

The **undo max-link-number** command restores the default maximum number of mesh links that can be established between APs.

By default, a maximum of eight mesh links can be established between APs. After you enable FWA for a mesh profile using the **fwa enable** command, a maximum of 32 mesh links can be established between APs by default.

Format

max-link-number *link-num*

undo max-link-number

Parameters

Parameter	Description	Value
link-num	Specifies the maximum number of mesh links that can be established between APs.	The value is an integer that ranges from 1 to 32. **NOTE** After you enable FWA for a mesh profile using the **fwa enable** command, the default value of *link-num* is 32, and the value ranges from 1 to 32.

Views

Mesh profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an AP sets up too many Mesh links with neighboring APs, network indicators, such as the throughput cannot meet customer needs, affecting user experience. To improve user experience, you can run the **max-link-number** command to set the maximum number of mesh links that can be established between APs according to actual situations.

Impact

If the number of mesh links of an AP has reached the maximum, the AP does not set up new mesh links with neighboring APs.

Example

Set the maximum number of mesh links that can be established between APs to **3**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-profile name test
[HUAWEI-wlan-mesh-prof-test] max-link-number 3
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.13.17 mesh-id

Function

The **mesh-id** command sets a Mesh ID for a Mesh profile.

The **undo mesh-id** command restores the Mesh ID of a Mesh profile to the default value.

By default, the Mesh ID of a Mesh profile is **HUAWEI-WLAN-MESH**.

Format

mesh-id *name*

undo mesh-id

Parameters

Parameter	Description	Value
name	Specifies the Mesh ID of a Mesh profile.	The value is a string of 1 to 32 case-sensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").

Views

Mesh profile view

Default Level

2: Configuration level

Usage Guidelines

The Mesh ID of a Mesh profile is similar to the SSID. On a Mesh network, AP radios discover available Mesh services of other APs based on the Mesh ID.

Each Mesh profile must have a Mesh ID. The default Mesh ID of a Mesh profile is **HUAWEI-WLAN-MESH**. You can run the **mesh-id** command to set a Mesh ID for a Mesh profile.

Example

Create the Mesh profile **test** and set the Mesh ID of the profile to **mesh-net**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-profile name test
[HUAWEI-wlan-mesh-prof-test] mesh-id mesh-net
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.13.18 mesh-profile

Function

The **mesh-profile** command creates a Mesh profile or displays the Mesh profile view.

The **undo mesh-profile** command deletes a Mesh profile.

By default, the system provides the Mesh profile **default**.

Format

mesh-profile name *profile-name*

undo mesh-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a Mesh profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all Mesh profiles. **NOTE** The Mesh profile **default** cannot be deleted.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a Mesh profile is applied to an AP radio, Mesh VAPs are created on the radio.

Each Mesh profile must have a Mesh ID. The default Mesh ID of a Mesh profile is **HUAWEI-WLAN-MESH**. You can run the **mesh-id** command to set a Mesh ID for a Mesh profile.

Example

Create the Mesh profile **test** and set the Mesh ID of the profile to **mesh-net**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-profile name test
[HUAWEI-wlan-mesh-prof-test] mesh-id mesh-net
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.13.19 mesh-profile radio

Function

The **mesh-profile radio** command binds a Mesh profile to an AP group or AP.

The **undo mesh-profile radio** command unbinds a Mesh profile from an AP group or AP.

By default, no Mesh profile is bound to an AP group or AP.

Format

mesh-profile *profile-name* **radio** { **all** | *radio-id* }

undo mesh-profile radio { **all** | *radio-id* }

Parameters

Parameter	Description	Value
profile-name	Specifies the name of the Mesh profile bound to an AP group or AP.	The Mesh profile must exist.
all	Binds a Mesh profile to all AP radios.	-
radio-id	Binds a Mesh profile to a specified AP radio.	The radio ID must exist.

Views

AP group view, AP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a Mesh profile is bound to an AP group or AP, a Mesh VAP will be generated on AP radios to provide Mesh services for users.

Prerequisites

A Mesh profile has been created and properly configured.

Precautions

Among the VAPs created after a Mesh profile is bound to a radio, the VAP with the WLAN ID 16 cannot be occupied.

An AP radio can only have one Mesh profile bound.

Since the WLAN WDS and Mesh functions are mutually exclusive, the WDS and Mesh profiles cannot be applied to an AP radio at the same time.

Example

Bind the Mesh profile **test** to radio **0** of APs in the AP group **group1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name group1
[HUAWEI-wlan-ap-group-group1] mesh-profile test radio 0
```

11.13.20 mesh-profile (AP group radio view or AP radio view)

Function

The **mesh-profile** command binds a Mesh profile to an AP radio.

The **undo mesh-profile** command unbinds a Mesh profile from an AP radio.

By default, no Mesh profile is bound to an AP radio.

Format

mesh-profile *profile-name*

undo mesh-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of the Mesh profile bound to an AP radio.	The Mesh profile must exist.

Usage Guidelines

Usage Scenario

After a Mesh profile is bound to an AP group radio or an AP radio, a Mesh VAP will be generated on the specified AP radio to provide Mesh services for users.

Prerequisites

A Mesh profile has been created and properly configured.

Precautions

Among the VAPs created after a Mesh profile is bound to a radio, the VAP with the WLAN ID 16 cannot be occupied.

An AP radio can only have one Mesh profile bound.

This command has the same function as the **mesh-profile radio** command. You can use either of them.

Example

Bind the Mesh profile **test** to radio **0** of APs in the AP group **group1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name group1
[HUAWEI-wlan-ap-group-group1] radio 0
[HUAWEI-wlan-group-radio-group1/0] mesh-profile test
```

11.13.21 mesh-role

Function

The **mesh-role** command configures a Mesh role for an AP in the AP system profile.

The **undo mesh-role** command restores the default Mesh role of an AP in the AP system profile.

By default, the Mesh role of an AP is **mesh-node** not in leaf mode in the AP system profile.

Format

mesh-role { **mesh-portal** | **mesh-node** [**leaf**] }

undo mesh-role

Parameters

Parameter	Description	Value
mesh-portal	Sets the Mesh role of an AP to **mesh-portal** in the AP system profile.	-
mesh-node	Sets the Mesh role of an AP to **mesh-node** in the AP system profile.	-
leaf	Configures a Mesh node to work in leaf mode. If this parameter is not specified, the node works in non-leaf mode.	-

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

APs on a Mesh network can be classified as the following types:

- MP (**mesh-node**): Any Mesh points (MPs) that can support AP functions. They provide both Mesh service and user access service.

  If an MP needs to support low-speed mobility, configure the **mesh-node** AP to work in leaf mode. In leaf mode, the MP functions only as the termination point of a Mesh route and cannot establish a link with an MP that has not gone online and is not enabled with offline service holding.
- MPP (**mesh-portal**): Mesh points that connect the Mesh network to other types of networks and forward communication traffic on a Mesh network.

Configure Mesh roles of APs based on service requirements. If an AP needs to provide both Mesh and user access services, set the Mesh role of the AP to **mesh-node**. If an AP is located at the Mesh network ingress or needs to connect MPs on the local Mesh network to external networks, set the Mesh role of the AP to **mesh-portal**.

NOTE

To ensure the overall Mesh network performance, you are not advised to configure the user access service on a **mesh-portal** AP.

Example

Set the Mesh role of an AP to **mesh-portal** in the AP system profile **test**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name test
[HUAWEI-wlan-ap-system-prof-test] mesh-role mesh-portal
```

11.13.22 mesh-route aging-time

Function

The **mesh-route aging-time** command sets the aging time of a Mesh route.

The **undo mesh-route aging-time** command restores the default aging time of a Mesh route.

By default, the aging time of a Mesh route is 5 seconds.

Format

mesh-route aging-time *aging-time*

undo mesh-route aging-time

Parameters

Parameter	Description	Value
aging-time *aging-time*	Specifies the aging time of a Mesh route.	The value is an integer that ranges from 1 to 15, in seconds.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

If a Mesh node cannot receive routing frames from a neighboring node for a period of time greater than or equal to the aging time of a Mesh route, the Mesh node considers the Mesh route unreachable and will reselect a route.

If services are interrupted due to great changes in the radio environment, a smaller value for the aging time of a Mesh route can shorten the service interruption time. However, this may cause frequent route reselection, leading to network flapping. Therefore, you need to configure a proper aging time for Mesh routes based on actual situations.

In Mesh link failover scenarios, you can set the aging time of Mesh routes to 1 second so that Mesh routes can be aged out quickly, achieving fast link failover.

Example

Set the aging time of a Mesh route to 10s.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan view] ap-system-profile name test
[HUAWEI-wlan-ap-system-prof-test] mesh-route aging-time 10
```

11.13.23 mesh-whitelist-profile

Function

The **mesh-whitelist-profile** command creates a Mesh whitelist profile or displays the Mesh whitelist profile view.

The **undo mesh-whitelist-profile** command deletes a Mesh whitelist profile.

By default, no Mesh whitelist profile is available in the system.

Format

mesh-whitelist-profile name *whitelist-name*

undo mesh-whitelist-profile { **all** | **name** *whitelist-name* }

Parameters

Parameter	Description	Value
name *whitelist-name*	Specifies the name of a Mesh whitelist profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all Mesh whitelist profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

After a Mesh whitelist profile is created, run the **peer-ap mac (Mesh whitelist profile view)** command in the Mesh whitelist profile view to add MAC addresses of the allowed peer APs to the profile.

Example

Create the Mesh whitelist profile **whitelist** and add the MAC address **0001-0001-0001** to the whitelist profile. Bind the Mesh whitelist profile **whitelist** to radio **0** of APs in the AP group **group1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-whitelist-profile name whitelist
[HUAWEI-wlan-mesh-whitelist-whitelist] peer-ap mac 0001-0001-0001
[HUAWEI-wlan-mesh-whitelist-whitelist] quit
[HUAWEI-wlan-view] ap-group name group1
[HUAWEI-wlan-ap-group-group1] radio 0
[HUAWEI-wlan-group-radio-group1/0] mesh-whitelist-profile whitelist
```

11.13.24 mesh-whitelist-profile (AP group radio view or AP radio view)

Function

The **mesh-whitelist-profile** command binds a Mesh whitelist profile to an AP radio.

The **undo mesh-whitelist-profile** command unbinds a Mesh whitelist profile from an AP radio.

By default, no Mesh whitelist profile is bound to an AP radio.

Format

mesh-whitelist-profile *whitelist-name*

undo mesh-whitelist-profile

Parameters

Parameter	Description	Value
whitelist-name	Specifies the name of the Mesh whitelist profile bound to an AP radio.	The Mesh whitelist profile must exist.

Views

AP group radio view, AP radio view

Default Level

2: Configuration level

Usage Guidelines

After a Mesh whitelist profile is applied to an AP radio, the AP radio can only set up Mesh links with neighboring APs whose MAC addresses are in the Mesh whitelist profile.

NOTE

On a Mesh network where ATs are deployed, after FWA is enabled in a Mesh profile using the **fwa enable** command, you can complete the Mesh service configuration without the need to bind a Mesh whitelist profile to an AP radio. However, in other Mesh application scenarios, an AP radio must have a Mesh whitelist profile bound, and the Mesh whitelist profile must have MAC addresses configured.

An AP radio can only have one Mesh whitelist profile bound. If you run the command multiple times on the same AP radio, the latest configuration overwrites the old one.

Example

Create the Mesh whitelist profile **whitelist** and add the MAC address **0001-0001-0001** to the whitelist profile. Bind the Mesh whitelist profile **whitelist** to radio **0** of APs in the AP group **group1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-whitelist-profile name whitelist
[HUAWEI-wlan-mesh-whitelist-whitelist] peer-ap mac 0001-0001-0001
[HUAWEI-wlan-mesh-whitelist-whitelist] quit
[HUAWEI-wlan-view] ap-group name group1
[HUAWEI-wlan-ap-group-group1] radio 0
[HUAWEI-wlan-group-radio-group1/0] mesh-whitelist-profile whitelist
```

11.13.25 mpp-active-reselection disable

Function

The **mpp-active-reselection disable** command disables active MPP reselection.

The **undo mpp-active-reselection** command enables active MPP reselection.

By default, active MPP reselection is enabled.

Format

mpp-active-reselection disable

undo mpp-active-reselection

Parameters

None

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After active MPP reselection is enabled on an MP, the MP evaluates MPPs of the same Mesh ID and on the same channel based on the signal strength of Mesh links, the number of link hops, and the number of Mesh links. If a more preferable MPP is available, the MP selects the MPP as its Mesh gateway.

If active MPP reselection is disabled, an MP can only passively reselect MPPs. When the minimum RSSI of all Mesh links on the optimal route to the current MPP is lower than the RSSI threshold of a Mesh link, the MPP reselection process is triggered.

Precautions

This configuration is invalid for the MPP.

In train-to-ground communication scenarios, this configuration takes effect only on vehicle-mounted APs working in client mode but not those working in Mesh handover mode. This is because in Mesh handover mode, vehicle-mounted APs use the link handover algorithm to select the MPP.

Active MPP reselection will cause service loss. Configure the function according to actual needs.

Example

Disable active MPP reselection.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name test
[HUAWEI-wlan-ap-system-prof-test] mpp-active-reselection disable
```

11.13.26 nd trust port (Mesh profile view)

Function

The **nd trust port** command enables an ND trusted port in a Mesh profile.

The **undo nd trust port** command disables an ND trusted port in a Mesh profile.

By default, an ND trusted port is enabled in a Mesh profile.

Format

nd trust port

undo nd trust port

Parameters

None

Views

Mesh profile view

Default Level

2: Configuration level

Usage Guidelines

After an ND trusted port is enabled in a Mesh profile and the Mesh profile is applied to an AP, the AP receives valid ND protocol packets and forwards the packets to STAs or peer APs so that the STAs can obtain valid IPv6 addresses and go online.

Example

Enable an ND trusted port in the Mesh profile **test**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-profile name test
[HUAWEI-wlan-mesh-prof-test] nd trust port
```

11.13.27 peer-ap mac (Mesh whitelist profile view)

Function

The **peer-ap mac** command adds MAC addresses of neighboring APs that are allowed to connect to an AP to a Mesh whitelist profile.

The **undo peer-ap mac** command deletes the MAC addresses of neighboring APs from a Mesh whitelist profile.

By default, no MAC address of a neighboring AP is added to a Mesh whitelist profile.

Format

peer-ap mac *mac-address*

undo peer-ap mac *mac-address*

Parameters

Parameter	Description	Value
mac-address	Specifies the MAC address of a neighboring AP to be added to a Mesh whitelist profile.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.

Views

Mesh whitelist profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a Mesh whitelist profile is created, you can run the **peer-ap mac** command to add neighboring APs' MAC addresses to the profile.

If a Mesh whitelist profile is bound to a Mesh profile, only APs with MAC addresses in the Mesh whitelist profile can access the local AP, and other APs are denied access.

Precautions

A maximum of 64 MAC addresses can be added to a Mesh whitelist.

Example

Create the Mesh whitelist profile **whitelist** and add the MAC address **0001-0001-0001** to the whitelist profile. Bind the Mesh whitelist profile **whitelist** to radio **0** of APs in the AP group **group1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-whitelist-profile name whitelist
[HUAWEI-wlan-mesh-whitelist-whitelist] peer-ap mac 0001-0001-0001
[HUAWEI-wlan-mesh-whitelist-whitelist] quit
[HUAWEI-wlan-view] ap-group name group1
[HUAWEI-wlan-ap-group-group1] radio 0
[HUAWEI-wlan-group-radio-group1/0] mesh-whitelist-profile whitelist
```

11.13.28 priority-map dscp (Mesh profile view)

Function

The **priority-map dscp** command configures the mapping from DSCP priorities to 802.11e user priorities on the Mesh air interface.

The **undo priority-map dscp** command restores the default mapping from DSCP priorities to 802.11e user priorities on the Mesh air interface.

Table 11-271 describes the mapping from DSCP priorities to 802.11e user priorities by default.

Table 11-271 Mapping from DSCP priorities to 802.11e user priorities

DSCP Priority	802.11e User Priority
0-7	0
8-15	1
16-23	2
24-31	3

DSCP Priority	802.11e User Priority
32-39	4
40-47	5
48-55	6
56-63	7

Format

priority-map dscp { *dscp-value1* [**to** *dscp-value2*] } &<1-10> **dot11e** *dot11e-value*

undo priority-map dscp

Parameters

Parameter	Description	Value
dscp *dscp-value1*	Specifies the DSCP priority of 802.3 packets.	The value is an integer that ranges from 0 to 63. A larger value indicates a higher priority.
to *dscp-value2*	Specifies the DSCP priority of 802.3 packets.	The value is an integer that ranges from 0 to 63. A larger value indicates a higher priority.
dot11e *dot11e-value*	Specifies the 802.11e user priority.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.

Views

Mesh profile view

Default Level

2: Configuration level

Usage Guidelines

On a Mesh network, you can run this command to configure the mapping from DSCP priorities of 802.3 packets to 802.11e user priorities on the Mesh air interface of an AP.

Example

Map DSCP priorities 0-6 to 802.11e user priority 0 on the Mesh air interface.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-profile name test
[HUAWEI-wlan-mesh-prof-test] priority-map dscp 0 to 6 dot11e 0
```

11.13.29 priority-map trust (Mesh profile view)

Function

The **priority-map trust** command configures the priority mapping to be trusted by the Mesh air interface.

The **undo priority-map trust** command restores the default priority mapping to be trusted by the Mesh air interface.

By default, the Mesh air interface trusts the mapping from DSCP priorities to 802.11e user priorities.

Format

priority-map trust { **dot1p** | **dscp** }

undo priority-map trust

Parameters

Parameter	Description	Value
dot1p	Indicates that the Mesh air interface trusts the mapping from 802.1p priorities to 802.11e user priorities.	-
dscp	Indicates that the Mesh air interface trusts the mapping from DSCP priorities to 802.11e user priorities.	-

Views

Mesh profile view

Default Level

2: Configuration level

Usage Guidelines

On a Mesh network, when 802.1p or DSCP priorities in data packets need to be mapped to 802.11e user priorities and the packets are transmitted through a Mesh link, run this command.

Example

Configure the Mesh air interface to trust the mapping from 802.1p priorities to 802.11e user priorities.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-profile name test
[HUAWEI-wlan-mesh-prof-test] priority-map trust dot1p
```

11.13.30 security-profile (Mesh profile view)

Function

The **security-profile** command binds a security profile to a Mesh profile.

The **undo security-profile** command restores the default security profile bound to a Mesh profile.

By default, the security profile **default-mesh** is bound to a Mesh profile.

Format

security-profile *profile-name*

undo security-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of the security profile bound to a Mesh profile.	The security profile must exist.

Views

Mesh profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before a Mesh profile is applied to an AP radio to establish Mesh links, the Mesh profile must have a security profile bound to ensure Mesh link security.

Precautions

After a security profile is bound to a Mesh profile, the authentication policy and encryption mode in the security profile cannot be changed, but the authentication key can be changed.

A Mesh profile can only have one security profile bound. If you run the command multiple times in the same Mesh profile view, the latest configuration overwrites the old one.

Example

Create the security profile **sec** and set the security policy to WPA2+PSK+AES. Create the Mesh profile **test** and bind the security profile to the Mesh profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] security-profile name sec
[HUAWEI-wlan-sec-prof-sec] security wpa2 psk pass-phrase YsHsjx_202206 aes
[HUAWEI-wlan-sec-prof-sec] quit
[HUAWEI-wlan-view] mesh-profile name test
[HUAWEI-wlan-mesh-prof-test] security-profile sec
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.13.31 vlan tagged (Mesh profile view)

Function

The **vlan tagged** command adds one or a group of VLANs to a Mesh profile in tagged mode.

The **undo vlan tagged** command deletes VLANs from a Mesh profile.

By default, no VLAN is configured in a Mesh profile.

Format

vlan tagged { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

undo vlan tagged { { *vlan-id1* [**to** *vlan-id2*] } &<1-10> | **all** }

Parameters

Parameter	Description	Value
vlan-id1 [**to** *vlan-id2*]	Specifies the tagged VLAN ID. - *vlan-id1* specifies the first VLAN ID. - **to** *vlan-id2* specifies the last VLAN ID. *vlan-id2* must be larger than *vlan-id1*. *vlan-id1* and *vlan-id2* specify a range of VLANs. If **to** *vlan-id2* is not specified, only the VLAN specified by *vlan-id1* is added to the Mesh profile in tagged mode. You can specify a maximum of 10 VLAN ranges at a time. The entered VLAN ranges cannot overlap.	- The value of *vlan-id1* is an integer that ranges from 1 to 4094. - The value of *vlan-id2* is an integer that ranges from 1 to 4094.
all	Deletes all tagged VLANs from a Mesh profile.	-

Views

Mesh profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a Mesh network, different VAPs may be configured on the MPP and MPs, or VLANs may be dynamically authorized to STAs on the MPs. If the VLAN or VLANs used by an MP are not created on the MPP, STA packets are discarded on the MPP. To address this, you can run the **vlan tagged** command to create VLANs used by the MPs on the MPP to ensure normal forwarding of STA packets.

Precautions

The VLAN or VLANs specified using the **vlan tagged** command take effect only on the MPP.

A maximum of 256 VLANs can be added to a Mesh profile.

Example

Create the Mesh profile **test** and add VLANs 3, 4, 5, 6, 10, and 12 to the Mesh profile in tagged mode.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] mesh-profile name test
[HUAWEI-wlan-mesh-prof-test] vlan tagged 3 to 6 10 12
```

11.13.32 wideband enable

Function

The **wideband enable** command enables the wideband function, that is, the 4.9 GHz frequency band, of the regulatory domain profile.

The **undo wideband enable** command disables the wideband function, that is, the 4.9 GHz frequency band, of the regulatory domain profile.

By default, the wideband function of the regulatory domain profile is disabled.

The 4.9 GHz frequency band is not supported by AirEngine series APs.

NOTE

Before using the 4.9 GHz frequency band, ensure that you have obtained the 4.9 GHz license from the local administrative department and use the band properly.

Format

wideband enable

undo wideband enable

Parameters

None

Views

Regulatory domain profile

Default Level

2: Configuration level

Usage Guidelines

The wideband function enables AP radios on the 5 GHz frequency band to use the 4.9 GHz frequency band. The 4.9 GHz frequency band is applicable only to outdoor backhaul scenarios but not wireless coverage services. It is mainly used by WDS and Mesh backhaul links. The 4.9 GHz frequency band is not within the DFS reselection channel range.

The following table lists channels and frequency distribution of the 4.9 GHz frequency band.

Channel ID	Parameter	Description
184	Frequency band	4.9 GHz

Channel ID	Parameter	Description
	Center frequency (MHz)	4920
	Upper frequency (MHz)	4910
	Lower frequency (MHz)	4930
188	Frequency band	4.9 GHz
	Center frequency (MHz)	4940
	Upper frequency (MHz)	4930
	Lower frequency (MHz)	4950
192	Frequency band	4.9 GHz
	Center frequency (MHz)	4960
	Upper frequency (MHz)	4950
	Lower frequency (MHz)	4970
196	Frequency band	4.9 GHz
	Center frequency (MHz)	4980
	Upper frequency (MHz)	4970
	Lower frequency (MHz)	4990

The 4.9 GHz frequency band supports channel bandwidths of 20 MHz and 40 MHz. Channels 184+188 or 192+196 can be bundled into a 40 MHz channel. Similar to the 5 GHz frequency band, the 4.9 GHz frequency band complies with 802.11a/n/ac.

After the wideband function of the regulatory domain profile is enabled, APs bound to this profile are automatically reset.

Example

Enable the wideband function of the regulatory domain profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] regulatory-domain-profile name test
[HUAWEI-wlan-regulate-domain-test] wideband enable
Warning: To use the 4.9 GHz frequency band, apply for a license from the related department. When this
frequency band takes effect,
the AP will be reset. Continue? [Y/N]y
```

11.14 Vehicle-Ground Fast Link Handover Configuration Commands

11.14.1 Command Support

WLAN-AC commands are supported only by the following models: S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.

11.14.2 antenna-output

Function

The **antenna-output** command configures an output mode of a 2.4G/5G antenna.

The **undo antenna-output** command restores the default output mode of a 2.4G/5G antenna.

By default, a 2.4G/5G antenna uses split output.

Format

antenna-output { **split** | **combine** }

undo antenna-output

Parameters

Parameter	Description	Value
split	Indicates the split mode of a 2.4G/5G antenna.	-
combine	Indicates the combination mode of a 2.4G/5G antenna.	-

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In train-ground communication scenarios, you can use the **antenna-output split** command to configure the split mode of a 2.4G/5G antenna. The antenna uses either the 2.4 GHz radio to provide wireless coverage in the carriage, or the 5 GHz radio to provide wireless bridging between carriages.

In train-ground communication scenarios, you can use the **antenna-output combine** command to configure the combination mode of a 2.4G/5G antenna. The antenna uses the 2.4 GHz and 5 GHz radios to simultaneously provide wireless bridging between carriages.

Precautions

This command is supported only by APs supporting antenna combination and split modes.

Example

Configure the combination mode of a 2.4G/5G antenna.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name apsys1
[HUAWEI-wlan-ap-system-prof-apsys1] antenna-output combine
```

11.14.3 client-mode enable

Function

The **client-mode enable** command enables the Mesh client mode.

The **undo client-mode enable** command disables the Mesh client mode.

By default, the Mesh client mode is disabled.

Format

client-mode enable

undo client-mode enable

Parameters

None

Views

Mesh profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the Mesh client is enabled for vehicle-mounted APs, trackside APs must also have the Mesh client enabled to set up a Mesh link.

Precautions

The Mesh handover mode and Mesh client mode are mutually exclusive in a Mesh profile.

A vehicle-ground communication scenario supports either the Mesh handover mode or the Mesh client mode, but not both. Ensure that the same Mesh mode (handover or client) is configured on vehicle-mounted APs and trackside APs. Otherwise, Mesh links may fail to be set up for vehicle-ground communication, or services are affected even if Mesh links can be set up.

Radios of a trackside AP cannot have both the Mesh handover and client modes configured. For example, if radio 1 and radio 2 of a trackside AP have the Mesh handover mode and Mesh client mode configured, respectively, the AP will fail to set up a Mesh link with a vehicle-mounted AP.

Example

Enable the Mesh client mode for Mesh profile **test**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-profile name test
[HUAWEI-wlan-mesh-prof-test] client-mode enable
```

11.14.4 display mesh-handover-profile

Function

The **display mesh-handover-profile** command displays reference or configuration information about a Mesh handover profile.

Format

display mesh-handover-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays reference information about all Mesh handover profiles.	-
name *profile-name*	Displays information about a specified Mesh handover profile.	The Mesh handover profile must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display mesh-handover-profile** command to view the number of times a Mesh handover profile is referenced by a Mesh profile or parameter settings of a specified Mesh handover profile.

Example

Display reference information about all Mesh handover profiles.

```
<HUAWEI> display mesh-handover-profile all
--------------------------------------------------------------------------------
Profile name                          Reference
--------------------------------------------------------------------------------
default                              0
test                                 2
--------------------------------------------------------------------------------
Total: 2
```

Table 11-272 Description of the **display mesh-handover-profile all** command output

Item	Description
Profile name	Name of a Mesh handover profile. To configure this parameter, run the **mesh-handover-profile** command.
Reference	Number of times a Mesh handover profile is referenced by a Mesh profile.

Display information about the Mesh handover profile **test**.

```
<HUAWEI> display mesh-handover-profile name test
--------------------------------------------------------------------------------
Handover location based algorithm switch            : disable
Handover probe interval(ms)                         : 100
Doppler optimize switch                             : enable
Doppler optimize level                              : low
Hal half-band switch                                : enable
--------------------------------------------------------------------------------
```

Table 11-273 Description of the **display mesh-handover-profile name** command output

Item	Description
Handover location based algorithm switch	Status of the location-based enhanced fast link handover algorithm. ● disable: The algorithm is disabled. ● enable: The algorithm is enabled. To configure this parameter, run the **location-based-algorithm enable** command.
Handover probe interval	Mesh link probe interval. To configure this parameter, run the **link-probe-interval** command.
Doppler optimize switch	Whether Doppler optimization is enabled in a Mesh handover scenario. ● disable: This function is disabled. ● enable: This function is enabled. To configure this parameter, run the **doppler-optimize disable** command.
Doppler optimize level	Doppler optimization mode in a Mesh handover scenario. To configure this parameter, run the **doppler-optimize level** command.
Hal half-band switch	Whether the half-band function is enabled on AP radios in Mesh handover scenarios. ● disable: This function is disabled. ● enable: This function is enabled. To configure this parameter, run the **hal half-band disable** command.

11.14.5 display mesh-neighbor-rssi

Function

The **display mesh-neighbor-rssi** command displays RSSI information collected by an AP.

Format

display mesh-neighbor-rssi [**ap-name** *ap-name* **radio** *radio-id* | **ap-id** *ap-id* **radio** *radio-id*] [**max-neighbor-number** *max-number*]

Parameters

Parameter	Description	Value
ap-name *ap-name*	Displays RSSI information collected by the AP with a specified name. If this parameter is not specified, RSSI information collected by all APs is displayed.	The AP name must exist.
ap-id *ap-id*	Displays RSSI information collected by the AP with a specified ID. If this parameter is not specified, RSSI information collected by all APs is displayed.	The AP ID must exist.
radio *radio-id*	Displays RSSI information collected by a specified radio.	The radio ID must exist.
max-neighbor-number *max-number*	Specifies the maximum number of neighboring APs of which RSSI information collected by the AP can be displayed. If this parameter is not specified, RSSI information about all neighboring APs collected by the AP is displayed.	The value is an integer that ranges from 1 to 256.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command applies only to APs on a Mesh network. A local AP can collect RSSI information of a neighboring AP only when the neighboring AP and local AP are added to Mesh whitelists of each other.

Example

Display RSSI information collected by all APs.

```
<HUAWEI> display mesh-neighbor-rssi
Info: This operation may take a few seconds, please wait.done.
AP name/MAC/Radio/Location-ID  Neighbor AP/MAC/Location-ID  RSSI  Update Time
--------------------------------------------------------------------------------
area_1/00e0-fc12-3456/0/1      -/00e0-fc12-3457/-           -43   20:55:16
--------------------------------------------------------------------------------
Total: 1
```

Table 11-274 Description of the **display mesh-neighbor-rssi** command output

Item	Description
AP name/MAC/Radio/Location-ID	Name, MAC address, radio ID, and location ID of the local AP. **NOTE** If APs are named based on their locations, this field displays as AP name/MAC/Radio/Location-ID; otherwise, this field displays as hyphen (-).
Neighbor AP/MAC/Location-ID	Name, MAC address, and location ID of a neighboring AP. **NOTE** If APs are named based on their locations, this field displays as AP name/MAC/Radio/Location-ID; otherwise, this field displays as hyphen (-).
RSSI	RSSI of a neighboring AP.
Update Time	Time when RSSI information is collected.

11.14.6 display references mesh-handover-profile

Function

The **display references mesh-handover-profile** command displays information about Mesh profiles by which a specified Mesh handover profile is referenced.

Format

display references mesh-handover-profile name *profile-name*

Parameters

Parameter	Description	Value
name *profile-name*	Displays information about the Mesh profiles by which a specified Mesh handover profile is referenced.	The Mesh handover profile must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display references mesh-handover-profile** command to check the Mesh profiles by which a Mesh handover profile is referenced.

Example

Display information about Mesh profiles by which the Mesh handover profile **test** is referenced.

```
<HUAWEI> display references mesh-handover-profile name test
--------------------------------------------------------------------------------
Reference type                 Reference name
--------------------------------------------------------------------------------
Mesh profile                   profile-1
Mesh profile                   profile-2
--------------------------------------------------------------------------------
Total: 2
```

Table 11-275 Description of the **display references mesh-handover-profile** command output

Item	Description
Reference type	Type of the profile by which a Mesh handover profile is referenced. A Mesh handover profile can only be referenced by a Mesh profile.
Reference name	Name of the profile by which a Mesh handover profile is referenced. To configure this parameter, run the **mesh-handover-profile (Mesh profile view)** command in the Mesh profile view.

11.14.7 doppler-optimize disable

Function

The **doppler-optimize disable** command disables the Doppler optimization function in a Mesh handover scenario.

The **undo doppler-optimize disable** command enables the Doppler optimization function in a Mesh handover scenario.

By default, the Doppler optimization function is enabled in a Mesh handover scenario.

Format

doppler-optimize disable

undo doppler-optimize disable

Parameters

None

Views

Mesh handover profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The Doppler optimization function reduces the impact of the Doppler effect on radio signals in vehicle-ground communication scenarios, thereby improving air interface performance.

Precautions

In Mesh vehicle-ground communication scenarios, it is recommended that the Doppler optimization function be disabled when vehicles are stationary to prevent impact on air interface performance.

Example

Disable the Doppler optimization function in a Mesh handover scenario.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-handover-profile name test
[HUAWEI-wlan-mesh-handover-test] doppler-optimize disable
```

11.14.8 doppler-optimize level

Function

The **doppler-optimize level** command configures the Doppler optimization mode in a Mesh handover scenario.

The **undo doppler-optimize level** command restores the default Doppler optimization mode in a Mesh handover scenario.

The default Doppler optimization mode is low in a Mesh handover scenario.

Format

doppler-optimize level { **low** | **medium** }

undo doppler-optimize level

Parameters

Parameter	Description	Value
low	Sets the Doppler optimization mode to low. This configuration is recommended when the average vehicle speed is less than or equal to 80 km/h.	-
medium	Sets the Doppler optimization mode to medium. This configuration is recommended when the average vehicle speed is greater than 80 km/h.	-

Views

Mesh handover profile view

Default Level

2: Configuration level

Usage Guidelines

The Doppler optimization function reduces the impact of the Doppler effect on radio signals in vehicle-ground communication scenarios, thereby improving air interface performance.

In practice, the Doppler optimization mode needs to be adjusted based on the main speed range of vehicles.

Example

Set the Doppler optimization mode to medium.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-handover-profile name test
[HUAWEI-wlan-mesh-handover-test] doppler-optimize level medium
```

11.14.9 hal half-band disable

Function

The **hal half-band disable** command disables the half-band function on AP radios.

The **undo hal half-band disable** command enables the half-band function on AP radios.

By default, the half-band function is enabled on AP radios.

Format

hal half-band disable

undo hal half-band disable

Parameters

None

Views

Mesh handover profile view

Default Level

2: Configuration level

Usage Guidelines

In vehicle-ground communication Mesh handover scenarios, some RF ports on an AP may have no antennas installed. In this case, information on these ports will be lost when information is transmitted based on the half-band algorithm, deteriorating performance. To address this issue, you can run this command to disable the half-band function.

Example

Disable the half-band function on AP radios.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-handover-profile name test
[HUAWEI-wlan-mesh-handover-test] hal half-band disable
```

11.14.10 location-based-algorithm enable

Function

The **location-based-algorithm enable** command enables the location-based enhanced link handover algorithm.

The **undo location-based-algorithm enable** command disables the location-based enhanced link handover algorithm.

By default, the location-based enhanced link handover algorithm is disabled.

Format

location-based-algorithm enable

undo location-based-algorithm enable

Parameters

None

Views

Mesh handover profile view

Default Level

2: Configuration level

Usage Guidelines

After the location-based enhanced link handover algorithm is enabled, the vehicle-mounted AP will switch the active link to the nearest trackside AP that meets handover requirements.

In vehicle-ground communication scenarios, signals of a trackside AP distant from a train may be temporarily better than the trackside AP near the train due to radio environment changes. If an active link handover occurs at this time, the active link may be incorrectly switched to the distant trackside AP. To prevent incorrect handovers and improve vehicle-ground communication quality, you can use the location-based enhanced link handover algorithm. This algorithm requires that trackside APs be named in ascending or descending order of sequence numbers.

Trackside APs should be named in *head-name_sequence-number* format. *head-name* describes track line information and can be different for trackside APs on the same track. It is recommended that you set the same *head-name* for APs on a track to differentiate tracks. *sequence-number* of APs along a track must be in descending or ascending order. The sequence numbers of trackside APs can be set with unequal steps. *head-name* and *sequence-number* are separated using an underscore (_), for example, L1_001, L1_002, L1_005, L1_010.

Example

Enable the location-based enhanced link handover algorithm.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-handover-profile name test
[HUAWEI-wlan-mesh-handover-test] location-based-algorithm enable
```

11.14.11 link-probe-interval

Function

The **link-probe-interval** command sets a Mesh link probe interval in a Mesh handover profile.

The **undo link-probe-interval** command restores the default Mesh link probe interval in a Mesh handover profile.

By default, the Mesh link probe interval is 100 ms in a Mesh handover profile.

Format

link-probe-interval *value*

undo link-probe-interval

Parameters

Parameter	Description	Value
value	Specifies the interval for detecting Mesh links.	The value is an integer that ranges from 50 to 6000, in milliseconds. The default value is 100.

Views

Mesh handover profile view

Default Level

2: Configuration level

Usage Guidelines

In vehicle-ground communication scenarios, a trackside AP periodically sends unicast probe frames to detect RSSIs of Mesh links and executes the handover algorithm based on the detection result. A larger interval delays link handover, interrupting vehicle-ground communications. A smaller interval increases air port costs and burden. Therefore, you need to configure a proper interval for detecting Mesh links according to train operating conditions.

Precautions

You are advised to set the same Mesh link probe interval for vehicle-mounted APs and trackside APs.

Example

Set the Mesh link probe interval to 150 ms in the Mesh handover profile **test**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-handover-profile name test
[HUAWEI-wlan-mesh-handover-test] link-probe-interval 150
```

11.14.12 mesh-handover-profile

Function

The **mesh-handover-profile** command creates a Mesh handover profile or displays the Mesh handover profile view.

The **undo mesh-handover-profile** command deletes a Mesh handover profile.

By default, the system provides the Mesh handover profile **default**.

Format

mesh-handover-profile name *profile-name*

undo mesh-handover-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a Mesh handover profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all Mesh handover profiles. **NOTE** The Mesh handover profile **default** cannot be deleted.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

After a Mesh handover profile is bound to a Mesh profile, the Mesh profile can provide the vehicle-ground fast link handover function and apply to vehicle-ground communication scenarios.

Example

Create the Mesh handover profile **handover** and bind it to the Mesh profile **test**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-handover-profile name handover
[HUAWEI-wlan-mesh-handover-handover] quit
[HUAWEI-wlan-view] mesh-profile name test
[HUAWEI-wlan-mesh-prof-test] mesh-handover-profile handover
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.14.13 mesh-handover-profile (Mesh profile view)

Function

The **mesh-handover-profile** command binds a Mesh handover profile to a Mesh profile.

The **undo mesh-handover-profile** command unbinds a Mesh handover profile from a Mesh profile.

By default, no Mesh handover profile is bound to a Mesh profile.

Format

mesh-handover-profile *profile-name*

undo mesh-handover-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of the Mesh handover profile bound to a Mesh profile.	The Mesh handover profile must exist.

Views

Mesh profile view

Default Level

2: Configuration level

Usage Guidelines

You can run the **mesh-handover-profile** command to bind a Mesh handover profile to a Mesh profile so that the Mesh profile can provide the vehicle-ground fast link handover function and apply to vehicle-ground communication scenarios.

Example

Create the Mesh handover profile **handover** and bind it to the Mesh profile **test**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] mesh-handover-profile name handover
[HUAWEI-wlan-mesh-handover-handover] quit
[HUAWEI-wlan-view] mesh-profile name test
[HUAWEI-wlan-mesh-prof-test] mesh-handover-profile handover
Warning: This action may cause service interruption. Continue?[Y/N]y
```

11.15 Hotspot 2.0 Configuration Commands

NOTE

Hotspot 2.0 is not supported by the following APs.

- AirEngine 9700D-S (including matching ORUs)
- AirEngine X77X
- AirEngine X76X

11.15.1 Command Support

WLAN-AC commands are supported only by the following models: S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.

11.15.2 cellular-network-profile

Function

The **cellular-network-profile** command creates a cellular network profile or displays the view of an existing cellular network profile.

The **undo cellular-network-profile** command deletes a cellular network profile.

By default, no cellular network profile exists in the system.

Format

cellular-network-profile name *profile-name*

undo cellular-network-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a cellular network profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Delete all cellular network profiles.	-

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can configure Hotspot 2.0 services on cellular networks. When connecting to the networks, user terminals can obtain network information from APs, which helps them to select desired networks.

Follow-up Procedure

Run the **plmn-id** command to configure the PLMN identifier and run the **cellular-network-profile (Hotspot2.0 profile view)** command to bind the cellular network profile to a Hotspot2.0 profile to make the cellular network profile take effect.

Example

Create the cellular network profile **cellular-network-profile1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] cellular-network-profile name cellular-network-profile1
[HUAWEI-wlan-cellular-net-cellular-network-profile1]
```

11.15.3 cellular-network-profile (Hotspot2.0 profile view)

Function

The **cellular-network-profile** command binds a cellular network profile to a Hotspot2.0 profile.

The **undo cellular-network-profile** command unbinds a cellular network profile from a Hotspot2.0 profile.

By default, no cellular network profile is bound to a Hotspot2.0 profile.

Format

cellular-network-profile *profile-name*

undo cellular-network-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a cellular network profile.	The cellular network profile must exist.

Views

Hotspot2.0 profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can configure Hotspot 2.0 services on a cellular network. When connecting to the network, user terminals need to obtain the cellular network identifier (3GPP Cellular PLMN) from APs to select desired networks. You can run the **cellular-network-profile** command to create a cellular network profile and the **plmn-id** command to configure the Public Land Mobile Network (PLMN) identifier of the network operator, and then bind the cellular network profile to a Hotspot 2.0 profile to make the configuration take effect.

Example

Bind cellular network profile **cellular-network-profile1** to the Hotspot 2.0 profile **hotspot**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] hotspot2-profile name hotspot
[HUAWEI-wlan-hotspot2-prof-hotspot] cellular-network-profile cellular-network-profile1
```

11.15.4 connection-capability-profile

Function

The **connection-capability-profile** command creates a connection capability profile or displays the view of an existing connection capability profile.

The **undo connection-capability-profile** command deletes a connection capability profile.

By default, no connection capability profile exists in the system.

Format

connection-capability-profile name *profile-name*

undo connection-capability-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a connection capability profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all connection capability profiles.	-

2: Configuration level

Usage Guidelines

Usage Scenario

You can configure Hotspot2.0 services for networks. When user terminals connect to the networks, they can obtain network connection capability information from APs, including allowed protocols and ports, which helps them to select desired networks. You can run the **connection-capability-profile** command to create a connection capability profile and run the **connection-capability** command to set whether networks support specific IP protocols and ports. After that, you bind the connection capability profile to a Hotspot2.0 profile.

Example

Bind the connection capability profile **connection-capability-profile1** to the Hotspot2.0 profile **hotspot**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] hotspot2-profile name hotspot
[HUAWEI-wlan-hotspot2-prof-hotspot] connection-capability-profile connection-capability-profile1
```

11.15.6 connection-capability

Function

The **connection-capability** command sets whether Hotspot2.0 networks support common IP protocols and ports.

The **undo connection-capability** command restores the default setting.

By default, no supported protocol is specified in a connection capability profile.

Format

connection-capability { **esp** | **icmp** | **tcp-ftp** | **tcp-http** | **tcp-pptp-vpn** | **tcp-ssh** | **tcp-tls-vpn** | **tcp-voip** | **udp-ike2-4500** | **udp-ike2-500** | **udp-voip** } { **on** | **off** }

undo connection-capability { **esp** | **icmp** | **tcp-ftp** | **tcp-http** | **tcp-pptp-vpn** | **tcp-ssh** | **tcp-tls-vpn** | **tcp-voip** | **udp-ike2-4500** | **udp-ike2-500** | **udp-voip** }

Parameters

Parameter	Description	Value
esp	Sets the supported protocol to ESP and port number to 0.	-
icmp	Sets the supported protocol to ICMP and port number to 0.	-
tcp-ftp	Sets the supported protocol to FTP and port number to 20. FTP is not a secure protocol, and it is not recommended.	-

Parameter	Description	Value
tcp-http	Sets the supported protocol to HTTP and port number to 80. HTTP is not a secure protocol, and it is not recommended.	-
tcp-pptp-vpn	Sets the protocol for VPN services to PPTP and port number to 1723.	-
tcp-ssh	Sets the supported protocol to SSH.	-
tcp-tls-vpn	Sets the supported protocol to the TLS VPN protocol and port number to 443.	-
tcp-voip	Sets the supported protocol to the TCP VoIP protocol and port number to 5060.	-
udp-ike2-4500	Sets the supported protocol to the IKEv2 protocol and port number to 4500.	-
udp-ike2-500	Sets the supported protocol to the IKEv2 protocol and port number to 500.	-
udp-voip	Sets the supported protocol to the UDP VoIP protocol and port number to 5060.	-
on	Supports specified IP protocols and ports.	-
off	Indicates that specified IP protocols and ports are not supported.	-

Table 11-281 Description of the **display hotspot2-profile name** *profile-name* command output

Item	Description
Network type	Type of a Hotspot 2.0 network. To configure this parameter, run the **network-authen-type** command.
Internet access	Whether a Hotspot 2.0 network supports Internet access. To configure this parameter, run the **network-authen-type** command.

Item	Description
Venue group code	Venue group code of a Hotspot 2.0 network. To configure this parameter, run the **venue-type** command.
Venue type code	Venue type code of a Hotspot 2.0 network. To configure this parameter, run the **venue-type** command.
HESSID	HESSID of a Hotspot 2.0 network. To configure this parameter, run the **hessid** command.
IPv4 address availability	Types of IPv4 addresses on a Hotspot 2.0 network. To configure this parameter, run the **ipv4-address-avail** command.
IPv6 address availability	Types of IPv6 addresses on a Hotspot 2.0 network. To configure this parameter, run the **ipv6-address-avail** command.
Network authentication type	Hotspot 2.0 network authentication type. To configure this parameter, run the **network-authen-type** command.
Redirect URL	Redirection URL if the Hotspot 2.0 network authentication type is set to Portal authentication. To configure this parameter, run the **network-authen-type** command.
P2P information element	Whether a Hotspot 2.0 network allows for cross connections between P2P devices. To configure this parameter, run the **p2p-cross-connect disable** command.
cellular-network-profile	Cellular network profile bound to a Hotspot 2.0 profile. To configure this parameter, run the **cellular-network-profile (Hotspot 2.0 profile view)** command.

Item	Description
connection-capability-profile	Connection capability profile bound to a Hotspot 2.0 profile. To configure this parameter, run the **connection-capability-profile (Hotspot 2.0 profile view)** command.
operator-name-profile	Operator name profile bound to a Hotspot 2.0 profile. To configure this parameter, run the **operator-name-profile (Hotspot 2.0 profile view)** command.
operating-class-profile	Operating class profile bound to a Hotspot 2.0 profile. To configure this parameter, run the **operating-class-profile (Hotspot 2.0 profile view)** command.
operator-domain-profile	Operator domain profile bound to a Hotspot 2.0 profile. To configure this parameter, run the **operator-domain-profile (Hotspot 2.0 profile view)** command.
NAI-realm-profile	NAI realm profile bound to a Hotspot 2.0 profile. To configure this parameter, run the **nai-realm-profile (Hotspot 2.0 profile view)** command.
venue-name-profile	Venue name profile bound to a Hotspot 2.0 profile. To configure this parameter, run the **venue-name-profile (Hotspot 2.0 profile view)** command.
roaming-consortium-profile	Roaming consortium profile bound to a Hotspot 2.0 profile. To configure this parameter, run the **roaming-consortium-profile (Hotspot 2.0 profile view)** command.

11.15.10 display nai-realm-profile

Function

The **display nai-realm-profile** command displays the configuration of a NAI realm profile.

Format

display nai-realm-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays all NAI realm profiles.	-
name *profile-name*	Displays the configuration of a specified NAI realm profile.	The NAI realm profile must exist.

Usage Guidelines

You can run the command to view the configuration of NAI realm profiles.

Example

Display the configuration of all NAI realm profiles.

```
<HUAWEI> display nai-realm-profile all
------------------------------------------------------------
Profile name        Reference
------------------------------------------------------------
nai-realm-profile1  1
------------------------------------------------------------
Total: 1
```

Table 11-282 Description of the **display nai-realm-profile all** command output

Item	Description
Profile name	Name of a NAI realm profile.
Reference	Number of times a NAI realm profile is referenced.

Display the configuration of the NAI realm profile **nai-realm-profile1**.

```
<HUAWEI> display nai-realm-profile name nai-realm-profile1
--------------------------------------------------------------------------------
Index              Method                  ID/Parameter           Realm-name
--------------------------------------------------------------------------------
0                  All                     -/-                    attwireless.com
--------------------------------------------------------------------------------
```

Table 11-283 Description of the **display nai-realm-profile name** *profile-name* command output

Item	Description
Index	Index of a NAI realm member.
Method	Extensible Authentication Protocol (EAP) authentication method of a NAI realm. To configure this parameter, run the **nai-realm** command.
ID/Parameter	EAP authentication ID and parameters of a NAI realm. To configure this parameter, run the **nai-realm** command.
Realm-name	Name of a NAI realm. To configure this parameter, run the **nai-realm** command.

11.15.11 display operating-class-profile

Function

The **display operating-class-profile** command displays the configuration of an operating class profile.

Format

display operating-class-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
all	Displays the configuration of all operating class profiles.	-
name *profile-name*	Displays the configuration of a specified operating class profile.	The operating class profile must exist.

11.15.25 domain-name

Function

The **domain-name** command configures a domain name for a hotspot operator.

The **undo domain-name** command deletes the domain name of a hotspot operator.

By default, no domain name is configured for a hotspot operator.

Format

domain-name *domain-name*

undo domain-name *domain-name*

Parameters

Parameter	Description	Value
domain-name	Specifies the domain name of a hotspot operator.	The value is a string of 1 to 63 characters in compliance with RFC1035. It does not contain question marks (?) or spaces, and cannot begin or end with double quotation marks (" ").

Views

Operator domain profile view

Default Level

2: Configuration level

Usage Guidelines

After a domain name is configured for a hotspot operator, terminals can query the domain name through ANQP to select desired networks.

Example

Configure domain name **attwireless.com** for a hotspot operator.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] operator-domain-profile name operator-domain-profile1
[HUAWEI-wlan-op-domain-prof-operator-domain-profile1] domain-name attwireless.com
```

11.15.26 hessid

Function

The **hessid** command configures a Homogenous Extended Service Set Identifier (HESSID) for a Hotspot2.0 network.

The **undo hessid** command deletes an HESSID.

By default, no HESSID is configured.

Format

hessid *mac-address*

undo hessid

Parameters

Parameter	Description	Value
mac-address	Specifies an HESSID.	The value is in H-H-H format. An H is a hexadecimal number of 4 digits.

2: Configuration level

Usage Guidelines

Usage Scenario

When multiple Hotspot2.0 networks are available, user terminals need to identify service providers of the connected networks. An SSID is not as unique as an HESSID, which can uniquely identify APs of the same service provider. Among the APs, the BSSID of one AP is used as the HESSID. The HESSID is an optional parameter in a Hotspot2.0 profile. Beacon and Probe Response frames sent from Hotspot2.0-capable APs carry network parameter information, which helps user terminals to determine whether network parameters need to be renewed.

Precautions

If the HESSID is configured repeatedly, only the latest HESSID takes effect.

Example

Set the HESSID to **00e0-fc12-3456** in Hotspot2.0 profile **hotspot**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] hotspot2-profile name hotspot
[HUAWEI-wlan-hotspot2-prof-hotspot] hessid 00e0-fc12-3456
```

11.15.27 hotspot2-profile

Function

The **hotspot2-profile** command creates a Hotspot2.0 profile or displays the view of an existing Hotspot2.0 profile.

The **undo hotspot2-profile** command deletes a Hotspot2.0 profile.

By default, no Hotspot2.0 profile is available.

Format

hotspot2-profile name *profile-name*

undo hotspot2-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a Hotspot2.0 profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all Hotspot2.0 profiles.	-

Views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure Hotspot2.0 services, create a Hotspot2.0 profile, configure network parameters in the Hotspot2.0 profile view, and bind the Hotspot2.0 profile to a VAP profile.

Follow-up Procedure

Configure the network type, roaming consortium list, and NAI realm list in the Hotspot2.0 profile and bind the Hotspot2.0 profile to a VAP profile to make the configuration take effect.

Precautions

- In a Hotspot2.0 profile, network parameters and Internet access status are mandatory and can be configured using the **network-type** command.
- Ensure that at least one of the following ANQP parameters is configured in a Hotspot2.0 profile.
  - Roaming consortium list: Run the **roaming-consortium-profile (Hotspot2.0 profile view)** command to bind a roaming consortium profile to the Hotspot2.0 profile.
  - NAI realm list: Run the **nai-realm-profile (Hotspot2.0 profile view)** command to bind a NAI realm profile to the Hotspot2.0 profile.
  - 3GPP cellular network: Run the **cellular-network-profile (Hotspot2.0 profile view)** command to bind a cellular network profile to the Hotspot2.0 profile.
- The following ANQP parameters are recommended.
  - Roaming consortium list: Run the **roaming-consortium-profile (Hotspot2.0 profile view)** command to bind a roaming consortium profile to the Hotspot2.0 profile.
  - Domain name list: Run the **operator-domain-profile (Hotspot2.0 profile view)** command to bind an operator domain profile to the Hotspot2.0 profile.

Example

Create Hotspot2.0 profile **hotspot**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] hotspot2-profile name hotspot
[HUAWEI-wlan-hotspot2-prof-hotspot]
```

11.15.28 hotspot2-profile (VAP profile view)

Function

The **hotspot2-profile** command binds a Hotspot 2.0 profile to a VAP profile.

The **undo hotspot2-profile** command unbinds a Hotspot 2.0 profile from a VAP profile.

By default, no Hotspot 2.0 profile is bound to a VAP profile.

Format

hotspot2-profile *profile-name*

undo hotspot2-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a Hotspot 2.0 profile.	The Hotspot 2.0 profile must exist.

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can configure network parameters through Hotspot 2.0 profiles. After Hotspot 2.0 profiles are applied, STAs can obtain network information from APs and access the networks. After a Hotspot 2.0 profile is configured, bind it to a VAP profile to make the configuration take effect.

Precautions

The Hotspot 2.0 service configuration requires the authentication mode of WPA2-802.1X. Ensure that the security profile bound to the VAP profile meets this requirement.

When you perform the following operations on a VAP bound to a radio, services are interrupted:

- Bind a Hotspot 2.0 profile to the VAP profile.
- Unbind a Hotspot 2.0 profile from the VAP profile.
- Modify the parameters in a Hotspot 2.0 profile bound to the VAP profile.

Therefore, exercise caution when performing these operations.

Example

Bind the Hotspot 2.0 profile **hotspot** to the VAP profile **vap-profile1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap-profile1
[HUAWEI-wlan-vap-prof-vap-profile1] hotspot2-profile hotspot
```

11.15.29 ipv4-address-avail

Function

The **ipv4-address-avail** command configures available types of IPv4 addresses on a Hotspot2.0 network.

The **undo ipv4-address-avail** command deletes available types of IPv4 addresses on a Hotspot2.0 network.

By default, no available type of IPv4 addresses is configured.

Format

ipv4-address-avail { **not-available** | **available** | **port-restricted** [**single-nat** | **double-nat**] | **private** { **single-nat** | **double-nat** } | **unknown** }

undo ipv4-address-avail

Parameters

Parameter	Description	Value
not-available	Indicates that IPv4 addresses are not available.	-
available	Indicates that IPv4 addresses are available.	-
port-restricted [**single-nat** | **double-nat**]	Indicates port restricted IPv4 addresses are available. ● **single-nat**: Single-NATed and port-restricted IPv4 addresses are available. ● **single-nat**: Double-NATed and port-restricted IPv4 addresses are available.	-
private { **single-nat** | **double-nat** }	Indicates that private IPv4 addresses are available. ● **single-nat**: Single-NATed private IPv4 addresses are available. ● **double-nat**: Double-NATed private IPv4 addresses are available.	-
unknown	Indicates that availability of the IPv4 address type is not known.	-

Views

Hotspot2.0 profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When user terminals connect to a Hotspot2.0 network, Hotspot2.0 can transfer available IPv4 address types as ANQP parameters to the user terminals through

APs. In this way, the user terminals can know the IP address types they can obtain after connecting to the network.

Example

Set IPv4 addresses to **available** in hotspot2.0 profile **hotspot**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] hotspot2-profile name hotspot
[HUAWEI-wlan-hotspot2-prof-hotspot] ipv4-address-avail available
```

11.15.30 ipv6-address-avail

Function

The **ipv6-address-avail** command configures available types of IPv6 addresses on a Hotspot 2.0 network.

The **undo ipv6-address-avail** command deletes available types of IPv6 addresses on a Hotspot 2.0 network.

By default, no available type of IPv6 addresses is configured.

Format

ipv6-address-avail { **not-available** | **available** | **unknown** }

undo ipv6-address-avail

Parameters

Parameter	Description	Value
not-available	Indicates that IPv6 addresses are not available.	-
available	Indicates that IPv6 addresses are available.	-
unknown	Indicates that the availability of IPv6 address types is not known.	-

Views

Hotspot 2.0 profile view

2: Configuration level

Usage Guidelines

Usage Scenario

When STAs connect to a Hotspot 2.0 network, Hotspot 2.0 can transfer available IPv6 address types as ANQP parameters to the STAs through APs. In this way, the STAs can know the IPv6 address types they can obtain after connecting to the network.

Example

Configure IPv6 addresses to be available in the Hotspot 2.0 profile **hotspot**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] hotspot2-profile name hotspot
[HUAWEI-wlan-hotspot2-prof-hotspot] ipv6-address-avail available
```

11.15.31 nai-realm-profile

Function

The **nai-realm-profile** command creates a NAI realm profile or displays the view of an existing NAI realm profile.

The **undo nai-realm-profile** command deletes a NAI realm profile.

By default, no NAI realm profile is available in the system.

Format

nai-realm-profile name *profile-name*

undo nai-realm-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a NAI realm profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all NAI realm profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A NAI realm profile is used to configure the network access identifier (NAI) realm name, authentication mode, and authentication parameters for networks accessible to users.

Example

Create NAI realm profile **nai-realm-profile1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] nai-realm-profile name nai-realm-profile1
[HUAWEI-wlan-nai-realm-prof-nai-realm-profile1]
```

11.15.32 nai-realm-profile (Hotspot2.0 profile view)

Function

The **nai-realm-profile** command binds a NAI realm profile to a Hotspot2.0 profile.

The **undo nai-realm-profile** command unbinds a NAI realm profile from a Hotspot2.0 profile.

By default, no NAI realm profile is bound to a Hotspot2.0 profile.

Format

nai-realm-profile *profile-name*

undo nai-realm-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a NAI realm profile.	The NAI realm profile must exist.

Views

Hotspot2.0 profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can configure Hotspot2.0 services on a non-cellular network. When connecting to the non-cellular network, user terminals can obtain service provider information of the network, including the NAI realm name and authentication mode. This facilitates terminal access. You can run the **nai-realm-profile** command to create a NAI realm profile and the **nai-realm** command in the NAI realm profile view to configure NAI realms, and then bind the NAI realm profile to a Hotspot2.0 profile to make the configuration take effect.

Example

Bind NAI realm profile **nai-realm-profile1** to Hotspot2.0 profile **hotspot**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] hotspot2-profile name hotspot
[HUAWEI-wlan-hotspot2-prof-hotspot] nai-realm-profile nai-realm-profile1
```

11.15.33 nai-realm

Function

The **nai-realm** command configures a network access identifier (NAI) realm.

The **undo nai-realm** command deletes a NAI realm.

By default, no NAI realm is configured.

Format

nai-realm realm-name *realm-name* [**eap-method-type** *eap-method-type* [**eap-authen-id** *eap-authen-id* **eap-authen-para** *eap-authen-para*]]

undo nai-realm realm-name *realm-name* [**eap-method-type** *eap-method-type* [**eap-authen-id** *eap-authen-id*]]

Parameters

Parameter	Description	Value
realm-name *realm-name*	Specifies a NAI realm name.	The value is a string of 1 to 63 characters. It does not contain question marks (?) or spaces, and cannot begin or end with double quotation marks (" ").

Parameter	Description	Value
eap-method-type *eap-method-type*	Specifies an EAP authentication mode for a NAI realm.	Enumerated value: - eap-aka: EAP-AKA authentication - eap-sim: GSM Subscriber Identity Modules - eap-tls: EAP-TLS - eap-ttls: EAP-TTLS
eap-authen-id *eap-authen-id*	Specifies an EAP authentication ID for a NAI realm.	The value is an integer that ranges from 0 to 255.
eap-authen-para *eap-authen-para*	Specifies the EAP authentication parameter of a NAI realm.	The value is an integer that ranges from 0 to 255.

Views

NAI realm profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you configure a NAI realm, terminals can access the configured operator network.

Precautions

- If you configure the same name for NAI realms, the NAI realm with fuzzy command configuration will overwrite the NAI realm with exact command configuration.

  For example, the **nai-realm realm-name attwireless.com** command configuration will overwrite the **nai-realm realm-name attwireless.com eap-method-type eap-aka** command configuration, and the **nai-realm realm-name attwireless.com eap-method-type eap-aka** command configuration will overwrite the **nai-realm realm-name attwireless.com eap-method-type eap-aka eap-authen-id 1 eap-authen-para 1** command configuration.
- NAI realms are deleted according to the longest matching rule.

For example, the NAI realm configured using the **nai-realm realm-name attwireless.com** command cannot be deleted using the **undo nai-realm realm-name attwireless.com eap-method-type eap-aka** command.

Example

Configure NAI realm **attwireless.com**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] nai-realm-profile name nai-realm-profile1
[HUAWEI-wlan-nai-realm-prof-nai-realm-profile1] nai-realm realm-name attwireless.com
```

11.15.34 network-authen-type

Function

The **network-authen-type** command sets a network authentication type for a Hotspot2.0 profile.

The **undo network-authen-type** command deletes a network authentication type.

By default, no network authentication type is configured.

Format

network-authen-type { **acceptance** [**redirect-url** *url*] | **dns-redirection** | **http-https-redirection redirect-url** *url* | **online-enroll** }

undo network-authen-type

Parameters

Parameter	Description	Value
acceptance	Indicates acceptance of terms and conditions.	-
redirect-url *url*	Specifies the redirected URL address.	-
dns-redirection	Indicates DNS redirection.	-
http-https-redirection	Indicates HTTP and HTTPS redirection.	-
online-enroll	Indicates online enrollment.	-

Views

Hotspot2.0 profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Beacon and Probe Response frames sent from Hotspot2.0-capable APs carry network parameter information, which helps user terminals to discover and select proper networks. If the network operator requests user terminals to execute specified actions, for example, opening a web page for Portal authentication, the Additional Steps Required for Access (ASRA) field must be set to 1, indicating that user terminals must implement extra authentication when connecting to a network. You can run the **network-authen-type** command to specify a network authentication type.

Example

Set the network authentication type to online enrollment in Hotspot2.0 profile **hotspot**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] hotspot2-profile name hotspot
[HUAWEI-wlan-hotspot2-prof-hotspot] network-authen-type online-enroll
```

11.15.35 network-type

Function

The **network-type** command sets a network type and Internet access status in a Hotspot2.0 profile.

The **undo network-type** command restores the default network type and Internet access status.

By default, the network type is set to **wildcard**, and Internet access is not supported.

Format

network-type { **emergency-service** | **personal-device** | **private** | **private-guest** | **public-chargeable** | **public-free** | **test** | **wildcard** } [**internet-access**]

undo network-type

Parameters

Parameter	Description	Value
emergency-service	Indicates an emergency service network.	-

Parameter	Description	Value
personal-device	Indicates a personal device network.	-
private	Indicates a private network.	-
private-guest	Indicates a private network with guest access.	-
public-chargeable	Indicates a chargeable public network.	-
public-free	Indicates a free public network.	-
test	Indicates a test network.	-
wildcard	Indicates a wildcard network.	-
internet-access	Indicates that Internet access is supported.	-

Views

Hotspot2.0 profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When multiple Hotspot2.0 networks are available, user terminals need to obtain information of each network to select the network to access. The network type and Internet access status are mandatory in a Hotspot2.0 profile. Beacon and Probe Response frames sent from Hotspot2.0-capable APs carry network parameter information, which helps user terminals to discover and select proper networks.

Precautions

If the command is executed repeatedly, only the latest configuration takes effect.

Example

Set the network type to free public network and configure the network to provide Internet access in Hotspot2.0 profile **hotspot**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] hotspot2-profile name hotspot
[HUAWEI-wlan-hotspot2-prof-hotspot] network-type public-free internet-access
```

11.15.36 operating-class-indication

Function

The **operating-class-indication** command configures an operating class indication.

The **undo operating-class-indication** command deletes an operating class indication.

By default, no operating class indication is configured in the system.

Format

operating-class-indication *operating-class-value*

undo operating-class-indication *operating-class-value*

Parameters

Parameter	Description	Value
operating-class-value	Indicates the operating class indication.	The value is an integer that ranges from 1 to 255.

Views

Operating class profile view

Default Level

2: Configuration level

Usage Guidelines

After an operating class indication is configured, users can obtain the indication through ANQP for network selection.

You can configure a maximum of 32 operating class indications using this command.

Example

Set the operating class indication to **95**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] operating-class-profile name operating-class-profile1
[HUAWEI-wlan-op-class-prof-operating-class-profile1] operating-class-indication 95
```

11.15.37 operating-class-profile

Function

The **operating-class-profile** command creates an operating class profile or displays the view of an existing operating class profile.

The **undo operating-class-profile** command deletes an operating class profile.

By default, no operating class profile is configured in the system.

Format

operating-class-profile name *profile-name*

undo operating-class-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Indicates the name of the operating class profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Indicates to delete all operating class profiles.	-

Views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The operating class profile is used to configure the operating class indication of AP in on the hotspot2.0 network. When a STA accesses the network, it can obtain channel information used to access a Wi-Fi frequency from AP so that the STA can set up a connection.

Example

Create an operating class profile named **operating-class-profile1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] operating-class-profile name operating-class-profile1
[HUAWEI-wlan-op-class-prof-operating-class-profile1]
```

11.15.38 operating-class-profile (Hotspot2.0 profile view)

Function

The **operating-class-profile** command binds the specified operating class profile to a Hotspot2.0 profile view.

The **undo operating-class-profile** command unbinds the specified operating class profile from a Hotspot2.0 profile view.

By default, no operating class profile is bound to a Hotspot2.0 profile view.

Format

operating-class-profile *profile-name*

undo operating-class-profile

Parameters

Parameter	Description	Value
profile-name	Indicates the name of the operating class profile.	The value must be the name of an existing operating class profile.

Views

Hotspot2.0 profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a STA accesses a Hotspot2.0 network, it can obtain channel information used to access a Wi-Fi frequency from the AP so that the STA can set up a connection. Before binding an operating class profile to a Hotspot2.0 profile, you need to run the **operating-class-profile** command to create an operating class profile and run the **operating-class-indication** command in the profile view to configure an operating class indication.

Example

Bind the operating class profile **operating-class-profile1** to the **hotspot** profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] hotspot2-profile name hotspot
[HUAWEI-wlan-hotspot2-prof-hotspot] operating-class-profile operating-class-profile1
```

11.15.39 operator-domain-profile

Function

The **operator-domain-profile** command creates a network domain name profile or displays the view of an existing network domain name profile.

The **undo operator-domain-profile** command deletes a network domain name profile.

By default, no network domain name profile is available in the system.

Format

operator-domain-profile name *profile-name*

undo operator-domain-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Indicates the network domain name profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Indicates to delete all network domain name profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A network domain name profile is used to configure the operator domain profile. STAs can obtain the domain name information through ANQP, which is used as a basis for network selection.

Example

Create a network domain name profile named **operator-domain-profile1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] operator-domain-profile name operator-domain-profile1
[HUAWEI-wlan-op-domain-prof-operator-domain-profile1]
```

11.15.40 operator-domain-profile (Hotspot2.0 profile view)

Function

The **operator-domain-profile** command binds the specified operator domain profile to a Hotspot2.0 profile view.

The **undo operator-domain-profile** command unbinds the specified operator domain profile from a Hotspot2.0 profile view.

By default, no operator domain profile is bound to a Hotspot2.0 profile.

Format

operator-domain-profile *profile-name*

undo operator-domain-profile

Parameters

Parameter	Description	Value
profile-name	Indicates the name of the operator domain profile.	The value must be the name of an existing operator domain profile.

Views

Hotspot2.0 profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a STA accesses the Hotspot2.0 network, it can obtain the network operator domain name information from the AP so that the STA can select a network. Before binding an operator domain profile to a Hotspot2.0 profile, run the **operator-domain-profile** command to create an operator domain profile and run the **domain-name** command in the profile view to configure the operator name.

Example

Bind the operator domain profile **operator-domain-profile1** to the **hotspot** profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] hotspot2-profile name hotspot
[HUAWEI-wlan-hotspot2-prof-hotspot] operator-domain-profile operator-domain-profile1
```

11.15.41 operator-friendly-name

Function

The **operator-friendly-name** command configures the operator friendly name.

The **undo operator-friendly-name** command deletes the operator friendly name.

By default, no operator friendly name is configured in an operator name profile view.

Format

operator-friendly-name language-code *language-code* **name** *name*

undo operator-friendly-name language-code *language-code* **name** *name*

Parameters

Parameter	Description	Value
language-code *language-code*	Indicates the language.	The value is a string of 2 to 3 characters. For the value of each language, see the definition in ISO639-2 *Codes for the Representation of Names of Languages*. For example, the value is **chi**, **zho**, or **zh** for Chinese, and **eng** for English.

Parameter	Description	Value
name *name*	Indicates the operator friendly name.	The value is a string of 1 to 64 case-sensitive characters. ● English venue name: The value is a string of visible characters without question marks (?) and spaces. It cannot begin or end with double quotation marks (" "). ● Non-English venue name: It cannot contain half-width question marks (?). To enter a non-English venue name, ensure that the remote login terminal supports the UTF-8 encoding format; otherwise, the name cannot be displayed.

Views

Operator name profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a STA accesses the Hotspot2.0 network, it can obtain the operator name from the AP. This command configures the language environment names so that users can select a proper language.

If you need to enter a non-English name, you must use a tool to convert it into hexadecimal UTF-8 code.

Precautions

If you run the **operator-friendly-name** multiple times, multiple operator friendly names are configured. A maximum of 32 names can be configured.

Example

Set the operator friendly name to **operator-name-profile1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] operator-name-profile name operator-name-profile1
[HUAWEI-wlan-op-name-prof-operator-name-profile1] operator-friendly-name language-code eng
name att
```

11.15.42 operator-name-profile

Function

The **operator-name-profile** command creates an operator name profile or displays the view of an existing operator name profile.

The **undo operator-name-profile** command deletes the operator name profile.

By default, no operator name profile is available in the system.

Format

operator-name-profile name *profile-name*

undo operator-name-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Indicates the name of the operator name profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Indicates to delete all operator name profiles.	-

2: Configuration level

Usage Guidelines

Usage Scenario

When a STA accesses the Hotspot2.0 network, it can obtain the operator name from the AP. Before binding an operator name profile to a Hotspot2.0 profile, run the **operator-name-profile** command to create an operator name profile and run the **operator-friendly-name** command in the profile view to configure the operator name.

Example

Bind the operator name profile **operator-name-profile1** to the **hotspot** profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] hotspot2-profile name hotspot
[HUAWEI-wlan-hotspot2-prof-hotspot] operator-name-profile operator-name-profile1
```

11.15.44 p2p-cross-connect disable

Function

The **p2p-cross-connect disable** command configures P2P management information to prevent cross connections of P2P devices.

The **undo p2p-cross-connect disable** command deletes P2P management information.

By default, P2P management information is not configured.

Format

p2p-cross-connect disable

undo p2p-cross-connect disable

Parameters

None.

Views

Hotspot2.0 profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Hotspot2.0 provides security measures for STAs. It prevents direct access between STAs to reduce the STA attack possibility. The P2P protocol allows direct communication between STAs; therefore, a Hotspot2.0-supported AP can add P2P management information into Beacon. In the management information, STAs are not allowed to set up P2P connections with each other.

Precautions

The **p2p-cross-connect disable** command is not recommended. An AP does not support the P2P protocol or process P2P packets; therefore, it is unnecessary to remove P2P management information from packets.

Example

Configure P2P management information in the **hotspot** profile.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] hotspot2-profile name hotspot
[HUAWEI-wlan-hotspot2-prof-hotspot] p2p-cross-connect disable
```

11.15.45 plmn-id

Function

The **plmn-id** command configures the Public Land Mobile Network (PLMN) identifier.

The **undo plmn-id** command deletes the PLMN identifier.

By default, no PLMN identifier is configured in the cellular network profile.

Format

plmn-id *plmn-id*

undo plmn-id *plmn-id*

Parameters

Parameter	Description	Value
plmn-id	Indicates the PLMN identifier.	The value is an integer that ranges from 10000 to 999999.

Views

Cellular network profile view

Default Level

2: Configuration level

Usage Guidelines

After the **plmn-id** command is executed, the AP notifies STAs of the operator information on the Hotspot2.0 network. The STAs can obtain the PLMN identifier to determine whether to select the cellular network according to the Hotspot2.0 network.

If you run the **plmn-id** multiple times, multiple PLMN identifiers are configured. A maximum of 32 PLMN identifiers can be configured.

Example

Set the PLMN identifier to 10001.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] cellular-network-profile name cellular-network-profile1
[HUAWEI-wlan-cellular-net-cellular-network-profile1] plmn-id 10001
```

11.15.46 roaming-consortium-oi

Function

The **roaming-consortium-oi** command configures the roaming consortium identifier of the Hotspot2.0 network.

The **undo roaming-consortium-oi** command deletes the roaming consortium identifier of the Hotspot2.0 network.

By default, no roaming consortium identifier is configured for the Hotspot2.0 network.

Format

roaming-consortium-oi *oi-value* [**in-beacon**]

undo roaming-consortium-oi *oi-value*

Parameters

Parameter	Description	Value
oi-value	Indicates the roaming consortium identifier, which is used to identify operators.	The format is HH-HH-HH or HH-HH-HH-HH-HH, in which H is in the hexadecimal format.
in-beacon	Indicates that the Beacon and probe-response frames sent by the AP contain the roaming consortium identifier.	-

Views

Roaming consortium profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If STAs may roam between the Hotspot2.0 network and a network of another operator, you can configure the OI of the operator that provides the roaming service so that STAs can select networks.

Precautions

If you run this command multiple times, multiple OIs are configured. A maximum of 32 OIs can be configured in a roaming consortium profile. To configure OIs in the roaming consortium profile, the first OI must carry the **in-beacon** parameter. A maximum of three OIs can be configured to carry the **in-beacon** parameter.

Example

Add an OI **00-11-22** to the profile **roaming-consortium-profile1** and add the OI to the Beacon and probe-response frames sent by the AP.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] roaming-consortium-profile name roaming-consortium-profile1
[HUAWEI-wlan-ro-co-prof-roaming-consortium-profile1] roaming-consortium-oi 00-11-22 in-beacon
```

11.15.47 roaming-consortium-profile

Function

The **roaming-consortium-profile** command creates a roaming consortium profile or displays the view of an existing roaming consortium profile.

The **undo roaming-consortium-profile** command deletes a roaming consortium profile.

By default, no roaming consortium profile is created.

Format

roaming-consortium-profile name *profile-name*

undo roaming-consortium-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a roaming consortium profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all roaming consortium profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When configuring Hotspot2.0 services, configure network parameters according to operator requirements. When connecting to networks, user terminals can obtain the network parameters to select desired networks. If the user terminals need to roam among Hotspot2.0 networks of different operators, configure a roaming consortium profile and add the organization identifiers (OIs) of the operators to the roaming consortium profile. In this way, after the user terminals connect to a network of an operator in the profile, they can roam to networks of the other operators while maintaining online.

Follow-up Procedure

Run the **roaming-consortium-oi** command to configure the roaming consortium OI in the roaming consortium profile.

Example

Create the roaming consortium profile **roaming-consortium-profile1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] roaming-consortium-profile name roaming-consortium-profile1
[HUAWEI-wlan-ro-co-prof-roaming-consortium-profile1]
```

11.15.48 roaming-consortium-profile (Hotspot2.0 profile view)

Function

The **roaming-consortium-profile** command binds a roaming consortium profile to a Hotspot2.0 profile.

The **undo roaming-consortium-profile** command unbinds a roaming consortium profile from a Hotspot2.0 profile.

By default, no roaming consortium profile is bound to a Hotspot2.0 profile.

Format

roaming-consortium-profile *profile-name*

undo roaming-consortium-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a roaming consortium profile.	The roaming consortium profile must exist.

Views

Hotspot2.0 profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can configure Hotspot2.0 services for networks. When user terminals connect to the networks, they can obtain OIs of the operators used for STA roaming, which helps them select desired networks. You can run the **roaming-consortium-profile** command to create a roaming consortium profile and the **roaming-consortium-oi** command in the roaming consortium profile view to configure operator OIs, and then bind the roaming consortium profile to a Hotspot2.0 profile to make the configuration take effect.

Example

Bind roaming consortium profile **roaming-consortium-profile1** to the Hotspot 2.0 profile **hotspot**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] hotspot2-profile name hotspot
[HUAWEI-wlan-hotspot2-prof-hotspot] roaming-consortium-profile roaming-consortium-profile1
```

11.15.49 venue-name-profile

Function

The **venue-name-profile** command creates a venue name profile or displays the view of an existing venue name profile.

The **undo venue-name-profile** command deletes a venue name profile.

By default, no venue name profile is created.

Format

venue-name-profile name *profile-name*

undo venue-name-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a venue name profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Deletes all venue name profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When configuring Hotspot2.0 services, configure network parameters according to operator requirements. When connecting to networks, user terminals can obtain the network parameters to select desired networks. The venue name describes physical locations of a network and is an optional parameter.

Follow-up Procedure

Run the **venue-name** command in the venue name profile view to configure the venue name. After creating a venue name profile, bind it to a Hotspot2.0 profile.

Example

Create the venue name profile **venue-name-profile1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] venue-name-profile name venue-name-profile1
[HUAWEI-wlan-ve-na-prof-venue-name-profile1]
```

11.15.50 venue-name-profile (Hotspot2.0 profile view)

Function

The **venue-name-profile** command binds a venue name profile to a Hotspot2.0 profile.

The **undo venue-name-profile** command unbinds a venue name profile from a Hotspot2.0 profile.

By default, no venue name profile is bound to a Hotspot2.0 profile.

Format

venue-name-profile *profile-name*

undo venue-name-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a venue name profile.	The venue name profile must exist.

Views

Hotspot2.0 profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can configure Hotspot2.0 services for networks. When connecting to the networks, user terminals can obtain location information of the networks from APs, which helps them to select desired networks. You can run the **venue-name-profile** command to create a venue name profile and the **venue-name** command in the venue name profile view to configure venue names, and then bind the venue name profile to a Hotspot2.0 profile to make the configuration take effect.

Example

Bind venue name profile **venue-name-profile1** to Hotspot2.0 profile **hotspot**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] hotspot2-profile name hotspot
[HUAWEI-wlan-hotspot2-prof-hotspot] venue-name-profile venue-name-profile1
```

11.15.51 venue-name

Function

The **venue-name** command configures a venue name for a Hotspot 2.0 network.

The **undo venue-name** command deletes the configured venue name.

By default, no venue name is configured.

Format

venue-name language-code *language-code* **name** *venue-name*

undo venue-name language-code *language-code* **name** *venue-name*

Parameters

Parameter	Description	Value
language-code *language-code*	Specifies the language type.	The value is a string of 2 to 3 characters. For the value of each language, see the definition in ISO639-2 *Codes for the Representation of Names of Languages*. For example, the value is **chi**, **zho**, or **zh** for Chinese, and **eng** for English.

Parameter	Description	Value
name *venue-name*	Specifies the venue name.	The value is a string of 1 to 64 case-sensitive characters. ● English venue name: The value is a string of visible characters without question marks (?) and spaces. It cannot begin or end with double quotation marks (" "). ● Non-English venue name: It cannot contain half-width question marks (?). To enter a non-English venue name, ensure that the remote login terminal supports the UTF-8 encoding format; otherwise, the name cannot be displayed.

Views

Venue name profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can use the command to configure venue names for Hotspot 2.0 networks to identify physical locations of the networks, which helps user terminals select desired networks. You can set the venue names in multiple languages for user groups of different languages.

Precautions

This command can be configured repeatedly. A maximum of 32 venue names can be configured in a venue name profile.

Example

Set the language to English and configure the venue name **CenterStation** in venue name profile **venue-name-profile1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] venue-name-profile name venue-name-profile1
[HUAWEI-wlan-ve-na-prof-venue-name-profile1] venue-name language-code eng name CenterStation
```

11.15.52 venue-type

Function

The **venue-type** command configures the venue type of a Hotspot2.0 network.

The **undo venue-type** command deletes the configured venue type.

By default, no venue type information is configured for a Hotspot2.0 network.

Format

venue-type group-code *venue-group* **type-code** *type-code-value*

undo venue-type

Parameters

Parameter	Description	Value
group-code *venue-group*	Specifies the venue group type.	The value is an integer that ranges from 0 to 255. For meanings of different venue group values, see **7.3.1.34 Venue Info field** defined in IEEE Std 802.11u-2011.
type-code *type-code-value*	Specifies the venue subtype.	The value is an integer that ranges from 0 to 255. For meanings of different venue subtype values, see **7.3.1.34 Venue Info field** defined in IEEE Std 802.11u-2011.

Views

Hotspot2.0 profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When multiple Hotspot2.0 networks are available, user terminals need to obtain information of each network to select the network to access. The venue type information is optional in a Hotspot2.0 profile. Beacon and Probe Response frames sent from Hotspot2.0-capable APs carry network parameter information, which helps user terminals to discover and select proper networks.

group-code and **type-code** determine the venue type and identify the network location. As predefined in the 802.11u protocol:

- If **group-code** is set to 2 (Business) and **type-code** to 3, the venue type indicates **Fire Station**.
- If **group-code** is set to 3 (Educational) and **type-code** to 3, the venue type indicates **University or College**.

Precautions

If the command is executed repeatedly, only the latest configuration takes effect.

Example

Set the venue type to **University or College** in Hotspot2.0 profile **hotspot**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] hotspot2-profile name hotspot
[HUAWEI-wlan-hotspot2-prof-hotspot] venue-type group-code 3 type-code 3
```

11.16 IoT AP Configuration Commands

11.16.1 Command Support

- WLAN-AC commands are supported only by the following models: S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.
- IoT cards are supported only by the following models:
  - AirEngine 5760-22W, AirEngine 5760-22WD, AirEngine 5760-51, AirEngine 6760-X1, AirEngine 6760-X1E, AirEngine 8760-X1-PRO
  - AirEngine 5761-11W, AirEngine 5761-11WD, AirEngine 5761-12W, AirEngine 5761-21, AirEngine 5761S-11, AirEngine 5761S-11W, AirEngine 5761S-21, AirEngine 6761-21T, AirEngine 6761S-21T
  - AirEngine 5761-11, AirEngine 5761S-12, AirEngine 5761S-13, AirEngine 6761-21, AirEngine 6761S-21, AirEngine 6761-21E
  - AirEngine 5762-13W, AirEngine 5762-15HW, AirEngine 5762S-13W
  - AirEngine 5762-16W
  - AirEngine 8761-X1
  - AirEngine 5762-17W
  - AirEngine 8771-X1T

Only intrinsically safe APs (AirEngine 5761-11EI) support the baud rate configuration for communication between APs and IoT cards.

11.16.2 antenna-status

Function

The **antenna-status** command configures an IoT card to use the external or built-in antenna of an AP's IoT module.

The **undo antenna-status** command restores the default antenna selection policy for an IoT card.

By default, an IoT card is not configured to use the external or built-in antenna of an AP's IoT module.

Format

antenna-status { **external** | **internal** }

undo antenna-status

Parameters

Parameter	Description	Value
external	Configures an IoT card to use the external antenna of an AP's IoT module.	-
internal	Configures an IoT card to use the built-in antenna of an AP's IoT module.	-

Views

IoT profile view

Default Level

2: Configuration level

Usage Guidelines

By default, an IoT card uses the built-in 2.4 GHz antenna of an AP's IoT module for communication. You can install the external antenna as required and run the **antenna-status external** command to configure the IoT card to use the external antenna for communication.

NOTE

The external and built-in antennas cannot be used together in an IoT module. If there are multiple IoT cards, the cards must use the same type of antennas for communication. For configuration details, see Card 1.

When the **display ap-card all** or **display ap** *ap-id* **card** { **all** | *card-number* | **usb** } command is run to check information about an IoT card, whether the card uses the built-in or external antenna for communication is also displayed in the command output.

Example

Configure an IoT card to use the external antenna of an AP's IoT module.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] iot-profile name profile1
[HUAWEI-wlan-iot-prof-profile1] antenna-status external
```

11.16.3 baud-rate

Function

The **baud-rate** command configures the baud rate used by an AP to communicate with an IoT card.

The **undo baud-rate** command restores the default baud rate used by an AP to communicate with an IoT card.

By default, no baud rate is configured, and an AP can automatically adapt to the baud rate.

NOTE

This function is supported only by intrinsically safe APs (AirEngine 5761-11EI) that support communication with the uninterruptible power supply (UPS).

Format

baud-rate { **9600** | **19200** | **38400** | **57600** | **115200** | **921600** }

undo baud-rate

Parameters

Parameter	Description	Value
9600 | **19200** | **38400** | **57600** | **115200** | **921600**	Specifies the baud rate used by an AP to communicate with an IoT card.	-

Views

IoT card interface view

Default Level

2: Configuration level

Usage Guidelines

APs with common cards can automatically adapt to the baud rate of an IoT card. However, for some cards, such as those with RS485 serial ports, APs cannot automatically adapt to the card baud rate. In this case, run this command to set the baud rate to the same as that of the corresponding cards.

Example

Set the baud rate used by APs in an AP group to communicate with an IoT card to 9600 bit/s.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] card 1
[HUAWEI-wlan-group-card-default/1]  baud-rate 9600
```

Set the baud rate used by an AP to communicate with an IoT card to 9600 bit/s.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-id 0
[HUAWEI-wlan-ap-0] card 1
[HUAWEI-wlan-card-0/1] baud-rate 9600
```

11.16.4 card connect-type

Function

The **card connect-type** command configures the connection type between IoT cards and APs.

The **undo card connect-type** command restores the default connection type between IoT cards and APs.

By default, IoT cards communicate with APs through serial interfaces.

Format

card connect-type { **ethernet** | **serial** | **container** }

undo card connect-type

Parameters

Parameter	Description	Value
ethernet	Configures IoT cards to communicate with APs through Ethernet interfaces.	-
serial	Configures IoT cards to communicate with APs through serial interfaces.	-
container	Configures IoT cards to communicate with a third-party server by loading the third-party container image.	-

Views

AP system profile view, IoT card interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When **serial** is configured for communication between IoT cards and APs, the communication rate does not exceed the maximum baud rate of serial interfaces, that is, 115200 bit/s. This connection type applies to scenarios with a light traffic volume. The connection type of **ethernet** applies to scenarios where electronic shelf labels (ESLs) are deployed.

Before using IoT cards of other vendors, contact the vendors to confirm the connection types supported by the cards.

Precautions

- The configurations in different views take effect in descending priority as follows: IoT card interface view of an AP > IoT card interface view of an AP group > AP system profile view.

Example

Configure IoT cards to communicate with APs through Ethernet interfaces.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ab
[HUAWEI-wlan-ap-system-prof-ab] card connect-type ethernet
```

11.16.5 config-agent permit ip-address

Function

The **config-agent permit ip-address** command configures trusted host computers.

The **undo config-agent permit ip-address** command deletes the configuration of trusted host computers.

By default, no trusted host computer is configured.

Format

config-agent permit ip-address *ip-address* { *net-mask* | *mask-len* }

undo config-agent permit ip-address

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address of a trusted host computer.	The value is in dotted decimal notation.
net-mask	Specifies the mask of the IP address of a trusted host computer.	The value is in dotted decimal notation.
mask-len	Specifies the mask length.	The value is an integer that ranges from 0 to 32.

Views

IoT profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To prevent unauthorized devices from attacking an AP, you can configure trusted host computers. In this way, only hosts within the specified IP address range can communicate with the AP functioning as a server and send the AP the configuration to be delivered to the IoT card.

If no trusted host computer is configured, any host computers with reachable routes to the AP can communicate with the AP, which brings security risks to the AP.

Precautions

After the **type cas-edu** command is executed to set the card type to **cas-edu**, the **config-agent permit ip-address** command cannot be executed.

Example

Configure the IP address of a trusted host computer and its mask.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] iot-profile name wlan-iot
[HUAWEI-wlan-iot-prof-wlan-iot] config-agent permit ip-address 10.2.3.4 255.255.255.0
```

11.16.6 display ap card

Function

The **display ap card** command displays details about AP cards.

Format

display ap *ap-id* **card** { **all** | *card-number* | **usb** }

Parameters

Parameter	Description	Value
ap-id	Specifies an AP ID.	The AP ID must exist.
all	Specifies all AP cards.	-
card-number	Specifies an IoT card interface number.	The interface number must exist.
usb	Specifies the USB interface on an IoT card.	-

Views

Table 11-303 Description of the **display ap card** command output

Item	Description
IOT card status	Card status. - present: A card is installed in the slot. - absent: No card is installed in the slot.
Card connect type	Connection type between an IoT card and the AP.
Physical connection type	Connection type between the IoT card and AP.
Connected status	Whether the actual connection type of an IoT card matches the current initialized connection type of the AP.
Support card information	Whether card information can be queried.
Protocol version	Protocol version. The current version number is 1.

Item	Description
Wireless standard	Wireless protocol supported by a card. The value is a 10-byte ASCII character set, for example, RFID, ANT, ZigBee, BT4.0, and Weightless.
Frequency	Card frequency. The value is an 8-byte ASCII character set, for example, 2.4G, 900M, 2.4/5G, or any value from 433M to 915M.
Vendor name	Vendor code. The value is an 8-byte ASCII character set, for example, ENJOYOR.
Card type	Card model. The value is a 12-byte ASCII character set, for example, TOEAPV1.2.
Hardware version	Hardware version of the card. The value is a 2-byte ASCII character set. The value is fixed in the following pattern: VA for the first version, VB for the second version, VC for the third version, and so on.
Firmware version	Firmware version of the card. The value is a 4-byte number, for example, 00.01.00.01.
Card serial number	Module ID of the card. The value is a 16-byte BCD character set.
Baud-rate	Baud rate for serial communication on an IoT card slot.
Frame-version	Frame format of an extension interface.
Antenna status	Whether an IoT card uses the built-in or external antenna. ● External: external antenna ● Internal: built-in antenna
Card IP	IP address of a card.
Card MAC	MAC address of an IoT card.
Central frequency	Center frequency of an IoT card.
Card bandwidth	Bandwidth of an IoT card.
Connect server status	Connection status between an IoT card and the server.

Item	Description
Server name	Name of the server connected to an IoT card.
Subnet mask	Subnet mask length.
Gateway address	Gateway address.
USB status	Actual working status of the USB function on an AP.

11.16.7 display ap-card statistics

Function

The **display ap-card statistics** command displays statistics on the packets received and sent by cards on APs.

Format

display ap-card statistics { **all** | **ap-id** *ap-id* [**card** { *card-number* | **usb** }] }

Parameters

Parameter	Description	Value
all	Specifies cards on all APs.	-
ap-id *ap-id*	Specifies an AP ID.	The AP ID must exist.
card *card-number*	Specifies an IoT card interface number.	The interface number must exist.
usb	Specifies the USB interface on an IoT card.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check statistics on the packets received and sent by cards on APs. Only statistics about IoT cards with the serial connection type can be displayed.

Example

Display statistics on the packets received and sent by cards on all APs.

```
<HUAWEI> display ap-card statistics all
----------------------------------------------------------------------------------------------------
AP ID  Card-number  RX-packets  TX-packets  RX-bytes  TX-bytes
----------------------------------------------------------------------------------------------------
0      1            1           2           100       200
----------------------------------------------------------------------------------------------------
Total: 1
```

Display statistics on the packets received and sent by cards on AP 0.

```
<HUAWEI> display ap-card statistics ap-id 0
----------------------------------------------------------------------------------------------------
AP ID  Card-number  Card-status  RX-packets  TX-packets  RX-bytes  TX-bytes
----------------------------------------------------------------------------------------------------
0      1            present      1           2           100       200
0      2            absent       2           1           89        14
0      3            absent       0           0           0         0
0      usb           absent       0           0           0         0

```

Table 11-304 Description of the **display ap-card statistics** command output

Item	Description
AP ID	AP ID.
Card-number	Card number.
Card-status	Whether a card is installed in the slot. - absent: No card is installed in the slot. - present: A card is installed in the slot.
RX-packets	Number of packets sent to a card.
TX-packets	Number of packets received from a card.
RX-bytes	Number of bytes sent to a card.
TX-bytes	Number of bytes received from a card.

11.16.8 display ap-card all

Function

The **display ap-card all** command displays brief information about cards on all the APs.

Format

display ap-card all

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

To query brief information about cards on all the APs, run the **display ap-card all** command.

Precautions

No result is displayed if a card does not support query.

Example

Display brief information about cards on all the APs.

```
<HUAWEI> display ap-card all
Connected-status: The match status indicates that the card connection type matches
that on the device. Otherwise, mismatch is displayed. To modify the effective connection
type, run the card connect-type {serial|ethernet|container} command.
Frame-version: Frame format on extended interfaces.
------------------------------------------------------------------------------------------------------------------------------
-------
---------------------------
AP ID  Card-number  Wireless-standard  Vendor-name  Card-type     Card-connect-type  Connected-status

Total: 1
```

Table 11-305 Description of the **display ap-card all** command output

Item	Description
AP ID	AP ID.
Card-number	Card ID.

Item	Description
Wireless-standard	Wireless protocol supported by a card. The value is a 10-byte ASCII character set, for example, RFID, ANT, ZigBee, BT4.0, and Weightless.
Vendor-name	Vendor code. The value is an 8-byte ASCII character set, for example, ENJOYOR.
Card-type	Card model. The value is a 12-byte ASCII character set, for example, TOEAPV1.2.
Card-connect-type	Connection type between an IoT card and the AP.
Connected-status	Whether the actual connection type of an IoT card matches the current initialized connection type of the AP.
Antenna-status	Whether an IoT card uses the built-in or external antenna. ● External: external antenna ● Internal: built-in antenna
Baud-rate	Baud rate used for communication between the card and AP.
Frame-version	Frame format of an extension interface.
Serial-number	Module ID of a card. The value is a 16-byte BCD character set.

11.16.9 display iot-card iot-command-result

Function

The **display iot-card iot-command-result** command displays the execution results of commands transparently transmitted to IoT cards.

Format

display iot-card iot-command-result all

display iot-card iot-command-result ap ap-id *ap-id* **card** { *card-id* | **usb** }

Parameters

Parameter	Description	Value
all	Displays command execution results on all cards of all APs.	-
ap ap-id *ap-id*	Displays command execution results on cards of the AP with a specified ID.	The AP ID must exist.
card *card-id*	Displays command execution records on the card with a specified ID.	The value is an integer that ranges from 1 to 3.
card usb	Displays command execution results on USB cards.	-

Views

All views

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After a command is transparently transmitted to a card, you can run the **display iot-card iot-command-result** command to check the command execution result on the card.

Precautions

Example

Display execution results of commands transparently transmitted to all IoT cards.

```
<HUAWEI> display iot-card iot-command-result all
Ap information:
Total  :     [7]
Waiting:     [1]
Success:     [1]
Fail   :     [5]

------------------------------------------------------------------------------------------------------------------------
Total: 7
```

Table 11-306 Description of the **display iot-card iot-command-result all** command output

Item	Description
Total	Total number of command execution results.
Waiting	Number of command execution results that a card is waiting for from the AP.
Success	Number of commands that have been successfully executed.
Fail	Number of commands that fail to be executed.
AP-ID	ID of the AP where a card resides.
Card	Card ID.
Time	Time when the device transparently transmits a command to a card.
Command	Content of a command transparently transmitted to a card.

Item	Description
Transparent transmission result	Execution result of a command on a card: ● Success: The command has been successfully executed. ● Waiting: The card is waiting for a response from the AP. ● Fail: The command fails to be transmitted to the card. The failure reasons are as follows: – Card does not support this command: The card does not support this command. – Card is not installed: The card is not properly installed. – Time Out: The response of the card times out. Check the version of the card. If the card version does not support transparent transmission of commands, the command execution times out. – Card is busy: The card is executing another command. – Other reason: A system error occurs.
Card Response	Response of a card. The response is defined by the card vendor. For details, contact the card vendor.

11.16.10 display iot-profile

Function

The **display iot-profile** command displays the IoT profile configuration.

Format

display iot-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of an IoT profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Specifies all IoT profiles.	-

Views

All views

```

Table 11-308 Description of the **display iot-profile name wlan-IoT** command output

Item	Description
Type	Card type. To configure this parameter, run the **type (IoT profile view)** command.
Agent permit IP address	IP address of a trusted host computer. To configure this parameter, run the **config-agent permit ip-address** command.
Agent permit net-mask	Mask of the IP address of a trusted host computer. To configure this parameter, run the **config-agent permit ip-address** command.
Management server IP address	IP address of the host computer. To configure this parameter, run the **management-server** command.
Management server port	Port number of the host computer. To configure this parameter, run the **management-server** command.
ExtManagement server IP address	IP address of the host computer on the extended channel. To configure this parameter, run the **management-server** command.
ExtManagement server port	Port number of the host computer on the extended channel. To configure this parameter, run the **management-server** command.
Share key	Shared key. To configure this parameter, run the **share-key** command.

Item	Description
Antenna status	Whether an IoT card uses the built-in or external antenna. ● External: external antenna ● Internal: built-in antenna

11.16.11 display references iot-profile

Function

The **display references iot-profile** command displays reference information about an IoT profile.

Format

display references iot-profile name *profile-name*

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of an IoT profile.	The IoT profile name must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run this command to view reference information about an IoT profile.

Example

Display reference information about the IoT profile **wlan-IoT**.

```
<HUAWEI> display references iot-profile name wlan-IoT
--------------------------------------------------------------------------------
Reference type     Reference name                       Reference card
--------------------------------------------------------------------------------
AP group           default                              Card-1
--------------------------------------------------------------------------------
Total:1
```

Table 11-309 Description of the **display references iot-profile name wlan-IoT** command output

Item	Description
Reference type	Type of the object to which the IoT profile is bound.
Reference name	Name of the object to which the IoT profile is bound.
Reference card	Card to which the IoT profile is bound.

11.16.12 card

Function

The **card** command displays the IoT card interface view.

Format

card { *card-number* | **usb** }

Parameters

Parameter	Description	Value
card-number	Specifies an IoT card interface number.	The value is an integer that ranges from 1 to 3.
usb	Specifies the USB interface for an IoT card.	-

Views

AP group view, AP specific view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the communication parameters are configured between an AP and an IoT card, and between an AP and a host computer, you need to bind corresponding configuration profiles in the IoT card interface view to make the parameters take effect.

Prerequisites

The USB function of the AP has been enabled using the **usb enable** command.

Precautions

IoT cards of the cas-edu type do not support the USB interface.

Example

Display the IoT card interface view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] card 1
[HUAWEI-wlan-group-card-default/1]
```

11.16.13 iconnect enable

Function

The **iconnect enable** command enables the iConnect function on an AP so that the AP releases an iConnect SSID.

The **undo iconnect enable** command disables the iConnect function.

By default, the iConnect function is disabled.

Format

iconnect enable

undo iconnect enable

Parameters

None

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the iConnect function is enabled on an AP, the AP releases an iConnect SSID, through which IoT terminals can access the network. This implements plug-and-play of IoT terminals and enables the terminals to automatically load digital certificates.

Precautions

In the Navi AC scenario, an SSID cannot be configured as an iConnect SSID.

Example

Enable the iConnect function.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name vap1
[HUAWEI-wlan-vap-prof-vap1] iconnect enable
```

11.16.14 iot-card reboot

Function

The **iot-card reboot** command resets an IoT card of an AP.

Format

iot-card reboot ap ap-id *ap-id* **card** { *card-id* | **usb** }

Parameters

Parameter	Description	Value
ap ap-id *ap-id*	Specifies an AP ID.	The AP ID must exist.
card-id	Specifies the IoT card interface number.	The value is an integer that ranges from 1 to 3.
usb	Specifies the USB interface of an IoT card.	-

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

The **iot-card reboot** command resets an IoT card of an AP.

Example

Reset an IoT card on the USB interface of the AP with ID 0.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] iot-card reboot ap ap-id 0 card usb
```

11.16.15 iot-card reset-factory-configuration

Function

The **iot-card reset-factory-configuration** command restores factory defaults of an IoT card.

Format

iot-card reset-factory-configuration ap ap-id *ap-id* **card** *card-id*

Parameters

Parameter	Description	Value
ap ap-id *ap-id*	Specifies an AP ID.	The AP ID must exist.
card *card-id*	Specifies the ID of an IoT card.	The IoT card ID must exist.

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If an IoT card cannot communicate with the AP due to an error in IoT card parameter settings, you can run this command to restore factory defaults of the IoT card.

Example

Restore factory defaults of an IoT card.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] iot-card reset-factory-configuration ap ap-id 1 card 1
```

11.16.16 iot-card reset-network-configuration

Function

The **iot-card reset-network-configuration** command resets network parameters of an IoT card.

Format

iot-card reset-network-configuration ap ap-id *ap-id* **card** { *card-id* | **usb** }

Parameters

Parameter	Description	Value
ap ap-id *ap-id*	Specifies an AP ID.	The AP ID must exist.
card *card-id*	Specifies the ID of an IoT card.	The IoT card ID must exist.
card usb	Specifies an IoT card of the USB type.	-

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

An IoT card involves network parameters for communicating with a host computer (such as the card IP address, server IP address, and DNS address) and air interface parameters in a wireless environment. In most cases, when the wireless environment becomes stable, air interface parameters remain unchanged. When the wired environment changes, you can only run the **iot-card reset-network-configuration** command to reset network parameters of the IoT card. During this process, the air interface parameters remain unchanged.

This command is supported only by **Ethernet port cards**.

Example

Reset network parameters of an IoT card.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] iot-card reset-network-configuration ap ap-id 1 card 1
```

11.16.17 iot-card switch-firmware

Function

The **iot-card switch-firmware** command switches the active and standby partitions of an IoT card.

Format

iot-card switch-firmware ap ap-id *ap-id* **card** *card-id*

Parameters

Parameter	Description	Value
ap ap-id *ap-id*	Specifies an AP ID.	The AP ID must exist.
card *card-id*	Specifies the ID of an IoT card.	The IoT card ID must exist.

Views

WLAN view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Upon a fault on the current partition of an IoT card, you can run this command to switch to the other partition.

Example

Switch the active and standby partitions of an IoT card.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] iot-card switch-firmware ap ap-id 1 card 1
```

11.16.18 iot-profile (WLAN view)

Function

The **iot-profile** command creates an IoT profile and displays the IoT profile view.

The **undo iot-profile** command deletes an IoT profile.

By default, no IoT profile is created.

Format

iot-profile name *profile-name*

undo iot-profile { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of an IoT profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
all	Specifies all IoT profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An AP functions as a server or client to communicate with the host computer in bi-directional mode. When the AP reports data to the host computer, the AP functions as a client and the host computer functions as a server. When the AP receives data from the host computer, the AP functions as a server and the host computer functions as a client.

Example

Create IoT profile **profile1** and display the IoT profile view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] iot-profile name profile1
[HUAWEI-wlan-iot-prof-profile1]
```

11.16.19 iot-profile (IoT card interface view)

Function

The **iot-profile** command binds an IoT profile to an IoT card interface, and configures the local port number mapping the IoT card interface.

The **undo iot-profile** command unbinds an IoT profile from an IoT card interface.

By default, no IoT profile is bound to an IoT card interface.

Format

iot-profile *profile-name* **config-agent** { **tcp** | **udp** } [**port** *port*] [**ext-port** *ext-port*]

undo iot-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of an IoT profile.	The value is a string of 1 to 35 case-insensitive characters. It does not contain question marks (?) or spaces, and cannot start or end with double quotation marks (" ").
tcp	Configures the AP to communicate with the host computer using TCP.	-
udp	Configures the AP to communicate with the host computer using UDP.	-
port *port*	Specifies the source port for the first channel.	The value is an integer that ranges from 1025 to 55535. By default, the port number is a random port number in the range of 49152 to 65535. **NOTE** A port number within the range from 50200 to 50202 is recommended. If another port number is used, a port conflict may occur and an alarm is generated.

Parameter	Description	Value
ext-port *ext-port*	Specifies the source port for the extended channel.	The value is an integer that ranges from 1025 to 55535. By default, the port number is a random port number in the range of 49152 to 65535. **NOTE** A port number within the range from 50200 to 50202 is recommended. If another port number is used, a port conflict may occur and an alarm is generated.

Views

IoT card interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to bind an IoT profile, configure the communication protocol between the AP and host computer, and configure the source port number for the IoT card interface.

Example

Bind IoT profile **profile1** and set the local UDP port number to 50200.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] card 1
[HUAWEI-wlan-group-card-default/1] iot-profile profile1 config-agent udp port 50200
```

11.16.20 management-server

Function

The **management-server** command configures a host computer.

The **undo management-server** command deletes the host computer configuration.

By default, no host computer is configured.

Format

management-server { **domain** *domain-name* | **server-ip** *server-ip* } **server-port** *server-port-num* [**ext-channel**]

undo management-server { **domain** *domain-name* | **server-ip** *server-ip* } [**server-port** *server-port-num*] [**ext-channel**]

Parameters

Parameter	Description	Value
domain *domain-name*	Specifies the domain name of a host computer.	The value is a string of 1 to 63 case-insensitive characters without spaces. The value contains letters, digits, and underscores (_) or dots (**.**).
server-ip *server-ip*	Specifies the IP address of a host computer.	The value is in dotted decimal notation.
server-port *server-port-num*	Specifies the port number of a host computer.	The value is an integer that ranges from 1 to 65535.
ext-channel	Specifies an extension channel.	-

Views

IoT profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An AP functions as a server or client to communicate with a host computer in bi-directional mode. When the AP reports data (Huawei APs only transparently transmit data to the host computer, and do not parse or collect data) to the host computer, the AP functions as a client and the host computer functions as a server. When the AP receives data from the host computer, the AP functions as a server and the host computer functions as a client. The domain name/IP address and one port of at least one host computer must be configured. Otherwise, serial data reported by the AP will be discarded.

Precautions

You can configure multiple host computers. An IoT card of the **common** type supports a maximum of four host computers. After four host computers have been configured, you need to delete a host computer before adding a new host computer. Host computers can only be deleted or added, but cannot be modified. An IoT card of the **cas-edu** type supports only one host computer.

When a ZigBee card is used, information about two host computers must be configured. The channel of the second host computer is an extension channel specified by the **ext-channel** parameter. Only one extension channel can be configured. The two channels cannot be configured with the same port number and IP address, or the same port number and domain name.

When multiple host computers are configured, the device automatically selects one available host computer for link establishment rather than establish links with multiple host computers.

Example

Configure an IP address and a port number for a host computer.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] iot-profile name profile1
[HUAWEI-wlan-iot-prof-profile1] management-server server-ip 10.1.1.2 server-port 3000
```

11.16.21 reset ap-card statistics

Function

The **reset ap-card statistics** command clears statistics on the packets received and sent by cards on APs.

Format

reset ap-card statistics { **all** | **ap-id** *ap-id* [**card** { *card-number* | **usb** }] }

Parameters

Parameter	Description	Value
all	Specifies cards on all APs.	-
ap-id *ap-id*	Specifies an AP ID.	The AP ID must exist.
card *card-number*	Specifies an IoT card interface number.	The interface number must exist.

Parameter	Description	Value
usb	Specifies the USB interface on an IoT card.	-

Views

All views

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run this command to clear statistics on the packets received and sent by cards on APs. Only statistics about IoT cards with the serial connection type can be cleared.

Precautions

The statistics cannot be restored after being cleared.

Example

Clear statistics on the packets received and sent by cards on all APs.

```
<HUAWEI> reset ap-card statistics all
```

11.16.22 share-key

Function

The **share-key** command configures a shared key.

The **undo share-key** command deletes a shared key.

By default, no shared key is configured.

Format

share-key *key-value*

undo share-key

Parameters

Parameter	Description	Value
key-value	Specifies a shared key.	The value is a string of characters. ● The key in plaintext contains 6 to 32 characters. ● The key in ciphertext contains 48 or 68 characters. **NOTE** To ensure security, a shared key must be a combination of at least two of the following: digits, lowercase letters, uppercase letters, and special characters.

Views

IoT profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can configure a shared key to improve data communication security and ensure completeness of packets exchanged between an AP and host computers. The shared key must be the same on the AP and host computers.

Precautions

After the **type cas-edu** command is executed to set the card type to **cas-edu**, the **share-key** command cannot be executed.

Example

Set the shared key to **aabb0011@11**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] iot-profile name profile1
[HUAWEI-wlan-iot-prof-profile1] share-key aabb0011@11
```

11.16.23 type (IoT profile view)

Function

The **type** command sets the type of an IoT card.

The **undo type** command restores the default IoT card type.

The default type of an IoT card is **common**.

Format

type { **cas-edu** | **common** }

undo type

Parameters

Parameter	Description	Value
cas-edu	Indicates an IoT card that complies with IoT standards of the China Academy of Science.	-
common	Indicates an IoT card that complies with Huawei's IoT standards.	-

Views

IoT profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In an interconnection with the education system solution of the China Academy of Science, set the IoT card type to **cas-edu**. In other scenarios, set the IoT card type to **common**.

Precautions

After the IoT card type is modified in an IoT profile, other parameters in this IoT profile will restore to the default values.

If the **iot-profile (IoT card interface view)** command has been executed to bind an IoT profile, the IoT card type cannot be modified. The IoT card type can be modified only after the IoT profile is unbound.

After the **type cas-edu** command is executed to set the card type to **cas-edu**, the **config-agent permit ip-address** and **share-key** commands cannot be executed.

Example

Set the IoT card type to **cas-edu**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] iot-profile name wlan-iot
[HUAWEI-wlan-iot-prof-wlan-iot] type cas-edu
Warning: After the card type is modified, related configuration items in the profile are cleared. Continue?
[Y/N]:y
```

11.16.24 wired-port-profile (IoT card interface view)

Function

The **wired-port-profile** command binds a specified AP wired port profile to an IoT card.

The **undo wired-port-profile** command unbinds the AP wired port profile from an IoT card.

By default, no AP wired port profile is bound to an IoT card.

Format

wired-port-profile *profile-name*

undo wired-port-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of an AP wired port profile.	The AP wired port profile must exist.

Views

IoT card interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an IoT card communicates with an AP through an Ethernet interface, to configure this Ethernet interface, you can set parameters in an AP wired port profile and bind it to the IoT card.

Prerequisites

The IoT card has been configured to communicate with the AP through an Ethernet interface using the **card connect-type ethernet** command.

Example

Bind the AP wired port profile **wired-port1** to an IoT card.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wired-port-profile name wired-port1
[HUAWEI-wlan-wired-port-wired-port1] quit
[HUAWEI-wlan-view] ap-group name default
[HUAWEI-wlan-ap-group-default] card 1
[HUAWEI-wlan-group-card-default/1] wired-port-profile wired-port1
```

11.17 WLAN Traffic Optimization Commands

11.17.1 Command Support

WLAN-AC commands are supported only by the following models: S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.

11.17.2 display wlan igmp-snooping vap-cac

Function

The **display wlan igmp-snooping vap-cac** command displays the multicast CAC configuration and statistics on a VAP.

Format

display wlan igmp-snooping vap-cac { **ap-id** *ap-id* | **ap-name** *ap-name* }

Parameters

Parameter	Description	Value
ap-name *ap-name*	Specifies an AP name.	The AP name must exist.
ap-id *ap-id*	Specifies an AP ID.	The AP ID must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check the multicast CAC configuration and statistics on a VAP, including the bandwidth and user statistics.

Example

Display the multicast CAC configuration and statistics on VAPs of the AP with ID 0.

```
<HUAWEI> display wlan igmp-snooping vap-cac ap-id 0
Info: This operation may take a few seconds, please wait.done.
Rf            : Radio ID                 WID             : WLAN ID
CurBw         : Current bandwidth(kbps)   MaxBw           : Max bandwidth(kbps)
CurUser       : Current user number       MaxUser         : Max user number
BwUtilization : Bandwidth utilization     UserUtilization : User utilization
--------------------------------------------------------------------------------
Rf  WID  CurBw/MaxBw        BwUtilization  CurUser/MaxUser  UserUtilization
--------------------------------------------------------------------------------
0   1    0/11                 0%             0/6              0%
--------------------------------------------------------------------------------
Total: 1
```

Table 11-310 Description of the **display wlan igmp-snooping vap-cac** command output

Item	Description
Rf	Radio ID.
WID	WLAN ID.
CurBw/MaxBw	Current multicast bandwidth/ Maximum multicast bandwidth of a VAP.
BwUtilization	Multicast bandwidth utilization.
CurUser/MaxUser	Current number of multicast users/ Maximum number of multicast users on a VAP.
UserUtilization	Multicast user utilization.

11.17.3 igmp-snooping group-bandwidth (AP system profile view)

Function

The **igmp-snooping group-bandwidth** command configures the bandwidth of global multicast groups on an AP.

The **undo igmp-snooping group-bandwidth** command deletes the bandwidth of global multicast groups on an AP.

By default, the bandwidth of global multicast groups is not configured on an AP.

Format

igmp-snooping group-bandwidth start-group-address *start-group-address* **end-group-address** *end-group-address* **bandwidth** *bandwidth-value*

undo igmp-snooping group-bandwidth start-group-address *start-group-address* **end-group-address** *end-group-address*

Parameters

Parameter	Description	Value
start-group-address *start-group-address*	Specifies the start multicast group address.	The value is in dotted decimal notation.
end-group-address *end-group-address*	Specifies the end multicast group address.	The value is in dotted decimal notation.
bandwidth *bandwidth-value*	Specifies the bandwidth of multicast groups.	The value is an integer that ranges from 1 to 100000, in kbps.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can configure the bandwidth of multicast groups in an AP system profile according to the actual bandwidth of a multicast program. This configuration takes effect for the APs or AP groups to which this AP system profile is bound. When users request to order this multicast program, the collects statistics on the current multicast bandwidth of the VAP according to the configured bandwidth of global multicast groups, and compares the current bandwidth with the configured maximum bandwidth to determine whether to allow users to order this multicast program.

Precautions

You can configure the bandwidth for a maximum of 32 multicast group address segments. Addresses in one address segment must be different from those in another address segment. The configured address segments must contain valid multicast program addresses.

Example

Set the bandwidth to 100 kbps for multicast group address segment from 224.0.1.0 to 224.255.255.255.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] igmp-snooping group-bandwidth start-group-address
224.0.1.0 end-group-address 224.255.255.255 bandwidth 100
```

11.17.4 igmp-snooping max-bandwidth (traffic profile view)

Function

The **igmp-snooping max-bandwidth** command configures the maximum multicast bandwidth for a VAP.

The **undo igmp-snooping max-bandwidth** command deletes the maximum multicast bandwidth of a VAP.

By default, the maximum multicast bandwidth is not configured for a VAP.

Format

igmp-snooping max-bandwidth *max-bandwidth*

undo igmp-snooping max-bandwidth

Parameters

Parameter	Description	Value
max-bandwidth	Specifies the maximum multicast bandwidth of a VAP.	The value is an integer that ranges from 1 to 10000000, in kbit/s.

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The maximum multicast bandwidth is configured for a VAP in a traffic profile to limit the multicast traffic forwarding capacity of the VAP to which this traffic profile is bound. When the available multicast bandwidth of a VAP is insufficient, new users are prevented from joining multicast groups.

Precautions

After configuring the maximum multicast bandwidth for a VAP, run the **igmp-snooping group-bandwidth (AP system profile view)** command to configure the bandwidth of global multicast groups on the AP.

If the specified maximum multicast bandwidth is smaller than the actual volume of running multicast services, user services may be interrupted.

Example

Set the maximum multicast bandwidth to 500 kbit/s in traffic profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] igmp-snooping max-bandwidth 500
```

11.17.5 igmp-snooping max-user (traffic profile view)

Function

The **igmp-snooping max-user** command configures the maximum number of multicast group memberships for a VAP.

The **undo igmp-snooping max-user** command deletes the maximum number of multicast group memberships for a VAP.

By default, the maximum number of multicast group memberships is not configured for a VAP.

Format

igmp-snooping max-user *max-user*

undo igmp-snooping max-user

Parameters

Parameter	Description	Value
max-user	Specifies the maximum number of multicast group memberships on a VAP.	The value is an integer that ranges from 1 to 1000.

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The maximum number of multicast group memberships on a VAP is configured in a traffic profile to limit access of multicast users on the VAP to which this traffic profile is bound. When the number of multicast group memberships on a VAP reaches the maximum value, new users are prevented from joining multicast groups.

Precautions

If the specified maximum number of multicast group memberships is smaller than the actual number of access multicast users, user services may be interrupted.

Example

Set the maximum number of multicast group memberships to 10 on the VAP to which traffic profile **p1** is bound.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] igmp-snooping max-user 10
```

11.17.6 igmp-snooping enable (traffic profile view)

Function

The **igmp-snooping enable** command enables IGMP snooping in a traffic profile.

The **undo igmp-snooping enable** command disables IGMP snooping in a traffic profile.

By default, IGMP snooping is disabled in a traffic profile.

Format

igmp-snooping enable

undo igmp-snooping enable

Parameters

None

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IGMP snooping is a basic Layer 2 multicast function that forwards and controls multicast traffic at the data link layer. IGMP snooping runs on a Layer 2 device and analyzes IGMP messages exchanged between a Layer 3 device and hosts to set up and maintain a Layer 2 multicast forwarding table. The Layer 2 device forwards multicast packets based on the Layer 2 multicast forwarding table.

After you disable IGMP snooping in a traffic profile using the **undo igmp-snooping enable** command, all IGMP snooping configurations in the traffic profile are deleted. When you run the **igmp-snooping enable** command to enable IGMP snooping again, all IGMP snooping configurations are restored to the default settings on the device.

Prerequisites

The traffic profile has been created using the **traffic-profile (WLAN view)** command.

This command is used to enable Layer 2 multicast services. To ensure multicast service experience, you are advised to run the **traffic-optimize broadcast-suppression other-multicast disable** command in the AP system profile view to disable rate limiting for multicast packets. In addition, run the **anti-attack flood igmp disable** and **anti-attack flood other-multicast disable** commands in the VAP profile view to disable floor attack defense for multicast packets.

When multicast services are enabled, the multicast services may be affected if rate limiting for multicast packets is enabled on an AP. In this case, you are advised to run the **traffic-optimize broadcast-suppression rate-threshold (AP system profile view)** command to adjust the rate limit threshold for multicast packets.

When multicast services are enabled, the multicast services may be affected if flood attack defense is disabled in the VAP profile view. In this case, you are advised to run the **anti-attack flood { igmp | other-multicast } sta-rate-threshold** *sta-rate-threshold* command to adjust the flood attack threshold for multicast packets.

Example

Enable IGMP snooping in traffic profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] igmp-snooping enable
```

11.17.7 igmp-snooping report-suppress (Traffic profile view)

Function

The **igmp-snooping report-suppress** command enables suppression of IGMP Report and Leave message in a traffic profile.

The **undo igmp-snooping report-suppress** command cancels configuration of IGMP Report and Leave message suppression in a traffic profile.

By default, IGMP Report and Leave message suppression is disabled in a traffic profile.

Format

igmp-snooping report-suppress

undo igmp-snooping report-suppress

Parameters

None

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a Layer 2 device receives an IGMP Membership Report message (Report or Leave message) from a group member, the Layer 2 device forwards the message to the directly connected Layer 3 device. A group member host sends a Membership Report message in the following situations:

- When joining a multicast group, a host sends a Report message. When a multicast group has multiple members in a VLAN, the Layer 3 device receives duplicate Report messages from the member hosts.
- When receiving an IGMP General Query message, a host sends a Report message. Hosts use a timer to suppress duplicate Report messages in the same network segment. However, if the timer values on hosts are the same, the Layer 3 device can still receive duplicate Report messages.
- A host running IGMPv2 or IGMPv3 sends a Leave message when leaving a multicast group. When a multicast group has multiple members in a VLAN, the Layer 3 device receives duplicate Leave messages from the member hosts.

After this function is configured, a Layer 2 device forwards only one IGMP Membership Report message to the upstream device in the following scenarios: When the first member joins a multicast group or a host sends a Report message in response to an IGMP Query message, the Layer 2 device forwards a Report message to the upstream device. The upstream device then creates or maintains the matching forwarding entry based on the Report message. When the last member of a group leaves the group, the Layer 2 device forwards a Leave message to the upstream device. The upstream device then deletes the matching forwarding entry. This reduces the number of IGMP messages on the network.

Prerequisites

IGMP snooping has been enabled using the **igmp-snooping enable (traffic profile view)** command.

Example

Enable suppression of IGMP Report and Leave messages in traffic profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] igmp-snooping enable
[HUAWEI-wlan-traffic-prof-p1] igmp-snooping report-suppress
```

11.17.8 mld-snooping enable (traffic profile view)

Function

The **mld-snooping enable** command enables MLD snooping in a traffic profile.

The **undo mld-snooping enable** command disables MLD snooping in a traffic profile.

By default, MLD snooping is disabled in a traffic profile.

Format

mld-snooping enable

undo mld-snooping enable

Parameters

None

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **mld-snooping enable** command to enable MLD snooping in a traffic profile.

After you disable MLD snooping in a traffic profile using the **undo mld-snooping enable** command, all MLD snooping configurations in the traffic profile are deleted. When you run the **mld-snooping enable** command to enable MLD snooping again, all MLD snooping configurations are restored to the default settings in the traffic profile.

Prerequisites

A traffic profile has been created.

Before enabling MLD snooping in a traffic profile, run the **sta-ipv6-service enable** commands to enable the function of processing STA IPv6 services in the WLAN view.

Example

Enable MLD snooping in traffic profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] mld-snooping enable
```

11.17.9 service-guarantee

Function

The **service-guarantee** command configures the service guarantee mode.

The **undo service-guarantee** command restores the default service guarantee mode.

The default service guarantee mode is performance-first.

Format

service-guarantee { **performance-first** | **reliability-first** }

undo service-guarantee

Parameters

Parameter	Description	Value
performance-first	Sets the service guarantee mode to performance-first.	-
reliability-first	The service guarantee mode is set to reliability-first.	-

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an AP is connected to a VR device, retransmission of lost packets has a great impact on user experience. Therefore, you can set the service guarantee mode to reliability first. That is, when the VR throughput requirement is met, the air interface rate can be lowered properly to reduce jitter and delay caused by packet loss and retransmission, improving user experience. It is recommended that the service assurance mode be set to reliability first in VR gaming scenarios and to performance first in VR video scenarios.

Precautions

Changing the service guarantee mode will interrupt services of associated STAs.

Traffic optimization in VR scenarios is supported only by APs in compliance with 802.11ac Wave 2, 802.11ax and later standards.

Example

Set the service guarantee mode to reliability-first.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name ssid1
[HUAWEI-wlan-ssid-prof-ssid1] service-guarantee reliability-first
```

11.17.10 traffic-optimize arp-proxy enable

Function

The **traffic-optimize arp-proxy enable** command enables ARP proxy on the device.

The **undo traffic-optimize arp-proxy enable** command disables ARP proxy on the device.

By default, ARP proxy is disabled.

Format

traffic-optimize arp-proxy enable

undo traffic-optimize arp-proxy enable

Parameters

None

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an ARP Request packet is sent from a user or the network to another user, the AC or AP enabled with ARP proxy can reply to this packet. Compared with the function of converting ARP multicast packets to ARP unicast packets, ARP proxy can reduce the number of times a sleeping terminal is awakened to save power.

Precautions

The ARP proxy function is not available for roaming users.

Example

Enable ARP proxy on the device in the traffic profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] traffic-optimize arp-proxy enable
```

11.17.11 traffic-optimize bcmc deny all

Function

The **traffic-optimize bcmc deny all** command configures the air interface to deny downlink broadcast and multicast packets.

The **undo traffic-optimize bcmc deny all** command cancels the configuration of denying downlink broadcast and multicast packets on the air interface.

By default, the air interface does not deny downlink broadcast or multicast packets.

Format

traffic-optimize bcmc deny all [**except mdns**]

undo traffic-optimize bcmc deny all

Parameters

Parameter	Description	Value
except mdns	If this parameter is configured, mDNS packets are allowed to pass through when the air interface is configured to deny broadcast and multicast packets.	-

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an IP network, the ARP, ND, and DHCP protocols are the basic network protocols and serve as the basis for packet forwarding on the entire network.

Broadcast or multicast packets of protocols other than the ARP, ND, and DHCP protocols are optional on the IP network. When no services rely on transmission of these broadcast or multicast packets on the network, you can run the command to configure the air interface to deny all broadcast and multicast packets to improve the air interface performance.

Precautions

Before using the **traffic-optimize bcmc deny all** command to configure the air interface to deny downlink broadcast and multicast packets on the AP, run the **undo learn-client-address { ipv4 | ipv6 } disable** command to enable STA address learning and the **traffic-optimize bcmc unicast-send** { **arp** | **nd** | **dhcp** | **mdns** } * command to configure the broadcast/multicast-to-unicast conversion function on the air interface. Otherwise, the ARP, ND, and DHCP packets may fail to be forwarded.

Example

Configure the air interface to deny downstream broadcast and multicast packets in the traffic profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] traffic-optimize bcmc deny all
```

11.17.12 traffic-optimize bcmc unicast-send

Function

The **traffic-optimize bcmc unicast-send** { **arp** | **nd** | **dhcp** | **mdns** }* command configures the broadcast/multicast-to-unicast conversion function on the air interface.

The **undo traffic-optimize bcmc unicast-send** { **arp** | **nd** | **dhcp** | **mdns** }* command cancels the configuration of the broadcast/multicast-to-unicast conversion function on the air interface.

The **undo traffic-optimize bcmc unicast-send** command restores the default configuration.

By default, the broadcast/multicast-to-unicast conversion function is enabled for ARP, ND, and DHCP packets but disabled for mDNS packets on the air interface.

Format

traffic-optimize bcmc unicast-send { **arp** | **nd** | **dhcp** | **mdns** }*

undo traffic-optimize bcmc unicast-send { **arp** | **nd** | **dhcp** | **mdns** }*

undo traffic-optimize bcmc unicast-send

Parameters

Parameter	Description	Value
arp	Specifies ARP packets.	-
nd	Specifies ND packets.	-
dhcp	Specifies DHCP packets.	-
mdns	Specifies mDNS packets.	-

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an air interface sends a large number of broadcast or multicast packets when being busy, the performance of the air interface will drop. To prevent this situation, you can configure the broadcast/multicast-to-unicast conversion function to reduce the number of broadcast or multicast packets transmitted on the air interface. This improves air interface performance at the price of increased CPU usage.

Prerequisites

The **undo learn-client-address { ipv4 | ipv6 } disable** command has been executed to enable STA address learning.

Example

Configure the broadcast/multicast-to-unicast conversion function for **DHCP** packets in the traffic profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] traffic-optimize bcmc unicast-send dhcp
```

11.17.13 traffic-optimize bcmc unicast-send mismatch-action drop

Function

The **traffic-optimize bcmc unicast-send mismatch-action drop** command discards broadcast or multicast packets that fail to be converted into unicast packets on air interfaces.

The **undo traffic-optimize bcmc unicast-send mismatch-action drop** command restores the default action, that is, send broadcast or multicast packets that fail to be converted into unicast packets on air interfaces to all users in unicast mode.

By default, if broadcast or multicast packets fail to be converted into unicast packets on air interfaces, the packets are discarded.

Format

traffic-optimize bcmc unicast-send mismatch-action drop

undo traffic-optimize bcmc unicast-send mismatch-action drop

Parameters

None

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, if broadcast or multicast packets fail to be converted into unicast packets on air interfaces, the packets are discarded. To enable the system to send these packets to all users, run the **undo traffic-optimize bcmc unicast-send mismatch-action drop** command.

Prerequisites

- The **traffic-optimize bcmc unicast-send** command has been executed to configure the function of converting broadcast or multicast packets to unicast packets on an air interface.
- The **undo learn-client-address { ipv4 | ipv6 } disable** command has been executed to enable STA address learning.

Example

Configure the system to send the broadcast or multicast packets that fail to be converted into unicast packets on air interfaces to all users.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] undo traffic-optimize bcmc unicast-send mismatch-action drop
```

11.17.14 traffic-optimize broadcast-suppression

Function

The **traffic-optimize broadcast-suppression** command sets the maximum traffic volume of broadcast packets that can pass through a traffic profile.

The **undo traffic-optimize broadcast-suppression** command cancels the limit on the maximum traffic volume of broadcast packets that can pass through a traffic profile.

By default, broadcast packets are not suppressed in a traffic profile.

Format

traffic-optimize broadcast-suppression packets *packets-rate*

undo traffic-optimize broadcast-suppression

Parameters

Parameter	Description	Value
packets *packets-rate*	Specifies the number of packets transmitted per second.	The value is an integer that ranges from 0 to 14881000, in pps.

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a large number of broadcast packets are transmitted on a network, a lot of network resources are occupied, and services on the network are affected.

To prevent broadcast storms, you can run the **traffic-optimize broadcast-suppression** command to configure the maximum traffic volume of broadcast packets that can pass through a traffic profile. When the traffic volume of broadcast packets reaches the maximum in a traffic profile, the system discards excess broadcast packets to control the traffic volume in a proper range.

Precautions

Traffic suppression on the wireless side takes effect only for incoming traffic on the AP's air interface.

Example

Set the maximum traffic volume of broadcast packets that can pass through to 21600 pps in traffic profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] traffic-optimize broadcast-suppression packets 21600
```

11.17.15 traffic-optimize multicast-suppression

Function

The **traffic-optimize multicast-suppression** command sets the maximum traffic volume of multicast packets in a traffic profile.

The **undo traffic-optimize multicast-suppression** command cancels the limit on the maximum traffic volume of multicast packets in a traffic profile.

By default, multicast packets are not suppressed in a traffic profile.

Format

traffic-optimize multicast-suppression packets *packets-rate*

undo traffic-optimize multicast-suppression

Parameters

Parameter	Description	Value
packets *packets-rate*	Specifies the number of packets transmitted per second.	The value ranges from 0 to 14881000, in pps.

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a large number of multicast packets are transmitted on a network, a lot of network resources are occupied, and services on the network are affected.

To ensure normal service transmission on a network, you can run the **traffic-optimize multicast-suppression** command to configure the maximum multicast traffic volume in a traffic profile. When the traffic volume of multicast packets reaches the maximum, the system discards excess multicast packets to control the traffic volume in a proper range.

Precautions

Traffic suppression on the wireless side takes effect only for incoming traffic on the AP's air interface.

Example

Set the maximum traffic volume of multicast packets to 21600 pps in the traffic profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] traffic-optimize multicast-suppression packets 21600
```

11.17.16 traffic-optimize multicast-unicast enable

Function

The **traffic-optimize multicast-unicast enable** command enables the multicast-to-unicast conversion function in a traffic profile.

The **undo traffic-optimize multicast-unicast enable** command disables the multicast-to-unicast conversion function in a traffic profile.

By default, the multicast-to-unicast conversion function is disabled in a traffic profile.

NOTE

Multicast-to-unicast conversion of data packets on the air interface is not supported by the following model:

- AirEngine 8771-X1T

Format

traffic-optimize multicast-unicast enable

undo traffic-optimize multicast-unicast enable

Parameters

None

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can enable the multicast-to-unicast conversion function in scenarios that have high requirements on multicast stream transmission, such as high-definition (HD) video on demand (VOD) scenarios.

After this function is enabled, an AP listens on Report and Leave packets to maintain multicast-to-unicast entries. When sending multicast packets to STAs, the AP converts the multicast packets into unicast packets based on the multicast-to-unicast entries to improve multicast stream transmission efficiency.

Example

Enable the multicast-to-unicast conversion function in the traffic profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] traffic-optimize multicast-unicast enable
```

11.17.17 traffic-optimize multicast-unicast dynamic-adaptive disable

Function

The **traffic-optimize multicast-unicast dynamic-adaptive disable** command disables adaptive multicast-to-unicast conversion in a traffic profile.

The **undo traffic-optimize multicast-unicast dynamic-adaptive disable** command enables adaptive multicast-to-unicast conversion in a traffic profile.

By default, adaptive multicast-to-unicast conversion is enabled in a traffic profile.

NOTE

Multicast-to-unicast conversion of data packets on the air interface is not supported by the following model:

- AirEngine 8771-X1T

Format

traffic-optimize multicast-unicast dynamic-adaptive disable

undo traffic-optimize multicast-unicast dynamic-adaptive disable

Usage Guidelines

Usage Scenario

After adaptive multicast-to-unicast conversion is enabled, when the air interface performance becomes a bottleneck during multicast-to-unicast conversion, an AP automatically switches the multicast group containing the minimum number of STAs to the multicast mode. After the air interface performance is improved and keeps being improved for a period of time, the AP automatically switches the multicast group containing the maximum number of STAs to the unicast mode. In this way, the air interface performance is automatically adjusted without manual intervention, improving wireless user experience.

Pre-configuration Tasks

The multicast-to-unicast conversion function has been enabled in the traffic profile using the **traffic-optimize multicast-unicast enable** command.

Example

Disable adaptive multicast-to-unicast conversion in traffic profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] traffic-optimize multicast-unicast enable
[HUAWEI-wlan-traffic-prof-p1] traffic-optimize multicast-unicast dynamic-adaptive disable
```

11.17.18 traffic-optimize nd-proxy enable

Function

The **traffic-optimize nd-proxy enable** command enables ND proxy on the device.

The **undo traffic-optimize nd-proxy enable** command disables ND proxy on the device.

By default, ND proxy is disabled.

Format

traffic-optimize nd-proxy enable

undo traffic-optimize nd-proxy enable

Parameters

None

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an ND Request packet is sent from a user or the network to another user, the AC or AP enabled with ND proxy can reply to this packet. Compared with the function of converting ND multicast packets to unicast packets, ND proxy can reduce the number of times a sleeping terminal is awakened to save power.

Precautions

The ND proxy function is not available for roaming users.

Example

Enable ND proxy on the device in the traffic profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] traffic-optimize nd-proxy enable
```

11.17.19 traffic-optimize sta-bridge-forward disable

Function

The **traffic-optimize sta-bridge-forward disable** command configures the function of denying packets destined for bridge STAs on the air interface.

The **undo traffic-optimize sta-bridge-forward disable** command cancels the function of denying packets destined for bridge STAs on the air interface.

By default, the air interface does not deny packets destined for bridge STAs.

Format

traffic-optimize sta-bridge-forward disable

undo traffic-optimize sta-bridge-forward disable

Parameters

None

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Some terminals on the wireless network can provide bridging functions. The terminals associate with APs with their MAC addresses and connect to multiple Layer 3 wired devices in the downlink direction. The connected Layer 3 wired devices can also obtain IP addresses and forward traffic through the APs. The APs consider that the associated terminals have multiple IP addresses. You can run the command to configure the function of denying packets destined for bridge STAs on the air interface. This can reduce the number of packets transmitted on the air interfaces and improve the air interface performance.

Example

Configure the function of denying packets destined for bridge STAs on the air interface in the traffic profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] traffic-optimize sta-bridge-forward disable
```

11.17.20 traffic-optimize tcp adjust-mss

Function

The **traffic-optimize tcp adjust-mss** command sets the maximum segment size (MSS) of TCP packets in a traffic profile.

The **undo traffic-optimize tcp adjust-mss** command deletes the configured MSS of TCP packets in a traffic profile.

By default, the MSS of TCP packets in a traffic profile is not configured.

Format

traffic-optimize tcp adjust-mss *value*

undo traffic-optimize tcp adjust-mss

Parameters

Parameter	Description	Value
value	Specifies the MSS of TCP packets in a traffic profile.	The value is an integer that ranges from 128 to 2048, in bytes.

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The MSS is an option defined in the TCP protocol and refers to the maximum length of TCP packets that can be received by a device. When setting up a TCP connection, the local and peer devices negotiate an MSS value to determine the maximum data length of TCP packets. If the length of TCP packets sent from the peer device exceeds the MSS value, the packets are fragmented.

Precautions

- To prevent TCP packets from being fragmented, you must configure a proper MSS based on the maximum transmission unit (MTU). The MTU is the option to determine whether IP packets will be fragmented. If the size of an IP packet exceeds the MTU, the IP packet will be fragmented. To ensure that a complete packet is transmitted properly, the MSS value plus all the header lengths (TCP header and IP header) cannot exceed the MTU. For example, a CAPWAP-encapsulated TCP packet consists of an outer IP header (20 bytes), a UDP header (8 bytes), a CAPWAP header (8 bytes), an ETH header (18 bytes), an inner IP header (20 bytes), a TCP header (20 bytes), and TCP data. If the default MTU is 1500 on the device, the MSS value can be set to a maximum of 1406 bytes so that the CAPWAP-encapsulated TCP packet is not fragmented by the device. In case that the CAPWAP header or TCP header carries option fields, it is recommended that you set the MSS to 1380 bytes.
- The MSS configured by the **traffic-optimize tcp adjust-mss** command takes effect on the AP as a TCP client or server. Additionally, if packets of other devices as clients pass through the AP, the negotiation result is modified based on the MSS configured using this command only when the MSS received by the AP is larger than that configured using this command.
- If you run the **traffic-optimize tcp adjust-mss** command in the same interface view multiple times, only the latest configuration takes effect.

Example

Set the MSS of TCP packets to 1200 bytes in the traffic profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] traffic-optimize tcp adjust-mss 1200
```

11.17.21 traffic-optimize unicast-suppression

Function

The **traffic-optimize unicast-suppression** command sets the maximum traffic volume of unknown unicast packets in a traffic profile.

The **undo traffic-optimize unicast-suppression** command cancels the limit on the maximum traffic volume of unknown unicast packets in a traffic profile.

By default, unknown unicast packets are not suppressed in a traffic profile.

Format

traffic-optimize unicast-suppression packets *packets-rate*

undo traffic-optimize unicast-suppression

Parameters

Parameter	Description	Value
packets *packets-rate*	Specifies the number of packets transmitted per second.	The value ranges from 0 to 14881000, in pps.

Views

Traffic profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a large number of unknown unicast packets are transmitted on a network, a lot of network resources are occupied, and services on the network are affected.

To prevent broadcast storms, you can run the **traffic-optimize unicast-suppression** command to configure the maximum traffic volume of unknown unicast packets that can pass through an interface. When the traffic volume of unknown unicast packets reaches the maximum on an interface, the system discards excess unknown unicast packets to control the traffic volume in a proper range.

Precautions

Traffic suppression on the wireless side takes effect only for incoming traffic on the AP's air interface.

Example

Set the maximum traffic volume of unknown unicast packets to 21600 pps in the traffic profile **p1**.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] traffic-profile name p1
[HUAWEI-wlan-traffic-prof-p1] traffic-optimize unicast-suppression packets 21600
```

11.18 Centralized License Control Commands

11.18.1 Command Support

WLAN-AC commands are supported only by the following models: S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.

11.18.2 license centralized enable

Function

The **license centralized enable** command enables centralized license control.

The **undo license centralized enable** command disables centralized license control.

By default, centralized license control is disabled.

Format

license centralized enable

undo license centralized enable

Parameters

None

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When centralized license control is enabled on both the license server and license clients, licenses in the license resource pool can be centrally controlled on the license server and shared by both the license server and license clients.

Example

Enable centralized license control.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] license centralized enable
```

11.18.3 license server

Function

The **license server** command specifies the IP address of the license server on a license client. This IP address must be the same as the CAPWAP source address configured on the license server.

The **undo license server** command deletes the local IP address of the license server on a license client.

By default, no IP address is set for the license server.

Format

license server ip-address *ip-address*

undo license server

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies the IPv4 address of the license server.	The value is in dotted decimal notation.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After centralized license control is enabled, you can run the **license server** command on a license client to set an IP address for the license server, so that the license client can set up a link with the license server and be managed by the license server.

Prerequisites

The local IP address of the license client has been configured. Run the **license client source ip-address** *ip-address* command to configure the local IP address of the license client.

- When multiple CAPWAP source addresses exist, use this configuration to specify one CAPWAP source address as the local address.
- If the license client is a single device, the source address configuration is not required. Instead, the CAPWAP source address is used as the local address of the license client by default.

Example

Set the IP address for the license server to 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] license server ip-address 10.1.1.1
```

11.18.4 license client source

Function

The **license client source** command configures a local IP address for a license client.

The **undo license client source** command deletes the local IP address of a license client.

By default, the first CAPWAP source IP address is used as the local IP address of a license client.

Format

license client source ip-address *ip-address*

undo license client source

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies the local IPv4 address of the license client.	The value is in dotted decimal notation.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

- When multiple CAPWAP source addresses exist, use this configuration to specify one CAPWAP source address as the local address.
- If the license client is a single device, the source address configuration is not required. Instead, the CAPWAP source address is used as the local address of the license client by default.

Example

Set the local IP address of a license client to 10.1.2.1.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] license client source ip-address 10.1.2.1
```

11.18.5 display license centralized configuration

Function

The **display license centralized configuration** command displays the configuration of centralized license control.

Format

display license centralized configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check whether centralized license control is enabled and the IP address of the license server.

Example

Display the configuration of centralized license control on the license server.

```
<HUAWEI> display license centralized configuration
------------------------------------------------
License centralized server enable :    enable
License server IP                 :    -
------------------------------------------------
```

Display the configuration of centralized license control on a license client.

```
<HUAWEI> display license centralized configuration
------------------------------------------------
License centralized server enable :    enable
License server IP                 :    10.1.1.1
License local IP                  :    10.1.1.2
------------------------------------------------
```

Table 11-311 Description of the **display license centralized configuration** command output

Item	Description
License centralized server enable	Whether centralized license control is enabled. - enable: Centralized license control is enabled. - disable: Centralized license control is disabled. To configure this parameter, run the **license centralized enable** command.
License server IP	IP address of the license server. To configure this parameter on a license client, run the **license server** command.
License local IP	Local IP address of the license client. To configure this parameter on a license client, run the **license client source** command. If this parameter is not configured, **-** is displayed.

11.18.6 display license resource usage detail

Function

The **display license resource usage detail** command displays the license resource usage in the license resource pool or on a single AC.

Format

display license resource usage detail

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

- If centralized license control is enabled, you can run this command on the license server to check the license resource usage in the license resource pool, on all license servers, and on all license clients. On a license client, you can run this command to check the license resource usage in the license resource pool and on the local AC.
- When centralized license control is disabled, you can run this command to check the license resource usage on the local AC and backup AC.

Example

Display the license resource usage on a license server.

```
<HUAWEI> display license resource usage detail
Remain(days): Remaining days of the license resource pool after the client goes offline
Current role        :  server
Used/Total resource:  300/1100
----------------------------------------------------------------------------------------------------
MAC              Role           State     Local License  Used     Remain(days)    IP
----------------------------------------------------------------------------------------------------
0000-0000-0015     server         normal   100          200      -             -
0000-0000-0017     client         normal   600          100      -             1.1.1.3
0000-0000-0018     client         fault    100          -        20            1.1.1.5
----------------------------------------------------------------------------------------------------
Total records: 4
```

Display the license resource usage on a license client.

```
<HUAWEI> display license resource usage detail
Remain(days): Remaining days of the license resource pool after the client goes offline
Current role        :  client
Used/Total resource:  300/1100
----------------------------------------------------------------------------------------------------
MAC            Role           State     Local License  Used     Remain(days)    IP

0000-0000-0023   client         normal   600          100      -             1.1.1.3
----------------------------------------------------------------------------------------------------
Total records: 1
```

Display the license resource usage on an AC when centralized license control is not in effect.

```
<HUAWEI> display license resource usage detail
Remaining days: Remaining days of the backup license
Used/Total resource    :    0/4
----------------------------------------------------------------------------------------------------
 AC MAC           License     Backup Time                  Remaining Days    Backup Mode
----------------------------------------------------------------------------------------------------
 Local AC         4           -                            -               -
----------------------------------------------------------------------------------------------------
Total records: 1
```

Table 11-312 Description of the **display license resource usage detail** command output

Item	Description
Current role	Role of the current AC. ● server ● client

Item	Description
Used/Total resource	License resource usage, that is, ratio of the number of used licenses to the total number of licenses.
MAC	MAC address of an AC.
Role	Role of an AC. ● server ● client
State	State of the link between a license client and the license server. ● normal: The license client is properly connected to the license server. ● fault: The license client is disconnected from the license server.
Local License	Number of loaded licenses on an AC.
Used	Number of used licenses on an AC.
Remain(days)	Remaining days of the license resource pool after the license client is disconnected from the license server.
IP	IP address used by a license client to set up a link with the license server.
AC MAC	MAC address of the backup AC. **Local AC** indicates the local AC.
License	Number of loaded licenses on the AC.
Backup Time	Time when licenses are backed up. This field is unavailable currently and is displayed as **-**.
Remaining Days	Remaining days of the backup license. This field is unavailable currently and is displayed as **-**.
Backup Mode	Backup mode. This field is unavailable currently and is displayed as **-**.

11.19 WLAN Reliability Commands

11.19.1 Command Support

WLAN-AC commands are supported only by the following models: S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.

11.19.2 ac protect alarm-restrain enable

Function

The **ac protect alarm-restrain enable** command enables AP Fault alarm suppression.

The **undo ac protect alarm-restrain enable** command disables AP Fault alarm suppression.

By default, AP Fault alarm suppression is disabled.

Format

ac protect alarm-restrain enable

undo ac protect alarm-restrain enable

Parameters

None

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In dual-link cold backup scenarios, after an AP becomes **Fault** on the active AC, switches to the standby AC, and works properly, the active AC generates an AP Fault alarm. If AP Fault alarms are not needed in this case, you can run this command to enable AP Fault alarm suppression.

After AP Fault alarm suppression is enabled, the active and standby ACs generate AP Fault alarms only when both ACs detect that an AP becomes faulty on them.

Precautions

The active and standby ACs notify each other of the AP status by exchanging packets. If communication between the ACs fails, AP Fault alarm suppression cannot take effect.

AP Fault alarm suppression can only suppress the AP Fault alarms caused by heartbeat timeout. If an AP is deleted or restarted using the **undo ap** or **ap-reset** command, the alarms cannot be suppressed.

Example

Enable AP Fault alarm suppression.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ac protect alarm-restrain enable
```

11.19.3 ac protect cold-backup kickoff-station

Function

The **ac protect cold-backup kickoff-station** command enables the function of disconnecting STAs in open system authentication mode when an active/standby switchover is implemented between ACs that have dual-link cold backup configured.

The **undo ac protect cold-backup kickoff-station** command restores the default setting.

By default, STAs using open system authentication remain connected to APs when an active/standby AC switchover is implemented.

Format

ac protect cold-backup kickoff-station

undo ac protect cold-backup kickoff-station

Parameters

None

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

An active/standby switchover between two ACs that have dual-link cold backup configured causes a short service interruption.

- STAs not using open system authentication are disconnected from APs and need to go online again after the active/standby switchover.
- By default, STAs using open system authentication remain connected to APs and do not need to go online again after the active/standby switchover. You can run the **ac protect cold-backup kickoff-station** command to configure the STAs to be disconnected when an active/standby AC switchover is implemented.

Example

Enable the function of disconnecting STAs in open system authentication mode when an active/standby switchover is implemented between ACs that have dual-link cold backup configured.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ac protect cold-backup kickoff-station
```

11.19.4 ac protect link-switch packet-loss echo-probe-time

Function

The **ac protect link-switch packet-loss echo-probe-time** command specifies the number of Echo packets sent within a statistics collection interval.

The **undo ac protect link-switch packet-loss echo-probe-time** command restores the default number of Echo packets sent within a statistics collection interval.

By default, the number of Echo packets sent within a statistics collection interval is 20.

Format

ac protect link-switch packet-loss echo-probe-time *echo-probe-time*

undo ac protect link-switch packet-loss echo-probe-time

Parameters

Parameter	Description	Value
echo-probe-time	Specifies the number of Echo packets.	The value is an integer that ranges from 6 to 100.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the active/standby link switchover mode is set to the network stabilization mode, ACs periodically check whether the network stabilization of active and standby links meets the condition for triggering an active/standby link switchover and collect statistics about the specified number of Echo packets at each interval to calculate the network stabilization.

In N+1 backup scenarios, only one of the primary and backup ACs sets up a CAPWAP link with an AP at the same time. The network stabilization of this link can be calculated through Echo packets. The network stabilization of the link between the AP and another AC can be calculated through Primary Discovery packets. Statistics about Primary Discovery packets can also be collected by setting the parameter *echo-probe-time*.

Prerequisites

The active/standby link switchover mode has been set to the network stabilization mode using the **ac protect link-switch mode network-stabilization** command.

Example

Set the number of Echo packets sent within a statistics collection interval to 30.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name abc
[HUAWEI-wlan-ap-system-prof-abc] ac protect link-switch packet-loss echo-probe-time 30
```

11.19.5 ac protect link-switch mode

Function

The **ac protect link-switch mode** command configures the active/standby link switchover mode.

The **undo ac protect link-switch mode** command restores the default active/standby link switchover mode.

By default, the active/standby link switchover mode is the priority mode.

Format

ac protect link-switch mode { **priority** | **network-stabilization** }

undo ac protect link-switch mode

Parameters

Parameter	Description	Value
priority	Sets the active/standby link switchover mode to the priority mode.	-
network-stabilization	Sets the active/standby link switchover mode to the network stabilization mode.	-

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In dual-link cold backup or hot standby scenarios, an AP simultaneously sets up active and standby links with active and standby ACs, respectively. If the active link is faulty, the AP switches service traffic to the standby link and goes online on the standby AC. When the active link recovers, the AP detects that this link has a higher priority than the other one and triggers a revertive switchover. After 20 Echo intervals, the AP switches service traffic back to the active AC.

- To enable an AP to preferentially switch service traffic to the active link, set the active/standby link switchover mode to the priority mode.
- To allow an AP to use a link with high network stabilization, set the active/standby link switchover mode to the network stabilization mode. When the condition for triggering an active/standby link switchover is met, the AP preferentially switches service traffic to the link on a network with higher stabilization. In this case, whether an active/standby link switchover is performed is only related to the network stabilization of links but not related to the active and standby roles of links. You can run the **ac protect link-switch packet-loss** { **gap-threshold** *gap-threshold* | **start-threshold** *start-threshold* } command to configure the condition for triggering an active/standby link switchover.

In N+1 backup scenarios, APs set up links only with the primary ACs. When a link between an AP and a primary AC fails, the AP sets up a link with the backup AC and goes online on the backup AC. When the primary AC is recovered, a revertive switchover is triggered. The AP switches the link back to the primary AC after 20 Echo intervals.

- To enable an AP to preferentially go online on the primary AC, set the active/standby link switchover mode to the priority mode.
- To allow an AP to use a link with high network stabilization, set the active/standby link switchover mode to the network stabilization mode.

Precautions

The active/standby link switchover mode applies to active and standby ACs configured using the **ac protect protect-ac** and **priority** commands, or the **primary-access** and **backup-access** commands.

Example

Set the active/standby link switchover mode to the network stabilization mode.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name abc
[HUAWEI-wlan-ap-system-prof-abc] ac protect link-switch mode network-stabilization
```

11.19.6 ac protect link-switch packet-loss

Function

The **ac protect link-switch packet-loss** command configures the packet loss rate start and difference thresholds for an active/standby link switchover.

The **undo ac protect link-switch packet-loss** command restores the default packet loss rate start and difference thresholds for an active/standby link switchover.

By default, the packet loss rate start and difference thresholds for an active/standby link switchover are 20% and 15%, respectively.

Format

ac protect link-switch packet-loss { **gap-threshold** *gap-threshold* | **start-threshold** *start-threshold* }

undo ac protect link-switch packet-loss { **gap-threshold** | **start-threshold** }

Parameters

Parameter	Description	Value
gap-threshold *gap-threshold*	Specifies the packet loss rate difference threshold for an active/standby link switchover.	The value is an integer that ranges from 5 to 60, in percentage.
start-threshold *start-threshold*	Specifies the packet loss rate start threshold for an active/standby link switchover.	The value is an integer that ranges from 5 to 60, in percentage.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the active/standby link switchover mode is set to the network stabilization mode, ACs check whether the network stabilization of active and standby links meets the condition for triggering an active/standby link switchover. If so, service traffic is switched to the link with higher network stabilization. If not, the switchover is not performed.

In dual-link cold backup and hot standby scenarios, the network stabilization of active and standby links is determined based on the Echo packet loss rate. The active/standby link switchover is performed when the following conditions are met:

1. APs collect statistics about the specified number of Echo packets forwarded through the link in use at each interval and find that the calculated packet loss rate is higher than the packet loss rate start threshold.
2. The packet loss rate of the link in use is higher than that of the other link, and the difference between the two links' packet loss rates is higher than the packet loss rate difference threshold.

In N+1 backup scenarios, the network stabilization of the link between an AP and the current AC is determined by the Echo packet loss rate, and that of the link between the AP and another AC is determined by the Primary Discovery packet loss rate. The conditions for triggering an active/standby switchover are the same as those for dual-link cold backup and hot standby scenarios.

Prerequisites

The active/standby link switchover mode has been set to the network stabilization mode using the **ac protect link-switch mode network-stabilization** command.

Example

Set the packet loss rate start threshold for an active/standby link switchover to 30%.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name abc
[HUAWEI-wlan-ap-system-prof-abc] ac protect link-switch packet-loss start-threshold 30
```

11.19.7 ac protect enable

Function

The **ac protect enable** command enables dual-link backup globally and disables N+1 backup.

The **undo ac protect enable** command disables dual-link backup globally and enables N+1 backup.

By default, dual-link backup is disabled globally, and N+1 backup is enabled.

Format

ac protect enable

undo ac protect enable

Parameters

None

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To ensure service stability, an AP needs to establish connections with two ACs. The two ACs work in active/standby mode. The active AC provides services for APs, whereas the standby AC is a backup to the active AC.

Follow-up Procedure

After dual-link backup or N+1 backup is enabled globally, configure the AC priority and standby AC IP address to implement dual-link backup or N+1 backup.

Precautions

Ensure that active and standby ACs deliver the same WLAN service configuration to an AP that connects to the two ACs.

Example

Enable dual-link backup globally and disable N+1 backup.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ac protect enable
Warning: This operation maybe cause AP reset, continue?[Y/N]:y
```

11.19.8 ac protect priority

Function

The **ac protect priority** command configures the AC priority in the WLAN view.

The **undo ac protect priority** command restores the default AC priority in the WLAN view.

By default, the AC priority in the WLAN view is 0.

Format

ac protect priority *priority*

undo ac protect priority

Parameters

Parameter	Description	Value
priority	Specifies the AC priority.	The value is an integer that ranges from 0 to 7. A smaller value indicates a higher priority.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an AP goes online, ACs deliver their priorities to the AP. The AP selects the AC with a higher priority as the active AC and establishes a CAPWAP tunnel with the active AC.

To implement dual-link backup on all the APs connected to an AC, configure the AC priority and standby AC IP address in the WLAN view to reduce the configuration workload.

Precautions

If the AC priority is configured in the WLAN view and AP system profile view before an AP goes online, the AC priority configured in the AP system profile view is delivered to the AP. If no AC priority is configured in the AP system profile view, the AC priority configured in the WLAN view is delivered to the AP.

Example

Set the AC priority to 3 in the WLAN view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ac protect priority 3
```

11.19.9 ac protect protect-ac

Function

The **ac protect protect-ac** command configures the standby AC IP address in the WLAN view.

The **undo ac protect protect-ac** command restores the default standby AC IP address in the WLAN view.

By default, no standby AC IP address is configured in the WLAN view.

Format

ac protect protect-ac *ip-address*

undo ac protect protect-ac

Parameters

Parameter	Description	Value
ip-address	Specifies an IPv4 address for the standby AC.	The value is in dotted decimal notation.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To implement dual-link backup on all the APs connected to an AC, configure the AC priority and standby AC IP address in the WLAN view to reduce the configuration workload.

Precautions

If standby AC IP addresses are configured in both the WLAN view and AP system profile view before an AP goes online, the standby AC IP address configured in the AP system profile view is delivered to an AP. If no standby AC IP address is configured in the AP system profile view, the standby AC IP address configured in the WLAN view is delivered to an AP. If no standby AC IP address is configured in the WLAN view, dual-link backup is disabled.

The standby AC's IP address must be set to the same as the CAPWAP source address of the standby AC.

Example

Set the standby AC IP address to 10.33.12.56 in the WLAN view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ac protect protect-ac 10.33.12.56
```

11.19.10 ac protect restore disable

Function

The **ac protect restore disable** command disables global revertive switching.

The **undo ac protect restore disable** command enables global revertive switching.

By default, global revertive switching is enabled.

Format

ac protect restore disable

undo ac protect restore disable

Parameters

None

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

AC1 is the active AC and AC2 is the standby AC. When the link between AC1 and an AP fails, AC2 takes the active role.

When the link between AC1 and the AP recovers, the AP detects that AC1 priority is higher than AC2 and instructs AC1 and AC2 to perform revertive switching. AC1 then becomes the active AC again.

Precautions

- The **undo wlan ac protect restore disable** command must be used before an AP goes online and dual-link backup is implemented. In this way, the AC delivers the revertive switching configuration to the AP when the AP goes online.
- If global revertive switching is disabled, traffic of an AP cannot be switched back to AC1 when the link between AC1 and the AP restores.
- The command takes effect after an AP restart.

Example

Disable global revertive switching.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ac protect restore disable
```

11.19.11 backup-access

Function

The **backup-access** command configures a backup AC IP address.

The **undo backup-access** command restores the default backup AC IP address.

By default, no backup AC IP address is configured.

Format

backup-access ip-address *ip-address*

undo backup-access

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies an IPv4 address of the backup AC.	The value is in dotted decimal notation.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In AC backup scenarios, a backup AC IP address is configured so that APs can establish CAPWAP tunnels to the backup AC if they fail to establish CAPWAP tunnels to the primary AC.

Precautions

- The configurations of **primary-access** and **backup-access** take effect only if both the commands are run to configure different IP addresses.
- **primary-access** and **backup-access** cannot be configured with **priority** or **protect-ac**.
- It is not recommended that **primary-access** and **backup-access** be configured with **ac protect protect-ac** or **ac protect priority**.
- The configuration takes effect only after the AP is restarted.
- The IP addresses specified by **primary-access** and **backup-access** must be configured the same as CAPWAP source IP addresses. If the CAPWAP source addresses have been translated using NAT, set the **primary-access** and **backup-access** IP addresses to the translated addresses.

Example

Set the backup AC IP address to 10.33.12.78.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] ap-system-profile name sys1
[HUAWEI-wlan-ap-system-prof-sys1] backup-access ip-address 10.33.12.78
```

11.19.12 display ac protect

Function

The **display ac protect** command displays AC dual-link backup configuration.

Format

display ac protect

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view AC dual-link backup configuration.

Example

Display AC dual-link backup configuration.

```
<HUAWEI> display ac protect
------------------------------------------------------------
Protect state             : disable
Protect AC                : -
Priority                  : 0
Protect restore           : enable
Coldbackup kickoff station: disable
Alarm restrain            : disable
------------------------------------------------------------
```

Table 11-313 Description of the **display ac protect** command output

Item	Description
Protect state	Whether global dual-link backup and N+1 backup are enabled. ● disable: Global dual-link backup is disabled, and N+1 backup is enabled. ● enable: Global dual-link backup is enabled, and N+1 backup is disabled. To configure the parameter, run the **ac protect enable** command.
Protect AC	Standby AC IP address. To configure the parameter, run the **ac protect protect-ac** command.
Priority	Priority of the local AC. To configure the parameter, run the **ac protect priority** command.
Protect restore	Whether global revertive switching is enabled on the AC. To configure the parameter, run the **ac protect restore disable** command.
Coldbackup kickoff station	Whether to enable the function of disconnecting STAs in open system authentication mode when an active/standby switchover is implemented between ACs that have dual-link cold backup configured. To configure the parameter, run the **ac protect cold-backup kickoff-station** command.
Alarm restrain	Whether to enable AP fault alarm suppression. To configure the parameter, run the **ac protect alarm-restrain enable** command.

11.19.13 primary-access

Function

The **primary-access** command configures a primary AC IP address.

The **undo primary-access** command restores the default primary AC IP address.

By default, no primary AC IP address is configured.

Format

primary-access ip-address *ip-address*

undo primary-access

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies an IPv4 address of the primary AC.	The value is in dotted decimal notation.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In AC backup scenarios, a primary AC IP address is configured. When APs attempt to go online, they preferentially associate with the primary AC and establish CAPWAP tunnels.

Precautions

- The configurations of **primary-access** and **backup-access** take effect only if both the commands are run to configure different IP addresses.
- **primary-access** and **backup-access** cannot be configured with **priority** or **protect-ac**.
- It is not recommended that **primary-access** and **backup-access** be configured with **ac protect protect-ac** or **ac protect priority**.
- The configuration takes effect only after the AP is restarted.
- The IP addresses specified by **primary-access** and **backup-access** must be configured the same as CAPWAP source IP addresses. If the CAPWAP source addresses have been translated using NAT, set the **primary-access** and **backup-access** IP addresses to the translated addresses.

Example

Set the primary AC IP address to 10.33.12.56.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name sys1
[HUAWEI-wlan-ap-system-prof-sys1] primary-access ip-address 10.33.12.56
```

11.19.14 priority

Function

The **priority** command sets the AC priority in the AP system profile view.

The **undo priority** command restores the AC priority to the default setting in the AP system profile view.

By default, no AC priority is configured in the AP system profile view.

Format

priority *priority-level*

undo priority

Parameters

Parameter	Description	Value
priority-level	Specifies the AC priority.	The value is an integer that ranges from 0 to 7. A smaller value indicates a higher priority.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an AP goes online, ACs deliver their priorities to the AP. The AP selects the AC with the highest priority as the active AC and establishes a CAPWAP tunnel with the active AC.

Precautions

If the AC priority is configured in the WLAN view and AP system profile view before an AP goes online, the AC priority configured in the AP system profile view is delivered to the AP. If no AC priority is configured in the AP system profile view, the AC priority configured in the WLAN view is delivered to the AP.

If ACs deliver the same priorities to the AP, the AP selects the AC with the lowest AP load as the active AC. If both AC priorities and AP load are the same, the AP selects the AC with the lowest STA load as the active AC. If AC priorities, AP load, and STA load are the same, the AP selects the AC with the smallest IP address as the active AC to establish a CAPWAP tunnel. The AP or STA load equals the number of allowed APs or STAs minus the number of existing APs or STAs.

Example

Set the AC priority to 3 in the AP system profile view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] priority 3
```

11.19.15 protect-ac

Function

The **protect-ac** command configures the standby AC's IP address in the AP system profile view.

The **undo protect-ac** command restores the standby AC's IP address to the default setting in the AP system profile view.

By default, no standby AC's IP address is configured in the AP system profile view.

Format

protect-ac ip-address *ip-address*

undo protect-ac

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies an IPv4 address for the standby AC.	The value is in dotted decimal notation.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To enable an AP to establish connections with two ACs (active and standby ACs) to implement dual-link backup, you can run this command to configure the standby AC IP address in the AP system profile view.

Precautions

If standby AC's IP addresses are configured in both the WLAN view and AP system profile view, the standby AC's IP address configured in the AP system profile view is delivered to an AP. If no standby AC's IP address is configured in the AP system profile view, the standby AC's IP address configured in the WLAN view is delivered to an AP.

The IP address of the standby AC cannot be specified as the IP address of the local device. Otherwise, the backup function does not take effect.

The standby AC's IP address must be set to the same as the CAPWAP source address of the standby AC.

Example

Set the standby AC's IP address to 10.3.3.3 in the AP system profile view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name ap-system1
[HUAWEI-wlan-ap-system-prof-ap-system1] protect-ac ip-address 10.3.3.3
```

11.20 WMI Commands

11.20.1 Command Support

WLAN-AC commands are supported only by the following models: S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.

11.20.2 ap log module

Function

The **ap log module** command enables APs to report logs of the module with a specified ID to a WMI server.

The **undo ap log module mid** *mid* command disables APs from reporting logs of the module with a specified ID to a WMI server.

The **undo ap log module all** command disables APs from reporting logs of all modules to a WMI server.

By default, APs do not report logs of any module to a WMI server.

Format

ap log module mid *mid* [**name** *name*]

undo ap log module { **mid** *mid* | **all** }

Parameters

Parameter	Description	Value
mid *mid*	Specifies a module ID.	The value is in hexadecimal notation. Set the value to the ID of a module registered with the information center. **NOTE** You can enter **mid ?** to obtain the predefined ID of a module and the module name. You can run the **display info-center statistics** command on an AP to query more module IDs.
name *name*	Specifies a module name. The value must correspond to the value of **mid**.	The value is a string of 1 to 24 characters.

Views

WMI profile view

Default Level

2: Configuration level

Usage Guidelines

If APs need to report logs to a WMI server, specify the ID of a module whose logs are to be reported and enable the log report function. Otherwise, the APs do not report logs of this module.

To enable APs to report logs of multiple modules, run this command repeatedly to specify multiple module IDs.

Example

Enable APs to report logs of the module **C1480000** to a WMI server.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wmi-server name abc
[HUAWEI-wlan-wmi-server-prof-abc] ap log module mid c1480000
```

11.20.3 collect-item (WMI profile view)

Function

The **collect-item** command configures whether APs report collected data to a WMI server and specifies the data collection interval.

The **undo collect-item** command restores the default configuration for APs to report collected data to a WMI server and restores the default data collection interval.

Table 11-314 lists the default state of whether APs report data to the WMI server and the default data collection intervals. (The default values are recommended.)

Table 11-314 Default settings of the data reporting function and data collection interval

Data Type	Default State	Default Data Collection Interval (Unit: Second)
Site guest data	Enabled	300
CPCAR data	Enabled	300
Device monitoring data	Enabled	10
Enhanced Media Delivery Index (eMDI) data	Enabled	10
Interface monitoring data	Enabled	60
Wireless device location data	Disabled	60
Log data	Enabled	300
Radio data of neighboring wireless devices	Enabled	60
Radio monitoring data	Enabled	10
SSID monitoring data	Enabled	60
STA data	Enabled	10
AI roaming data	Enabled	300
DHCP option information about STAs	Disabled	300
User agent (UA) information in the HTTP packets sent by STAs.	Disabled	300
Service information in the mDNS packets sent by STAs	Disabled	300
DNS data	Disabled	60
Non-Wi-Fi device information	Disabled	60

Data Type	Default State	Default Data Collection Interval (Unit: Second)
iPCA 2.0 measurement information	Enabled	Real-time
LLDP neighbor data	Enabled	Real-time
Spectrum analysis data	Disabled	Real-time

Format

collect-item { **application-statistics-data** | **cpcar-data** | **device-data** | **emdi-data** | **interface-data** | **log-data** | **neighbor-device-data** | **radio-data** | **ssid-data** | **terminal-data** | **ai-roam-data** } { **interval** *interval* | **disable** }

undo collect-item { **application-statistics-data** | **cpcar-data** | **device-data** | **emdi-data** | **interface-data** | **log-data** | **neighbor-device-data** | **radio-data** | **ssid-data** | **terminal-data** | **ai-roam-data** }

collect-item { **location-data** | **terminal-dhcp-option-data** | **terminal-http-ua-data** | **terminal-mdns-data** | **dns-data** | **non-wifi-data** } { **interval** *interval* | **enable** }

undo collect-item { **location-data** | **terminal-dhcp-option-data** | **terminal-http-ua-data** | **terminal-mdns-data** | **dns-data** | **non-wifi-data** }

collect-item { **s-ipfpm-data** | **lldp-data** } **disable**

undo collect-item { **s-ipfpm-data** | **lldp-data** } **disable**

collect-item spectrum-data enable

undo collect-item spectrum-data enable

Parameters

Parameter	Description	Value
application-statistics-data	Indicates site guest data. This parameter is not supported by RUs.	-
cpcar-data	Indicates CPCAR data.	-
device-data	Indicates device monitoring data.	-
emdi-data	Indicates eMDI data. This parameter is not supported by Fit central APs or RUs.	-

Parameter	Description	Value
interface-data	Indicates interface monitoring data.	-
location-data	Indicates wireless device location data. This parameter is not supported by Fit central APs.	-
log-data	Indicates log data.	-
neighbor-device-data	Indicates radio data of neighboring wireless devices. This parameter is not supported by Fit central APs.	-
radio-data	Indicates radio monitoring data. This parameter is not supported by Fit central APs.	-
ssid-data	Indicates SSID monitoring data. This parameter is not supported by Fit central APs.	-
terminal-data	Indicates STA data. This parameter is not supported by Fit central APs.	-
ai-roam-data	Indicates AI roaming data.	-
terminal-dhcp-option-data	Indicates DHCP Option information (Options 12, 55, and 60) in the DHCP packets sent by STAs.	-
terminal-http-ua-data	Indicates UA information in the HTTP packets sent by STAs.	-
terminal-mdns-data	Indicates service information in the mDNS packets sent by STAs.	-
dns-data	Indicates DNS information. **NOTE** DNS information can be reported from APs only to iMaster NCE-CampusInsight.	-

Parameter	Description	Value
non-wifi-data	Indicates non-Wi-Fi device information.	-
s-ipfpm-data	Indicates iPCA 2.0 measurement information.	-
lldp-data	Indicates LLDP neighbor data. **NOTE** LLDP neighbor data of APs can be reported only to iMaster NCE-Campus.	-
spectrum-data	Indicates spectrum analysis data.	-
interval *interval*	Specifies the data collection interval.	The value is an integer, in seconds. The value range is as follows: ● **location-data**: 1 to 1800 ● Other data: 5 to 1800
disable	Disables APs from reporting collected data to the WMI server.	-
enable	Enables APs to report collected data to the WMI server.	-

Views

WMI profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can configure APs to report collected data to the WMI server and set the data collection interval as required. You can run this command multiple times to configure APs to report different types of data to the WMI server.

Precautions

For APs that can only transparently report collected information, the collection interval is fixed at 5 minutes, and is unconfigurable.

Example

Set the interval for collecting device monitoring data to 500 seconds.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wmi-server name abc
[HUAWEI-wlan-wmi-server-prof-abc] collect-item device-data interval 500
```

11.20.4 collect-location-data enable

Function

The **collect-location-data enable** command enables the device to collect wireless device location data.

The **undo collect-location-data enable** command disables the device from collecting wireless device location data.

By default, the device does not collect wireless device location data.

Format

collect-location-data enable

undo collect-location-data enable

Parameters

None

Views

Location profile view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to enable the device to collect and report wireless device location data to a WMI server for customer flow analysis.

Example

Enable the device to collect wireless device location data.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] location-profile name default
[HUAWEI-wlan-location-prof-default] collect-location-data enable
```

11.20.5 collect-location-data rssi-threshold

Function

The **collect-location-data rssi-threshold** command configures the RSSI threshold for wireless device location data.

The default RSSI threshold for wireless device location data is -75 dBm.

Format

collect-location-data rssi-threshold *rssi-threshold*

Parameters

Parameter	Description	Value
rssi-threshold	Specifies an RSSI threshold.	The value is an integer that ranges from -95 to 0, in dBm.

Views

Location profile view

Default Level

2: Configuration level

Usage Guidelines

After the device is enabled to collect wireless device location data, only data with the RSSI of higher than the threshold is collected.

Example

Set the RSSI threshold for wireless device location data to -72 dBm.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] location-profile name default
[HUAWEI-wlan-location-prof-default] collect-location-data rssi-threshold -72
```

11.20.6 display references wmi-server

Function

The **display references wmi-server** command displays reference information about a WMI profile.

Format

display references wmi-server name *wmi-server-name*

Parameters

Parameter	Description	Value
name *wmi-server-name*	Displays reference information about a specified WMI profile.	The WMI profile must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display references wmi-server** command to view reference information about a WMI profile.

Example

Display reference information about the WMI profile **abc**.

```
<HUAWEI> display references wmi-server name abc
------------------------------------------------------------------------
Reference type              Reference name              Reference Index
------------------------------------------------------------------------
AP system profile           a                           1
------------------------------------------------------------------------
Total: 1
```

Table 11-315 Description of the **display references wmi-server name** *wmi-server-name* command output

Item	Description
Reference type	Type of the profile by which a WMI profile is referenced.
Reference name	Name of the profile by which a WMI profile is referenced.
Reference Index	Index for referencing a WMI profile to the AP system profile.

11.20.7 display wmi-server

Function

The **display wmi-server** command displays configuration and reference information about a WMI profile.

Format

display wmi-server { **all** | **name** *wmi-server-name* }

Parameters

Parameter	Description	Value
all	Displays information about all WMI profiles.	-
name *wmi-server-name*	Displays information about a specified WMI profile.	The WMI profile must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view configuration and reference information about a WMI profile.

Example

Display information about all WMI profiles.

```

Table 11-317 Description of the **display wmi-server name** command output

Item	Description
Server ip	IP address of the primary WMI server. To configure this parameter, run the **server ip-address** *ip-address* **port** *port* (WMI profile view) command.
Server port	Port number of the primary WMI server. To configure this parameter, run the **server ip-address** *ip-address* **port** *port* (WMI profile view) command.
Server backup ip	IP address of the backup WMI server. To configure this parameter, run the **server backup ip-address** *ip-address* **port** *port* (WMI profile view) command.

Item	Description
Server backup port	Port number of the backup WMI server. To configure this parameter, run the **server backup ip-address** *ip-address* **port** *port* (WMI profile view) command.
Report interval(s)	Data report interval. To configure this parameter, run the **report-interval** *interval* (WMI profile view) command.
Max packet-size(Kbyte)	Maximum size of reported data. To configure this parameter, run the **max-packet-size** *size* (WMI profile view) command.
Alive interval(min)	Interval at which the AP attempts to connect to the WMI server. To configure this parameter, run the **keepalive interval** *interval* (WMI profile view) command.
Retry interval(min)	Interval at which the AP attempts to reconnect to the WMI server. To configure this parameter, run the **keepalive retry-interval** *retry-interval* (WMI profile view) command.
Retry number	Number of attempts the AP reconnects to the WMI server. To configure this parameter, run the **keepalive retry-number** *retry-number* (WMI profile view) command.
Device enable	Whether device monitoring data collection is enabled. To configure this parameter, run the **collect-item device-data disable** command.
Device data interval(s)	Interval at which device monitoring data is collected. To configure this parameter, run the **collect-item device-data interval** *interval* command.
Ssid enable	Whether SSID monitoring data collection is enabled. To configure this parameter, run the **collect-item ssid-data disable** command.
Ssid data interval(s)	Interval at which SSID monitoring data is collected. To configure this parameter, run the **collect-item ssid-data interval** *interval* command.
Radio enable	Whether radio monitoring data collection is enabled. To configure this parameter, run the **collect-item radio-data disable** command.

Item	Description
Radio data interval(s)	Interval at which radio monitoring data is collected. To configure this parameter, run the **collect-item radio-data interval** *interval* command.
Interface enable	Whether interface monitoring data collection is enabled. To configure this parameter, run the **collect-item interface-data disable** command.
Interface data interval(s)	Interval at which interface monitoring data is collected. To configure this parameter, run the **collect-item interface-data interval** *interval* command.
Terminal enable	Whether STA data collection is enabled. To configure this parameter, run the **collect-item terminal-data disable** command.
Terminal data interval(s)	Interval at which STA data is collected. To configure this parameter, run the **collect-item terminal-data interval** *interval* command.
Log enable	Whether log data collection is enabled. To configure this parameter, run the **collect-item log-data disable** command.
Log data interval(s)	Interval at which log data is collected. To configure this parameter, run the **collect-item log-data interval** *interval* command.
Location enable	Whether wireless device location data collection is enabled. To configure this parameter, run the **collect-item location-data enable** command.
Location data interval(s)	Interval at which wireless device location data is collected. To configure this parameter, run the **collect-item location-data interval** *interval* command.
Neighbor device enable	Whether surrounding radio data collection is enabled. To configure this parameter, run the **collect-item neighbor-device-data disable** command.
Neighbor device data interval(s)	Interval at which surrounding radio data is collected. To configure this parameter, run the **collect-item neighbor-device-data interval** *interval* command.
CP-CAR enable	Whether CPCAR data collection is enabled. To configure this parameter, run the **collect-item cpcar-data disable** command.

Item	Description
CP-CAR data interval(s)	Interval at which CPCAR data is collected. To configure this parameter, run the **collect-item cpcar-data interval** *interval* command.
EMDI enable	Whether eMDI data collection is enabled. To configure this parameter, run the **collect-item emdi-data disable** command.
EMDI data interval(s)	Interval at which eMDI data is collected. To configure this parameter, run the **collect-item emdi-data interval** *interval* command.
Application statistics enable	Whether site guest data collection is enabled. To configure this parameter, run the **collect-item application-statistics-data disable** command.
Application statistics data interval(s)	Interval at which site guest data is collected. To configure this parameter, run the **collect-item application-statistics-data interval** *interval* command.
Terminal DHCP option enable	Whether collection of DHCP Option information (Options 12, 55, and 60) in the DHCP packets sent by STAs is enabled. To configure this parameter, run the **collect-item terminal-dhcp-option-data enable** command.
Terminal DHCP option data interval(s)	Interval at which DHCP Option information (Options 12, 55, and 60) in the DHCP packets sent by STAs is collected. To configure this parameter, run the **collect-item terminal-dhcp-option-data interval** *interval* command.
Terminal HTTP UA enable	Whether collection of UA information in the HTTP packets sent by STAs is enabled. To configure this parameter, run the **collect-item terminal-http-ua-data enable** command.
Terminal HTTP UA data interval(s)	Interval at which UA information in the HTTP packets sent by STAs is collected. To configure this parameter, run the **collect-item terminal-http-ua-data interval** *interval* command.
Terminal mDNS enable	Whether collection of service information in the mDNS packets sent by STAs is enabled. To configure this parameter, run the **collect-item terminal-mdns-data enable** command.

Item	Description
Terminal mDNS data interval(s)	Interval at which service information in the mDNS packets sent by STAs is collected. To configure this parameter, run the **collect-item terminal-mdns-data interval** *interval* command.
DNS enable	Whether DNS data collection is enabled. To configure this parameter, run the **collect-item dns-data enable** command.
DNS data interval(s)	Interval at which DNS data is collected. To configure this parameter, run the **collect-item dns-data interval** *interval* command.
Non WiFi data enable	Whether collection of non-Wi-Fi device data is enabled. To configure this parameter, run the **collect-item non-wifi-data enable** command.
Non WiFi data interval(s)	Interval at which non-Wi-Fi device data is collected. To configure this parameter, run the **collect-item non-wifi-data interval** *interval* command.
Log module ID	ID of the module whose logs are to be reported. To configure this parameter, run the **ap log module mid** *mid* [**name** *name*] command.
S-ipfpm enable	Whether iPCA 2.0 measurement information collection is enabled. To configure this parameter, run the **collect-item s-ipfpm-data disable** command.
AI roam data enable	Whether AI roaming data collection is enabled. To configure this parameter, run the **collect-item ai-roam-data disable** command.
AI roam data interval(s)	Interval at which AI roaming data is collected. To configure this parameter, run the **collect-item ai-roam-data interval** *interval* command.
Lldp enable	Whether LLDP neighbor data collection is enabled. To configure this parameter, run the **collect-item lldp-data disable** command.
PKI realm	PKI realm used for interconnection with a WMI server. To configure this parameter, run the **pki realm** *realm-name* command.
Spectrum data enable	Whether spectrum analysis data collection is enabled. To configure this parameter, run the **collect-item spectrum-data enable** command.

11.20.8 keepalive (WMI profile view)

Function

The **keepalive** command configures connection parameters between APs and the WMI server.

The **undo keepalive** command restores the default settings of connection parameters between APs and the WMI server.

By default, the heartbeat interval is 3 minutes, the reconnection interval is 5 minutes, and the number of reconnection attempts is 0.

Format

keepalive { **interval** *interval* | **retry-interval** *retry-interval* | **retry-number** *retry-number* } *

undo keepalive

Parameters

Parameter	Description	Value
interval *interval*	Specifies the heartbeat interval.	The value is an integer that ranges from 1 to 60, in minutes.
retry-interval *retry-interval*	Specifies the reconnection interval after an AP is disconnected from the server.	The value is an integer that ranges from 5 to 60, in minutes.
retry-number *retry-number*	Specifies the number of reconnection attempts.	The value is an integer that ranges from 0 to 4294967295. The value 0 indicates that the server and APs always attempt to reconnect to each other.

Views

WMI profile view

Default Level

2: Configuration level

Usage Guidelines

None

Example

Set the number of reconnection attempts to 5.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wmi-server name abc
[HUAWEI-wlan-wmi-server-prof-abc] keepalive retry-number 5
```

11.20.9 max-packet-size (WMI profile view)

Function

The **max-packet-size** command configures the maximum data length of KPI information sent by APs to a WMI server.

The **undo max-packet-size** command restores the default maximum data length of KPI information sent by APs to a WMI server.

By default, the maximum data length of KPI information sent by APs to a WMI server is 5 KB.

Format

max-packet-size *size*

undo max-packet-size

Parameters

Parameter	Description	Value
size	Specifies the maximum data length of reported information.	The value is an integer that ranges from 4 to 256, in KB.

Views

WMI profile view

Default Level

2: Configuration level

Usage Guidelines

Based on the network status, you can run the **max-packet-size** command to configure the maximum data length of KPI information sent by APs to a WMI server.

Example

Set the maximum data length of KPI information sent by APs to a WMI server to 6 KB.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] wmi-server name abc
[HUAWEI-wlan-wmi-server-prof-abc] max-packet-size 6
```

11.20.10 mdns-snooping enable

Function

The **mdns-snooping enable** command enables the mDNS snooping function.

The **undo mdns-snooping enable** command disables the mDNS snooping function.

By default, mDNS snooping is disabled.

Format

mdns-snooping enable

undo mdns-snooping enable

Parameters

None

Views

VAP profile view

Default Level

2: Configuration level

Usage Guidelines

In terminal type identification scenarios, you can enable mDNS snooping on a VAP. In this manner, the device can collect information from mDNS packets sent by terminals connected to the VAP and report the collected information to a WMI server for terminal type identification.

Example

Enable mDNS snooping.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] vap-profile name abc
[HUAWEI-wlan-vap-prof-abc] mdns-snooping enable
```

11.20.11 pki realm (WMI profile view)

Function

The **pki realm** command configures a PKI realm for interconnection between APs and a WMI server.

The **undo pki realm** command restores the default PKI realm for interconnection between APs and a WMI server.

By default, the PKI realm for interconnection between APs and a WMI server is **default**.

Format

pki realm *realm-name*

undo pki realm

Parameters

Parameter	Description	Value
realm-name	Specifies the name of a PKI realm.	The PKI realm name must exist.

Views

WMI profile view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to configure a PKI realm for interconnection between APs and a WMI server.

Example

Configure the PKI realm **test** for interconnection between APs and a WMI server.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wmi-server name abc
[HUAWEI-wmi-server] pki realm test
```

11.20.12 report-interval (WMI profile view)

Function

The **report-interval** command sets the interval for APs to report KPI information to a WMI server.

The **undo report-interval** command restores the default interval for APs to report KPI information to a WMI server.

By default, APs report KPI information to a WMI server at an interval of 60 seconds.

Format

report-interval *interval*

undo report-interval

Parameters

Parameter	Description	Value
interval	Specifies the interval for APs to report KPI information to a WMI server.	The value is an integer that ranges from 10 to 300, in seconds.

Views

WMI profile view

Default Level

2: Configuration level

Usage Guidelines

You can configure the interval for APs to report KPI information to a WMI server based on the device usage, network resource usage, and the server's requirements for real-time information collection. A shorter interval indicates that data is more frequently data, which occupies more device and network resources. A long interval cannot ensure real-time information on the server.

Example

Set the interval for APs to report KPI information to a WMI server to 30 seconds.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wmi-server name abc
[HUAWEI-wlan-wmi-server-prof-abc] report-interval 30
```

11.20.13 server (WMI profile view)

Function

The **server** command configures the destination address and port number of the primary WMI server to which APs report KPI information.

The **undo server** command restores the default destination address and port number of the primary WMI server to which APs report KPI information.

By default, the destination address and port number of the primary WMI server to which APs report KPI information are not configured.

Format

server ip-address *ip-address* **port** *port*

undo server

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies the IP address of the server.	The value is in dotted decimal notation.
port *port*	Specifies the port number of the server.	The value is an integer that ranges from 1 to 65535. - Use port 10032 to report data to iMaster NCE-Campus. - Use port 27371 to report data to iMaster NCE-CampusInsight.

Views

WMI profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you configure a correct IP address and port number of a WMI server, APs can correctly report KPI information to the specified server.

NOTE

DNS information can be reported from APs only to iMaster NCE-CampusInsight.

Precautions

When the primary/backup WMI server scheme is used, run the **server backup ip-address** *ip-address* **port** *port* (WMI profile view) command to configure the destination address and port number of the backup WMI server after configuring the primary WMI server. If the primary/backup WMI server scheme is not used, you only need to configure the destination address and port number of the primary WMI server. Do not configure the backup server before configuring the primary server.

If the backup WMI server has been configured and you run the **undo server** command to restore the primary WMI server to the default value, the backup WMI server is also restored to the default value.

Example

Configure the destination IP address and port number for APs to report KPI information.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] wmi-server name abc
[HUAWEI-wlan-wmi-server-prof-abc] server ip-address 10.10.11.11 port 10032
```

11.20.14 server backup (WMI profile view)

Function

The **server backup** command configures the destination IP address and port number of the backup WMI server to which APs report KPI information.

The **undo server backup** command restores the default destination IP address and port number of the backup WMI server to which APs report KPI information.

By default, the destination IP address and port number of the backup WMI server to which APs report KPI information are not configured.

Format

server backup ip-address *ip-address* **port** *port*

undo server backup ip-address

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies the IP address of the server.	The value is in dotted decimal notation.
port *port*	Specifies the port number of the server.	The value is an integer that ranges from 1 to 65535. ● Use port 10032 to report data to iMaster NCE-Campus. ● Use port 27371 to report data to iMaster NCE-CampusInsight.

Views

WMI profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the primary/backup WMI server scheme is used, you can run this command to configure the destination IP address and port number of the backup WMI server so that the APs can report KPI information to the specified backup WMI server.

After the primary/backup scheme is configured, if an AP fails to connect to the primary WMI server, the AP attempts to connect to the backup WMI server. If the connection still fails, the AP attempts to reconnect to the primary and backup WMI servers until the connection is successful.

NOTE

DNS information can be reported from APs only to iMaster NCE-CampusInsight.

Precautions

The destination IP address and port number of the primary WMI server have been configured using the **server ip-address** *ip-address* **port** *port* (WMI profile view) command.

Example

Configure the destination IP address and port number of the backup WMI server to which APs report KPI information.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wmi-server name abc
[HUAWEI-wlan-wmi-server-prof-abc] server ip-address 10.10.11.11 port 10032
[HUAWEI-wlan-wmi-server-prof-abc] server backup ip-address 10.10.11.12 port 10032
```

11.20.15 wmi-server (AP system profile view)

Function

The **wmi-server** command binds a WMI profile to the AP system profile.

The **undo wmi-server** command unbinds a WMI profile from the AP system profile.

By default, no WMI profile is bound to an AP system profile.

Format

wmi-server *profile-name* **index** *index*

undo wmi-server index *index*

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a WMI profile.	The WMI profile name must exist.

Parameter	Description	Value
index *index*	Specifies an index.	The value is an integer that can be 1 or 2. **NOTE** To report KPI information to iMaster NCE-Campus, specify index 1. To report KPI information to iMaster NCE-CampusInsight, specify index 2.

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

A WMI profile can take effect only after being bound to an AP system profile.

NOTE

Do not bind two WMI profiles with the same destination address and port number to avoid waste of destination server resources.

Example

Bind WMI profile **abc** to the AP system view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-system-profile name apsys
[HUAWEI-wlan-ap-system-prof-apsys] wmi-server abc index 1
```

11.20.16 wmi-server (WLAN view)

Function

The **wmi-server** command creates a WMI profile and displays the WMI profile view.

The **undo wmi-server** command deletes a WMI profile.

By default, no WMI profile is created.

Format

wmi-server name *profile-name*

undo wmi-server { **name** *profile-name* | **all** }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a WMI profile.	The value is a string of 1 to 35 case-insensitive characters, without spaces or quotation marks (?). It cannot start or end with double quotation masks (").
all	Specifies all WMI profiles.	-

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

You can set parameters for APs to report KPI information to the WMI server in the WMI profile.

Example

Create a WMI profile **abc** and display the WMI profile view.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] wmi-server name abc
[HUAWEI-wlan-wmi-server-prof-abc]
```

11.21 Configuration Commands for the Zero-Roaming Distributed Wi-Fi Solution

11.21.1 display ap oru status

Function

The **display ap oru status** command displays the status of ORUs and AUs connected to DAPs.

NOTE

ORU management is supported only by the DAP AirEngine 9700D-S.

Format

display ap oru status { **all** | **ap-id** *ap-id* }

Parameters

Parameter	Description	Value
all	Displays the status of ORUs and AUs connected to all DAPs.	-
ap-id *ap-id*	Displays the status of ORUs and AUs connected to a specified DAP.	The AP ID must exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command is used to query the IDs, status, and versions of ORUs and AUs connected to a specified DAP or all DAPs.

Example

Display the status of ORUs and AUs connected to all DAPs.

```
<HUAWEI> display ap oru status all
Y: Normal N: Absent A: Abnormal U: Upgrading D: Disabled -: Unknown
ORUx: ORUx status(AU0 status/AU1 status/AU2 status/AU3 status/AU4 status/AU5 status/AU6 status/AU7
status)
-----------------------------------------------------------------------------------------------------------------------------
-----------------------------------
AP ID   ORU0              ORU1              ORU2              ORU3              ORU4              ORU5
ORU6              ORU7
-----------------------------------------------------------------------------------------------------------------------------
-----------------------------------
5       N(N/N/N/N/N/N/N/N) N(N/N/N/N/N/N/N/N) N(N/N/N/N/N/N/N/N) Y(Y/Y/N/N/N/N/N/N)
N(N/N/N/N/N/N/N/N) N(N/N/N/N/N/N/N/N) N(N/N/N/N/N/N/N/N) N(N/N/N/N/N/N/N/N)
-----------------------------------------------------------------------------------------------------------------------------
-----------------------------------
```

Table 11-318 Description of the **display ap oru status all** command output

Item	Description
AP ID	AP ID.

Item	Description
ORUx	Status of ORU*x* and its connected AUs. The possible status of an ORU includes: ● Y: Normal ● N: Absent ● A: Abnormal ● U: Upgrading ● D: Disabled ● -: Unknown The possible status of an AU includes: ● Y: Normal ● N: Absent ● -: Unknown

Display the status of ORUs and AUs connected to the DAP with the ID of 1.

```
<HUAWEI> display ap oru status ap-id 1
Y: Normal N: Absent -: Unknown
------------------------------------------------------------------------------------------
ORU  SN        Status    AU status           Temperature(degree C)  Version
------------------------------------------------------------------------------------------
0    XXX       Absent    N/N/N/N/N/N/N/N        -                 0
1    XXX       Absent    N/N/N/N/N/N/N/N        -                 0
2    XXX       Absent    N/N/N/N/N/N/N/N        -                 0
3    XXX       Normal     Y/Y/N/N/N/N/N/N       35                 7

```

Table 11-319 Description of the **display ap oru status ap-id** command output

Item	Description
ORU	ORU ID.
SN	ORU SN.
Status	ORU status.
AU status	AU status.
Temperature(degree C)	ORU temperature. When the ORU state is **Absent** or **Disabled**, the temperature is displayed as a hyphen (-).
Version	Version number of the ORU.

11.21.2 distribute-mode enable

Function

The **distribute-mode enable** command enables the DAP network collaboration function.

The **undo distribute-mode enable** command restores the default state of the DAP network collaboration function.

By default, the DAP network collaboration function is disabled.

NOTE

Network collaboration functions (including intranet and extranet collaboration, and DAP backup) are supported only by the AirEngine 6761-21E with external antennas.

Format

distribute-mode enable

undo distribute-mode enable

Parameters

None

Views

AP system profile view

Default Level

2: Configuration level

Usage Guidelines

This command is used to enable the DAP network coordination function. After an extranet AP or backup AP is connected to a DAP, you can run this command to enable the distributed AP network collaboration function. In this way, the extranet AP or backup AP can share the ORUs and AUs connected to the DAP, thereby achieving the backup solution or the integrated deployment of the intranet and extranet within the same coverage area.

Precautions

When configuring a backup solution, you also need to run the **type service-backup distribute** command to set the VAP type of the backup AP to distributed-AP backup service.

Example

Enable the DAP network collaboration function.

```
<HUAWEI> system-view
[HUAWEI] wlan
```

```
[HUAWEI-wlan-view] ap-system-profile name system1
[HUAWEI-wlan-ap-system-prof-system1] distribute-mode enable
```

11.21.3 oru reboot

Function

The **oru reboot** command restarts ORUs.

NOTE

ORU management is supported only by the DAP AirEngine 9700D-S.

Format

oru reboot ap-id *ap-id* [**oru-id** *oru-id*]

Parameters

Parameter	Description	Value
ap-id *ap-id*	Restarts the ORUs connected to a DAP with a specified ID.	The AP ID must exist.
oru-id *oru-id*	Restarts the ORU with a specified ID. If this parameter is not specified, all ORUs connected to the specified DAP are restarted.	The value is an integer that ranges from 0 to 7.

Views

WLAN view

Default Level

2: Configuration level

Usage Guidelines

When maintaining ORUs, you can run this command to restart ORUs as required.

Example

Restart the ORU connected to the DAP with the ID of 1.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] oru reboot ap-id 1
```

11.21.4 fastpass users

Function

The **fastpass users** command configures the FastPass function for VIP users on a DAP.

The **undo fastpass** command restores the default status of the FastPass function for VIP users on a DAP.

By default, the FastPass function for VIP users is enabled on the 2.4 GHz radio, the number of FastPass users is 5, the FastPass scheduling period is 20 ms, and the percentage of FastPass users in the scheduling period is 25%.

NOTE

The VIP FastPass function is supported only by the DAP AirEngine 9700D-S.

The FastPass function for VIP users applies only to the 2.4 GHz frequency band, and does not take effect after the configuration is delivered in the 5G radio profile view.

Format

fastpass users *value* [**period** *period-value* **ratio** *ratio-value*]

undo fastpass

Parameters

Parameter	Description	Value
value	Specifies the number of FastPass users.	The value is an integer that ranges from 0 to 10. When this parameter is set to 0, this function is disabled. The default value is 5.
period *period-value*	Specifies the FastPass scheduling period.	The value is of enumerated type, which can be 20, 40, 60, 80, or 100, in milliseconds. The default value is 20.
ratio *ratio-value*	Specifies the percentage of FastPass users in the scheduling period.	The value is an integer that ranges from 5 to 75, in percentage. The default value is 25.

Views

2G radio profile view, 5G radio profile view

Default Level

2: Configuration level

Usage Guidelines

In a zero-roaming distributed scenario, when the 2.4 GHz frequency band experiences severe interference and the channel utilization exceeds 60%, you can configure the FastPass function for VIP users to prevent packet loss and frame freezing, thereby preferentially ensuring user experience of important intranet services.

When the number of FastPass users specified by the parameter *value* is set to 0, this function is disabled.

When the channel utilization exceeds 60%, you are advised to set the number of FastPass users to 10, the FastPass scheduling period to 60 ms, and the percentage of FastPass users to 75%.

Example

Set the number of FastPass users to 10, the FastPass scheduling period to 60 ms, and the percentage of FastPass users in the scheduling period to 75%.

```
<HUAWEI> system-view
[HUAWEI] wlan
[HUAWEI-wlan-view] radio-2g-profile name default
[HUAWEI-wlan-radio-2g-prof-default] fastpass users 10 period 60 ratio 75
```

12 Reliability Commands

12.1 BFD Configuration Commands

12.1.1 Command Support

Only the following switch models support BFD:

S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S.

12.1.2 authentication-mode (BFD)

Function

The **authentication-mode** command configures BFD session authentication information.

The **undo authentication-mode** command deletes the configured BFD session authentication information.

By default, BFD session authentication information is not configured.

Format

authentication-mode met-sha1 key-id *key-id-value* **cipher** *cipher-text* **nego-packet** [**timeout-interval** *interval-value*]

undo authentication-mode

Parameters

Parameter	Description	Value
met-sha1	Specifies MSHA1 to decrypt and authenticate.	-
key-id *key-id-value*	Specifies the authentication key ID of a BFD session.	The value is an integer that ranges from 1 to 255.
cipher *cipher-text*	Specifies a ciphertext BFD authentication password. You can enter either a simple or ciphertext password, but the password is displayed in ciphertext in the configuration file.	The value is a string of characters. ● The value is a string of 1 to 20 characters for simple authentication passwords. ● The value is a string of 20 to 148 characters for ciphertext authentication passwords. **NOTE** The characters exclude question marks (?) and spaces. However, if a password string is between a pair of quotation marks, the string can contain spaces.
nego-packet	Authenticates BFD negotiation packets.	-
timeout-interval *interval-value*	Specifies the negotiation timeout period of a BFD session.	The value is an integer ranging from 1 to 10000, in seconds. This parameter has no default value. **NOTE** After a BFD negotiation timeout period is configured, the BFD negotiation timeout timer is started when the BFD session goes Down (the event is not triggered by a link fault detected). If the timer has expired but the BFD session is still Down, the link protocol of the associated interface goes Down.

Views

BFD session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a network demanding higher security, run the **authentication-mode** command to configure BFD session authentication information to improve network security. In a specific access scenario, for example, when a multicast BFD session is associated with the protocol status of an interface, you need to configure authentication information for the BFD session on the interface. BFD negotiation can succeed, the BFD-associated protocol status of the interface can be activated, and users can access the device through this interface only when the BFD session authentication information on both ends is consistent.

Prerequisites

BFD has been globally enabled using the **bfd** command in the system view.

A BFD session used to detect the physical link status has been created using the **bfd bind peer-ip default-ip** command in the system view.

Precautions

If you run the **authentication-mode** command to configure BFD session authentication information, BFD renegotiation will be performed. BFD renegotiation can succeed only when the BFD session authentication information on both ends is consistent.

Adding, modifying, or deleting BFD session authentication information may interrupt the service associated with the BFD session.

Example

Configure multicast BFD session authentication information.

```
<HUAWEI> system-view
[HUAWEI] bfd test bind peer-ip default-ip interface GigabitEthernet0/0/1
[HUAWEI-bfd-session-test] authentication-mode met-sha1 key-id 5 cipher YsHsjx_202206 nego-packet
timeout-interval 5
```

12.1.3 bfd

Function

The **bfd** command enables the global Bidirectional Forwarding Detection (BFD) function and displays the BFD view.

The **undo bfd** command disables global BFD.

By default, global BFD is disabled.

Format

bfd

undo bfd

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To fast detect link faults, run the **bfd** command in the system view to enable global BFD.

Precautions

BFD must be enabled globally before BFD parameters are configured.

NOTICE

Running the **undo bfd** command in the system view may affect services associated with BFD and deletes all BFD sessions on the device. To restore the BFD function, you have to re-configure BFD sessions.

Example

Enable the global BFD function.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd]
```

12.1.4 bfd bind peer-ip

Function

The **bfd bind peer-ip** command creates a BFD session, specifies the peer IP address, and displays the BFD session view.

The **undo bfd** *session-name* command deletes a specified BFD session and cancels the peer IP address.

By default, BFD binding is not created.

Format

bfd *session-name* **bind peer-ip** *ip-address* [**vpn-instance** *vpn-name*] [**interface** *interface-type interface-number*] [**source-ip** *ip-address*]

undo bfd *session-name*

Parameters

Parameter	Description	Value
session-name	Specifies the name of a BFD session.	The value is a string of 1 to 15 case-sensitive characters without spaces. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
peer-ip *ip-address*	Specifies the peer IP address bound to the BFD session.	-
vpn-instance *vpn-name*	Specifies the name of a Virtual Private Network (VPN) instance that is bound to a BFD session.	The value must be an existing VPN instance name.
interface *interface-type interface-number*	Specifies the type and number of the interface bound to the BFD session. ● *interface-type* specifies the type of the interface. ● *interface-number* specifies the number of the interface.	-

Parameter	Description	Value
source-ip *ip-address*	Indicates the source IP address carried in BFD packets. ● During BFD session negotiation, if the source IP address is not specified, the system searches the local routing table for an outbound interface from which the peer IP address is reachable. The IP address of this outbound interface is used as the source IP address of the BFD packets sent by the local end. ● When a BFD session is detecting links, if this parameter is not specified, the system uses a fixed source IP address in BFD packets. When BFD is used with the Unicast Reverse Path Forwarding (URPF) function, you must manually configure the source IP address in BFD packets because the URPF function checks the source IP address in received packets. **NOTE** For details about URPF, see URPF Configuration in the *S300, S500, S2700, S5700, and S6700 V200R023C00 Configuration Guide - Security*.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To fast detect and monitor links, create BFD sessions.

To create a BFD binding, pay attention to the following points:

- If only the peer IP address is specified, BFD is configured to detect the multi-hop link.
- If the peer IP address and local interface are specified, BFD is configured to detect the single-hop link, that is, a specific route with this interface as the outbound interface and with the peer IP address as the next-hop address.
- If both the peer IP address and the VPN instance are specified, BFD is configured to detect the multi-hop link in the VPN instance.
- The single-hop link in the VPN instance is detected if both the peer IP address, VPN instance, and local interface are specified.

Prerequisites

Global BFD has been enabled by using the **bfd** command in the system view.

Follow-up Procedure

- Run the **discriminator** command to set the local and remote discriminators for the current BFD session.

Precautions

- When creating a single-hop BFD session, bind the single-hop BFD session to the peer IP address and the local address. You only need to bind a multi-hop BFD session to the peer IP address.
- When the BFD configuration items are created, the system checks only the format of the IP address. The BFD session cannot be established if an incorrect peer IP address or source IP address is bound.
- When a multi-hop BFD session is configured, the value of **peer-ip** or **source-ip** cannot be the IP address of a GRE tunnel interface.
- When a multi-hop BFD session is configured and the peer IP address is the same as the 32-bit destination IP address of an LDP or static LSP, the BFD session is associated with the LSP. That is, if the BFD session detects a fault, an LSP switchover is performed.

Example

Create a BFD session named **atob** to detect the single-hop link from VLANIF100 to the peer IP address at 10.10.10.2.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] bfd atob bind peer-ip 10.10.10.2 interface vlanif 100
```

Create a BFD session named **atoc** to detect the multi-hop link to the peer IP address 10.10.20.2.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] bfd atoc bind peer-ip 10.10.20.2
```

12.1.5 bfd bind peer-ip default-ip

Function

The **bfd bind peer-ip default-ip** command creates a BFD binding for detecting the physical status of a link.

The **undo bfd** *session-name* command deletes a specified BFD session and the created BFD binding.

By default, no BFD binding for monitoring physical status of a link is configured.

Format

bfd *session-name* **bind peer-ip default-ip interface** *interface-type interface-number* [**source-ip** *ip-address*] [**auto**]

undo bfd *session-name*

Parameters

Parameter	Description	Value
session-name	Specifies the session name of BFD.	The value is a string of 1 to 15 characters without spaces. **NOTE** When quotation marks are used around the string, spaces are allowed in the string.
peer-ip default-ip	Indicates the default multicast IP address that is bound to a BFD session.	By default, BFD uses the multicast IP address 224.0.0.184. You can set the multicast IP address by running the **default-ip-address** command.

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of the interface bound to a BFD session. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
source-ip *ip-address*	Indicates the source IP address carried in BFD packets. If the source IP address is not specified, the system searches the local routing table for an outbound interface from which the peer IP address can be reached. The IP address of this outbound interface is used as the source IP address of BFD packets sent by the local end. Generally, this parameter is not required. When BFD is used with the Unicast Reverse Path Forwarding (URPF) function, you must manually configure the source IP address in BFD packets because the URPF function checks the source IP address in received packets. **NOTE** For details about URPF, see URPF Configuration in the *S300, S500, S2700, S5700, and S6700 V200R023C00 Configuration Guide - Security*.	-
auto	Enables automatic negotiation of local and remote discriminators.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If **source-ip** is specified, the URPF-enabled device does not incorrectly discard BFD packets. Ensure that the source IP address is correct. The system only checks whether the source IP address is valid (for example, it cannot be a multicast or broadcast address) without checking correctness.

Precautions

When the **bfd bind peer-ip default-ip** command is used to configure a BFD session, ring protocols cannot be configured on the interface bound to the BFD session. Otherwise, MAC address flapping may occur.

If the IP address of an outbound interface is changed after a BFD session is configured, the source IP address of BFD packets is not updated.

NOTE

If automatic negotiation of local and remote discriminators is not configured, run the **commit** command to commit the configuration to make the configuration take effect.

Unlike common static BFD sessions, static BFD sessions with automatically negotiated discriminators have separate characteristics:

- The **bfd bind peer-ip source-ip auto** command can be run and immediately create a static BFD session with automatically negotiated discriminators, without the **commit** command executed.
- Parameters of a static BFD session with automatically negotiated discriminators take effect immediately after being modified, without the **commit** command executed. The parameters include the minimum interval at which BFD packets are sent and received and the detection multiplier.
- The **commit** command can be run for a static BFD session with automatically negotiated discriminators to support the forward version compatibility.

Example

Create a BFD session named **test**, and then detect the one-hop link that is bound to the local interface GigabitEthernet0/0/1 through the default multicast IP address.

```
<HUAWEI> system-view
[HUAWEI] bfd test bind peer-ip default-ip interface gigabitethernet 0/0/1
[HUAWEI-bfd-session-test]
```

12.1.6 bfd bind peer-ip source-ip auto

Function

The **bfd bind peer-ip source-ip auto** command creates a static BFD session with automatically negotiated discriminators.

The **undo bfd** *session-name* command deletes a specified BFD session.

By default, no static BFD session with automatically negotiated discriminators is established.

Format

bfd *session-name* **bind peer-ip** *ip-address* [**vpn-instance** *vpn-name*] [**interface** *interface-type interface-number*] **source-ip** *ip-address* **auto**

undo bfd *session-name*

Parameters

Parameter	Description	Value
session-name	Specifies the name of a BFD session.	The value is a string of 1 to 15 case-sensitive characters without spaces. **NOTE** When quotation marks are used around the string, spaces are allowed in the string.
peer-ip *ip-address*	Specifies the peer IP address bound to the BFD session.	-
vpn-instance *vpn-name*	Specifies the name of a Virtual Private Network (VPN) instance that is bound to a BFD session.	The value must be an existing VPN instance name.
interface-type interface-number	Specifies the type and number of the interface bound to the BFD session. ● *interface-type* specifies the type of the interface. ● *interface-number* specifies the number of the interface.	-

Parameter	Description	Value
source-ip *ip-address*	Indicates the source IP address carried in BFD packets, that is, IP address of the outbound interface.	-
auto	Enables automatic negotiation of local and remote discriminators.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The local device where a BFD session with automatically negotiated parameters is configured can negotiate with the remote device where a dynamic BFD session is configured; however, the local device enabled with static BFD can establish a BFD session with the remote device enabled with static BFD only. When configuring a BFD session with automatically negotiated parameters or a static BFD session, you can specify the BFD session name. The name of a dynamic BFD session is generated dynamically. When the network changes, the name of the dynamic BFD session may change.

When the remote end is configured with dynamic BFD and the local end needs to be configured with association between BFD and static route (BFD session name needs to be specified during association configuration), a BFD session with automatically negotiated parameters can be configured on the local end. Then the local end can establish a BFD session with the remote end enabled with dynamic BFD and association between BFD and static route can be implemented.

When creating a static BFD session with automatically negotiated discriminators, pay attention to the following points:

- If only the peer IP address is specified, BFD is configured to detect the multi-hop link.
- If the peer IP address and local interface are specified, BFD is configured to detect the single-hop link, that is, a specific route with this interface as the outbound interface and with the peer IP address as the next-hop address.
- Ensure that the source IP address is correct. The system only checks whether the source IP address is valid (for example, it cannot be a multicast or broadcast address) without checking correctness.

- If both the peer IP address and the VPN instance are specified, BFD is configured to detect the multi-hop link in the VPN instance.
- If the peer IP address, VPN instance, and local interface are specified, BFD is configured to detect the single-hop link in the VPN instance.

Prerequisites

Global BFD has been enabled by using the **bfd** command in the system view.

Precautions

- When creating a BFD session, bind the BFD session to the peer IP address and the local address.
- When the BFD configuration items are created, the system checks only the format of the IP address. The BFD session cannot be established if an incorrect peer IP address or source IP address is bound.

NOTE

Unlike common static BFD sessions, static BFD sessions with automatically negotiated discriminators have separate characteristics:

- The **bfd bind peer-ip source-ip auto** command can be run and immediately create a static BFD session with automatically negotiated discriminators, without the **commit** command executed.
- Parameters of a static BFD session with automatically negotiated discriminators take effect immediately after being modified, without the **commit** command executed. The parameters include the minimum interval at which BFD packets are sent and received and the detection multiplier.
- The **commit** command can be run for a static BFD session with automatically negotiated discriminators to support the forward version compatibility.

Example

Create a static BFD session with automatically negotiated discriminators.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] bfd atob bind peer-ip 10.1.1.2 interface vlanif 100 source-ip 10.1.1.1 auto
```

12.1.7 bfd bind peer-ipv6

Function

The **bfd bind peer-ipv6** command creates a BFD6 session to detect IPv6 links.

The **undo bfd** *bfd-name* command deletes a specified BFD6 session.

By default, no BFD6 session is created for IPv6 links.

Format

bfd *session-name* **bind peer-ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*] [**interface** *interface-type interface-number*] [**source-ipv6** *ipv6-address*]

undo bfd *session-name*

Parameters

Parameter	Description	Value
session-name	Specifies the name of a BFD6 session.	The value is a string of 1 to 15 case-sensitive characters without spaces. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
peer-ipv6 *ipv6-address*	Specifies the peer IPv6 address bound to a BFD6 session.	-
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance bound to a BFD6 session.	The value must be an existing VPN instance name.
interface *interface-type interface-number*	Specifies the local Layer 3 outbound interface bound to a BFD6 session. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Parameter	Description	Value
source-ipv6 *ipv6-address*	Specifies the source IPv6 address carried in BFD packets. Generally, you do not need to set this parameter. If you do not specify the source IP address, the system automatically sets the source IP address according to the following rules: ● During BFD for IPv6 session negotiation, if the source IPv6 address is not specified, the system searches the local routing table for an outbound interface from which the peer IP address is reachable. The IPv6 address of this outbound interface is used as the source IP address of the BFD packets sent by the local end. ● If this parameter is not specified when a BFD for IPv6 session is detecting links, the system uses a fixed source IPv6 address in BFD packets. **NOTE** When BFD is used with Unicast Reverse Path Forwarding (URPF), you must manually configure the source IPv6 address in BFD packets because URPF checks the source IPv6 address in received packets.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To fast detect and monitor IPv6 links, you can create BFD for IPv6 sessions.

When creating a BFD for IPv6 binding, pay attention to the following points:

- If only the peer IPv6 address is specified, BFD is configured to detect the multi-hop link.
- A single-hop link is detected if both the peer IPv6 address and the local interface are specified. That is, a BFD6 session detects a specific route with this interface as the outbound interface and with the peer IPv6 address as the next hop address.
- If both the peer IPv6 address and the VPN instance are specified, the created BFD6 session detects the multi-hop links in the VPN instance.

- The single-hop links in a VPN instance are detected if both the peer IPv6 address, VPN instance, and local interface are specified.

NOTE

The **source-ipv6** parameter prevents BFD packets from being discarded incorrectly by URPF. The system checks only the source IPv6 address type (it cannot be a multicast or broadcast address), but does not check the address correctness. Therefore, you must manually check the correctness of the source IPv6 address.

When a multi-hop BFD6 session is configured, the value of **peer-ipv6** or **source-ipv6** cannot be the IPv6 address of a GRE tunnel interface.

Prerequisites

Global BFD has been enabled using the **bfd** command in the system view.

Follow-up Procedure

After creating a BFD for IPv6 session and entering its view, perform the following mandatory operations:

1. Run the **discriminator** command to set the local and remote discriminators for the BFD for IPv6 session.
2. Run the **commit** command to commit the configuration.

Perform the following optional operations according to your needs:

- Run the **description** command to configure description for the BFD for IPv6 session.
- Run the **min-tx-interval** command to set the interval for sending BFD for IPv6 packets.
- Run the **min-rx-interval** command to set the interval for receiving BFD for IPv6 packets.
- Run the **detect-multiplier** command to set the local detection multiplier.
- Run the **process-pst** command to configure the Port State Table (PST) of the BFD session.
- Run the **wtr** command to set the Wait-to-Recovery (WTR) time for the BFD for IPv6 session.

Precaution

- The BFD for IPv6 session detects links bidirectionally, so the **bfd bind peer-ipv6** command must be run on both ends of each link.
- After a BFD for IPv6 session is created:
  - If you change the source IPv6 address of outbound interface during session negotiation, the source IPv6 address in BFD packets is also changed.
  - If you change the source IPv6 address of outbound interface during session detection, the source IPv6 address in BFD packets is not changed.

Example

Create a BFD6 session named **atob** to detect a single-hop link.

```
<HUAWEI> system-view
[HUAWEI] bfd
```

```
[HUAWEI-bfd] quit
[HUAWEI] bfd atob bind peer-ipv6 2001:db8:1::1 interface vlanif 10
[HUAWEI-bfd-session-atob] discriminator local 1
[HUAWEI-bfd-session-atob] discriminator remote 2
[HUAWEI-bfd-session-atob] commit
```

Create a BFD6 session named **atoc** to detect a multi-hop link from which BFD6 packets reach 2001:db8:1::1.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] bfd atoc bind peer-ipv6 2001:db8:1::1
[HUAWEI-bfd-session-atoc] discriminator local 3
[HUAWEI-bfd-session-atoc] discriminator remote 4
[HUAWEI-bfd-session-atoc] commit
```

12.1.8 bfd bind peer-ipv6 source-ipv6 auto

Function

The **bfd bind peer-ipv6 source-ipv6 auto** command creates a static BFD6 session with automatically negotiated discriminators.

The **undo bfd** *bfd-name* command deletes a specified BFD6 session.

By default, no static BFD6 session with automatically negotiated discriminators.

Format

bfd *session-name* **bind peer-ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*] [**interface** *interface-type interface-number*] **source-ipv6** *ipv6-address* **auto**

undo bfd *session-name*

Parameters

Parameter	Description	Value
session-name	Specifies the name of a BFD6 session.	The value is a string of 1 to 15 case-sensitive characters without spaces. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
peer-ipv6 *ipv6-address*	Specifies the peer IPv6 address bound to a BFD6 session.	-
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance bound to a BFD6 session.	The value must be an existing VPN instance name.

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the local Layer 3 outbound interface bound to a BFD6 session. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
source-ipv6 *ipv6-address*	Specifies the source IPv6 address carried in BFD packets.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The local device where a BFD session with automatically negotiated parameters is configured can negotiate with the remote device where a dynamic BFD session is configured; however, the local device enabled with static BFD can establish a BFD session with the remote device enabled with static BFD only. When configuring a BFD session with automatically negotiated parameters or a static BFD session, you can specify the BFD session name. The name of a dynamic BFD session is generated dynamically. When the network changes, the name of the dynamic BFD session may change.

When the remote end is configured with dynamic BFD and the local end needs to be configured with association between BFD and static route (BFD session name needs to be specified during association configuration), a BFD session with automatically negotiated parameters can be configured on the local end. Then the local end can establish a BFD session with the remote end enabled with dynamic BFD and association between BFD and static route can be implemented.

When creating a static BFD for IPv6 session with automatically negotiated discriminators, pay attention to the following points:

- If only the peer IPv6 address is specified, BFD is configured to detect the multi-hop link.
- A single-hop link is detected if both the peer IPv6 address and the local interface are specified. That is, a BFD6 session detects a specific route with this interface as the outbound interface and with the peer IPv6 address as the next hop address.
- If both the peer IPv6 address and the VPN instance are specified, the created BFD6 session detects the multi-hop links in the VPN instance.

- If the peer IPv6 address, VPN instance, and local interface are specified, the created BFD6 session detects the single-hop links in the VPN instance.

Prerequisites

Global BFD has been enabled using the **bfd** command in the system view.

Follow-up Procedure

After creating a static BFD for IPv6 session with automatically negotiated discriminators and entering its view, perform the following mandatory operations:

- Run the **description** command to configure description for the BFD for IPv6 session.
- Run the **min-tx-interval** command to set the interval for sending BFD packets.
- Run the **min-rx-interval** command to set the interval for receiving BFD packets.
- Run the **detect-multiplier** command to set the local detection multiplier.
- Run the **process-pst** command to configure the Port State Table (PST) of the BFD session.
- Run the **wtr** command to set the Wait-to-Recovery (WTR) time for the BFD for IPv6 session.

Precaution

A static BFD for IPv6 session and a static BFD6 session with automatically negotiated discriminators have the following differences:

- The local and remote discriminators must be specified for a static BFD for IPv6 session.
- The local and remote discriminators are optional for a static BFD6 session with automatically negotiated discriminators.

If the IPv6 address of outbound interface is changed for a BFD for IPv6 session, the source IPv6 address in BFD packets is not changed.

The source address is mandatory for a static BFD6 session with automatically negotiated discriminators.

Example

Create a static BFD6 session named **atob** with the automatically negotiated discriminators to detect a single-hop link.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] bfd atob bind peer-ipv6 2001:db8:1::1 interface gigabitethernet 0/0/1 source-ipv6
2001:db8:1::1 auto
[HUAWEI-bfd-session-atob]
```

Create a static BFD6 session named **atoc** with the automatically negotiated discriminators to detect the multi-hop link from which BFD6 packets reach 2001:db8:1::1.

```
<HUAWEI> system-view
[HUAWEI] bfd
```

```
[HUAWEI-bfd] quit
[HUAWEI] bfd atoc bind peer-ipv6 2001:db8:1::1 source-ipv6 2001:db8:1::1 auto
[HUAWEI-bfd-session-atoc]
```

12.1.9 bfd one-arm-echo

Function

The **bfd one-arm-echo** command configures the BFD echo function.

The **undo bfd** command deletes a specified BFD session and cancels the binding.

By default, the BFD echo function is not configured.

Format

bfd *session-name* **bind peer-ip** *peer-ip* [**vpn-instance** *vpn-instance-name*] **interface** *interface-type interface-number* [**source-ip** *ip-address*] **one-arm-echo**

undo bfd *session-name*

Parameters

Parameter	Description	Value
session-name	Specifies the name of a BFD session supporting the BFD echo function.	The value is a string of 1 to 15 case-insensitive characters without spaces. **NOTE** When quotation marks are used around the string, spaces are allowed in the string.
peer-ip *peer-ip*	Specifies the peer IP address bound to the BFD session.	The value is in dotted decimal notation.
vpn-instance *vpn-instance-name*	Specifies the name of a Virtual Private Network (VPN) instance that is bound to a BFD session.	The value must be an existing VPN instance name.
interface-type interface-number	Specifies the type and number of the interface bound to a BFD session. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-

Parameter	Description	Value
source-ip *ip-address*	Indicates the source IP address carried in BFD packets. This parameter should be configured.	-
one-arm-echo	Indicates a BFD session supporting the BFD echo function.	-

2: Configuration level

Usage Guidelines

Usage Scenario

Among two directly connected devices, one device supports BFD, whereas the other device does not support BFD. To rapidly detect forwarding failures between the two devices, configure a BFD session supporting the BFD echo function on the BFD-supporting device. The BFD-supporting device sends an Echo Request packet to the remote device. The remote device sends the Echo Request packet back along the same path to detect the forwarding link connectivity.

When you configure a BFD session supporting the BFD echo function:

- Specify **source-ip** *ip-address*. Ensure that the source IP address is correct. The system only checks whether the source IP address is valid (for example, it cannot be a multicast or broadcast address) without checking correctness. When URPF is enabled, ensure that **source-ip** *ip-address* can be pinged from the remote device so that the URPF-enabled device does not incorrectly discard BFD packets.
- On a network, some devices discard packets with the same source and destination IP addresses, so you are advised to set the value of **source-ip** *ip-address* to be different from the IP address of the outbound interface.
- If a VPN instance is specified, BFD is configured to detect the one-hop link in the VPN instance.

Prerequisites

Global BFD has been enabled using the **bfd** command in the system view.

Precautions

The difference between a BFD session supporting the BFD echo function and a common BFD session is as follows:

- When configuring a BFD session supporting the BFD echo function, you can only specify **local** *discr-value* in the **discriminator** command.
- You can only run the **min-echo-rx-interval** command to change the interval for receiving BFD packets.

NOTE

- If the IP address of an outbound interface is changed after a BFD session is configured, the source IP address of BFD packets is not updated.
- The BFD echo function is only applicable to single-hop BFD sessions.
- After the **bfd one-arm-echo** command is executed, run the **commit** command to commit the configuration to make the configuration take effect.

Example

Configure a BFD session **test** supporting the BFD echo function.

```
<HUAWEI> system-view
[HUAWEI] bfd test bind peer-ip 10.10.10.1 interface vlanif 100 source-ip 10.10.10.2 one-arm-echo
[HUAWEI-bfd-session-test] discriminator local 100
[HUAWEI-bfd-session-test] commit
```

12.1.10 bfd session-name

Function

The **bfd** command displays the view of a specified BFD session.

The **undo bfd** command deletes a specified BFD session.

Format

bfd *session-name*

undo bfd *session-name*

Parameters

Parameter	Description	Value
session-name	Specifies the name of a BFD session.	The value is a string of 1 to 15 characters without spaces. **NOTE** When quotation marks are used around the string, spaces are allowed in the string.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure the created BFD session, run the **bfd** *session-name* command to enter the specified BFD session view.

Prerequisites

A BFD session has been created by using either of the following commands:

- **bfd bind peer-ip**
- **bfd bind peer-ip default-ip**
- **bfd bind peer-ip source-ip auto**
- **bfd one-arm-echo**

Precautions

The **bfd** *session-name* command displays the BFD session view regardless of whether the BFD session status is Up.

After the functional parameters of the BFD session are set, you must run the **commit** command to make (expect static BFD session with automatically negotiated discriminators), the configurations take effect.

If the BFD session is in the Down state, after you run the **bfd** *session-name* command to enter the BFD session view and set functional parameters, the configurations can immediately take effect after being committed using the **commit** command.

Example

Enter the view of the BFD session named **session**.

```
<HUAWEI> system-view
[HUAWEI] bfd session
[HUAWEI-bfd-session-session]
```

12.1.11 bfd session nonexistent-config-check

Function

The **bfd session nonexistent-config-check enable** command enables the device to check whether the associated BFD session is deleted.

The **undo bfd session nonexistent-config-check disable** command enables the device to check whether the associated BFD session is deleted.

The **bfd session nonexistent-config-check disable** command disables the device from checking whether the associated BFD session is deleted.

By default, the device is enabled to check whether the associated BFD session is deleted.

Format

bfd session nonexistent-config-check enable

undo bfd session nonexistent-config-check disable

bfd session nonexistent-config-check disable

Parameters

None

Views

BFD view

Default Level

2: Configuration level

Usage Guidelines

After BFD for IPv4/IPv6 static routes and association between VRRP/VRRP6/E-Trunk and BFD are configured, deleting the BFD session may cause the association function to become ineffective. You can run the **bfd session nonexistent-config-check enable** command to enable the device to check whether the associated BFD session is deleted. When the associated BFD session is being deleted, the system displays a message indicating that the BFD session cannot be deleted. This function prevents the associated BFD session from being deleted incorrectly.

Example

Disable the device from checking whether the associated BFD session is deleted.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] bfd session nonexistent-config-check disable
```

12.1.12 commit

Function

The **commit** command commits the BFD session configuration.

Format

commit

Parameters

None

Views

BFD session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To make the modification on a BFD session take effect, you must run the **commit** command.

Precautions

- To establish a BFD session, the interface bound to the BFD session must be Up and there is a reachable route to the peer IP address.
- If conditions for BFD session setup are not met, the system keeps the configuration entries of the BFD session. The BFD session, however, cannot be established when you use the **commit** command.
- The system periodically scans BFD configuration entries that are committed but not used to establish sessions. If conditions are met, a session is established.
- The number of BFD sessions that can be established in the system is limited. When the number of established BFD sessions reaches the upper limit and you use the **commit** command to commit the configurations of a new BFD session, the system generates a log indicating that the BFD session cannot be established and sends traps.
- After creating a BFD session, if you need to modify session parameters, such as **process-pst**, **process-interface-status**, **min-tx-interval**, **min-rx-interval**, **detect-multiplier**, **tos-exp (BFD session view)**, **wtr**, **description**, **authentication-mode (BFD)**, **trigger if-down delay** or **receiving-admindown trigger if-down** you can directly run the corresponding commands without running the **commit** command, and the modification takes effect immediately.
- After running the **bfd bind peer-ip source-ip auto** command to create configurations for a static BFD session with automatically negotiated discriminators, you do not need to run the **commit** command to commit the configurations. BFD sessions can be automatically established, and relevant configurations are labeled with the commit tags. The **commit** command can still be used but does not take effect.

Example

Commit the BFD session configuration.

```
<HUAWEI> system-view
[HUAWEI] bfd test bind peer-ip default-ip interface gigabitethernet 0/0/1
[HUAWEI-bfd-session-test] discriminator local 22
[HUAWEI-bfd-session-test] discriminator remote 33
[HUAWEI-bfd-session-test] commit
```

12.1.13 dampening timer-interval

Function

The **dampening timer-interval** command configures BFD session flapping suppression timers.

The **undo dampening timer-interval** command restores the default configuration.

BFD session flapping suppression timers start by default.

The default initial, secondary, and maximum BFD session flapping suppression timer values are 2000 ms, 5000 ms, and 12000 ms, respectively.

Format

dampening timer-interval maximum *maximum-milliseconds* **initial** *initial-milliseconds* **secondary** *secondary-milliseconds*

undo dampening timer-interval [**maximum** *maximum-milliseconds* **initial** *initial-milliseconds* **secondary** *secondary-milliseconds*]

Parameters

Parameter	Description	Value
maximum *maximum-milliseconds*	Specifies a maximum BFD session flapping suppression timer value.	The value is an integer ranging from 1 to 3600000, in milliseconds. The default value is 12000.
initial *initial-milliseconds*	Specifies an initial BFD session flapping suppression timer value.	The value is an integer ranging from 1 to 3600000, in milliseconds. The default value is 2000.
secondary *secondary-milliseconds*	Specifies a secondary BFD session flapping suppression timer value.	The value is an integer ranging from 1 to 3600000, in milliseconds. The default value is 5000.

Views

BFD session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If BFD detects link Down, services are switched. A penalty mechanism is provided to delay BFD session negotiation and prevent frequent service switchovers, protecting link resources and reducing link resource consumption.

To configure BFD session flapping suppression timers, run the **dampening timer-interval** command.

Prerequisites

BFD has been globally enabled using the **bfd** command in the system view.

Configuration Impact

After the **dampening timer-interval** command is run:

1. When a BFD session flaps for the first time, the initial BFD session flapping suppression timer starts. If the BFD session flaps again before the initial BFD session flapping suppression timer expires, BFD session renegotiation is triggered after the initial BFD session flapping suppression timer expires.
2. After the initial BFD session flapping suppression timer ends, the secondary BFD session flapping suppression timer starts. If the BFD session flaps before the secondary BFD session flapping suppression timer expires, BFD session renegotiation is triggered after the secondary BFD session flapping suppression timer expires. After that, the timer value is *secondary-milliseconds* x $2^{(n-1)}$, where *n* is the number of times that the secondary BFD session flapping suppression timer starts.
3. After the timer value of *secondary-milliseconds* x $2^{(n-1)}$ is greater than or equal to the value specified by *maximum-milliseconds*, the BFD session uses the value specified by *maximum-milliseconds* as a flapping delay three consecutive times. Then, the BFD session flapping delay is recalculated based on Step 1.

Precautions

The configured maximum BFD session flapping suppression timer value must be greater than the configured initial or secondary BFD session flapping suppression timer value. Otherwise, the configuration fails.

Do not configure both the **dampening timer-interval** and **wtr** commands. Otherwise, the BFD session recovery period becomes long.

Example

Set a maximum, initial, and secondary BFD session flapping suppression timer values to 20000 ms, 1000 ms, and 3000 ms, respectively.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] dampening timer-interval maximum 20000 initial 1000 secondary 3000
```

12.1.14 default-ip-address

Function

The **default-ip-address** command configures the default multicast IP address used by all BFD sessions.

The **undo default-ip-address** command restores the default multicast IP address.

By default, BFD uses the multicast IP address 224.0.0.184.

Format

default-ip-address *ip-address*

undo default-ip-address

Parameters

Parameter	Description	Value
ip-address	Specifies the default multicast IP address.	The value ranges from 224.0.0.107 to 224.0.0.250.

Views

BFD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When using BFD to detect the physical status of a link, you may not specify the peer IP address. In certain situations, the peer such as the member link of the Eth-Trunk is not assigned an IP address. In this case, you need to bind a BFD session to a multicast IP address and send BFD control packets to the multicast IP address.

You must change the default multicast IP address in the following situations:

- On the network, other protocols use the multicast IP address.
- If multiple BFD sessions exist on a path, for example, Layer 3 interfaces are connected through Layer 2 switching devices that support BFD, configure different default multicast IP addresses for the devices where different BFD sessions are established. In this manner, BFD packets can be correctly forwarded.

Prerequisites

BFD has been enabled globally using the **bfd** command in the system view.

Precautions

If the **bfd bind peer-ip default-ip** command has been run in the system view, the **default-ip-address** command cannot be used to change the default BFD multicast address.

Example

Set the default multicast IP address to 224.0.0.150.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] default-ip-address 224.0.0.150
```

12.1.15 description (BFD session view)

Function

The **description** command configures the description of a BFD session.

The **undo description** command deletes the description of a BFD session.

By default, the description of a BFD session is empty.

Format

description *description*

undo description

Parameters

Parameter	Description	Value
description	Specifies the description of a BFD session.	The value is a string of 1 to 51 case-sensitive characters with spaces.

Views

BFD session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In practice, multiple BFD sessions need to be configured. To differentiate BFD sessions, run the **description** command to configure a description for a BFD session. A meaningful description is recommended.

Configuration Impact

It is difficult to identify a BFD session that is not configured or whose description is deleted.

Precautions

If you run the **description** command in the same BFD session view multiple times, only the latest configuration takes effect.

The **description** command takes effect only for statically configured BFD sessions but does not take effect for dynamic BFD sessions or BFD sessions with automatically negotiated discriminators.

Example

Set the description of the BFD session named **atoc**.

```
<HUAWEI> system-view
[HUAWEI] bfd atoc
[HUAWEI-bfd-session-atoc] description SwitchA_to_SwitchC
```

12.1.16 detect-multiplier

Function

The **detect-multiplier** command sets the local detection multiplier.

The **undo detect-multiplier** command restores the default local detection multiplier.

By default, the local detection multiplier is 3.

Format

detect-multiplier *multiplier*

undo detect-multiplier

Parameters

Parameter	Description	Value
multiplier	Specifies the local detection multiplier of a BFD session.	The value is an integer that ranges from 3 to 50.

Views

BFD session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The local detection multiplier determines the detection time of a BFD session.

Detection time = Received Detect Multi of the remote system x Max (Local RMRI/ Received DMTI)

where

- Detect Multi: local detection multiplier, which is set by using the **detect-multiplier** command
- Required Min Rx Interval (RMRI): minimum interval for receiving BFD packets, which is set by using the **min-rx-interval** command
- Desired Min Tx Interval (DMTI): minimum interval for sending BFD packets, which is set by using the **min-tx-interval** command

You can increase or reduce the local detection multiplier based on actual networking. On a stable link, there is no need to frequently detect the link status, so you can increase the local detection multiplier.

If no BFD packet is received from the peer device within the detection time, the link is considered as faulty and the BFD session enters the Down state. To reduce the usage of system resources, when the BFD session is detected in Down state, the system adjusts the sending interval to a random value greater than 1000 ms. When the BFD session becomes Up, the configured interval is restored.

Configuration Impact

- On an unstable link, if the local detection multiplier is small, the BFD session may flap. It is recommended that a larger local detection multiplier be used.
- When other protocols are associated with BFD, if a larger local detection multiplier is used, the BFD session takes a long period of time to detect faults on the link and traffic is switched to the backup link after the specified period. Packets may be lost during this period.

Precautions

Both ends of a BFD session can use different local detection multipliers.

Example

Set the local detection multiplier of the BFD session **atoc** to 10.

```
<HUAWEI> system-view
[HUAWEI] bfd atoc
[HUAWEI-bfd-session-atoc] detect-multiplier 10
```

12.1.17 discriminator

Function

The **discriminator** command sets local and remote discriminators for a static BFD session.

Format

discriminator { **local** *discr-value* | **remote** *discr-value* }

Parameters

Parameter	Description	Value
local *discr-value*	Specifies the local discriminator of a BFD session	The value is an integer that ranges from 1 to 8191.
remote *discr-value*	Specifies the remote discriminator of a BFD session	The value is an integer that ranges from 1 to 4294967295.

Views

BFD session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When creating a static BFD session, run the **discriminator** command to set local and remote discriminators. Otherwise, the static BFD session cannot be set up. The local and remote discriminators differentiate BFD sessions between two systems.

Precautions

- Only static BFD sessions require settings of local and remote discriminators.
- The local discriminator of the local system and the remote discriminator of the remote system must be the same. If the local discriminator of the local system and the remote discriminator of the remote system are different, a static BFD session cannot be set up.
- After the local and remote discriminators of a static BFD session are configured, the local and remote discriminators cannot be modified. To modify the local and remote discriminators of a static BFD session, delete the BFD session and reconfigure the local and remote discriminators.

Example

Set the local discriminator of a BFD session to 80 and the remote discriminator to 800.

```
<HUAWEI> system-view
[HUAWEI] bfd atoc
[HUAWEI-bfd-session-atoc] discriminator local 80
[HUAWEI-bfd-session-atoc] discriminator remote 800
```

12.1.18 display bfd configuration

Function

The **display bfd configuration** command displays the BFD session configuration.

Format

display bfd configuration { **all** | **static** } [**for-lsp** | **for-pw** | **for-te** | **for-vsi-pw**] [**verbose**] (S5731-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H and S6730-H)

display bfd configuration { **ldp-lsp peer-ip** *ip-address* **nexthop** *nexthop* [**interface** *interface-type interface-number*] | **static-lsp** *lsp-name* } [**verbose**] (S5731-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730S-H and S6730-H)

display bfd configuration mpls-te interface *interface-type interface-number* [**te-lsp**] [**verbose**](S5731-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730S-H and S6730-H)

display bfd configuration pw interface *interface-type interface-number* [**secondary**] [**verbose**](S5731-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730S-H and S6730-H)

display bfd configuration vsi-pw vsi *vsi-name* **peer** *peer-address* [**vc-id** *vc-id*] [**verbose**](S5731-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730S-H and S6730-H)

display bfd configuration passive-dynamic [**peer-ip** *ip-address* **remote-discriminator** *discriminator*] [**verbose**] (S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S)

display bfd configuration { **static name** *session-name* | **dynamic** | **static-auto** | **peer-ip** { **default-ip** | *ip-address* [**vpn-instance** *vpn-instance-name*] } | **discriminator** *local-discr-value* } [**verbose**]

display bfd configuration peer-ipv6 *ipv6-address* [**vpn-instance** *vpn-instance-name*] [**verbose**]

display bfd configuration { **all** | **static** } **[for-ip** | **for-ipv6**] [**verbose**]

Parameters

Parameter	Description	Value
all	Displays the configurations of all BFD sessions.	-
static	Displays the configurations of static BFD sessions.	-

Parameter	Description	Value
for-vsi-pw	Displays the configurations of the BFD sessions for detecting VSI PWs.	-
for-ip	Displays the configurations of the BFD sessions for detecting IP links.	-
for-lsp	Displays the configurations of the BFD sessions for detecting LSPs.	-
for-pw	Displays the configurations of the BFD sessions for detecting PWs.	-
for-te	Displays the configurations of the BFD sessions for detecting TE tunnels.	-
vsi-pw	Displays the configurations of the BFD sessions for detecting VSI PWs.	-
vsi *vsi-name*	Displays the configuration of the BFD session with the specified VSI instance name.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
peer *peer-address*	Displays the configuration of the BFD session for detecting a VSI PW with the specified peer IPv4 address.	The value is in dotted decimal notation.
peer-ip *ip-address*	Displays the configuration of the BFD session bound to the specified peer IP address.	-

Parameter	Description	Value
vc-id *vc-id*	Displays the configuration of the BFD session with the specified VC ID.	The value is an integer that ranges from 1 to 4294967295.
passive-dynamic	Displays the configurations of the BFD sessions dynamically created by the end in passive mode.	-
remote-discriminator *discriminator*	Displays the configuration of the BFD session with the local discriminator of the source device initiating the BFD session.	The value is an integer that ranges from 1 to 4294967295.
verbose	Displays detailed BFD configurations.	-
name *session-name*	Displays the configuration of the static BFD session with the specified name.	The value is a string of 1 to 15 characters without spaces. **NOTE** If the string is enclosed within double quotation marks ("), the string can contain spaces.
dynamic	Displays dynamic BFD configurations and the configurations of static BFD sessions with automatically negotiated discriminators.	-
discriminator *local-discr-value*	Displays the configuration of the BFD session with the specified local discriminator.	The value is an integer that ranges from 1 to 16383.
default-ip	Displays statistics about multicast BFD sessions.	-
vpn-instance *vpn-instance-name*	Displays the configuration of the BFD session bound to a specified VPN instance.	The value must be an existing VPN instance name.

Parameter	Description	Value
static-auto	Displays the configuration of the static BFD session with the automatically negotiated discriminators.	-
ldp-lsp	Displays the configurations of the BFD sessions for detecting LDP LSPs.	-
nexthop *nexthop*	Displays the configuration of the BFD session with the specified next hop address.	The value is in dotted decimal notation.
interface-type interface-number	Displays BFD binding information on the specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
static-lsp	Displays the configurations of the BFD sessions for detecting static LSPs.	-
lsp-name	Displays the configuration of the BFD session for detecting the static LSP with the specified name.	The value is a string of 1 to 19 case-sensitive characters.
mpls-te	Displays the configurations of the BFD sessions for detecting MPLS TE tunnels.	-
te-lsp	Displays the configuration of the BFD session for detecting the primary LSP bound to a TE tunnel.	-

Parameter	Description	Value
pw	Displays the configurations of the BFD sessions for detecting PWs.	-
secondary	Displays the configuration of the BFD session for detecting the secondary PW.	-
peer-ipv6 *ipv6-address*	Displays the configuration of the BFD6 session bound to a specified IPv6 address.	-
for-ipv6	Displays the configurations of static or all BFD6 sessions.	-

Views

All views

1: Monitoring level

Usage Guidelines

Usage Scenario

When multiple BFD sessions exist, you can view information about certain BFD sessions by specifying the parameters such as the type, name, and peer IP address.

Precautions

If a static BFD session with automatically negotiated discriminators and a dynamic BFD session share the same configurations, you can view that the shared session configurations by BFD session type (static and dynamic).

Example

Display the configurations of all BFD sessions.

```
<HUAWEI> display bfd configuration all
--------------------------------------------------------------------------------
CFG Name        CFG Type       LocalDiscr MIndex    SessNum  Commit   AdminDown
--------------------------------------------------------------------------------
atob            S_IP_PEER      -          512       0        False    False
test            S_IP_PEER      1          513       0        False    False
zzz             S_IP_IF        3          514       0        False    False
--------------------------------------------------------------------------------
    Total Commit/Uncommit CFG Number : 0/3
```

Table 12-1 Description of the display bfd configuration command output

Item	Specification
CFG Name	BFD session name.
CFG Type	BFD session setup type: ● S_IP_IF: indicates a single-hop BFD session that is established statically and bound to an interface. ● S_IP_PEER: indicates a multi-hop BFD session that is established statically. ● S_STA_LSP: indicates a BFD session that is established statically and used for detecting an LSP. ● S_LDP_LSP: indicates a BFD session that is established statically and used for detecting an LDP LSP. ● S_TE_LSP: indicates a BFD session that is statically established and used for detecting a TE LSP. ● S_TE_TNL: indicates a BFD session that is statically established and used for detecting a TE tunnel. ● S_PW: indicates a BFD session that is statically established and used for detecting a PW. ● S_VSI_PW: indicates a BFD session that is statically established and used for detecting a VSI PW. ● Dynamic: indicates a BFD session that is dynamically established. ● Entire_Dynamic: indicates a BFD session that is entirely and dynamically established. ● S_AUTO_IF: indicates a static single-hop BFD session with automatically negotiated discriminators. ● S_AUTO_PEER: indicates a static multi-hop BFD session with automatically negotiated discriminators.
LocalDiscr	Local discriminator of the BFD session. To set the local discriminator of the BFD session, run the **discriminator** command.
MIndex	Configuration entry index of a BFD session.
SessNum	Number of BFD sessions in a configuration entry.
Commit	Flag of enabling a BFD session. After you run the **commit** command to commit configurations in the BFD session view, the flag is displayed as **True**. Otherwise, it is displayed as **False**.

Item	Specification
AdminDown	Flag of the management status of a BFD session. After you run the **shutdown (BFD session view)** command to disable the local session in the BFD session view, the flag is displayed as **True**. Otherwise, it is displayed as **False**.
Total Commit/ Uncommit CFG Number	Total number of BFD sessions that are committed through the **commit** command in the BFD session view and total number of BFD sessions that are not committed.

Display detailed configurations of all BFD sessions.

```

Table 12-2 Description of the display bfd configuration all verbose command output

Item	Specification
BFD Session Configuration Name	BFD session name.
Local Discriminator	Local discriminator of a BFD session. To set the local discriminator of a BFD session, run the **discriminator** command.
Remote Discriminator	Remote discriminator of a BFD session. To set the remote discriminator of a BFD session, run the **discriminator** command.
BFD Bind Type	BFD session binding type: ● Peer IP Address: indicates multi-hop BFD for an IP link. ● Interface: indicates single-hop BFD for an IP link. ● STATIC_LSP: indicates that a static LSP is detected. ● LDP_LSP: indicates that an LDP LSP is detected. ● TE_LSP: indicates that an LSP bound to a TE tunnel is detected. ● TE_TUNNEL: indicates that a TE tunnel is detected. ● PW: indicates that a PW is detected. ● VSI_PW: indicates that a VSI PW is detected.

Item	Specification
Bind Session Type	Mode in which a BFD session is established: - Static: indicates the BFD sessions that are established through the static configurations. - Dynamic: indicates the BFD sessions that are triggered dynamically. - Static_Auto: indicates the statically established BFD sessions with automatically negotiated discriminators. - Entire_Dynamic: indicates the BFD sessions that are entirely and dynamically triggered.
Bind Peer Ip Address	Peer IP address of a BFD session or multicast IP address bound to a BFD session.
Bind Interface	Local interface bound to a BFD session.
Track Interface	Interface tracked by the BFD session.
TOS-EXP	Priority of a BFD packet. To set the priority of a BFD packet, run the **tos-exp** command.
Local Detect Multi	Local detection multiplier. To set the local detection multiplier, run the **detect-multiplier** command.
Min Tx Interval (ms)	Minimum interval for sending BFD packets. To set the minimum interval for sending BFD packets, run the **min-tx-interval** command.
Min Rx Interval (ms)	Minimum interval for receiving BFD packets. To set the minimum interval for receiving BFD packets, run the **min-rx-interval** command.
WTR Interval (ms)	WTR time. To set the WTR time, run the **wtr** command.
Process PST	Flag for processing the Port Status Table (PST). If the **process-pst** command is configured, this field is displayed as **Enable**. Otherwise, it is displayed as **Disable**.
Auth Key ID	Authentication key ID of a BFD session.
Auth Timer	Negotiation timeout period of a BFD session, in seconds.
Meticulous Auth	Authentication flag - **True**: strict - **False**: non-strict

Item	Specification
Auth Type	BFD authentication type: - **NONE**: no authentication - **SIMPLE**: simple password authentication - **MD5**: MD5 authentication - **MMD5**: meticulous MD5 authentication - **SHA1**: SHA1 authentication - **MSHA1**: meticulous SHA1 authentication
Proc interface status	Flag of association between the BFD session status and the interface status. If the **process-interface-status** command is configured, this field is displayed as Enable. Otherwise, it is displayed as **Disable**.
Bind Application	Application bound to the BFD session.
Session Description	Description of the BFD session. To set the description of the BFD session, run the **description** command.
Session Create Status	Status of BFD session creation: - Success - Failed
Total Commit/Uncommit CFG Number	Total number of BFD sessions that are committed through the **commit** command in the BFD session view and total number of BFD sessions that are not committed.

12.1.19 display bfd interface

Function

The **display bfd interface** command displays information about a BFD-enabled interface.

Format

display bfd interface [*interface-type interface-number*]

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of the interface bound to the BFD session. ● *interface-type* specifies the type of the interface. ● *interface-number* specifies the number of the interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display bfd interface** command displays information about a BFD-enabled interface, including the BFD session bound to the interface and the BFD session status.

Example

Display information about a BFD-enabled interface.

```
<HUAWEI> display bfd interface
--------------------------------------------------------------------------------
Interface Name          MIndex       Sess-Count      BFD-State
--------------------------------------------------------------------------------
Vlanif100               256          1               up
--------------------------------------------------------------------------------
    Total Interface Number : 1
```

Table 12-3 Description of the display bfd interface command output

Item	Description
Interface Name	Name of the BFD-enabled interface.
MIndex	Index of the interface entry.
Sess-Count	Number of BFD sessions bound to the interface.

Item	Description
BFD-State	BFD status of an interface. The value can be up or down. **NOTE** If a BFD session is bound to the interface and configured with the **process-interface-status** command, the BFD session's status is displayed (The interface is up when the BFD session is in the AdminDown or Receive AdminDown state). Otherwise, the interface's physical status is displayed. If multiple BFD sessions are bound to the interface, only one BFD session can be configured with the **process-interface-status** command.
Total Interface Number	Number of the BFD-enabled interface.

12.1.20 display bfd session

Function

The **display bfd session** command displays information about BFD sessions.

Format

display bfd session { **dynamic** | **discriminator** *discr-value* | **peer-ip** { **default-ip** | *ip-address* [**vpn-instance** *vpn-instance-name*] } | **static-auto** } [**verbose**]

display bfd session { **all** | **static** } [**for-lsp** | **for-pw** | **for-te** | **for-vsi-pw**] [**verbose**](S5731-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H and S6730-H)

display bfd session { **ldp-lsp peer-ip** *ip-address* **nexthop** *ip-address* [**interface** *interface-type interface-number*] | **static-lsp** *lsp-name* } [**verbose**] (S5731-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H and S6730-H)

display bfd session mpls-te interface *interface-type interface-number* [**te-lsp**] [**verbose**] (S5731-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H and S6730-H)

display bfd session pw interface *interface-type interface-number* [**secondary**] [**verbose**] (S5731-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H and S6730-H)

display bfd session passive-dynamic [**peer-ip** *ip-address* **remote-discriminator** *remote-discr-value*] [**verbose**] (S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S)

display bfd session { **vsi-pw vsi** *vsi-name* **peer** *peer-address* [**vc-id** *vc-id*] } [**verbose**] (S5731-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H and S6730-H)

display bfd session peer-ipv6 *ipv6-address* [**vpn-instance** *vpn-instance-name*] [**verbose**]

display bfd session { **all** | **static** } **[for-ip** | **for-ipv6**] [**verbose**]

Parameters

Parameter	Description	Value
all	Displays information about all BFD sessions.	-
static	Displays information about all static BFD sessions.	-
for-ip	Displays information about the BFD sessions for detecting IP links.	-
for-lsp	Displays information about the BFD sessions for detecting LSPs.	-
for-pw	Displays information about the BFD sessions for detecting PWs.	-
for-te	Displays information about the BFD sessions for detecting TE tunnels.	-
for-vsi-pw	Displays information about the BFD sessions for detecting VSI PWs.	-
vsi-pw	Displays information about the BFD session for detecting a VSI PW.	-
vsi-name	Displays information about the BFD session with the specified VSI instance name.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
peer *peer-address*	Displays information about the BFD session for detecting a VSI PW with the specified peer IPv4 address.	The value is in dotted decimal notation.

Parameter	Description	Value
nexthop *ip-address*	Displays information about the BFD session with the specified next hop address.	The value is in dotted decimal notation.
interface *interface-type interface-number*	Displays information about the BFD session with the specified outbound interface.	-
vc-id *vc-id*	Displays information about the BFD session with the specified VC ID.	The value is a decimal integer ranging from 1 to 4294967295.
verbose	Displays detailed information about BFD sessions.	-
dynamic	Displays information about all dynamic BFD sessions and static BFD sessions negotiated with discriminators.	-
passive-dynamic	Displays information about all dynamic BFD sessions created on the end in passive mode.	-
discriminator *discr-value*	Displays information about the BFD session with a specified discriminator. You can specify only a local discriminator.	The value is an integer that ranges from 1 to 16383.
remote-discriminator *remote-discr-value*	Displays information about the BFD session with a specified discriminator. You can specify only a remote discriminator.	The value is an integer that ranges from 1 to 4294967295.
peer-ip *ip-address*	Displays information about the BFD session bound to the specified peer IP address.	The value is in dotted decimal notation.
default-ip	Displays statistics about multicast BFD sessions.	-

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays information about the BFD session bound to the specified VPN instance.	The value must be an existing VPN instance name.
static-auto	Displays the information about the static BFD sessions with the automatically negotiated discriminators.	-
ldp-lsp	Displays information about the BFD sessions for detecting LDP LSPs.	-
static-lsp	Displays information about the BFD sessions for detecting static LSPs.	-
lsp-name	Displays information about the BFD session for detecting the static LSP with the specified name.	The value is a string of 1 to 19 case-sensitive characters without spaces.
mpls-te	Displays information about the BFD sessions for detecting MPLS TE tunnels.	-
te-lsp	Displays information about the BFD session for detecting the primary LSP bound to a TE.	-
pw	Displays information about the BFD sessions for detecting PWs.	-
secondary	Displays information about the BFD session for detecting the secondary PW.	-
peer-ipv6 *ipv6-address*	Displays information about the BFD6 session bound to a specified IPv6 address.	-
for-ipv6	Displays information about static or all BFD6 sessions.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display bfd session** command displays information about BFD sessions.

Prerequisites

BFD has been enabled globally.

Precautions

- When a BFD session changes from Down to Up, if the WTR time of the session is not 0, BFD sends a notification that the session becomes Up only after the WTR time expires.
- If a static BFD session with automatically negotiated discriminators and a dynamic BFD session are bound to the same peer IP address, the **display bfd session** command displays the same entry for the static BFD session or dynamic BFD session.

Example

Display the summary of all BFD sessions.

```
<HUAWEI> display bfd session all
--------------------------------------------------------------------------------
Local Remote     PeerIpAddr      State     Type        InterfaceName
--------------------------------------------------------------------------------
10    11         10.10.10.2      Up        S_IP_IF     Vlanif31
8192  0          10.10.10.2      Down      S_AUTO_IF   Vlanif31
--------------------------------------------------------------------------------
     Total UP/DOWN Session Number : 1/1
```

Table 12-4 Description of the display bfd session command output

Item	Description
Local	Local discriminator of the BFD session. To set the local discriminator, run the **discriminator** command.
Remote	Remote discriminator of the BFD session. To set the remote discriminator, run the **discriminator** command.
PeerIpAddr	Peer IP address bound to the BFD session.

Item	Description
InterfaceName	Outbound interface bound to the BFD session. In multi-hop BFD, this field is displayed as - because no interface is bound to a BFD session.
State	BFD session status: ● Init: The BFD session is in the initialized state. ● Up: indicates that the BFD session is in Up state. ● Down: indicates that the BFD session is in Down state. ● AdmDown: indicates that a BFD session is AdminDown when the **shutdown (BFD session view)** command is run.

Item	Description
Type	BFD session type: ● S_TE_LSP: indicates a BFD session that is established statically and bound to a TE LSP. ● S_TE_TNL: indicates a BFD session that is established statically and bound to a TE tunnel. ● S_IP_PEER: indicates a BFD session that is established statically and bound to an IP link. ● S_IP_IF: indicates a BFD session that is established statically and bound to an interface. ● S_LDP_LSP: indicates a BFD session that is established statically and bound to a dynamic LSP. ● S_PW(M): indicates a BFD session that is established statically and bound to the primary PW. ● S_PW(S): indicates a BFD session that is established statically and bound to the secondary PW. ● S_STA_LSP: indicates a BFD session that is established statically and bound to a static LSP. ● S_VSI_PW: indicates a BFD session that is established statically and bound to a VSI PW. ● D_IP_PEER: indicates a BFD session that is created dynamically and bound to an IP link. ● D_IP_IF: indicates a BFD session that is established dynamically and bound to an interface. ● D_LDP_LSP: indicates a BFD session that is established dynamically and bound to a dynamic LSP. ● D_TE_LSP: indicates a BFD session that is established dynamically and bound to a TE LSP. ● D_PW(S): indicates a BFD session that is established dynamically and bound to the secondary PW. ● D_PW(M): indicates a BFD session that is established dynamically and bound to the primary PW. ● E_Dynamic: indicates a BFD session that is established entirely and dynamically. After you enable the function of dynamically establishing a BFD session on the destination of an LSP, this session type is created. ● S_AUTO_IF: indicates a static single-hop BFD session with automatically negotiated discriminators. ● S_AUTO_PEER: indicates a static multi-hop BFD session with automatically negotiated discriminators.
Total UP/ DOWN Session Number	Number of BFD sessions in Up or Down state.

Display detailed information about all BFD sessions.

```
<HUAWEI> display bfd session all verbose

```

Table 12-5 Description of the display bfd session all verbose command output

Item	Description
Session MIndex	Index of BFD session entries.
State	Status of a BFD session.
Name	Name of a BFD session.
Local Discriminator	Local discriminator of the BFD session. To set the local discriminator of the BFD session, run the **discriminator** command.
Remote Discriminator	Remote discriminator of the BFD session. To set the remote discriminator of the BFD session, run the **discriminator** command.

Item	Description
Session Detect Mode	BFD detection modes: ● Asynchronous Mode Without Echo Function: indicates the asynchronous mode without the echo function. ● Demand Mode Without Echo Function: indicates the demand mode without the echo function.
BFD Bind Type	BFD session binding type: ● STATIC_LSP: indicates that a static LSP is detected. ● LDP_LSP: indicates that an LDP LSP is detected. ● TE_TUNNEL: indicates that a TE tunnel is detected. ● TE_LSP: indicates that an LSP bound to a TE is detected. ● PW: indicates that a PW is detected. ● Peer IP Address: indicates that a multi-hop IP link is detected. ● When one-hop BFD is used to detect an IP link, this field is displayed as **Interface** and the name of the bound local interface. ● VSI_PW: indicates that a VSI PW is detected. ● Static_Auto: indicates the BFD session with automatically negotiated discriminators.
Bind Session Type	Indicates the ways of establishing BFD sessions: ● Static: indicates that a BFD session is established manually. ● Dynamic: indicates that a BFD session is established dynamically. ● Static_Auto: indicates that a BFD session is established with automatically negotiated discriminators. ● Entire_Dynamic: indicates that a BFD session is triggered entirely and dynamically. After you enable the function of dynamically establishing a BFD session on the destination of an LSP, this session type is created.
Bind Peer Ip Address	Peer IP address bound to the BFD session.
NextHop Ip Address	IP address of the next hop.
Bind Interface	Outbound interface bound to the BFD session.

Item	Description
Bind Source Ip Address	Source IP address of the local interface bound to the BFD session. This field can be displayed only when the source IP address is specified for the BFD session that is created by running the **bfd bind peer-ip** or **bfd bind peer-ip default-ip** command.
FSM Board Id	Number of the processing board where the state machine works.
TOS-EXP	Priority of a BFD packet. To set the priority of a BFD packet, run the **tos-exp** command.
Min Tx Interval (ms)	Configured minimum interval for sending BFD packets. To set the minimum interval for sending BFD packets, run the **min-tx-interval** command.
Min Rx Interval (ms)	Configured minimum interval for receiving BFD packets. To set the minimum interval for receiving BFD packets, run the **min-rx-interval** command.
Actual Tx Interval (ms)	Actual minimum interval for sending BFD packets.
Actual Rx Interval (ms)	Actual minimum interval for receiving BFD packets.
Local Detect Multi	Local detection multiplier. To set the local detection multiplier, run the **detect-multiplier** command.
Detect Interval (ms)	BFD detection time.
Echo Passive	Whether the BFD passive Echo function is enabled: ● Enable ● Disable
Acl Number	ACL rule number
Destination Port	Number of the destination port of the BFD session packet. The single-hop BFD control packet uses destination port 3784 and the multi-hop BFD control packet uses 3784 or 4784.
TTL	TTL value of the BFD packet.
WTR Interval (ms)	WTR time of the BFD session. To set the WTR time of the BFD session, run the **wtr** command.

Item	Description
Process PST	Flag for processing the Port Status Table (PST). If the **process-pst** command is configured, this field is displayed as **Enable**. Otherwise, it is displayed as **Disable**.
Proc interface status	Flag of association between the BFD session status and the interface status. If the **process-interface-status** command is configured, this field is displayed as **Enable**. Otherwise, it is displayed as **Disable**.
Active Multi	Detection multiplier that is effective.
DSCP	DSCP value in the BFD session. The value ranges from 1 to 63. The value - indicates that the DSCP value does not take effect in the BFD session.
Auth Key ID	Authentication key ID of a BFD session
Auth Timer	Negotiation timeout period of a BFD session, in seconds
Meticulous Auth	Authentication flag ● **True**: strict ● **False**: non-strict
Auth Type	BFD authentication type: ● **NONE**: no authentication ● **SIMPLE**: simple password authentication ● **MD5**: MD5 authentication ● **MMD5**: meticulous MD5 authentication ● **SHA1**: SHA1 authentication ● **MSHA1**: meticulous SHA1 authentication
Xmit Auth Seq	Local sequence number of a BFD authentication session
Rcv Auth Seq	Remote sequence number of a BFD authentication session

Item	Description
Error Packet Info	Packet error information: - **Correct Pkt**: The packet is correct. - **Incorrect authentication type**: The authentication type is incorrect. - **Incorrect authentication length**: The authentication length is incorrect. - **Incorrect sequence number**: The sequence number is incorrect. - **Authentication failed**: The authentication fails. - **Incorrect authentication keyid**: The authentication key ID is incorrect. - **Local does not configure authentication**: Authentication is not configured at the local end. - **Remote does not configure authentication**: Authentication is not configured at the remote end.
Last Local Diagnostic	Local diagnostic cause for the last BFD session in Down state.
Bind Application	Application bound to the BFD session.
Session TX TmrID	Timer used for a BFD session to send packets.
Session Detect TmrID	BFD session detection timer.
Session Init TmrID	Timer for state machine initialization of a BFD session.
Session WTR TmrID	WTR timer of a BFD session.
Session Echo Tx TmrID	Timer used for a BFD session to send Echo packets.
PDT Index	Product information.
Session Description	Description of the BFD session. To set the description of the BFD session, run the **description** command.
Trigger If-down Delay Time (s)	Delay for a device to instruct the interface protocol to go down after the device detects a BFD down event, in seconds.
Receiving-admindown Trigger If-down	Whether the local device is enabled to instruct the interface protocol to go down upon receipt of an AdminDown packet.
Total UP/DOWN Session Number	Number of BFD sessions in Up or Down state.

12.1.21 display bfd statistics

Function

The **display bfd statistics** command displays global BFD statistics.

Format

display bfd statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display bfd statistics** command displays global BFD statistics.

Precautions

Before using the **display bfd statistics** command to view BFD statistics within a specified period, run the **reset bfd statistics** command to clear existing statistics.

Example

Display global BFD statistics.

```
<HUAWEI> display bfd statistics
Current Display Board Number : Main; Current Product Register Type : S5730-36C-HI
IP Multihop Destination Port : 3784
Total Up/Down Session Number : 1/1
Current Session Number :
    Static session      : 2                Dynamic session        : 0
    E_Dynamic session  : 0                 STATIC_AUTO session    : 0
    LDP_LSP session    : 0                 STATIC_LSP session     : 0

```

Table 12-6 Description of the display bfd statistics command output

Item	Description
Current Display Board Number	Number of the board where information is displayed.
Current Product Register Type	Type of the current product.
IP Multihop Destination Port	UDP port number.
Total Up/Down Session Number	Total number of BFD sessions in Up or Down state.
Current Session Number	Number of current BFD sessions.
Static session	Number of static BFD sessions.
Dynamic session	Number of dynamic BFD sessions.
E_Dynamic session	Number of entirely dynamic sessions.
STATIC_AUTO session	Number of BFD sessions with automatically negotiated discriminators.
LDP_LSP session	Number of BFD sessions for detecting an LDP LSP.
STATIC_LSP session	Number of BFD sessions for detecting a static LSP.
TE_TUNNEL session	Number of BFD sessions for detecting a TE tunnel.
TE_LSP session	Number of BFD sessions for detecting a TE LSP.
PW session	Number of BFD sessions for detecting a PW.
IP session	Number of BFD sessions for detecting an IP address.

Item	Description
LDP_TUNNEL session	Number of current BFD sessions for LDP tunnel
BGP_TUNNEL session	Number of current BFD sessions for BGP tunnel
PAF/LCS Name	Project name of the license file.
BFD_CFG_NUM	Maximum number of BFD sessions that can be globally configured.
BFD_IF_NUM	Maximum number of BFD sessions that can be bound to an interface.
BFD_SESSION_NUM	Maximum number of BFD sessions that can be globally established.
BFD_IO_SESSION_NUM	Maximum number of BFD sessions that can be established globally.
BFD_PER_TUNNEL_CFG_NUM	Maximum number of BFD sessions that can be configured on a tunnel.
IO Board Current Created Session Statistics Information : (slot/number)	Number of BFD sessions that are established.
Current Total Used Discriminator Num	Total number of currently configured discriminators.
IO Board Reserved Sessions Number Information : (slot/ number)	Number of BFD sessions that are reserved.
BFD HA Information	-
Core Current HA Status	HA status in the core: ● Normal: indicates that the HA status is normal. ● Batch Backup Going: indicates that backup is being performed. ● Slave Not Ready: indicates that the slave board is not ready. ● Smooth Going: indicates that smooth processing is being performed.

Item	Description
Shell Current HA Status	HA status in the shell: - Normal: indicates that the HA status is normal. - Batch Backup Going: indicates that backup is being performed. - Slave Not Ready: indicates that the slave board is not ready. - Smooth Going: indicates that smooth processing is being performed.
Ability of auto creating BFD session on egress	Whether the capability to establish an entirely dynamic BFD session is enabled.
Period of LSP Ping	Interval for sending LSP ping packets of dynamic BFD sessions for detecting an LSP/PW.
System Session Delay Up Timer	Status of the delay Up timer: - OFF: indicates that the system works properly. - Xs: indicates that the system recovers after X seconds and a BFD session can be Up.

12.1.22 display bfd statistics session

Function

The **display bfd statistics session** command displays BFD session statistics.

Format

display bfd statistics session { **all** | **static** } [**for-lsp** | **for-pw** | **for-te** | **for-vsi-pw**](S5731-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H and S6730-H)

display bfd statistics session { **ldp-lsp peer-ip** *ip-address* **nexthop** *nexthop-address* [**interface** *interface-type interface-number*] | **static-lsp** *lsp-name* | **mpls-te interface** *interface-type interface-number* [**te-lsp**] | **pw interface** *interface-type interface-number* [**secondary**] } (S5731-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H and S6730-H)

display bfd statistics session { **vsi-pw vsi** *vsi-name* **peer** *peer-address* [**vc-id** *vc-id*] } (S5731-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H and S6730-H)

display bfd statistics session { **dynamic** | **discriminator** *discr-value* | **peer-ip default-ip** | **peer-ip** *ip-address* [**vpn-instance** *vpn-instance-name*] | **static-auto** }

display bfd statistics session peer-ipv6 *ipv6-address* [**vpn-instance** *vpn-instance-name*]

display bfd statistics session { **all** | **static** } [**for-ip** | **for-ipv6**]

Parameters

Parameter	Description	Value
all	Displays statistics about all BFD sessions.	-
static	Displays statistics about static BFD sessions.	-
dynamic	Displays statistics about dynamic BFD sessions and static BFD sessions with automatically negotiated discriminators.	-
discriminator *discr-value*	Displays statistics about the BFD sessions with a local discriminator.	The value is an integer that ranges from 1 to 16383.
peer-ip default-ip	Displays statistics about multicast BFD sessions.	-
peer-ip *ip-address*	Displays statistics about the BFD session bound to the specified peer IP address.	-
static-auto	Displays statistics about the static BFD session with the automatically negotiated discriminators.	-
vpn-instance *vpn-instance-name*	Displays statistics about the BFD sessions bound to a specified VPN instance.	The value must be an existing VPN instance name.
for-ip	Displays statistics about the BFD sessions for detecting IP links.	-
for-pw	Displays statistics about the BFD sessions for detecting PWs.	-
for-lsp	Displays statistics about the BFD sessions for detecting LSPs.	-

Parameter	Description	Value
for-te	Displays statistics about the BFD sessions for detecting a TE tunnel.	-
for-vsi-pw	Displays statistics about the BFD sessions for detecting VSI PWs.	-
vsi *vsi-name*	Displays statistics about the BFD session with the specified VSI PW instance name.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
peer *peer-address*	Displays statistics about the BFD session for detecting a VSI PW with the specified peer IPv4 address.	The value is expressed in dotted decimal notation.
vc-id *vc-id*	Displays statistics about the BFD session with the specified VC ID.	The value is an integer that ranges from 1 to 4294967295.
ldp-lsp	Displays statistics about the BFD sessions for detecting LDP LSPs.	-
nexthop *nexthop-address*	Displays statistics about the BFD session with the specified next hop address.	The value is expressed in dotted decimal notation.
interface-type interface-number	Displays statistics about the BFD session with the specified outbound interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
static-lsp	Displays statistics about the BFD sessions for detecting static LSPs.	-

Parameter	Description	Value
lsp-name	Displays statistics about the BFD session for detecting the static LSP with the specified name.	The value is a string of 1 to 19 case-sensitive characters without spaces.
mpls-te	Displays statistics about the BFD sessions for detecting MPLS TE tunnels.	-
te-lsp	Displays statistics about the BFD session for detecting the primary LSP bound to a TE.	-
pw	Displays statistics about the BFD sessions for detecting PWs.	-
secondary	Displays statistics about the BFD session for detecting the secondary PW.	-
peer-ipv6 *ipv6-address*	Displays statistics about the BFD6 session bound to a specified IPv6 address.	-
for-ipv6	Displays statistics about static or all BFD6 sessions.	-

Usage Guidelines

Usage Scenario

The **display bfd statistics session** command displays BFD session statistics.

Precautions

- If static BFD with automatically negotiated discriminators and dynamic BFD share a session, you can specify **all**, **static-auto**, or **dynamic** for query.

- Before using the **display bfd statistics session** command to view BFD session statistics, run the **reset bfd statistics** command to clear existing statistics.

Example

Display statistics on all BFD sessions.

```
<HUAWEI> display bfd statistics session all
--------------------------------------------------------------------------------
Session MIndex : 16397        (Multi Hop)State : Up          Name : dyn_8196
--------------------------------------------------------------------------------
  Session Type                      : Dynamic
  Bind Type                         : IP
  Local/Remote Discriminator        : 8100/8101
  Received Packets                  : 1710577
  Send Packets                      : 1710593
  Received Bad Packets              : 0
  Send Bad Packets                  : 0
  Down Count                        : 0
  ShortBreak Count                  : 0
  Send Lsp Ping Count               : 0
  Dynamic Session Delete Count      : 0
  Create Time                       : 2011-10-23 14:28:34
  Last Down Time                    : 0000-00-00 00:00:00
  Total Time From Last DOWN         : ---D:--H:--M:--S
  Last Up Time                      : 2011-11-14 11:06:52+08:00
  Last Up Lasting Time              : 002D:16H:49M:17S
  Total Time From Create            : 000D:04H:45M:35S
  Auth Time (ms)                    : 0
  Auth Seq Known (ms)               : 0
  Trigger If-down Delay Time (ms)   : 0
--------------------------------------------------------------------------------

     Total Session Number : 1
```

Table 12-7 Description of the display bfd statistics session command output

Item	Description
Session MIndex	Index of BFD session entries.
State	Status of a BFD session.
Name	Name of a BFD session.
Session Type	Mode in which a BFD session is established: ● Static: indicates that a BFD session is established statically. ● Dynamic: indicates that a BFD session is established dynamically. ● Static_Auto: indicates that a BFD session is established with automatically negotiated discriminators. ● Entire_Dynamic: indicates the BFD sessions that are triggered entirely dynamically. After dynamic BFD session setup is enabled on the sink point of an LSP, a BFD session of this type is created.
Bind Type	BFD session binding type.

Item	Description
Local/Remote Discriminator	Local and remote discriminator of a BFD session. To set the local and remote discriminators of a BFD session, run the **discriminator** command.
Received Packets	Number of BFD packets received at the local end. This field can be deleted using the **reset bfd statistics** command.
Send Packets	Number of BFD packets sent by the local end. This field can be deleted using the **reset bfd statistics** command.
Received Bad Packets	Number of received error packets.
Send Bad Packets	Number of sent error packets.
Down Count	Number of times that a BFD session became Down.
ShortBreak Count	Number of times that a BFD session was transiently disconnected.
Send Lsp Ping Count	Number of LSP ping packets sent by the local end.
Dynamic Session Delete Count	Number of dynamic BFD sessions deleted.
Create Time	Time when a BFD session was created.
Last Down Time	Last time when a BFD session became Down.
Total Time From Last DOWN Down Status Lasting Time	Period from last time when a BFD session became Down to the current time. If a BFD session is Up, "Total Time From Last DOWN" is displayed. If a BFD session is Down, "Down Status Lasting Time" is displayed.
Last Up Time	Last time the BFD session becomes Up.
Last Up Lasting Time	Period from the last time when a BFD session is Up to the current time.
Total Time From Create	Period from the time when a BFD session was created to the current time.
Total Session Number	Number of BFD sessions.
Auth Time (ms)	Remaining time of the authentication timeout timer, in milliseconds
Auth Seq Known (ms)	Remaining time of the sequence number learning timer, in milliseconds

Item	Description
Trigger If-down Delay Time (ms)	Remaining time of the delay timer after which BFD instructs the interface to go down, in milliseconds
Total Session Number	Total number of BFD sessions

12.1.23 display bfd ttl

Function

The **display bfd ttl** command displays the globally configured TTL.

Format

display bfd ttl

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display bfd ttl** command displays the globally configured TTL.

Example

Display information about all globally configured TTLs.

```
<HUAWEI> display bfd ttl
------------------------------------------------------------------------
Peer IP                              Mask       Type          Value
------------------------------------------------------------------------
10.10.10.0                            24        single-hop     255
```

Table 12-8 Description of the display bfd ttl command output

Item	Specification
Peer IP	IP segment address.

Item	Specification
Mask	Mask length.
Type	Type of the BFD session. The value can be single-hop or multi-hop.
Value	Initial value of the global TTL value.

12.1.24 min-echo-rx-interval

Function

The **min-echo-rx-interval** command configures the minimum interval for receiving BFD packets of a BFD session supporting the BFD echo function.

The **undo min-echo-rx-interval** command restores the default minimum interval.

By default, the minimum interval is 1000 ms.

Format

min-echo-rx-interval *interval*

undo min-echo-rx-interval

Parameters

Parameter	Description	Value
interval	Specifies the minimum interval for receiving BFD packets of a BFD session supporting the BFD echo function.	The value is an integer that ranges from 100 to 1000, in milliseconds. - After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. - After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.

Views

BFD session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After creating a BFD session supporting the BFD echo function, you can set the minimum interval for receiving BFD packets of a BFD session supporting the BFD echo function.

Prerequisites

A BFD session supporting the echo function has been configured using the **bfd one-arm-echo** command.

Example

Set the minimum interval for receiving BFD packets of a BFD session supporting the BFD echo function to 100 ms.

```
<HUAWEI> system-view
[HUAWEI] bfd test
[HUAWEI-bfd-session-test] min-echo-rx-interval 100
```

12.1.25 min-rx-interval

Function

The **min-rx-interval** command sets the minimum interval for receiving BFD packets.

The **undo min-rx-interval** command restores the default minimum interval for receiving BFD packets.

By default, the minimum interval for receiving BFD packets is 1000 ms.

Format

min-rx-interval *interval*

undo min-rx-interval

Parameters

Parameter	Description	Value
interval	Specifies the minimum interval for receiving BFD packets.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.

Views

BFD session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The local detection multiplier determines the detection time of a BFD session.

Detection time = Received Detect Multi of the remote system x Max (Local RMRI/ Received DMTI)

where

- Detect Multi: local detection multiplier, which is set by using the **detect-multiplier** command
- Required Min Rx Interval (RMRI): minimum interval for receiving BFD packets, which is set by using the **min-rx-interval** command
- Desired Min Tx Interval (DMTI): minimum interval for sending BFD packets, which is set by using the **min-tx-interval** command

Precaution

- You can increase or reduce the minimum interval for receiving BFD packets based on actual networking. The minimum interval for receiving BFD packets determines the detection time of a BFD session. On an unstable link, if the minimum interval for receiving BFD packets is small, the BFD session may flap. You can increase the minimum interval for receiving BFD packets. The default value is recommended. Do not randomly change the minimum interval for receiving BFD packets.
- If no BFD packet is received from the peer device within the detection time, the link is considered as faulty and the BFD session enters the Down state. To reduce the usage of system resources, when the BFD session is detected in Down state, the system adjusts the sending interval to a random value greater than 1000 ms. When the BFD session becomes Up, the configured interval is restored.
- On the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, when the minimum interval for receiving BFD packets is smaller than 100 ms and the working mode of the switch is normal, the original BFD session needs to be deleted. Then set the working mode of the switch and reconfigure the BFD session.

Example

Set the minimum interval for receiving BFD packets to 500 ms.

```
<HUAWEI> system-view
[HUAWEI] bfd session
[HUAWEI-bfd-session-session] min-rx-interval 500
```

12.1.26 min-tx-interval

Function

The **min-tx-interval** command sets the minimum interval for sending BFD packets.

The **undo min-tx-interval** command restores the default minimum interval for sending BFD packets.

By default, the minimum interval for sending BFD packets is 1000 ms.

Format

min-tx-interval *interval*

undo min-tx-interval

Parameters

Parameter	Description	Value
interval	Specifies the minimum interval for sending BFD packets.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.

Usage Guidelines

Usage Scenario

The local detection multiplier determines the detection time of a BFD session.

Detection time = Received Detect Multi of the remote system x Max (Local RMRI/ Received DMTI)

where

- Detect Multi: local detection multiplier, which is set by using the **detect-multiplier** command
- Required Min Rx Interval (RMRI): minimum interval for receiving BFD packets, which is set by using the **min-rx-interval** command
- Desired Min Tx Interval (DMTI): minimum interval for sending BFD packets, which is set by using the **min-tx-interval** command

Precaution

- You can increase or reduce the minimum interval for sending BFD packets based on actual networking. The minimum interval for sending BFD packets determines the detection time of a BFD session. On an unstable link, if the minimum interval for sending BFD packets is small, the BFD session may flap. You can increase the minimum interval for sending BFD packets. The default value is recommended. Do not randomly change the minimum interval for sending BFD packets.
- If no BFD packet is received from the peer device within the detection time, the link is considered as faulty and the BFD session enters the Down state. To reduce the usage of system resources, when the BFD session is detected in Down state, the system adjusts the sending interval to a random value greater than 1000 ms. When the BFD session becomes Up, the configured interval is restored.
- On the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, when the minimum interval for sending BFD packets is smaller than 100 ms and the working mode of the switch is normal, the original BFD session needs to be deleted. Then set the working mode of the switch and reconfigure the BFD session.

Example

Set the minimum interval for sending BFD packets to 500 ms.

```
<HUAWEI> system-view
[HUAWEI] bfd session
[HUAWEI-bfd-session-session] min-tx-interval 500
```

12.1.27 multi-hop

Function

The **multi-hop** command configures the destination port number for a multi-hop BFD session.

The **undo multi-hop** command restores the default destination port number for a multi-hop BFD session.

By default, destination port 3784 is used in multi-hop BFD control packets.

Format

multi-hop destination-port { **3784** | **4784** }

undo multi-hop destination-port

Parameters

Parameter	Description	Value
3784	Indicates that destination port 3784 is used in multi-hop BFD control packets.	-
4784	Indicates that destination port 4784 is used in multi-hop BFD control packets.	-

Views

BFD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

As defined in the BFD draft, destination port 4784 is used by multi-hop BFD control packets. When the device running the latest version interworks with devices running earlier versions, destination port 3784 is used by multi-hop BFD control packets. When the device interworks with non-Huawei devices, destination port 4784 is used by multi-hop BFD control packets.

Precautions

- If destination port 4784 is used by multi-hop BFD control packets, the device fails to negotiate with the remote device on which destination port 3784 is used by multi-hop BFD control packets.
- If destination port 3784 is used by multi-hop BFD control packets, the device can successfully negotiate with the remote device on which destination port 4784 is used by multi-hop BFD control packets. On the device that is configured with destination port 3784, destination port 3784 is automatically updated to destination port 4784.
- If destination port 3784 is used by both multi-hop and single-hop BFD control packets, the single-hop and multi-hop BFD control packets are processed according to their TTLs.

- When a large number of multi-hop BFD sessions are set up, updating the destination ports may take a long time. Therefore, when a smaller interval for configuring multi-hop BFD sessions is used, the system displays a message indicating that the BFD session is being updated and you may try later.
- When the number of the destination port used in a multi-hop BFD control packet is updated, the BFD session in Up state may change to Down and then the BFD session is renegotiated.

NOTE

Determine to use port 3784 or 4784 before configuring a multi-hop BFD session between a Huawei device and a non-Huawei device. If the port number is not specified, you must change the port number after the BFD session becomes Up. Before changing the port number, shut down the BFD session. This is because changing the port number may cause all multi-hop BFD session to flap and affect services.

Example

Set the default destination port number to 4784 for multi-hop BFD control packets.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] multi-hop destination-port 4784
```

12.1.28 oam-bind ingress bfd-session trigger if-down egress interface

Function

The **oam-bind ingress bfd-session trigger if-down egress interface** command enables a BFD session to report faults to an interface.

The **undo oam-bind ingress bfd-session trigger if-down egress interface** command disables a BFD session from reporting faults to an interface.

By default, a BFD session is not enabled to report faults to an interface.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

oam-bind ingress bfd-session *bfd-session-id* **trigger if-down egress interface** *interface-type interface-number*

undo oam-bind ingress bfd-session *bfd-session-id* **trigger if-down egress interface** *interface-type interface-number*

Parameters

Parameter	Description	Value
bfd-session *bfd-session-id*	Specifies the local discriminator.	The value is an integer that ranges from 1 to 8191.
trigger if-down	Indicates that an interface goes Down when the BFD session associated with the interface detects a fault.	-
interface-type interface-number	Specifies the type and number of the interface bound to a BFD session. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

OAM management view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To enable a BFD session to report faults to an interface, run the **oam-bind ingress bfd-session trigger if-down egress interface** command.

Precautions

Before configuring a BFD session to report faults to an interface, pay attention to the following points:

- A BFD session has been created and its status is Up.
- The BFD session is a static BFD session.
- The BFD session and the interface are associated with each other. That is, after an interface is associated with BFD session 1, the interface cannot be associated with other BFD sessions. Similarly, BFD session 1 cannot be associated with other interfaces.

The ingress BFD session reports faults to the egress interface.

Example

Configure BFD session 1 to report faults to GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] oam-mgr
[HUAWEI-oam-mgr] oam-bind ingress bfd-session 1 trigger if-down egress interface gigabitethernet
0/0/1
```

12.1.29 peer-ip ttl

Function

The **peer-ip ttl** command configures the TTL value in BFD packets.

The **undo peer-ip ttl** command restores the default TTL value in BFD packets.

By default, the TTL value in BFD packets varies with the BFD session type. By default, for a static BFD session, the TTL value of a single-hop BFD packet is 255 and the TTL value of a multi-hop BFD packet is 254. For a dynamic BFD session, the TTL value of a single-hop BFD packet is 255 and the TTL value of a multi-hop BFD packet is 253.

Format

peer-ip *peer-ip mask-length* **ttl** { **single-hop** | **multi-hop** } *ttl-value*

undo peer-ip *peer-ip mask-length* **ttl** { **single-hop** | **multi-hop** }

Parameters

Parameter	Description	Value
peer-ip	Specifies the peer IP address bound to the BFD session.	-
mask-length	Specifies the mask length of the IP address.	The value is an integer that ranges from 8 to 32.
single-hop	Indicates the single-hop BFD session.	-
multi-hop	Indicates the multi-hop BFD session.	-
ttl-value	Specifies the TTL value in BFD packets.	The value is an integer that ranges from 1 to 255.

Views

BFD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can set the TTL value in BFD packets to enable the Huawei device to interwork with each other in different versions, with upgraded devices, and with non-Huawei devices.

Precautions

- The length of the IP segment address must match the mask. A long mask takes precedence over a short mask.
- The same IP segment addresses, masks, and TTL values of specified BFD session types cannot be configured simultaneously.
- When the IP network segment addresses and mask lengths are the same, the TTL value of a single-hop BFD session must be greater than the TTL value of a multi-hop BFD session.
- When a large number of BFD sessions are set up, updating the TTL value may take a long time. Therefore, when a smaller interval for configuring BFD sessions is used, the system displays a message indicating that the BFD session is being updated and you may try later.
- After the TTL value in multi-hop BFD packets is configured, you must configure the same peer IP address, mask length longer than the mask length for the TTL value in multi-hop BFD packets, and TTL value in single-hop BFD packets. This is because the TTL value in multi-hop BFD packets affects dynamic single-hop BFD sessions.

Example

Set the TTL value of single-hop BFD sessions to 254, the IP segment address to 10.10.10.0, and the mask length to 24.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] peer-ip 10.10.10.0 24 ttl single-hop 254
```

12.1.30 process-interface-status

Function

The **process-interface-status** command associates the BFD session status with the bound interface status.

The **undo process-interface-status** command restores the default setting.

By default, the BFD session status is not associated with the interface status. That is, the change of the BFD session status does not affect the interface status.

Format

process-interface-status [**reboot-no-impact**] [**protocol-down**]

undo process-interface-status [**reboot-no-impact**] [**protocol-down**]

Parameters

Parameter	Description	Value
reboot-no-impact	Disables the association between a multicast BFD session and interface during device startup.	-
protocol-down	After **protocol-down** is configured, when a BFD session detects a fault and enters the Down state, the protocol status of the associated interface becomes Down. In this case, the interface discards Layer 2 and Layer 3 packets but permits BFD packets.	-

Views

BFD session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a transmission device exists on a direct link, BFD detects a link fault faster than a link protocol on an interface. The link protocol status of a trunk or VLANIF interface depends on the link protocol status of member interfaces.

To help BFD rapidly report the detection result to the application, a BFD status attribute is added to the interface management module of each interface. This attribute indicates the status of the BFD session that is bound to the interface. The system obtains the interface status based on the link status, protocol status, and BFD status on the interface, and then reports the interface status to the application.

Precautions

When configuring the **process-interface-status** command, pay attention to the following points:

- The **process-interface-status** command takes effect for only the single-hop BFD session that uses the default multicast address. The BFD session can be associated to an interface status.
- After the **trigger if-down delay** and **commit** commands are run in sequence, if BFD negotiation fails, the Down state is reported to the interface.
- If multiple BFD sessions are bound to an interface, you can use the **process-interface-status** command for only one BFD session. The change of only one BFD session changes the status of the bound interface.
- The BFD session does not report the BFD status to the bound interface immediately after the **commit** command is executed because the BFD session may not be set up or not Up. This prevents the BFD session from reporting an incorrect state to the interface. When the BFD status changes, the BFD session reports the BFD status to the interface to trigger the interface status change.
- If the **process-interface-status** command is saved in the configuration file, the BFD session for which the **process-interface-status** command is run notifies an interface that the BFD session becomes Down when the device is restarted. This is because the initial status of the interface is Down.
- Before the BFD session status is associated with the interface status, the BFD configurations on two ends must be correct and matched. If the BFD session status on the local interface is Down, check whether the BFD configuration on the peer end is correct or whether the BFD session is shut down.
- If the BFD session must be synchronized to an interface immediately, ensure that the BFD configurations on the two ends are the same and run the **shutdown (BFD session view)** and **undo shutdown (BFD session view)** commands on the BFD session. When the **undo shutdown (BFD session view)** command is executed for a BFD session, a BFD session detection timer is started. If the BFD session becomes Up through negotiation before the timer times out, the BFD session notifies an interface of the Up state. Otherwise, the BFD session considers the link faulty and notifies the interface of the Down state. The status of a BFD session and the status of an interface can be synchronized in real time.
- After a master/slave main control board switchover is performed, BFD notifies the associated interface to update the interface status during data smoothing based on the post-switchover BFD session status and diagnostic information. Specifically:
    a. If the BFD session is up, BFD notifies the interface to go up.
    b. If the BFD session is down, BFD differentiates between authentication and non-authentication scenarios.
        - BFD notifies the interface to go down in an authentication scenario.
        - In a non-authentication scenario, if the diagnostic word is "Receive AdminDown" and the receiving-admindown trigger if-down command is run before the switchover is performed, BFD notifies the interface to go down. If the diagnostic word is not "Receive AdminDown", BFD notifies the interface to go down.

Example

Associate the BFD session with an interface to which the BFD session is bound.

```
<HUAWEI> system-view
[HUAWEI] bfd test
[HUAWEI-bfd-session-test] process-interface-status
```

12.1.31 process-pst

Function

The **process-pst** command enables the system to modify the port status table (PST) when the BFD session status changes.

The **undo process-pst** command restores the default configuration.

By default, the device is disabled from modifying the PST.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

process-pst

undo process-pst

Parameters

None

Views

BFD session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a BFD session that is enabled to modify the PST detects a BFD session Down event, the system modifies the corresponding entry in the PST.

Precautions

- You can only run the **process-pst** command in the BFD session view that is bound to LDP LSP, Static LSP, or MPLS TE.
- When configuring static BFD-based LDP FRR, you must configure the **process-pst** command.
- When configuring static BFD for CR-LSP and static BFD for TE, you must configure the **process-pst** command.
- For applications in which a fault detected by BFD is not sensed through the PST, you do not need to configure the **process-pst** command.

- In IP FRR scenarios, the PST function is automatically enabled for dynamic BFD sessions but cannot be configured for IP static BFD sessions bound to the same interface.

Example

Enable the system to modify the PST when the BFD session status changes.

```
<HUAWEI> system-view
[HUAWEI] bfd 4ldplsp bind ldp-lsp peer-ip 10.10.9.9 nexthop 10.10.10.10
[HUAWEI-bfd-lsp-session-4ldplsp] process-pst
```

12.1.32 receiving-admindown trigger if-down

Function

The **receiving-admindown trigger if-down** command enables a local device to instruct the interface protocol to go down immediately after receiving an admindown packet.

The **undo receiving-admindown trigger if-down** command disables a local device from instructing the interface protocol to go down immediately after receiving an admindown packet.

By default, the local device is disabled from instructing the interface protocol to go down immediately after receiving an admindown packet.

Format

receiving-admindown trigger if-down

undo receiving-admindown trigger if-down

Parameters

None

Views

BFD session view

Default Level

2: Configuration level

Usage Guidelines

After the **process-interface-status** command associates a BFD session with the status of an interface bound to the BFD session, a local device does not instruct the interface protocol to go down after the device receives an admindown packet. To enable an immediate notification, run the **receiving-admindown trigger if-down** command.

Prerequisites

The BFD session status has been associated with the status of the interface bound to the BFD session using the **process-interface-status** command.

Precautions

- This command is supported in both BFD authentication and non-authentication scenarios.
- This command takes effect only on multicast BFD.
- If the **trigger if-down delay** command is run, the local device can instruct the interface protocol to go down immediately after receiving an admindown packet.

Example

Enable the local device to instruct the interface protocol to go down immediately after receiving an admindown packet.

```
<HUAWEI> system-view
[HUAWEI] bfd test bind peer-ip default-ip interface gigabitethernet0/0/1
[HUAWEI-bfd-session-test] process-interface-status
[HUAWEI-bfd-session-test] receiving-admindown trigger if-down
```

12.1.33 reset bfd statistics

Function

The **reset bfd statistics** command clears statistics on received and sent packets of a BFD session.

Format

reset bfd statistics { **all** | **discriminator** *discr-value* }

Parameters

Parameter	Description	Value
all	Clears statistics on received and sent packets of all the BFD sessions.	-
discriminator *discr-value*	Clears statistics on received and sent packets of a BFD session with a specified discriminator.	The value is an integer that ranges from 1 to 16383.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The **reset bfd statistics** command clears statistics on received and sent packets of a BFD session.

Precautions

The deleted statistics on received and sent packets of a BFD session cannot be restored. Exercise caution when you use this command.

Example

Clear statistics on packets of all BFD sessions.

```
<HUAWEI> reset bfd statistics all
```

12.1.34 session-damping disable

Function

The **session-damping disable** command disables BFD session flapping suppression.

The **undo session-damping disable** command enables BFD session flapping suppression.

By default, BFD session flapping suppression is enabled.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

session-damping disable

undo session-damping disable

Parameters

None

Views

BFD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a BFD session frequently flaps, frequent link switchovers may occur, which results in packet loss. If multiple BFD sessions frequently flap on a device within a certain time, many device resources are consumed. When BFD session flapping suppression is enabled, the system establishes a more intelligent punishment mechanism for each BFD session, properly reducing the establishment of the BFD session. The system also periodically checks the flapping of all BFD sessions on the device, and more strictly suppresses the sessions with the most frequent flapping if necessary.

To allow the system to immediately start the next negotiation after a BFD session goes Down (excluding AdminDown), run the **session-damping disable** command to disable BFD session flapping suppression.

Precautions

When BFD session flapping suppression is enabled, the device can adjust the flapping suppression time based on the penalty value in addition to the value of the intelligent timer (**dampening timer-interval**). The penalty value is adjusted as follows:

1. When a BFD session goes Down each time, the penalty value of the BFD session increases by 20. The initial value is 0 and the maximum penalty value is 240.
2. When a BFD session keeps Up for 1s each time, the penalty value decreases by 1. The minimum penalty value is 0.
3. If the penalty value of a BFD session exceeds 45, the flapping suppression time is twice (that is, 2^1) the value of *maximum-milliseconds*. If the penalty value of a BFD session exceeds 90, the flapping suppression time is four times (that is, 2^2) the value of *maximum-milliseconds*, and so on. The *maximum-milliseconds* is configured using the **dampening timer-interval** command.
4. If a BFD session is suppressed by the intelligent timer, the penalty value is adjusted based on rules 1 and 2 and the BFD session does not enter the penalty suppression state. That is, rule 3 does not take effect. Rule 3 takes effect only when suppression by the intelligent timer ends.

When multiple BFD sessions exist on the device, the penalty value is adjusted considering Down events of all BFD sessions in a period of time.

The **session-damping disable** command takes effect for all types of BFD sessions.

Example

Disable BFD session flapping suppression.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] session-damping disable
```

12.1.35 shutdown (BFD session view)

Function

The **shutdown** command enables the BFD session to enter the AdminDown state.

The **undo shutdown** command enables a BFD session.

By default, a BFD session is enabled.

Format

shutdown

undo shutdown

Parameters

None

Views

BFD session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **shutdown** command enables the BFD session to enter the AdminDown state.

Prerequisites

A BFD session has been created.

Precautions

- To modify the configuration of a BFD session, run the **shutdown** command to disable the BFD session. After the configuration is modified successfully, run the **undo shutdown** command to enable the BFD session again.
- To disable a BFD session without affecting the upper-layer application, run the **shutdown** command to enable the BFD session to enter the AdminDown state.
- If a BFD session is associated with an interface, the status of the BFD session is not reported to the interface when the BFD session is shut down.

Example

Stop the BFD session **atoc**.

```
<HUAWEI> system-view
[HUAWEI] bfd atoc
[HUAWEI-bfd-session-atoc] shutdown
```

12.1.36 snmp-agent bfd trap-interval

Function

The **snmp-agent bfd trap-interval** command sets the interval at which traps are sent.

The **undo snmp-agent bfd trap-interval** command restores the default interval at which traps are sent.

By default, the interval at which traps are sent is 120s.

Format

snmp-agent bfd trap-interval *interval*

undo snmp-agent bfd trap-interval

Parameters

Parameter	Description	Value
interval	Specifies the interval at which traps are sent.	The value is an integer that ranges from 1 to 600, in seconds.

Views

BFD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the BFD module is enabled with the SNMP alarm function, the NMS will receive BFD Up or Down messages. If the BFD session flaps, the NMS receives a large number of traps. In this case, BFD traps need to be suppressed. Run the **snmp-agent bfd trap-interval** command to set the interval at which traps are sent to prevent overflow of traps.

Prerequisites

Global BFD has been enabled using the **bfd** command.

Example

Set the interval at which traps are sent to 100s.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] snmp-agent bfd trap-interval 100
```

12.1.37 tos-exp

Function

The **tos-exp** command sets the priority of BFD packets.

The **undo tos-exp** command restores the default priority of BFD packets.

By default, the priority of BFD packets is 7.

Format

tos-exp *tos-value*

undo tos-exp

Parameters

Parameter	Description	Value
tos-value	Specifies the priority of BFD packets. A larger value indicates a higher priority of BFD packets.	The value is an integer that ranges from 0 to 7. The default value is 7.

Views

BFD session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can change the priority of BFD packets in the following scenarios:

- Detect whether packets with different priorities on a link can be forwarded.
- Ensure that BFD packets with a higher priority are forwarded first.

Precautions

When congestion occurs, the system first sends BFD packets with a higher priority.

Only the priority of BFD packets of the BFD session that is established using single-hop BFD, multi-hop BFD, and BFD Echo function can be changed. The priority of BFD packets of the BFD session that is established through automatically negotiated discriminators cannot be changed.

Example

Set the priority of BFD packets for the BFD session **atob** to 5.

```
<HUAWEI> system-view
[HUAWEI] bfd atob
[HUAWEI-bfd-session-atob] tos-exp 5
```

12.1.38 trigger if-down delay

Function

The **trigger if-down delay** command sets a delay time after which a local device instructs the interface protocol to go down after the device detects a BFD down event.

The **undo trigger if-down delay** command restores the default delay time.

The default delay time is 0s.

Format

trigger if-down delay *delay-time*

undo trigger if-down delay

Parameters

Parameter	Description	Value
delay-time	Sets the delay time, after which a local device instructs the interface protocol to go down after the device detects a BFD down event.	The value is an integer ranging from 1 to 10000, in seconds.

Views

BFD session view

Default Level

2: Configuration level

Usage Guidelines

If no link fault is detected and negotiation of a BFD session times out, the BFD session goes down. In this case, if the BFD session is associated with the status of the interface bound to the BFD session, the link protocol of the interface also goes down. To delay the associated notification, run the **trigger if-down delay** command. If the BFD session is still down after the delay time elapses, the link status of the associated interface goes down.

Prerequisites

The BFD session status has been associated with the status of the interface bound to the BFD session using the **process-interface-status** command.

Precautions

- This command takes effect on multicast BFD only in BFD non-authentication scenarios and is mutually exclusive with the **authentication-mode** command.
- If the **receiving-admindown trigger if-down** command is run, the local device can instruct the interface protocol to go down immediately after receiving an admindown packet.

Example

Set the delay time to 50s, after which a local device instructs the interface protocol to go down after the device detects a BFD down event.

```
<HUAWEI> system-view
[HUAWEI] bfd test bind peer-ip default-ip interface gigabitethernet0/0/1
[HUAWEI-bfd-session-test] process-interface-status
[HUAWEI-bfd-session-test] trigger if-down delay 50
```

12.1.39 unlimited-negotiate

Function

The **unlimited-negotiate** command enables unlimited negotiation for a multicast BFD session.

The **undo unlimited-negotiate** command disables unlimited negotiation for a multicast BFD session.

By default, unlimited negotiation is disabled for a multicast BFD session.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

unlimited-negotiate

undo unlimited-negotiate

Parameters

None

Views

BFD session view

Default Level

2: Configuration level

Usage Guidelines

If a multicast BFD session is bound to a Layer 3 interface to which the line protocol current state of the interface is Down, the status of the session is set to Down. You can run the **unlimited-negotiate** command to restart session negotiation. If the link is normal, the session can go Up through negotiation.

Example

Enable unlimited negotiation for a multicast BFD session.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] bfd atob bind peer-ip default-ip interface gigabitethernet 0/0/1
[HUAWEI-bfd-session-atob] unlimited-negotiate
```

12.1.40 wtr

Function

The **wtr** command sets the WTR time of a BFD session.

The **undo wtr** command restores the default WTR time of a BFD session.

By default, the WTR time is 0, indicating that the status change of a BFD session is reported immediately.

Format

wtr *wtr-value*

undo wtr

Parameters

Parameter	Description	Value
wtr-value	Specifies the WTR time of a BFD session.	The value is an integer that ranges from 0 to 60, in minutes. The default value is 0.

Views

BFD session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a BFD session flaps, the WTR time prevents frequent active/standby switchovers of the application associated with the BFD session.

Precautions

- If the WTR time is set, the system reports the BFD session Up event to the upper-layer application only after the WTR timer expires. Other status change events are reported immediately, which are not affected by the WTR time.
- Both ends must use the same WTR time. Otherwise, when the session status changes at one end, applications at both ends detect different BFD session status.
- If the WTR time is set and a BFD session goes Down within the WTR time, the **Down Count** value is recorded, but the **Last Up Time** and **Last Up Lasting Time** values are not recorded.

Example

Set the WTR time of a BFD session to 10 minutes.

```
<HUAWEI> system-view
[HUAWEI] bfd atoc
[HUAWEI-bfd-session-atoc] wtr 10
```

12.2 VRRP Configuration Commands

12.2.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

12.2.2 admin-vrrp vrid

Function

The **admin-vrrp vrid** command specifies an mVRRP group.

The **undo admin-vrrp vrid** command deletes the specified mVRRP group.

By default, no mVRRP group is configured.

Format

admin-vrrp vrid *virtual-router-id*

undo admin-vrrp vrid *virtual-router-id*

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the virtual router ID (VRID) of an mVRRP group.	The value is an integer that ranges from 1 to 255.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An mVRRP group can be bound to VRRP groups. Once bound, the mVRRP group determines the master and backup status of the bound VRRP groups. mVRRP is used when multiple VRRP groups coexist, decreasing the number of VRRP Advertisement packets sent and minimize network bandwidth and system resource consumption.

NOTE

mVRRP provides the following functions:

- An mVRRP group used as the gateway can process both VRRP Advertisement packets and service packets.
- An mVRRP group that is not used as the gateway can only process VRRP Advertisement packets.

Precautions

An mVRRP group cannot be bound to another mVRRP group.

Example

Create VRRP group 1 on VLANIF 10 and configure it as an mVRRP group.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ip address 10.1.1.1 24
[HUAWEI-Vlanif10] vrrp vrid 1 virtual-ip 10.1.1.111
[HUAWEI-Vlanif10] admin-vrrp vrid 1
```

Create VRRP group 1 on GE0/0/1 and configure it as an mVRRP group.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 10.1.1.1 24
[HUAWEI-GigabitEthernet0/0/1] vrrp vrid 1 virtual-ip 10.1.1.111
[HUAWEI-GigabitEthernet0/0/1] admin-vrrp vrid 1
```

12.2.3 admin-vrrp6 vrid

Function

The **admin-vrrp6 vrid** command configures a VRRP6 group as an mVRRP6 group.

The **undo admin-vrrp6 vrid** command deletes the specified mVRRP6 group.

By default, no mVRRP6 group is configured.

Format

admin-vrrp6 vrid *virtual-router-id*

undo admin-vrrp6 vrid *virtual-router-id*

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the virtual router ID (VRID) of an mVRRP6 group.	The value is an integer that ranges from 1 to 255.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, MultiGE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, MultiGE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An mVRRP6 group can be bound to common VRRP6 groups. Once bound, the mVRRP6 group determines the status of the bound VRRP6 groups based on the binding. mVRRP6 is used when multiple VRRP6 groups coexist, decreasing the number of VRRP Advertisement packets sent and minimizing network bandwidth consumption.

NOTE

mVRRP6 provides the following functions:

- An mVRRP6 group used as the gateway can process both VRRP6 Advertisement packets and service packets.
- An mVRRP6 group that is not used as the gateway can only process VRRP6 Advertisement packets.

Precautions

An mVRRP6 group cannot be bound to another mVRRP6 group.

Example

Create VRRP6 group 1 on VLANIF 10 and configure it as an mVRRP6 group.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ipv6 enable
[HUAWEI-Vlanif10] ipv6 address FC00::1 64
[HUAWEI-Vlanif10] vrrp6 vrid 1 virtual-ip FE80::1 link-local
[HUAWEI-Vlanif10] admin-vrrp6 vrid 1
```

Create a VRRP6 group 1 on GE0/0/1 and configure it as an mVRRP6 group.

```
<HUAWEI> system-view
[HUAWEI] ipv6

12.2.4 arp learning passive enable

Function

The **arp learning passive enable** command enables passive ARP that allows a backup device in a VRRP backup group to learn ARP entries when receiving an ARP request message sent to a virtual IP address.

The **undo arp learning passive enable** command disables passive ARP.

By default, passive ARP is disabled so that a backup device in a VRRP backup group does not learn ARP entries when receiving an ARP request message sent to a virtual IP address.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

arp learning passive enable

undo arp learning passive enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the master and backup devices in a VRRP backup group receive an ARP request message sent to a virtual IP address, only the master device learns ARP entries and responds to the sender with the virtual MAC address. If a link or device fault causes the VRRP backup group to perform a master/backup switchover, a backup device must learn ARP entries on the user side before taking over traffic. As a result, service traffic is interrupted for a short time.

After you run the **arp learning passive enable** command to enable passive ARP, a backup device in a VRRP backup group learns ARP entries when receiving an ARP request message sent to a virtual IP address. If a VRRP backup group performs a master/backup switchover, the new master device can take over traffic without needing to relearn ARP entries, ensuring service continuity.

Precautions

Passive ARP cannot be configured together with strict ARP entry learning.

The passive ARP function is invalid for a VRRP group created on a VLANIF interface.

Example

Enable passive ARP.

```
<HUAWEI> system-view
[HUAWEI] arp learning passive enable
```

12.2.5 clear admin-vrrp

Function

The **clear admin-vrrp** command deletes the binding of an mVRRP group on the subcard that is not functioning.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

clear admin-vrrp binding interface *interface-type interface-number* **vrid** *virtual-router-id*

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of an interface where an mVRRP group is configured.	-
vrid *virtual-router-id*	Specifies the VRID of an mVRRP group.	The value is an integer that ranges from 1 to 255.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An mVRRP group is often bound to VRRP groups on an interface. If the subcard on which the mVRRP group is configured fails or is not properly installed, the binding is retained and will take effect when the subcard begins working properly. You can run the **display vrrp binding admin-vrrp member-vrrp** command to check whether configuration recovery is successful.

If the binding is not required, run the **clear admin-vrrp** command to delete the binding.

Prerequisites

The mVRRP group has been configured and VRRP groups have been bound to the mVRRP group.

Precautions

If the binding between the mVRRP group and VRRP groups is deleted, the status of the mVRRP group no longer determines the status of the bound VRRP groups.

The binding deleted using the **clear admin-vrrp** command cannot be restored.

Ensure that the interface name is correct when executing the **clear admin-vrrp** command. This is because the system does not verify the interface name.

Example

Delete the binding of the mVRRP group on the specified subcard that is not properly installed.

```
<HUAWEI> system-view
[HUAWEI] clear admin-vrrp binding interface gigabitethernet 0/0/1 vrid 1
```

12.2.6 clear admin-vrrp6

Function

The **clear admin-vrrp6** command deletes the binding of an mVRRP6 group on the member switch that is not functioning in a stack.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

clear admin-vrrp6 binding interface *interface-type interface-number* **vrid** *virtual-router-id*

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of an interface where an mVRRP6 group is configured.	-
vrid *virtual-router-id*	Specifies the VRID of an mVRRP6 group.	The value is an integer that ranges from 1 to 255.

2: Configuration level

Usage Guidelines

Usage Scenario

In a stack, an mVRRP6 group is often bound to VRRP6 groups on an interface. If the member switch on which the mVRRP6 group is configured fails or is not properly installed, the binding is retained and will take effect when the member switch begins working properly. You can run the **display vrrp6 binding admin-vrrp6 member-vrrp** command to check whether configuration recovery is successful.

If the binding is not required, run the **clear admin-vrrp6** command to delete the binding.

Prerequisites

The mVRRP6 group has been configured and VRRP6 groups have been bound to the mVRRP6 group.

Precautions

If the binding between the mVRRP6 group and VRRP6 groups is deleted, the status of the mVRRP6 group no longer determines the status of the bound VRRP6 groups.

The binding deleted using the **clear admin-vrrp6** command cannot be restored.

Ensure that the interface name is correct when executing the **clear admin-vrrp6** command. This is because the system does not verify the interface name.

Example

Delete the binding of the mVRRP6 group on the specified member switch that is not properly installed.

```
<HUAWEI> system-view
[HUAWEI] clear admin-vrrp6 binding interface gigabitethernet 0/0/1 vrid 1
```

12.2.7 display vrrp

Function

The **display vrrp** command displays the status and configuration parameters of VRRP groups.

Format

display vrrp [**interface** *interface-type interface-number*] [*virtual-router-id*] [**brief**]

display vrrp { **interface** *interface-type interface-number* [*virtual-router-id*] | *virtual-router-id* } **verbose**

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays the status of all VRRP groups on the specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
virtual-router-id	Displays the status of a VRRP group with the specified VRID.	The VRID of the VRRP group must have been created.

Parameter	Description	Value
brief	Displays brief information about a specified VRRP group. If this parameter is not specified, detailed information about a VRRP group is displayed.	-
verbose	Displays detailed information about a VRRP group.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display vrrp** command displays information about VRRP groups.

Example

Display information about all VRRP groups on the switch.

```
<HUAWEI> display vrrp
Vlanif100 | Virtual Router 1
    State : Master
    Virtual IP : 10.1.1.100
    Master IP : 10.1.1.2
    PriorityRun : 120
    PriorityConfig : 120
    MasterPriority : 120
    Preempt : YES   Delay Time : 20 s
    TimerRun : 2 s
    TimerConfig : 2 s
    Auth type : MD5   Auth key : ******
    Virtual MAC : 0000-5e00-0101
    Check TTL : YES
    Config type : normal-vrrp
    Backup-forward : disabled
    Track IF : Eth-Trunk0   Priority reduced : 60
    IF state : UP
    Track BFD : 69                    Priority reduced : 10
    BFD-session state : UP
    Create time : 2011-10-07 15:43:42 UTC-08:00
    Last change time : 2011-10-07 15:44:03 UTC-08:00
```

Table 12-9 Description of the **display vrrp** command output

Item	Description
Vlanif100 | Virtual Router 1	Interface where the VRRP group is configured and VRID of the VRRP group.
State	VRRP status of the device: ● Master: The device functions as the master in the VRRP group. ● Backup: The device functions as the backup in the VRRP group. ● Initialize: All VRRP groups begin in Initialize state. When the interface where a VRRP group is configured becomes Down or is Administratively Down, the VRRP group status is switched to Initialize.
Virtual IP	Virtual IP address of a VRRP group. To configure a virtual IP address for a VRRP group, run the **vrrp vrid virtual-ip** command.
Master IP	Primary IP address of the interface configured with the VRRP group on the master.
PriorityRun	Priority of the switch when the VRRP group runs. If the switch is the IP address owner in a VRRP group, the running priority of the switch in the group is displayed as **255**.
PriorityConfig	Priority configured for the switch using the **vrrp vrid priority** command. If the switch is the IP address owner and this value is not configured, the default priority 100 but not 255 is displayed.
MasterPriority	Priority of the master in the VRRP group. If the switch is the IP address owner in a VRRP group, the priority of the switch in the group is displayed as **255**.
Preempt	Preemption mode: ● YES: preemption ● NO: no preemption To disable the preemption mode, run the **vrrp vrid preempt-mode disable** command.
Delay Time	Preemption delay, in seconds. To set the preemption delay, run the **vrrp vrid preempt-mode timer delay** command.
TimerRun	Interval at which the master in the VRRP group sends VRRP Advertisement packets, in seconds.

Item	Description
TimerConfig	Configured interval at which the master in the VRRP group sends VRRP Advertisement packets, in seconds. To set the interval at which the master in the VRRP group sends VRRP Advertisement packets, run the **vrrp vrid timer advertise** command.
Auth type	VRRP Advertisement packet authentication mode: ● NONE: non-authentication ● SIMPLE: simple authentication ● MD5: MD5 authentication To set an authentication mode, run the **vrrp vrid authentication-mode** command. VRRPv3 does not support authentication.
Auth key	Authentication key. If authentication is configured, ****** is displayed. If no authentication is configured, this field is not displayed.
Virtual MAC	Virtual MAC address of the VRRP group.
Check TTL	Whether the TTL value of a VRRP Advertisement packet is checked: ● YES: The TTL value of a VRRP Advertisement packet is checked. ● NO: The TTL value of a VRRP Advertisement packet is not checked. To configure the switch to check the TTL value in a VRRP Advertisement packet, run the **vrrp un-check ttl** command.
Config type	VRRP group type: ● normal-vrrp: common VRRP group ● admin-vrrp: mVRRP group ● member-vrrp: service VRRP group
Backup-forward	Whether the backup is enabled to forward traffic: ● enabled ● disabled To configure the backup to forward traffic, run the **vrrp vrid backup-forward** command.
Track IF	Name of a monitored interface when the interface monitoring function of VRRP backup group is enabled. To configure the parameter, run the **vrrp vrid track interface** command.

Item	Description
Priority reduced or Priority increased	Value to which the device decreases or increases a priority if the tracked interface, BFD session, or EFM session goes Down. When the interface, BFD session, or EFM session tracked by the VRRP backup group goes Down, and the priority of the VRRP backup group is configured to increase, **Priorityincreased** is displayed. To configure the parameter, run the **vrrp vrid track bfd-session** or **vrrp vrid track interface** command.
IF state	Status of the interface monitored by VRRP: ● UP ● DOWN ● REMOVE
Track BFD	Local discriminator or name of the BFD session associated with the VRRP group. This field is displayed when only the BFD session is associated with the VRRP group. To configure the BFD session associate with the VRRP group, run the **vrrp vrid track bfd-session** command.
BFD-session state	Status of the BFD session associated with the VRRP group: ● UP: A BFD session is in Up state. ● DOWN: A BFD session is in Down state. ● AdminDown: A BFD session is in AdminDown state.
Create time	Time when the VRRP group was created.
Last change time	Last time the VRRP group status changed.

Display brief information about all VRRP groups on the switch.

```
<HUAWEI> display vrrp brief
Total:1     Master:0     Backup:0     Non-active:1
VRID  State        Interface                Type     Virtual IP
----------------------------------------------------------------
1     Initialize   Vlanif23                 Normal   10.1.1.100
```

Table 12-10 Description of the **display vrrp brief** command output

Item	Description
VRID	VRID of the VRRP group.

Item	Description
State	VRRP status of the switch: ● Master: The switch functions as the master in the VRRP group. ● Backup: The switch functions as the backup in the VRRP group. ● Initialize: All VRRP groups begin in Initialize state. When the interface where a VRRP group is configured becomes Down or is Administratively Down, the VRRP group status changes to Initialize.
Interface	Interface configured with the VRRP group.
Type	Type of a VRRP group: ● normal-vrrp: common VRRP group ● admin-vrrp: mVRRP group ● member-vrrp: service VRRP group
Virtual IP	Virtual IP address of the VRRP group.
Total	Number of VRRP groups.
Master	Number of VRRP groups in Master state.
Backup	Number of VRRP groups in Backup state.
Non-active	Number of VRRP groups in Non-active state.

12.2.8 display vrrp admin-vrrp

Function

The **display vrrp admin-vrrp** command displays the status and configuration of all mVRRP groups.

Format

display vrrp admin-vrrp

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can view basic information about an mVRRP group, including the interface where the mVRRP group is configured, and the VRID and status of the mVRRP group.

Example

Display the status and configuration of all mVRRP groups on the device.

```
<HUAWEI> display vrrp admin-vrrp
Admin-vrrp number: 1
Interface: Vlanif10,  admin-vrrp vrid: 1, state: Master
```

Table 12-11 Description of the **display vrrp admin-vrrp** command output

Item	Description
Admin-vrrp number	Number of mVRRP groups.
Interface	Name and number of the interface where the mVRRP group is configured.
admin-vrrp vrid	VRID of the mVRRP group.
state	Status of the mVRRP group: ● Master ● Backup ● Initialize

12.2.9 display vrrp binding admin-vrrp

Function

The **display vrrp binding admin-vrrp** command displays the binding of an mVRRP group, including member VRRP groups and interfaces where member VRRP groups are configured.

Format

display vrrp binding admin-vrrp [**interface** *interface-type interface-number*] [**vrid** *virtual-router-id*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of an interface where an mVRRP group is configured. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
vrid *virtual-router-id*	Specifies the VRID of an mVRRP group.	The value is an integer that ranges from 1 to 255.

Views

All views

Usage Guidelines

You can run the **display vrrp binding admin-vrrp** command to view the binding of an mVRRP group.

Example

Display the binding of an mVRRP group.

```
<HUAWEI> display vrrp binding admin-vrrp
Interface: Vlanif10,  admin-vrrp vrid: 1, state:Master
  Member-vrrp number: 3
    Interface: Vlanif11, vrid: 1, state: Master
    Interface: Vlanif12, vrid: 2, state: Master
    Interface: Vlanif13, vrid: 3, state: Master
```

Table 12-12 Description of the **display vrrp binding admin-vrrp** command output

Item	Description
Interface	Interface configured with the mVRRP group.
admin-vrrp vrid	VRID of the mVRRP group.

Item	Description
state	Status of the mVRRP group: - Master - Backup - Initialize
Member-vrrp number	Number of member VRRP groups bound to the mVRRP group.
Interface	Interface where the member VRRP group bound to the mVRRP group is configured.
vrid	VRID of the member VRRP group bound to the mVRRP group.
state	Status of the member VRRP group bound to the mVRRP group: - Master - Backup - Initialize

12.2.10 display vrrp binding admin-vrrp member-vrrp

Function

The **display vrrp binding admin-vrrp member-vrrp** command displays information about the binding between an mVRRP group and member VRRP groups.

Format

display vrrp binding admin-vrrp [**interface** *interface-type1 interface-number1*] [**vrid** *virtual-router-id1*] **member-vrrp** [**interface** *interface-type2 interface-number2*] [**vrid** *virtual-router-id2*]

Parameters

Parameter	Description	Value
interface *interface-type1 interface-number1*	Specifies the type and number of an interface configured with an mVRRP group. - *interface-type1* specifies the interface type. - *interface-number1* specifies the interface number.	-

Parameter	Description	Value
vrid *virtual-router-id1*	Specifies the VRID of an mVRRP group.	The value is an integer that ranges from 1 to 255.
interface *interface-type2 interface-number2*	Specifies the type and number of an interface configured with a member VRRP group. ● *interface-type2* specifies the interface type. ● *interface-number2* specifies the interface number.	-
vrid *virtual-router-id2*	Specifies the VRID of a member VRRP group.	The value is an integer that ranges from 1 to 255.

Usage Scenario

You can run the **display vrrp binding admin-vrrp member-vrrp** command to view information about the binding between an mVRRP group and member VRRP groups.

Example

Display information about the binding between an mVRRP group and member VRRP groups.

```
<HUAWEI> display vrrp binding admin-vrrp member-vrrp
Interface: Vlanif11,  admin-vrrp vrid: 1, state: Master
  Member-vrrp number: 3
    Interface: Vlanif10, vrid: 1, state: Master
    Interface: Vlanif10, vrid: 2, state: Master
    Interface: Vlanif12, vrid: 3, state: Master
```

Table 12-13 Description of the **display vrrp binding admin-vrrp member-vrrp** command output

Item	Description
Interface	Interface configured with the mVRRP group.
admin-vrrp vrid	VRID of the mVRRP group.
state	Status of the mVRRP group: ● Master ● Backup ● Initialize
Member-vrrp number	Number of member VRRP groups bound to the mVRRP group.
Interface	Interface where the member VRRP group bound to the mVRRP group is configured.
vrid	VRID of the member VRRP group bound to the mVRRP group.
state	Status of the member VRRP group bound to the mVRRP group: ● Master ● Backup ● Initialize

12.2.11 display vrrp protocol-information

Function

The **display vrrp protocol-information** command displays VRRP information.

Format

display vrrp protocol-information

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display vrrp protocol-information** command to view VRRP information.

Example

Display VRRP information.

```
<HUAWEI> display vrrp protocol-information
 VRRP protocol information is shown as below:
    VRRP protocol version : V2
    Send advertisement packet mode : send v2 only
```

Table 12-14 Description of the **display vrrp protocol-information** command output

Item	Description
VRRP protocol version	VRRP version number: ● V2 ● V3 To configure a VRRP version number, run the **vrrp version** command.
Send advertisement packet mode	Mode in which VRRP Advertisement packets are sent: ● send v2 only: Only VRRPv2 Advertisement packets are sent. ● send v3 only: Only VRRPv3 Advertisement packets are sent. It is displayed only when VRRPv3 is used. ● send v2v3 both: VRRPv2 and VRRPv3 Advertisement packets are sent. It is displayed only when VRRPv3 is used. To configure the mode in which VRRP Advertisement packets are sent, run the **vrrp vrid version-3 send-packet-mode** command in the interface view or run the **vrrp version-3 send-packet-mode** command in the system view.

12.2.12 display vrrp state-change interface vrid

Function

The **display vrrp state-change interface vrid** command displays status changes of a specified VRRP group. This command can display a maximum of 10 of the latest status changes of a VRRP group.

Format

display vrrp state-change interface *interface-type interface-number* **vrid** *virtual-router-id*

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an interface where status changes of a VRRP group are displayed. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
vrid *virtual-router-id*	Specifies the VRID of a VRRP group.	The VRID of the VRRP group must have been created.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When the VRRP status becomes abnormal, run the **display vrrp state-change interface vrid** command to view the last 10 status changes of the VRRP group, including the time at which the VRRP group status changed, the VRRP group status before and after the change, and the cause of the VRRP group status change. The command output helps you locate faults.

Example

Display status changes of VRRP group 1 on VLANIF 100.

```
<HUAWEI> display vrrp state-change interface vlanif 100 vrid 1
 Time                    SourceState   DestState     Reason
 ---------------------------------------------------------------
 2012-01-27 15:29:45       Backup        Master        Protocol timer expired
 2012-01-27 15:29:42       Initialize    Backup        Interface UP
```

Table 12-15 Description of the **display vrrp state-change interface vrid** command output

Item	Description
Time	Time when the VRRP group status changed.
SourceState	VRRP group status before the change: ● Master ● Backup ● Initialize
DestState	VRRP group status after the change: ● Master ● Backup ● Initialize
Reason	Cause of the VRRP status change: ● Admin-vrrp drove ● BFD configure deleted ● CFM session down ● CFM session up ● EFM configure deleted ● EFM session down ● EFM session up ● Interface up ● Interface down ● Ignore interface down ● Link BFD session down ● Link BFD session up ● Link BFD session deleted ● Link BFD down-number changed ● Peer BFD session down ● Priority calculation ● Protocol timer expired ● Track interface ● Track BFD session

12.2.13 display vrrp statistics

Function

The **display vrrp statistics** command displays statistics about sent and received packets of VRRP groups.

Format

display vrrp [**interface** *interface-type interface-number*] [*virtual-router-id*] **statistics**

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays statistics about sent and received packets of all VRRP groups on a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number. If this parameter is not specified, statistics about sent and received packets of all VRRP groups or a specified VRRP group on the device are displayed.	-
virtual-router-id	Displays statistics about sent and received packets of a specified VRRP group. If this parameter is not specified, statistics about sent and received packets of all VRRP groups on the device or a specified interface are displayed.	The VRID of the VRRP group must have been created.
statistics	Displays statistics about sent and received packets of a VRRP group.	-

Views

              Received packets with priority zero : 0
                  Sent packets with priority zero : 0
                    Received invalid type packets : 0
         Received unmatched address list packets : 0
             Unknown authentication type packets : 0
                  Mismatched authentication type : 0
                              Packet length errors : 0
       Discarded packets since track admin-vrrp : 0
                       Received attacking packets : 0
                        Received selfsend packets : 0
```

Table 12-16 Description of the display vrrp statistics command output

Item	Description
Checksum errors	CRC error count.
Version errors	Version error count.
Vrid errors	Number of VRID errors.
Other errors	Number of other errors.
Vlanif 100 | Virtual Router 1	Interface where the VRRP group is configured and VRID of the VRRP group.
Transited to master	Number of times the switch transitions to the Master state.
Transited to backup	Number of times the switch transitions to the Backup state.
Transited to initialize	Number of times the switch transitions to the Initialize state.
Received advertisements	Number of received VRRP Advertisement packets.
Sent advertisements	Number of sent VRRP Advertisement packets.
Advertisement interval errors	Number of times VRRP Advertisement packets are sent at an incorrect interval.
Failed to authentication check	Number of authentication failures.
Received ip ttl errors	Number of packets with TTL errors.
Received packets with priority zero	Number of received VRRP Advertisement packets with the priority of 0.
Sent packets with priority zero	Number of sent VRRP Advertisement packets with the priority of 0.
Received invalid type packets	Number of received VRRP Advertisement packets of invalid type.
Received unmatched address list packets	Number of packets with incorrect virtual IP address lists.
Unknown authentication type packets	Number of packets with an unknown authentication mode.
Mismatched authentication type	Number of packets with a non-matched authentication mode.
Packet length errors	Number of packets with incorrect length.
Discarded packets since track admin-vrrp	Number of received packets that are discarded after a VRRP group is bound to a management VRRP (mVRRP) group.

Item	Description
Received attacking packets	Number of received attack packets.
Received selfsend packets	Number of received packets sent by the switch.

12.2.14 display vrrp track bfd gratuitous-arp information

Function

The **display vrrp track bfd gratuitous-arp information** command displays information when a sub-interface is enabled to rapidly send gratuitous ARP packets during an active/standby switchover of a VRRP group triggered by its associated peer BFD session.

Format

display vrrp track bfd gratuitous-arp information

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display vrrp track bfd gratuitous-arp information** command displays information when a sub-interface is enabled to rapidly send gratuitous ARP packets during an active/standby switchover of a VRRP group triggered by its associated peer BFD session.

Example

Display information when a sub-interface is enabled to rapidly send gratuitous ARP packets during an active/standby switchover of a VRRP group triggered by its associated peer BFD session.

```
<HUAWEI> display vrrp track bfd gratuitous-arp information
--------------------------------------------------------------------------------
Interface                     Vrid      BFD-session Name        Status
```

```
--------------------------------------------------------------------------------
GigabitEthernet0/0/19.1          32        atob                  Active
--------------------------------------------------------------------------------
Total:1            Active:1            InActive:0
```

Table 12-17 Description of the **display vrrp track bfd gratuitous-arp information** command output

Item	Description
Interface	Interface configured with the VRRP group.
Vrid	VRID of the VRRP group.
BFD-session Name	Name of a BFD session.
Status	Status of the BFD session.
Total	Total number of peer BFD sessions.
Active	Number of BFD sessions in active state.
InActive	Number of BFD sessions in inactive state.

12.2.15 display vrrp6

Function

The **display vrrp6** command displays the status and configuration parameters of VRRP6 groups.

Format

display vrrp6 [**interface** *interface-type interface-number*] [**vrid** *virtual-router-id*] [**brief**]

display vrrp6 { **interface** *interface-type interface-number* [**vrid** *virtual-router-id*] | **vrid** *virtual-router-id* } **verbose**

Parameters

Parameter	Description	Description
interface *interface-type interface-number*	Displays the status of all VRRP6 groups on the specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number. If this parameter is not specified, information about all VRRP6 groups is displayed.	-
vrid *virtual-router-id*	Displays the status of a VRRP6 group with the specified VRID.	The VRID of the VRRP6 group must have been created.
brief	Displays brief information about a specified VRRP6 group.	-
verbose	Displays detailed information about a specified VRRP6 group.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can view the status and configuration of all VRRP6 groups based on networking, including interfaces where mVRRP6 groups are configured, and VRIDs and statuses of VRRP6 groups.

Example

Display information about all VRRP6 groups on the switch with VRID 4.

```
<HUAWEI> display vrrp6 vrid 4
Vlanif100 | Virtual Router 4
    State            : Master
    Virtual IP       : FE80::1:2
    Master IP : FE80::218:82FF:FED3:2AF1
```

```
  PriorityRun      : 200
  PriorityConfig   : 200
  MasterPriority   : 200
  Preempt          : YES                   Delay Time : 0 s
  TimerRun         : 100 cs
  TimerConfig      : 100 cs
  Virtual Mac      : 0000-5e00-0101
  Check hop limit  : YES
  Config type      : normal-vrrp
  Backup-forward   : disabled
  Create time      : 2012-05-22 17:40:56 UTC-08:00
  Last change time : 2012-05-22 17:41:03 UTC-08:00
```

Table 12-18 Description of the display vrrp6 command output

Item	Description
Vlanif100 | Virtual Router 4	Interface where the VRRP6 group is configured and VRID of the VRRP6 group.
State	VRRP6 status of the device: ● Master: The device functions as the master in the VRRP6 group. ● Backup: The device functions as the backup in the VRRP6 group. ● Initialize: All VRRP6 groups begin in Initialize state. When the status of an interface is Down or administratively Down, the VRRP6 group status changes to Initialize.
Virtual IP	Virtual IP address of the VRRP6 group. To configure a virtual IP address for a VRRP6 group, run the **vrrp6 vrid virtual-ip** command.
Master IP	Primary IP address of the interface configured with the VRRP6 group on the master.
PriorityRun	Priority of the switch when the VRRP6 group runs. If the switch is the IP address owner in a VRRP6 group, the running priority of the switch in the group is displayed as **255**.
PriorityConfig	Priority configured for the switch using the **vrrp6 vrid priority** command. If the switch is the IP address owner, the default priority 100 but not 255 is displayed.
MasterPriority	Priority of the master in the VRRP6 group. If the switch is the IP address owner in a VRRP6 group, the priority of the switch in the group is displayed as **255**.
Preempt	Preemption mode: ● YES: preemption ● NO: no preemption To disable the preemption mode, run the **vrrp6 vrid preempt-mode disable** command.

Item	Description
Delay Time	Preemption delay, in seconds. To set the preemption delay, run the **vrrp6 vrid preempt-mode timer delay** command.
TimerRun	Interval at which the master in the VRRP6 group sends VRRP Advertisement packets, in centiseconds.
TimerConfig	Configured interval at which the master in the VRRP6 group sends VRRP6 Advertisement packets, in centiseconds. To set the interval at which the master in the VRRP6 group sends VRRP6 Advertisement packets, run the **vrrp6 vrid timer advertise** command.
Virtual Mac	Virtual MAC address of the VRRP6 group.
Check hop limit	Whether the TTL value of a VRRP6 Advertisement packet is checked: ● YES: The TTL value of a VRRP6 Advertisement packet is checked. ● NO: The TTL value of a VRRP6 Advertisement packet is not checked. To configure the device to check the TTL value in a VRRP6 Advertisement packet, run the **vrrp6 un-check hop-limit** command.
Config type	Type of a VRRP6 group: ● normal-vrrp: common VRRP6 group ● admin-vrrp: mVRRP6 group ● member-vrrp: service VRRP6 group
Backup-forward	Whether the backup is enabled to forward traffic: ● enabled ● disabled
Create time	Time when the VRRP6 group was created.
Last change time	Last time the VRRP6 group status changed.

Display brief information about all VRRP6 groups on the device.

```
<HUAWEI> display vrrp6 brief
Total:2     Master:2     Backup:0     Non-active:0
VRID  State        Interface                Type     Virtual IP
----------------------------------------------------------------
1     Master       Vlanif66                 Normal   FE80::1
2     Master       Vlanif67                 Normal   FE80::1:3
```

Table 12-19 Description of the display vrrp6 brief command output

Item	Description
VRID	VRID of the VRRP6 group.
State	VRRP6 status of the switch: ● Master: The device functions as the master in the VRRP6 group. ● Backup: The device functions as the backup in the VRRP6 group. ● Initialize: All VRRP6 groups begin in Initialize state. When the interface where a VRRP group is configured becomes Down or is Administratively Down, the VRRP6 group status is switched to Initialize.
Interface	Interface configured with the VRRP6 group.
Type	Type of a VRRP6 group: ● normal-vrrp: common VRRP6 group ● admin-vrrp: mVRRP6 group ● member-vrrp: service VRRP6 group
Virtual IP	Virtual IP address of the VRRP6 group.
Total	Number of VRRP6 groups.
Master	Number of VRRP6 groups in Master state.
Backup	Number of VRRP6 groups in Backup state.
Non-active	Number of VRRP6 groups in Non-active state.

12.2.16 display vrrp6 admin-vrrp6

Function

The **display vrrp6 admin-vrrp6** command displays the status and configuration of all mVRRP6 groups.

Format

display vrrp6 admin-vrrp6

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can view the status and configuration of all mVRRP6 groups, including interfaces where mVRRP6 groups are configured, and VRIDs and statuses of the mVRRP6 groups.

Example

Display the status and configuration of all mVRRP6 groups on the device.

```
<HUAWEI> display vrrp6 admin-vrrp6
  Admin-vrrp6 number: 1
Interface: Vlanif100,  admin-vrrp6 vrid: 1, state: Master
```

Table 12-20 Description of the **display vrrp6 admin-vrrp6** command output

Item	Description
Admin-vrrp6 number	Number of mVRRP6 groups.
Interface	Interface configured with the mVRRP6 group.
admin-vrrp6 vrid	VRID of the mVRRP6 group.
state	Status of the mVRRP6 group: ● Master ● Backup ● Initialize

12.2.17 display vrrp6 binding admin-vrrp6

Function

The **display vrrp6 binding admin-vrrp6** command displays the binding of an mVRRP6 group and its member VRRP6 groups.

Format

display vrrp6 binding admin-vrrp6 [**interface** *interface-type interface-number*] [**vrid** *virtual-router-id*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of an interface where an mVRRP6 group is configured.	-
vrid *virtual-router-id*	Specifies the VRID of an mVRRP6 group.	The value is an integer that ranges from 1 to 255.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If the **interface** *interface-type interface-number* parameter is not specified, the **display vrrp6 binding admin-vrrp6** command displays the binding of mVRRP6 groups on all interfaces of the device.

Example

Display the binding of mVRRP6 groups on all interfaces.

```
<HUAWEI> display vrrp6 binding admin-vrrp6
Interface: Vlanif100,  admin-vrrp6 vrid: 1, state:Master
  Member-vrrp6 number: 1
    Interface: Vlanif200, vrid: 2, state: Master
```

Table 12-21 Description of the **display vrrp6 binding admin-vrrp6** command output

Item	Description
Interface	Interface configured with the mVRRP6 group.
admin-vrrp6 vrid	VRID of the mVRRP6 group.
state	Status of the mVRRP6 group: ● Master ● Backup ● Initialize
Member-vrrp6 number	Number of member VRRP6 groups bound to the mVRRP6 group.
Interface	Interface configured with a member VRRP6 group that is bound to the mVRRP6 group.

Item	Description
vrid	VRID of a member VRRP6 group bound to the mVRRP6 group.
state	Status of a member VRRP6 group bound to the mVRRP6 group: ● Master ● Backup ● Initialize

12.2.18 display vrrp6 binding admin-vrrp6 member-vrrp

Function

The **display vrrp6 binding admin-vrrp6 member-vrrp** command displays information about the binding between an mVRRP6 group and member VRRP6 groups.

Format

display vrrp6 binding admin-vrrp6 [**interface** *interface-type1 interface-number1*] [**vrid** *virtual-router-id1*] **member-vrrp** [**interface** *interface-type2 interface-number2*] [**vrid** *virtual-router-id2*]

Parameters

Parameter	Description	Value
interface *interface-type1 interface-number1*	Specifies the type and number of an interface configured with an mVRRP6 group.	-
vrid *virtual-router-id1*	Specifies the VRID of an mVRRP6 group.	The value is an integer that ranges from 1 to 255.
interface *interface-type2 interface-number2*	Specifies the type and number of an interface configured with a member VRRP6 group.	-
vrid *virtual-router-id2*	Specifies the VRID of a member VRRP6 group.	The value is an integer that ranges from 1 to 255.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display vrrp6 binding admin-vrrp6 member-vrrp** command displays the bindings between mVRRP6 backup groups and member VRRP6 backup groups on the network as required.

- If *interface-type1 interface-number1* is merely specified in the command, the command output displays all the bindings between mVRRP6 backup groups and member VRRP6 backup groups on the specified interface.
- If the command is specified with only *virtual-router-id1*, the command output displays the bindings between the specified mVRRP6 backup group and member VRRP6 backup groups.
- If the command is specified with only *interface-type1 interface-number1* and *virtual-router-id1*, the command output displays the bindings between the specified mVRRP6 backup group on the specified interface and member VRRP6 backup groups.
- If the command is only specified with *interface-type2 interface-number2*, the command output displays the bindings between member VRRP6 backup groups on the specified interface and mVRRP6 backup groups.
- If the command is specified with only *virtual-router-id2*, the command output displays the bindings between the specified member VRRP6 backup group and mVRRP6 backup groups.
- If the command is specified with only *interface-type2 interface-number2* and *virtual-router-id2*, the command output displays the bindings between the specified member VRRP6 backup group on the specified interface and mVRRP6 backup groups, and information about the mVRRP6 backup groups.

Example

Display information about the binding between an mVRRP6 group and member VRRP6 groups.

```
<HUAWEI> display vrrp6 binding admin-vrrp6 member-vrrp
Interface: Vlanif100, admin-vrrp6 vrid: 1, state: Master
  Member-vrrp number: 2
    Interface: Vlanif101, vrid: 2, state: Master
    Interface: Vlanif102, vrid: 3, state: Master
```

Display information about the binding between mVRRP6 group 1 and member VRRP6 groups on VLANIF 10.

```
<HUAWEI> display vrrp6 binding admin-vrrp6 interface vlanif 10 vrid 1 member-vrrp
Interface: Vlanif10,  admin-vrrp6 vrid: 1, state:Master
  Member-vrrp number: 3
          Interface: Vlanif100, vrrp6 vrid: 1, state: Master
          Interface: Vlanif101, vrrp6 vrid: 2, state: Master
          Interface: Vlanif102, vrrp6 vrid: 3, state: Master
```

Table 12-22 Description of the **display vrrp6 binding admin-vrrp6 member-vrrp** command output

Item	Description
Interface	Interface configured with the mVRRP6 group.
admin-vrrp6 vrid	VRID of the mVRRP6 group.
state	Status of the mVRRP6 group: - Master - Backup - Initialize
Member-vrrp number	Number of member VRRP6 groups bound to the mVRRP6 group.
Interface	Interface configured with the member VRRP6 group.
vrrp6 vrid	VRID of the member VRRP6 group.
state	Status of the member VRRP6 group.

12.2.19 display vrrp6 state-change interface vrid

Function

The **display vrrp6 state-change interface vrid** command displays status changes of a specified VRRP6 group. This command can display a maximum of the latest 10 status changes of a VRRP6 group.

Format

display vrrp6 state-change interface *interface-type interface-number* **vrid** *virtual-router-id*

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an interface where status changes of a VRRP6 group are displayed.	-
virtual-router-id	Specifies the VRID of a VRRP6 group.	The VRID of the VRRP6 group must have been created.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When the VRRP6 status becomes abnormal, run the **display vrrp6 state-change interface vrid** command to view the latest 10 status changes of the VRRP6 group. The command output includes the time when the VRRP6 group status changed, VRRP6 group status before and after each change, and causes of the status changes. The command output helps you locate faults.

Example

Display status changes of VRRP6 group 1 on VLANIF 100.

```
<HUAWEI> display vrrp6 state-change interface vlanif 100 vrid 1
Time                       SourceState  DestState   Reason
-------------------------------------------------------------------------------
2012-05-19 20:36:44            Initialize   Backup      interface up
2012-05-19 20:37:07            Backup       Master      protocol timer expired
```

Table 12-23 Description of the **display vrrp6 state-change interface vrid** command output

Item	Description
Time	Time when the VRRP6 status changed.
SourceState	Status before the change: ● Master ● Backup ● Initialize
DestState	Status after the change: ● Master ● Backup ● Initialize

Item	Description
Reason	Reason of the change in the status of the VRRP6 backup group: ● Admin-vrrp drove ● BFD configure deleted ● Interface up ● Interface down ● Link BFD session down ● Link BFD session up ● Link BFD session deleted ● Peer BFD session down ● Priority calculation ● Protocol timer expired ● Track interface ● Track BFD session

12.2.20 display vrrp6 statistics

Function

The **display vrrp6 statistics** command displays statistics about sent and received packets of VRRP6 groups.

Format

display vrrp6 [**interface** *interface-type interface-number*] [**vrid** *virtual-router-id*] **statistics**

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays statistics about sent and received packets of all VRRP6 groups on a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number. If this parameter is not specified, statistics about sent and received packets of all VRRP6 groups or a specified VRRP6 group on the switch are displayed.	-
vrid *virtual-router-id*	Displays statistics about sent and received packets of a specified VRRP6 group. If this parameter is not specified, statistics about sent and received packets of all VRRP6 groups on the switch or a specified interface are displayed.	The VRID of the VRRP6 group must have been created.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display vrrp6 statistics** command displays information about sent and received packets of VRRP6 groups.

Example

Display statistics about all VRRP6 Advertisement packets on the switch.

```
<HUAWEI> display vrrp6 statistics
  Checksum errors : 0
   Version errors : 0
      Vrid errors : 0
     Other errors : 0

  Vlanif100 | Virtual Router 1
                          Transited to master : 1
                          Transited to backup : 1
                      Transited to initialize : 0
                      Received advertisements : 0
                          Sent advertisements : 1000
                Advertisement interval errors : 0
               Failed to authentication check : 0
                       Received ip ttl errors : 0
           Received packets with priority zero : 0
               Sent packets with priority zero : 0
                 Received invalid type packets : 0
        Received unmatched address list packets : 0
            Unknown authentication type packets : 0
                 Mismatched authentication type : 0
                           Packet length errors : 0
     Discarded packets since track admin-vrrp : 0
                    Received attacking packets : 0
                     Received selfsend packets : 0
```

Table 12-24 Description of the **display vrrp6 statistics** command output

Item	Description
Checksum errors	CRC error count.
Version errors	Version error count.
Vrid errors	Number of VRID errors.
Other errors	Number of other errors.
Vlanif100 | Virtual Router 1	Interface where the VRRP6 group is configured and VRID of the VRRP6 group.
Transited to master	Number of times the switch transitions to the Master state.
Transited to backup	Number of times the switch transitions to the Backup state.
Transited to initialize	Number of times the switch transitions to the Initialize state.
Received advertisements	Number of received VRRP Advertisement packets.
Sent advertisements	Number of sent VRRP Advertisement packets.
Advertisement interval errors	Number of times VRRP Advertisement packets are sent at an incorrect interval.
Failed to authentication check	Number of authentication failures.
Received ip ttl errors	Number of packets with TTL errors.

Item	Description
Received packets with priority zero	Number of received VRRP Advertisement packets with the priority of 0.
Sent packets with priority zero	Number of sent VRRP Advertisement packets with the priority of 0.
Received invalid type packets	Number of received VRRP6 Advertisement packets of invalid type.
Received unmatched address list packets	Number of packets with incorrect virtual IPv6 address lists.
Unknown authentication type packets	Number of invalid authentication packets.
Mismatched authentication type	Number of packets with mismatching authentication types.
Packet length errors	Number of packets with incorrect length.
Discarded packets since track admin-vrrp	Number of received packets that are discarded after a VRRP6 group is bound to a management VRRP6 (mVRRP6) group.
Received attacking packets	Number of received attack packets.
Received selfsend packets	Number of received packets sent by the switch.

12.2.21 reset vrrp statistics

Function

The **reset vrrp statistics** command clears statistics about received and sent packets of VRRP groups.

Format

reset vrrp [**interface** *interface-type interface-number*] [**vrid** *virtual-router-id*] **statistics**

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Clears statistics about sent and received packets of all VRRP groups on a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number. If this parameter is not specified, statistics about sent and received packets of all VRRP groups or a specified VRRP group on the device are cleared.	-
vrid *virtual-router-id*	Clears statistics about sent and received packets of a specified VRRP group. If this parameter is not specified, statistics about sent and received packets of all VRRP groups or a specified VRRP group on the device are cleared.	The value is an integer that ranges from 1 to 255.

3: Management level

Usage Guidelines

Usage Scenario

Before recollecting statistics about VRRP Advertisement packets, run the **reset vrrp statistics** command to clear existing statistics.

Precautions

The cleared statistics cannot be restored. Exercise caution when executing the **reset vrrp statistics** command.

Example

Clear statistics about sent and received packets of VRRP group 1 on VLANIF100.

```
<HUAWEI> reset vrrp interface vlanif 100 vrid 1 statistics
```

Clear statistics about all the packets of VRRP group 1.

```
<HUAWEI> reset vrrp vrid 1 statistics
```

Clear statistics about packets of all VRRP groups on the switch.

```
<HUAWEI> reset vrrp statistics
```

12.2.22 reset vrrp6 statistics

Function

The **reset vrrp6 statistics** command clears statistics about received and sent packets of VRRP6 groups.

Format

reset vrrp6 [**interface** *interface-type interface-number*] [**vrid** *virtual-router-id*] **statistics**

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Clears statistics about sent and received packets of all VRRP6 groups on a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number. If this parameter is not specified, statistics about sent and received packets of all VRRP6 groups or a specified VRRP6 group on the device are cleared.	-

Parameter	Description	Value
vrid *virtual-router-id*	Clears statistics about sent and received packets of a specified VRRP6 group. If this parameter is not specified, statistics about sent and received packets of all VRRP6 groups or a specified VRRP6 group on the device are cleared.	The value is an integer that ranges from 1 to 255.

Usage Scenario

Before recollecting statistics about VRRP6 Advertisement packets, run the **reset vrrp6 statistics** command to clear existing statistics.

Precautions

The cleared statistics cannot be restored. Exercise caution when executing the **reset vrrp6 statistics** command.

Example

Clear statistics about sent and received packets of VRRP6 group 1 on VLANIF100.

```
<HUAWEI> reset vrrp6 interface vlanif 100 vrid 1 statistics
```

Clear statistics about all the packets of VRRP6 group 1.

```
<HUAWEI> reset vrrp6 vrid 1 statistics
```

Clear statistics about packets of all VRRP6 groups on the switch.

```
<HUAWEI> reset vrrp6 statistics
```

12.2.23 set vrrp max-group-number

Function

The **set vrrp max-group-number** command sets the maximum number of allowed VRRP groups (sum of VRRP4 and VRRP6 groups).

The **undo set vrrp max-group-number** command restores the default maximum number of allowed VRRP groups.

By default, a maximum of 64 VRRP groups can be configured.

Format

set vrrp max-group-number *max-group-number*

undo set vrrp max-group-number

Parameters

Parameter	Description	Value
max-group-number	Specifies the maximum number of allowed VRRP groups.	Enumerated type. The values are as follows: ● S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S: 64, 128, 192, 256, 320, 384, 448, 512, or 1000 ● S6735-S, S6720S-EI and S6720-EI: 64, 128, 192, 256, 320, or 384 ● S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, and S6720S-S: 64, 128, 192, or 256 ● S1720GW-E, S1720GWR-E, SS5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI: 64 or 128

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When more than 64 VRRP groups need to be configured, run this command to set the maximum number of allowed VRRP groups.

Precautions

- You are not advised to configure more than 64 VRRP groups.
- When more than 64 VRRP groups are configured, to reduce the frequency of sending VRRP Advertisement packets and the impact of VRRP Advertisement packets on network bandwidth and CPU performance, perform one of the following operations as prompted in addition to executing the **set vrrp max-group-number** command (You are advised to configure an mVRRP group):
  - Run the **vrrp vrid timer advertise** command to increase the interval for sending VRRP Advertisement packets (recommended interval: > 3s), and run the **cpu-defend dynamic-car enable** command to enable a switch to dynamically adjust the default CIR value for protocol packets.
  - Run the **vrrp vrid timer advertise** command to increase the interval for sending VRRP Advertisement packets (recommended interval: > 3s), and run the

    car { **packet-type** *packet-type* | **user-defined-flow** *flow-id* } **cir** *cir-value* [**cbs** *cbs-value*]

    command to increase the CPCAR for VRRP Advertisement packets. Adjust the CPCAR value as prompted. Improper CPCAR settings will affect services on your network.
  - Run the **admin-vrrp vrid** command to configure an mVRRP group.
  - For the S5735S-H, S5736-S, and S6720S-S:
    - When the number of VRRP groups on the device exceeds a specified value, ACL resources are occupied. In this situation, MAC mirroring may become invalid.
    - When a VRRP group is configured for a super-VLAN, the device delivers virtual MAC address entries corresponding to sub-VLANs of the super-VLAN. This occupies many resources. When configuring a VRRP group for a super-VLAN, pay attention to the following points:
      - The VRRP group can be configured for a maximum of 16 super-VLANs on the device.
      - The device allows a maximum of 312 virtual MAC address entries for VRRP. For example, there are 10 sub-VLANs in super-VLAN 100. When a VRRP group is configured on VLANIF 100, 11 virtual MAC address entries are occupied (1 super-VLAN + 10 sub-VLANs).

Example

Set the maximum number of allowed VRRP groups to 192.

```
<HUAWEI> system-view
[HUAWEI] set vrrp max-group-number 192
```

12.2.24 vrrp advertise send-mode

Function

The **vrrp advertise send-mode** command configures a mode in which the master sends VRRP Advertisement packets in a super-VLAN.

The **undo vrrp advertise send-mode** command restores the default mode in which the master sends VRRP Advertisement packets in a super-VLAN.

By default, the master sends VRRP Advertisement packets to a sub-VLAN that is Up and has the smallest VLAN ID in a super-VLAN.

NOTE

Only the S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

vrrp advertise send-mode { *sub-vlan-id* | **all** }

undo vrrp advertise send-mode

Parameters

Parameter	Description	Value
sub-vlan-id	Specifies the ID of a sub-VLAN where the master sends VRRP Advertisement packets.	The value is an integer that ranges from 1 to 4094.
all	Indicates that the master sends VRRP Advertisement packets to all sub-VLANs in a super-VLAN.	-

Views

VLANIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a VRRP group is configured in a super-VLAN, run the **vrrp advertise send-mode** command to configure the master to send VRRP Advertisement packets to a specified sub-VLAN or all sub-VLANs in the super-VLAN. If there are a large number of sub-VLANs in a super-VLAN, to save bandwidth, configure the master to send VRRP Advertisement packets to a specified sub-VLAN.

Prerequisites

A VRRP group has been configured on the VLANIF interface corresponding to the super-VLAN.

Precautions

Using **all** is not recommended. If **all** is configured, a super VLAN broadcasts a VRRP Advertisement packet to all its Sub-VLANs. This causes CPU usage to increase.

If both VRRP and static ARP are configured on a device, note the following issues:

- If VRRP is enabled on a VLANIF interface, a virtual IP address cannot be an IP address that maps to a MAC address in a static ARP entry. If a virtual IP address maps to a MAC address in a static ARP entry, a forwarding failure occurs. For example, if a MAC address in a static ARP entry on a VLANIF interface maps to an IP address of 10.1.1.1, the IP address of 10.1.1.1 cannot be a virtual IP address of a VRRP IPv4 backup group configured on the VLANIF interface.
- After a VLANIF interface is configured with a VRRP IPv4 backup group and a static ARP entry, the virtual IP address of the VRRP IPv4 backup group cannot be an IP address that maps to the MAC address in the static ARP entry. Otherwise, a forwarding failure occurs. For example, if a VRRP IPv4 backup group on a VLANIF interface is assigned an IP address of 10.1.1.1, the IP address of 10.1.1.1 cannot map to a MAC address in a static ARP entry configured on the VLANIF interface.

Example

Configure the master to broadcast VRRP Advertisement packets to sub-VLAN 50 in super-VLAN 100.

```
<HUAWEI> system-view
[HUAWEI] vlan 100
[HUAWEI-vlan100] aggregate-vlan
[HUAWEI-vlan100] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] vrrp vrid 1 virtual-ip 10.10.10.10
[HUAWEI-Vlanif100] vrrp advertise send-mode 50
```

12.2.25 vrrp arp send-mode simple

Function

The **vrrp arp send-mode simple** command configures the master on a QinQ termination sub-interface to send gratuitous ARP packets to the VLAN specified by the outer VLAN tag and the first VLAN in the VLAN range specified by the inner VLAN tag.

The **undo vrrp arp send-mode simple** command restores the default setting.

By default, the master on a QinQ termination sub-interface sends gratuitous ARP packets to the VLAN specified by the outer VLAN tag and all VLANs in the VLAN range specified by the inner VLAN tag.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

vrrp arp send-mode simple

undo vrrp arp send-mode simple

Parameters

None

Views

VE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When VRRP is deployed on a QinQ termination sub-interface, the system sends double-tagged ARP packets. If the inner VLAN tag specifies a VLAN range, the system sends ARP packets to all the VLANs in the VLAN range specified by the inner VLAN tag. This ensures that MAC address entries on the downstream device are updated immediately, but causes a heavy burden. The **vrrp arp send-mode simple** command configures the master on a QinQ termination sub-interface to send gratuitous ARP packets to the VLAN specified by the outer VLAN tag and the first VLAN in the VLAN range specified by the inner VLAN tag. This prevents excess gratuitous ARP packets from affecting the system.

NOTE

The **vrrp arp send-mode simple** command takes effect in VLANs specified only by the inner VLAN tag but not VLANs specified by the outer VLAN tag. For example, the VLAN ID in the outer tag ranges from 1 to 10 and the VLAN ID in the inner tag ranges from 1 to 10. After the **vrrp arp send-mode simple** command is run, gratuitous ARP packets are transmitted in only VLAN 1 (specified by the inner VLAn tag). A total of 10 gratuitous ARP packets (10 outer VLAN IDs x 1 inner VLAN ID) are sent.

Precautions

The **vrrp arp send-mode simple** command must be executed on a QinQ termination sub-interface.

Example

Configure VE sub-interface Virtual-Ethernet0/0/2.1 to send gratuitous ARP packets in VLAN 3.

```
<HUAWEI> system-view
[HUAWEI] interface virtual-ethernet0/0/2
[HUAWEI-Virtual-Ethernet0/0/2] ve-group 1 l3-access
[HUAWEI-Virtual-Ethernet0/0/2] quit
[HUAWEI] interface virtual-ethernet0/0/2.1
[HUAWEI-Virtual-Ethernet0/0/2.1] qinq termination pe-vid 5 ce-vid 3 to 20
[HUAWEI-Virtual-Ethernet0/0/2.1] vrrp vrid 1 virtual-ip 10.1.1.1
[HUAWEI-Virtual-Ethernet0/0/2.1] vrrp arp send-mode simple
```

12.2.26 vrrp gratuitous-arp timeout

Function

The **vrrp gratuitous-arp timeout** command configures an interval at which the master in a VRRP group sends gratuitous ARP packets or the master in a VRRP6 group sends ND packets.

The **undo vrrp gratuitous-arp timeout** command restores the default interval at which the master in a VRRP group sends gratuitous ARP packets or the master in a VRRP6 group sends ND packets.

The default interval is 120 seconds.

Format

vrrp gratuitous-arp timeout *time*

undo vrrp gratuitous-arp timeout

Parameters

Parameter	Description	Value
timeout *time*	Specifies an interval at which the master in a VRRP group sends gratuitous ARP packets or the master in a VRRP6 group sends ND packets.	The value is an integer that ranges from 30 to 1200, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The master in a VRRP group sends gratuitous ARP packets or the master in a VRRP6 group sends ND packets to its connected downstream switch to update the MAC entries on the downstream switch.

Precautions

- If a short interval is used, bandwidth resources will be consumed. If a long interval is used, MAC address entries on the downstream switch cannot be updated immediately.
- The interval at which the master sends gratuitous ARP or ND packets must be shorter than the aging time of MAC address entries on user devices.

Set the interval based on actual networking:

- To restore the default interval at which the master sends gratuitous ARP or ND packets, run the **undo vrrp gratuitous-arp timeout** command in the system view.
- If gratuitous ARP or ND packet do not need to be sent, run the **vrrp gratuitous-arp timeout disable** command in the system view.

Example

Set the interval at which the master in a VRRP group sends gratuitous ARP packets or the master in a VRRP6 group sends ND packets to 100 seconds.

```
<HUAWEI> system-view
[HUAWEI] vrrp gratuitous-arp timeout 100
```

12.2.27 vrrp gratuitous-arp timeout disable

Function

The **vrrp gratuitous-arp timeout disable** command disables the master device in a Virtual Router Redundancy Protocol for IPv4 (VRRP4) backup group from sending gratuitous ARP packets or the master device in a Virtual Router Redundancy Protocol for IPv6 (VRRP6) backup group from sending ND packets.

By default, the master device in a VRRP4 (or VRRP6) backup group sends gratuitous ARP (or ND) packets every 120 seconds.

Format

vrrp gratuitous-arp timeout disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The master device in a VRRP4 (or VRRP6) backup group sends gratuitous ARP (or ND) packets to its connected downstream switch to update the MAC entries on the downstream switch. Because ARP and NDP do not provide any security mechanisms, attackers can send spoofed ARP or ND packets to attack network devices. If high network security is required, run the **vrrp gratuitous-arp timeout disable** command to disable the master device in a VRRP4 backup group from sending gratuitous ARP packets or the master device in a VRRP6 backup group from sending ND packets.

Precautions

After the **vrrp gratuitous-arp timeout disable** command is run, the master device in a VRRP4 (or VRRP6) backup group no longer periodically sends gratuitous ARP (or ND) packets to its connected downstream switch. If a master/backup switchover occurs, the MAC entries on the downstream switch cannot be promptly updated. As a result, traffic is interrupted.

Example

Disable the master device in a VRRP4 backup group from sending gratuitous ARP packets or the master device in a VRRP6 backup group from sending ND packets.

```
<HUAWEI> system-view
[HUAWEI] vrrp gratuitous-arp timeout disable
```

12.2.28 vrrp recover-delay

Function

The **vrrp recover-delay** command sets the delay before a VRRP or VRRP6 group recovers.

The **undo vrrp recover-delay** command restores the default delay before a VRRP or VRRP6 group recovers.

By default, the delay before a VRRP or VRRP6 group recovers is 0.

Format

vrrp recover-delay *delay-value*

undo vrrp recover-delay

Parameters

Parameter	Description	Value
delay-value	Specifies the delay before a VRRP or VRRP6 group recovers.	The value is an integer that ranges from 0 to 60, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an interface or a BFD session associated with a VRRP or VRRP6 group alternates between Up and Down states, the VRRP or VRRP6 group status may flap, causing user traffic loss. To solve this problem, run the **vrrp recover-delay** command to set the delay before a VRRP or VRRP6 group recovers. A VRRP or VRRP6 group then only responds to the interface or BFD session Up event after the delay expires.

Precautions

- When the device in a VRRP or VRRP6 group restarts, the VRRP or VRRP6 group status may flap. It is recommended that the delay be set based on actual networking.
- After an interface or a BFD session associated with a VRRP or VRRP6 group alternates between Up and Down states, the system only records logs and alarms at one time during each delay. This prevents the same alarms from being displayed repeatedly.

Example

Set the delay before a VRRP group recovers to 5 seconds.

```
<HUAWEI> system-view
[HUAWEI] vrrp recover-delay 5
```

12.2.29 vrrp smooth-switching timer

Function

The **vrrp smooth-switching timer** command enables VRRP smooth switching and sets the interval contained in VRRP Advertisement packets during VRRP smooth switching.

The **undo vrrp smooth-switching timer** command disables VRRP smooth switching.

By default, VRRP smooth switching is enabled and the interval contained in VRRP Advertisement packets is 100s.

Format

vrrp smooth-switching timer *timer-value*

undo vrrp smooth-switching timer

Parameters

Parameter	Description	Value
timer-value	Specifies the interval contained in VRRP Advertisement packets during VRRP smooth switching. After VRRP smooth switching is enabled on the master, the master sends VRRP Advertisement packets at this interval during an active/standby switchover.	The value is an integer that ranges from 1 to 255, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an active/standby switchover occurs on the master in the stack system in a VRRP group, the master and backup may fail to communicate with each other during the switchover. During the switchover, the backup with the highest priority becomes the new master if backups receive no VRRP Advertisement packet after the VRRP Advertisement packet sending interval expires. In this situation, two masters coexist. After the active/standby switchover is complete on the original master, the original master switches to the master because its priority is higher than the new master. During this process, services are switched twice, causing unstable service transmission.

After VRRP smooth switching is enabled on the device in the stack system, backups learn the smooth switching time. This implementation extends the timeout interval for receiving VRRP Advertisement packets during VRRP smooth switching, ensuring stability of the VRRP group status.

Prerequisites

The device has been enabled to learn the interval for sending VRRP Advertisement packets using the **vrrp timer-advertise learning enable** command.

Precautions

After receiving VRRP Advertisement packets from the master, the non-master device checks the interval in VRRP Advertisement packets. If the interval in VRRP Advertisement packets is different from the interval of the non-master device, the non-master device learns the interval and adjusts its own interval to be the same as the learned interval.

- *timer-value* must be greater than the interval at which VRRP Advertisement packets are sent. Otherwise, the master may be busy during the switchover and unable to send VRRP Advertisement packets in a timely manner. As a result, a backup switches to the master.
- After the **undo vrrp timer-advertise learning enable** command is executed, VRRP smooth switching is also disabled.

Example

Enable VRRP smooth switching and set the interval contained in VRRP Advertisement packets during VRRP smooth switching to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] vrrp smooth-switching timer 20
```

12.2.30 vrrp timer-advertise learning enable

Function

The **vrrp timer-advertise learning enable** command enables the device to learn the interval for sending VRRP Advertisement packets.

The **vrrp timer-advertise learning disable** command disables the device from learning the interval for sending VRRP Advertisement packets.

The **undo vrrp timer-advertise learning enable** command disables the device from learning the interval for sending VRRP Advertisement packets.

By default, the device is enabled to learn the interval for sending VRRP Advertisement packets.

Format

vrrp timer-advertise learning enable

vrrp timer-advertise learning disable

undo vrrp timer-advertise learning enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a link fault triggers an active/standby switchover, VRRP smooth switching is enabled to prevent traffic loss. Before enabling VRRP smooth switching, run the **vrrp timer advertise learning enable** command to enable the device to learn the interval for sending VRRP Advertisement packets. Then non-master devices in the VRRP group will learn the interval at which VRRP Advertisement packets are sent and update their interval to be the same as the learned interval.

Prerequisites

A VRRP group has been created.

Precautions

If VRRP smooth switching has been enabled, running the **undo vrrp timer-advertise learning enable** command disables VRRP smooth switching.

The **undo vrrp timer-advertise learning enable** command is valid only for VRRPv2. If VRRPv3 is enabled using the **vrrp version** command, this function does not take effect.

Example

Enable the device to learn the interval for sending VRRP Advertisement packets.

```
<HUAWEI> system-view
[HUAWEI] vrrp timer-advertise learning enable
```

12.2.31 vrrp track bfd gratuitous-arp send enable

Function

The **vrrp track bfd gratuitous-arp send enable** command enables a sub-interface to rapidly send gratuitous ARP packets during an active/standby switchover of a VRRP group triggered by its associated peer BFD session.

The **undo vrrp track bfd gratuitous-arp send enable** command cancels the configuration.

By default, a sub-interface is not enabled to rapidly send gratuitous ARP packets during an active/standby switchover of a VRRP group triggered by its associated peer BFD session.

Format

vrrp track bfd gratuitous-arp send enable

undo vrrp track bfd gratuitous-arp send enable

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

None

Views

GE sub-interface view, MultiGE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a network where association between a VRRP group and a peer BFD session is configured, when the peer BFD session on the backup detects a fault on the active link, the peer BFD session notifies the VRRP group of performing an active/standby switchover. The new master sends gratuitous ARP packets to its downstream Layer 2 device through the software protocol stack so that traffic is switched to the new master.

To speed up traffic switching, run this command to enable a sub-interface to rapidly send gratuitous ARP packets during an active/standby switchover of a VRRP group triggered by its associated peer BFD session. When the peer BFD session on the backup detects the fault on the active link, the hardware rapidly sends gratuitous ARP packets to its downstream Layer 2 device so that traffic is switched to the new master.

Prerequisites

The **vrrp vrid** *virtual-router-id* **track bfd-session** { *bfd-session-id* | **session-name** *bfd-configure-name* } **peer** command has been configured on the sub-interface.

Precautions

Each peer BFD session triggers only one VRRP group to send gratuitous ARP packets.

Example

Enable gigabitethernet0/0/1.1 to rapidly send gratuitous ARP packets during an active/standby switchover of a VRRP group triggered by its associated peer BFD session.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1.1
[HUAWEI-GigabitEthernet0/0/1.1] vrrp vrid 1 track bfd-session 1 peer
[HUAWEI-GigabitEthernet0/0/1.1] vrrp track bfd gratuitous-arp send enable
```

12.2.32 vrrp un-check ttl

Function

The **vrrp un-check ttl** command disables the device from checking the TTL value in VRRP Advertisement packets.

The **undo vrrp un-check ttl** command enables the device to check the TTL value in VRRP Advertisement packets.

By default, the system checks the TTL value in VRRP Advertisement packets.

Format

vrrp un-check ttl

undo vrrp un-check ttl

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

The device checks the TTL value in received VRRP Advertisement packets. If the TTL value in a VRRP Advertisement packet is not 255, the device discards the VRRP Advertisement packet and generates a log about the VRRP Advertisement packet error.

On certain networks, especially on a network where the device interworks with non-Huawei devices, valid packets may be discarded if TTL check is enabled. You can configure the device not to check the TTL value in VRRP Advertisement packets.

Example

Disable the switch from checking the TTL value in VRRP Advertisement packets on VLANIF 100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] vrrp un-check ttl
```

Disable the switch from checking the TTL value in VRRP Advertisement packets on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] vrrp un-check ttl
```

12.2.33 vrrp version

Function

The **vrrp version** command configures a VRRP version number.

The **undo vrrp version** command restores the default VRRP version number.

By default, VRRPv2 is used.

Format

vrrp version { **v2** | **v3** }

undo vrrp version

Parameters

Parameter	Description	Value
v2	Indicates that VRRPv2 is used.	-
v3	Indicates that VRRPv3 is used.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If VRRPv2 and VRRPv3 are used on a network and devices running VRRPv2 need to communicate with devices running VRRPv3, run the **vrrp version** command to specify a VRRP version number.

Precautions

A VRRPv2 group can only send and receive VRRPv2 Advertisement packets. It discards the received VRRPv3 Advertisement packets.

A VRRPv3 group can send and receive both VRRPv2 and VRRPv3 Advertisement packets. You can configure a mode in which VRRPv3 Advertisement packets are sent so that devices running VRRPv2 and VRRPv3 can communicate.

Follow-up Procedure

After VRRPv3 is used, run the **vrrp version-3 send-packet-mode** command in the system view or the **vrrp vrid version-3 send-packet-mode** command in the interface view to configure a mode in which VRRP Advertisement packets are sent.

Example

Set the VRRP version of the device to VRRPv3.

```
<HUAWEI> system-view
[HUAWEI] vrrp version v3
```

12.2.34 vrrp version-3 send-packet-mode

Function

The **vrrp version-3 send-packet-mode** command configures a mode in which VRRPv3 Advertisement packets are sent.

The **undo vrrp version-3 send-packet-mode** command restores the default mode in which VRRPv3 Advertisement packets are sent.

By default, the mode is **v3-only**.

Format

vrrp version-3 send-packet-mode { **v2-only** | **v3-only** | **v2v3-both** }

undo vrrp version-3 send-packet-mode

Parameters

Parameter	Description	Value
v2-only	Indicates that the device sends only VRRPv2 Advertisement packets.	-
v3-only	Indicates that the device sends only VRRPv3 Advertisement packets.	-
v2v3-both	Indicates that the device sends both VRRPv2 and VRRPv3 Advertisement packets.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If devices in a VRRP group use different VRRP version numbers, the VRRP group may fail to negotiate the status. This is because a VRRPv2-enabled device can only receive VRRPv2 Advertisement packets and discards the received VRRPv3 Advertisement packets. You can configure a mode in which VRRP Advertisement packets are sent so that devices running VRRPv2 and VRRPv3 in the VRRP group can negotiate the status.

Precautions

- Only VRRPv3 supports this command.
- If both the **vrrp version-3 send-packet-mode** and **vrrp vrid version-3 send-packet-mode** commands are run, the **vrrp vrid version-3 send-packet-mode** command takes precedence over the **vrrp version-3 send-packet-mode** command.

NOTE

If a large number of VRRP groups are configured, **v2v3-both** is not recommended.

Example

Set the mode in which VRRPv3 Advertisement packets are sent to **v2-only**.

```
<HUAWEI> system-view
[HUAWEI] vrrp version-3 send-packet-mode v2-only
```

12.2.35 vrrp virtual-ip ping enable

Function

The **vrrp virtual-ip ping enable** command enables the master to respond to ping packets sent to a virtual IP address.

The **vrrp virtual-ip ping disable** command disables the master from responding to ping packets sent to a virtual IP address.

The **undo vrrp virtual-ip ping enable** command disables the master from responding to ping packets sent to a virtual IP address.

By default, the master is enabled to respond to ping packets sent to a virtual IP address.

Format

vrrp virtual-ip ping enable

vrrp virtual-ip ping disable

undo vrrp virtual-ip ping enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The switch allows user devices to ping a virtual IP address to serve the following purposes:

- Monitors the operating status of the master in a VRRP group.
- Monitors communication between a user device and a network connected by a default gateway using the virtual IP address.

Precautions

If the ping to a virtual IP address is enabled, a device on an external network can ping a virtual IP address. This imposes the switch to ICMP-based attacks.

After the **undo vrrp virtual-ip ping enable** command is run to disable the master from responding to ping packets sent to a virtual IP address, the host route for the virtual IP address is deleted. As a result, services transmitted using the host route are interrupted. For example, after the **undo vrrp virtual-ip ping enable** command is run, the GRE tunnel with the source IP address of a virtual IP address goes Down.

Example

Disable the master from responding to ping packets.

```
<HUAWEI> system-view
[HUAWEI] undo vrrp virtual-ip ping enable
```

12.2.36 vrrp virtual-ip route-advertise disable

Function

The **vrrp virtual-ip route-advertise disable** command disables a dynamic routing protocol from advertising routes generated by the virtual IP address of a VRRP group.

The **undo vrrp virtual-ip route-advertise disable** command enables a dynamic routing protocol to advertise routes generated by the virtual IP address of a VRRP group.

By default, a dynamic routing protocol is enabled to advertise routes generated by the virtual IP address of a VRRP group.

Format

vrrp virtual-ip route-advertise disable [**isis** | **ospf** | **rip**] *

undo vrrp virtual-ip route-advertise disable

NOTE

Only the S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support **isis**.

Parameters

Parameter	Description	Value
isis	Disables IS-IS from advertising the routes generated by the virtual IP address of a VRRP group.	-
ospf	Disables OSPF from advertising the routes generated by the virtual IP address of a VRRP group.	-
rip	Disables RIP from advertising the routes generated by the virtual IP address of a VRRP group.	-

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Direct routes generated by the virtual IP address of a VRRP group can be imported to a dynamic routing protocol. By default, these routes are advertised by a dynamic routing protocol to neighbors. In practice, a large number of routes may be generated by the virtual IP address of a VRRP group. If a dynamic routing protocol imports theses routes and advertises them to neighbors, there is a heavy burden on network devices and network performance deteriorates. You can run the **vrrp virtual-ip route-advertise disable** command to disable a dynamic routing protocol from advertising routes generated by the virtual IP address of a VRRP group.

Prerequisites

- A virtual IP address has been configured for a VRRP group.
- A dynamic routing protocol has imported routes generated by the virtual IP address of the VRRP group.

Precautions

After the **vrrp virtual-ip route-advertise disable** command is executed, routes generated by virtual IP addresses of all VRRP groups cannot be advertised by a dynamic routing protocol.

The **vrrp virtual-ip route-advertise disable** command is only valid for OSPF and IS-IS.

If routes generated by the virtual IP address of a VRRP group must be advertised by a dynamic routing protocol, do not run the **vrrp virtual-ip route-advertise disable** command.

Example

Disable a dynamic routing protocol from advertising routes generated by the virtual IP address of a VRRP group.

```
<HUAWEI> system-view
[HUAWEI] vrrp virtual-ip route-advertise disable
```

12.2.37 vrrp vrid authentication-mode

Function

The **vrrp vrid authentication-mode** command configures an authentication mode and an authentication key for a VRRP group.

The **undo vrrp vrid authentication-mode** command cancels the authentication mode and authentication key for a VRRP group.

By default, a VRRP group uses non-authentication.

Format

vrrp vrid *virtual-router-id* **authentication-mode** { **simple** { *key* | **plain** *key* | **cipher** *cipher-key* } | **md5** *md5-key* }

undo vrrp vrid *virtual-router-id* **authentication-mode**

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the VRID of a VRRP group.	The value is an integer that ranges from 1 to 255.
simple	Indicates simple authentication.	-
key	Specifies the authentication key in simple authentication mode.	The value is a string of 1 to 8 case-sensitive characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.
plain *key*	Specifies the authentication key in plain text authentication mode. **NOTE** If **plain** is selected, the password is saved in the configuration file in plain text. This brings security risks. It is recommended that you select **cipher** to save the password in cipher text.	The value is a string of 1 to 8 case-sensitive characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
cipher *cipher-key*	Specifies the authentication key in cipher text authentication mode.	The value a string of case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string. Passwords are saved in ciphertext in the configuration file with the length of 48. Either of the following passwords can be set: ● A simple text password is a string of 1 to 8 characters. ● A ciphertext password is a string of 32 or 48 characters. **NOTE** A 32-character ciphertext password configured in an earlier version is also supported in this version.
md5 *md5-key*	Specifies the authentication key in MD5 authentication mode.	The value a string of case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string. Passwords are saved in ciphertext in the configuration file with the length of 48. Either of the following passwords can be set: ● A simple text password is a string of 1 to 8 characters. ● A ciphertext password is a string of 24, or 32, or 48 characters. **NOTE** A 32-character ciphertext password configured in an earlier version is also supported in this version.

NOTE

For security purposes, you are advised to use MD5 as the authentication algorithm of VRRP.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To be compatible with VRRP defined in earlier version and interwork with other devices, VRRP provides simple authentication and MD5 authentication. The **vrrp vrid authentication-mode** command configures an authentication mode and an authentication key for a VRRP group.

Prerequisites

A VRRP group has been configured on a specified interface.

Precautions

Devices in a VRRP group must be configured with the same authentication mode and authentication key; otherwise, the VRRP group cannot negotiate the Master and Backup states.

Example

Set the authentication mode of the VRRP group with VRID 2 on VLANIF100 to MD5 authentication and set the authentication key to **Huawei-1**.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] vrrp vrid 2 virtual-ip 10.1.1.1
[HUAWEI-Vlanif100] vrrp vrid 2 authentication-mode md5 Huawei-1
```

Set the authentication mode of the VRRP group with VRID 2 on GE0/0/1 to MD5 authentication and set the authentication key to **Huawei-1**.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] vrrp vrid 2 virtual-ip 10.1.1.1
[HUAWEI-GigabitEthernet0/0/1] vrrp vrid 2 authentication-mode md5 Huawei-1
```

12.2.38 vrrp vrid backup-forward

Function

The **vrrp vrid backup-forward** command enables the backup device in a VRRP backup group to forward traffic.

The **undo vrrp vrid backup-forward** command disables the backup device in a VRRP backup group from forwarding traffic.

By default, the backup device in a VRRP backup group is disabled from forwarding traffic.

Format

vrrp vrid *virtual-router-id* **backup-forward**

undo vrrp vrid *virtual-router-id* **backup-forward**

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
virtual-router-id	Specifies the ID of a VRRP backup group.	The value is an integer ranging from 1 to 255.

Views

GE sub-interface view, MultiGE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VE sub-interface view

2: Configuration level

Usage Guidelines

Usage Scenario

On large aggregation networks of enterprises, terminal users use active and standby links to access aggregation devices that have a VRRP backup group deployed. The aggregation device connects to the active link is the master device, and that connects to the standby link is the backup device. If the active link or the master device fails, a link switchover occurs. However, the master/backup switchover in the VRRP backup group has not yet completed. Therefore, a traffic interruption occurs and lasts for a short period.

To prevent traffic interruptions in such scenarios, run the **vrrp vrid backup-forward** command to enable the backup device in a VRRP backup group to forward traffic. This configuration ensures carrier-class reliability.

Prerequisites

A VRRP backup group has been created using the **vrrp vrid virtual-ip** command in the interface view.

Precautions

The backup device can forward traffic with the destination MAC address being the virtual MAC address. If a downstream switch broadcasts a packet with the destination MAC address being the virtual MAC address, the backup device will also forward this packet. Therefore, two copies of this packet will be sent. To prevent duplicate traffic, do not run the **vrrp vrid backup-forward** command in scenarios other than the one where high reliability is required on large aggregation networks of enterprises.

Example

Create VRRP backup group 1 on GE0/0/2.1 and enable the backup device in the VRRP backup group to forward traffic.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/2.1
[HUAWEI-GigabitEthernet0/0/2.1] vrrp vrid 1 virtual-ip 10.1.1.100
[HUAWEI-GigabitEthernet0/0/2.1] vrrp vrid 1 backup-forward
```

12.2.39 vrrp vrid preempt-mode disable

Function

The **vrrp vrid preempt-mode disable** command configures the device in a VRRP group in non-preemption mode.

The **undo vrrp vrid preempt-mode** command restores the default preemption mode.

By default, the device uses the immediate preemption mode.

Format

vrrp vrid *virtual-router-id* **preempt-mode disable**

undo vrrp vrid *virtual-router-id* **preempt-mode**

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the VRID of a VRRP group.	The value is an integer that ranges from 1 to 255.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To enable the device with higher priority in a VRRP group to be the master, set the preemption mode on the device. In non-preemption mode, as long as the master is working properly, the backup with higher priority cannot be the master.

NOTE

When non-preemption is disabled, the preemption delay is restored to 0 seconds immediately.

Prerequisites

The **vrrp vrid virtual-ip** command has been executed on an interface to create a VRRP group.

Example

Configure VRRP group 1 in non-preemption mode on the VLANIF interface.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] vrrp vrid 1 virtual-ip 10.1.1.2
[HUAWEI-Vlanif100] vrrp vrid 1 preempt-mode disable
```

Configure VRRP group 1 in non-preemption mode on the Ethernet interface.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] vrrp vrid 1 virtual-ip 10.1.1.2
[HUAWEI-GigabitEthernet0/0/1] vrrp vrid 1 preempt-mode disable
```

12.2.40 vrrp vrid preempt-mode timer delay

Function

The **vrrp vrid preempt-mode timer delay** command sets the preemption delay for the device in a VRRP group.

The **undo vrrp vrid preempt-mode timer delay** command restores the default preemption delay for the device in a VRRP group.

By default, the preemption delay is 0 seconds.

Format

vrrp vrid *virtual-router-id* **preempt-mode timer delay** *delay-value*

undo vrrp vrid *virtual-router-id* **preempt-mode timer delay**

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the VRID of a VRRP group.	The value is an integer that ranges from 1 to 255.

Parameter	Description	Value
delay *delay-value*	Specifies the preemption delay.	The value is an integer that ranges from 0 to 3600, in seconds. The default value is 0.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the backup in a VRRP group does not receive VRRP Advertisement packets from the master within a specified period of time, the backup becomes the master. On an unstable network, even if the master is working properly, the backup may not receive packets from the master because of network congestion. In this case, the VRRP group status will flap and traffic is lost. To prevent frequent switching of the VRRP group status, run the **vrrp vrid preempt-mode timer delay** command to set the preemption delay so that the backup becomes the master only after the delay expires.

Precautions

You are advised to set the preemption delay of the backup in a VRRP group to 0, configure the master in preemption mode, and set the preemption delay to be longer than 15s. These settings allow a period of time for status synchronization between the uplink and downlink on devices in a VRRP group on an unstable network. If the preceding settings are not used, two masters coexist and user devices may learn an incorrect master address. As a result, traffic is interrupted.

- The preemption delay refers to the delay before the backup switches to the master. Therefore, the IP address owner is irrelevant to the preemption delay. After the IP address owner recovers, it becomes the master immediately, without any delay.
- On a stable network, a short preemption delay is recommended. When the master is faulty, the backup with the highest priority can rapidly switch to the master. This prevents traffic loss. On an unstable network, a long preemption delay is recommended. This prevents traffic loss caused by frequent switching of the VRRP group status.

Example

Set the preemption delay of VRRP group 1 to 5 seconds on the VLANIF interface.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] vrrp vrid 1 preempt-mode timer delay 5
```

Set the preemption delay of VRRP group 1 to 5 seconds on the Ethernet interface.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] vrrp vrid 1 preempt-mode timer delay 5
```

12.2.41 vrrp vrid priority

Function

The **vrrp vrid priority** command sets the priority of the device in a VRRP group.

The **undo vrrp vrid priority** command restores the default priority of the device in a VRRP group.

By default, the priority of the device in a VRRP group is 100.

Format

vrrp vrid *virtual-router-id* **priority** *priority-value*

undo vrrp vrid *virtual-router-id* **priority**

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the VRID of a VRRP group.	The value is an integer that ranges from 1 to 255.
priority *priority-value*	Specifies the priority of the device in a VRRP group.	The value is an integer that ranges from 1 to 254. A larger value indicates a higher priority.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure the device in a VRRP group as the default gateway, run the **vrrp vrid priority** command to specify the highest priority for the device so that the device can become the master.

Prerequisites

The **vrrp vrid virtual-ip** command has been executed to create a VRRP group.

Precautions

- Priority 0 is reserved in the system. Priority 255 is reserved for the IP address owner.
- When devices in a VRRP group have the same priority, the device that first changes to master state becomes the master. If devices attempt to be the master simultaneously, the device where the interface with the largest IP address is located becomes the master.

Example

Set the priority of the switch in VRRP group 1 to 150 on the VLANIF interface.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] vrrp vrid 1 virtual-ip 10.1.1.2
[HUAWEI-Vlanif100] vrrp vrid 1 priority 150
```

Set the priority of the switch in VRRP group 1 to 150 on the Ethernet interface.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] vrrp vrid 1 virtual-ip 10.1.1.2
[HUAWEI-GigabitEthernet0/0/1] vrrp vrid 1 priority 150
```

12.2.42 vrrp vrid timer advertise

Function

The **vrrp vrid timer advertise** command sets the interval at which the master sends VRRP Advertisement packets.

The **undo vrrp vrid timer advertise** command restores the default interval at which the master sends VRRP Advertisement packets.

By default, the master sends VRRP Advertisement packets every 1 second.

Format

vrrp vrid *virtual-router-id* **timer advertise** *advertise-interval*

undo vrrp vrid *virtual-router-id* **timer advertise**

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the VRID of a VRRP group.	The value is an integer that ranges from 1 to 255.

Parameter	Description	Value
advertise *advertise-interval*	Specifies the interval at which the master sends VRRP Advertisement packets.	The value is an integer, in seconds. In VRRPv2, the value ranges from 1 to 255. In VRRPv3, the value ranges from 1 to 40.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The master in a VRRP group sends VRRP Advertisement packets to backups at intervals to notify that it is working properly. If the backup with the highest priority does not receive any VRRP Advertisement packets from the master at the specified interval, it considers the master faulty and becomes the master. The **vrrp vrid timer advertise** command sets the interval at which the master sends VRRP Advertisement packets.

Prerequisites

The **vrrp vrid virtual-ip** command has been executed on an interface to create a VRRP group.

Precautions

If a longer interval is used, backups in the same VRRP group cannot detect the fault on the master in a timely manner, causing packet loss. If a shorter interval is used, system resources are occupied. In addition, when network traffic is heavy or the network is unstable, backups may not receive packets after the Master_Down_Interval timer expires. As a result, the VRRP group status is incorrectly switched. Set the interval based on actual networking. The algorithm for calculating the value of the Master_Down_Interval timer is as follows:

Master_Down_Interval = (3 x Advertisement_Interval) + Skew_time

Skew_Time = (256 – Priority) / 256

When the interval for sending VRRP Advertisement packets on the master and backup in the same VRRP group is different, the master sends VRRP Advertisement packets at the configured interval.

Example

Set the interval at which the master in VRRP group 1 sends VRRP Advertisement packets to 5 seconds on the VLANIF interface.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] vrrp vrid 1 virtual-ip 10.1.1.2
[HUAWEI-Vlanif100] vrrp vrid 1 timer advertise 5
```

Set the interval at which the master in VRRP group 1 sends VRRP Advertisement packets to 5 seconds on the Ethernet interface.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] vrrp vrid 1 virtual-ip 10.1.1.2
[HUAWEI-GigabitEthernet0/0/1] vrrp vrid 1 timer advertise 5
```

12.2.43 vrrp vrid track admin-vrrp vrid

Function

The **vrrp vrid track admin-vrrp vrid** command binds a VRRP group to an mVRRP group.

The **undo vrrp vrid track admin-vrrp** command unbinds a VRRP group from an mVRRP group.

By default, no VRRP group is bound to an mVRRP group.

Format

vrrp vrid *virtual-router-id1* **track admin-vrrp interface** *interface-type interface-number* **vrid** *virtual-router-id2* **unflowdown**

undo vrrp vrid *virtual-router-id1* **track admin-vrrp**

Parameters

Parameter	Description	Value
vrid *virtual-router-id1*	Specifies the VRID of a VRRP group.	The value is an integer that ranges from 1 to 255.
vrid *virtual-router-id2*	Specifies the VRID of an mVRRP group.	The value is an integer that ranges from 1 to 255.
interface-type interface-number	Specifies the type and number of an interface configured with an mVRRP group. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Parameter	Description	Value
unflowdown	Allows the interface where a VRRP group bound to an mVRRP group is configured to remain in Up state if the mVRRP group is in Backup or Initialize state.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If multiple VRRP groups are configured on the device, each group sends VRRP Advertisement packets to maintain its state machine. As a result, a large number of VRRP Advertisement packets are generated, which occupy network bandwidth resources and cause CPU performance to deteriorate. To solve the problem, run the **vrrp vrid track admin-vrrp vrid** command to bind a VRRP group to an mVRRP group. After a VRRP group is bound to an mVRRP group, the VRRP group does not send VRRP Advertisement packets to negotiate the Master and Backup states. The mVRRP group determines the status of the bound VRRP group. This method greatly reduces the impact of VRRP Advertisement packets on network bandwidth and CPU performance.

This mode is used on a network where uplink and downlink traffic can be transmitted along different paths. **unflowdown** can be configured to allow the mVRRP group to determine the status of its bound VRRP group. Uplink traffic travels through the master and then reaches the upper-layer network, and downlink traffic travels through either the master or backup to reach users.

Prerequisites

A VRRP group and an mVRRP group have been created.

Precautions

The **vrrp vrid track admin-vrrp vrid** command can be used only on the interface where the bound VRRP group is configured. This command cannot be used on the interface where an mVRRP group is configured.

VRRP4 and VRRP6 can be configured on an interface simultaneously. However, there are limitations:

- A VRRP4 group can be bound to only an mVRRP4 group, and a VRRP6 group can be bound to only an mVRRP6 group.

- At most one VRRP4 group and one VRRP6 group can be configured on an interface. In addition, **unflowdown** must be used. An interface cannot be configured with multiple VRRP4 or VRRP6 groups.

If multiple service VRRP backup groups are configured on an interface, a single service VRRP backup group can be bound to the mVRRP backup group.

Example

Bind VRRP group 1 to mVRRP group 2 on the VLANIF interface.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] vrrp vrid 1 track admin-vrrp interface vlanif 20 vrid 2 unflowdown
```

Bind VRRP group 1 to mVRRP group 2 on the Ethernet interface.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] vrrp vrid 1 track admin-vrrp interface GigabitEthernet 0/0/2 vrid 2
unflowdown
```

12.2.44 vrrp vrid track bfd-session

Function

The **vrrp vrid track bfd-session** command associates a VRRP group with a BFD session.

The **undo vrrp vrid track bfd-session** command disassociates a VRRP group from a BFD session.

By default, a VRRP group is not associated with a BFD session.

NOTE

Only the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

vrrp vrid *virtual-router-id* **track bfd-session** { *bfd-session-id* | **session-name** *bfd-configure-name* } [**increased** *value-increased* | **reduced** *value-reduced*]

undo vrrp vrid *virtual-router-id* **track bfd-session** [*bfd-session-id* | **session-name** *bfd-configure-name*]

vrrp vrid *virtual-router-id* **track bfd-session** { *bfd-session-id* | **session-name** *bfd-configure-name* } **peer** (Only the sub-interfaces of the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command)

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the VRID of a VRRP group.	The value is an integer that ranges from 1 to 255.
bfd-session-id	Specifies the local discriminator of the monitored BFD session.	The value is an integer that ranges from 1 to 8191.
session-name *bfd-configure-name*	Specifies the name of the monitored BFD session.	The value is a string of 1 to 15 case-insensitive characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.
increased *value-increased*	Specifies the value by which the priority increases when the monitored BFD session becomes Down.	The value is an integer that ranges from 1 to 255. The maximum priority value is 254.
reduced *value-reduced*	Specifies the value by which the priority decreases when the monitored BFD session becomes Down.	The value is an integer that ranges from 1 to 255. The priority can decrease to 1. By default, when the monitored BFD session becomes Down, the VRRP priority decreases by 10.
peer	Indicates that the monitored BFD session is a peer BFD session.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Association between a VRRP group and a BFD session implements the following functions:

1. Rapid active/standby switchover: When the link of a VRRP group or the master is faulty, the backup becomes the master after a certain period of time (second level), causing packet loss. You can associate the VRRP group with a BFD session on the backup so that the BFD session can rapidly detect communication faults of the VRRP group. When the BFD session detects a fault, it notifies the VRRP group that the priority of the backup needs to be increased. Then an active/standby switchover is triggered immediately. This millisecond-level switchover reduces traffic loss. When the monitored BFD session recovers, the original priority of the device in the VRRP group is restored.
2. Monitoring the uplink: Because VRRP cannot detect faults on the uplink of a VRRP group, services are interrupted. You can associate the VRRP group with a BFD session on the master so that the BFD session monitors the uplink status of the master. When the BFD session detects a fault on the uplink, it notifies the VRRP group that the priority of the master needs to be decreased. Then an active/standby switchover is triggered immediately. This reduces the impact of the uplink fault on service forwarding. When the monitored BFD session recovers, the original priority of the device in the VRRP group is restored.

Prerequisites

A VRRP group has been created and a static BFD session or a static BFD session with automatically negotiated discriminators has been created.

Precautions

After a VRRP group is associated with a BFD session, the BFD session type cannot be modified. Before deleting the BFD session type, you must delete all original configurations.

After a VRRP group is associated with a BFD session, set **increased** *value-increased* or **reduced** *value-reduced* to an appropriate value. This setting ensures that an active/standby switchover is performed immediately when the monitored BFD session becomes Down.

Multiple VRRP groups can monitor a BFD session, and a VRRP group can monitor a maximum of eight BFD sessions simultaneously.

NOTE

When associating a VRRP group with a BFD session, note the following points:

- The master and backup in the VRRP group must work in preemption mode. It is recommended that the preemption delay be 0 on the backup and larger than 0 on the master.
- If an IP address owner exists in the VRRP group, the VRRP group cannot monitor the BFD session.
- If **session-name** *bfd-configure-name* is specified, the VRRP group can be bound to only the static BFD session with automatically negotiated discriminators.
- If *bfd-session-id* is specified, the VRRP group can be bound to only the static BFD session.

Example

Configure VRRP group 1 to monitor the BFD session with local discriminator 1 on VLANIF 100.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] bfd abc bind peer-ip 10.1.1.1 interface vlanif 100
[HUAWEI-bfd-session-abc] discriminator local 1
[HUAWEI-bfd-session-abc] discriminator remote 2
[HUAWEI-bfd-session-abc] commit
[HUAWEI-bfd-session-abc] quit
[HUAWEI] interface vlanif 100

12.2.45 vrrp vrid track interface

Function

The **vrrp vrid track interface** command associates a VRRP group with an interface.

The **undo vrrp vrid track interface** command disassociates a VRRP group from an interface.

By default, a VRRP group is not associated with an interface.

Format

vrrp vrid *virtual-router-id* **track interface** *interface-type interface-number* [**increased** *value-increased* | **reduced** *value-reduced*]

undo vrrp vrid *virtual-router-id* **track interface** [*interface-type interface-number*]

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the VRID of a VRRP group.	The value is an integer that ranges from 1 to 255.
interface *interface-type interface-number*	Specifies the type and number of an interface monitored by a VRRP group. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number. **NOTE** A VRRP backup group can track Layer 2 and Layer 3 interfaces. ● If the tracked interface is a Layer 2 interface, the VRRP backup group tracks the physical status of the Layer 2 interface and changes its own priority based on the tracked physical status. ● If the tracked interface is a Layer 3 interface, the VRRP backup group tracks the protocol status of the Layer 3 interface and changes its own priority based on the tracked protocol status.	-
increased *value-increased*	Specifies the value by which the priority increases when the monitored interface becomes Down.	The value is an integer that ranges from 1 to 255. The maximum priority value is 254.

Parameter	Description	Value
reduced *value-reduced*	Specifies the value by which the priority decreases when the monitored interface becomes Down.	The value is an integer that ranges from 1 to 255. The priority can decrease to 1. By default, when the monitored interface goes Down, the VRRP priority of the device decreases by 10.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

VRRP can only detect the status change of the interface on which a VRRP group is configured. VRRP cannot detect faults on the uplink interface, causing service interruption. You can run the **vrrp vrid track interface** command to associate a VRRP group with a device interface not in the VRRP group. When the monitored interface becomes Down, the priority of the device is adjusted and an active/standby switchover is triggered. Therefore, services can be forwarded correctly. When the status of the monitored interface recovers, the original priority of the device in the VRRP group is restored.

Prerequisites

The **vrrp vrid virtual-ip** command has been executed on an interface to create a VRRP group.

Precautions

After a VRRP group is associated with an interface, set **increased** *value-increased* or **reduced** *value-reduced* to an appropriate value. This setting ensures that an active/standby switchover is performed immediately when the monitored interface becomes Down.

NOTE

- The master and backup in the VRRP group must work in preemption mode. It is recommended that the preemption delay be 0 on the backup and larger than 0 on the master.
- If the device is the IP address owner (the virtual router IP address is used as the actual interface address), you cannot associate a VRRP group with an interface.
- Multiple VRRP groups can monitor an interface, and a VRRP group can monitor a maximum of 8 interfaces simultaneously.

Example

Associate VRRP group 1 with VLANIF 10 and set **reduced** *value-reduced* to 50 when VLANIF 10 becomes Down.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 20
[HUAWEI-Vlanif20] vrrp vrid 1 virtual-ip 10.1.1.1
[HUAWEI-Vlanif20] vrrp vrid 1 track interface vlanif 10 reduced 50
```

Associate VRRP group 1 with GE0/0/2 and set reduced *value-reduced* to 50 when GE0/0/2 becomes Down.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] vrrp vrid 1 virtual-ip 10.1.1.1
[HUAWEI-GigabitEthernet0/0/1] vrrp vrid 1 track interface gigabitethernet0/0/2 reduced 50
```

12.2.46 vrrp vrid track ip route

Function

The **vrrp vrid track ip route** command associates a VRRP group with a route.

The **undo vrrp vrid track ip route** command disassociates a VRRP group from a route.

By default, a VRRP group is not associated with a route.

Format

vrrp vrid *virtual-router-id* **track ip route** *ip-address* { *mask-address* | *mask-length* } [**vpn-instance** *vpn-instance-name*] [**reduced** *value-reduced*]

undo vrrp vrid *virtual-router-id* **track ip route** [*ip-address* { *mask-address* | *mask-length* } [**vpn-instance** *vpn-instance-name*]]

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the VRID of a VRRP group.	The value is an integer that ranges from 1 to 255.
ip-address	Specifies the destination address of the monitored route.	The value is in dotted decimal notation.
mask-address	Specifies the mask of the destination address of the monitored route.	The value is in dotted decimal notation.
mask-length	Specifies the mask length of the destination address of the monitored route.	The value is an integer that ranges from 0 to 32.

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
reduced *value-reduced*	Specifies the value by which the master's priority decreases if the monitored route is withdrawn or becomes inactive.	The value is an integer that ranges from 1 to 255. The priority can decrease to 1. By default, the master's priority decreases by 10 if the associated route is withdrawn or becomes inactive.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To improve device reliability, two user gateways are configured to work in master/backup mode, and VRRP is enabled on these gateways to determine their Master and Backup states. Although a VRRP group has been configured, access devices may not detect route changes caused by the faulty uplink or network topology change. Consequently, data traffic is lost.

You can associate a VRRP group with a route for forwarding uplink traffic. When the route is withdrawn or becomes inactive, the master' priority is adjusted and an active/standby switchover is performed. When the status of the monitored route recovers, the original priority of the master in the VRRP group is restored.

Pre-configuration Tasks

A VRRP group and a routing protocol such as OSPF or IS-IS have been configured.

Precautions

The VRRP group to be associated with a route cannot contain an IP address owner.

The master and backup in the VRRP group must work in preemption mode. It is recommended that the preemption delay be 0 on the backup and non-0 on the master.

When associating a VRRP group with a route in a VPN instance, note the following points:

- If the VPN instance does not exist, association between the VRRP group and the VPN route cannot work.
- If the VPN instance is deleted after the VRRP group is associated with the VPN route, association between the VRRP group and the VPN route is also deleted.

Multiple VRRP groups can monitor a route, and a VRRP group can monitor a maximum of eight routes simultaneously.

Example

Configure VRRP group 1 to monitor the route on 10.2.1.0, and set the value by which the master's priority decreases if the monitored route is withdrawn or becomes inactive to 20.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] vrrp vrid 1 virtual-ip 10.1.1.12
[HUAWEI-Vlanif100] vrrp vrid 1 track ip route 10.2.1.0 24 reduced 20
```

12.2.47 vrrp vrid track nqa

Function

The **vrrp vrid track nqa** command associates a VRRP group with an NQA test instance to implement a rapid active/standby switchover.

The **undo vrrp vrid track nqa** command disassociates a VRRP group from an NQA test instance.

By default, a VRRP group is not associated with an NQA test instance.

Format

vrrp vrid *virtual-router-id* **track nqa** *admin-name test-name* [**reduced** *value-reduced*]

undo vrrp vrid *virtual-router-id* **track nqa** [*admin-name test-name*]

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the VRID of a VRRP group.	The value is an integer that ranges from 1 to 255.
admin-name	Specifies the administrator name of an NQA test instance.	The value is a string of 1 to 32 case-sensitive characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
test-name	Specifies the name of an NQA test instance.	The value is a string of 1 to 32 case-sensitive characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.
reduced *value-reduced*	Specifies the value by which the master's priority reduces if the NQA test instance detects that the uplink is unavailable.	The value is an integer that ranges from 1 to 255. The priority can decrease to 1. By default, the master's priority value decreases by 10 if the associated NQA test instance detects that the uplink is unavailable.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To improve device reliability, two user gateways are configured to work in master/backup mode, and VRRP is enabled on these gateways to determine their Master and Backup states. Although a VRRP group has been configured, the uplink may be unreachable and access devices may not detect the faulty uplink. Consequently, data traffic is lost.

You can associate a VRRP group with an NQA test instance to solve this problem. The NQA test instance periodically sends ICMP packets to detect whether the destination IP address of the uplink is reachable. When the destination IP address is unreachable, the NQA test instance reports the fault to the associated VRRP group and instructs the VRRP group to adjust the priority, implementing an active/standby switchover. When the status of the monitored NQA test instance recovers, the original priority of the master in the VRRP group is restored.

Prerequisites

An NQA test instance of ICMP has been configured.

Precautions

- The master and backup in the VRRP group must work in preemption mode. It is recommended that the preemption delay be 0 on the backup and non-0 on the master.
- The VRRP group to be associated with a route cannot contain an IP address owner.
- The VRRP group can only be associated with an NQA test instance of ICMP.
- A VRRP group can monitor a maximum of eight NQA test instances.

Example

Associate a VRRP group with NQA test instance **user user1** on VLANIF100 and set **reduced** *value-reduced* to 20 when the destination IP address is unreachable.

```
<HUAWEI> system-view
[HUAWEI] nqa test-instance user user1
[HUAWEI-nqa-user-user1] test-type icmp
[HUAWEI-nqa-user-user1] destination-address ipv4 10.1.1.1
[HUAWEI-nqa-user-user1] frequency 10
[HUAWEI-nqa-user-user1] probe-count 2
[HUAWEI-nqa-user-user1] start now
[HUAWEI-nqa-user-user1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] vrrp vrid 1 virtual-ip 10.2.1.12
[HUAWEI-Vlanif100] vrrp vrid 1 track nqa user user1 reduced 20
```

12.2.48 vrrp vrid version-3 send-packet-mode

Function

The **vrrp vrid version-3 send-packet-mode** command configures a mode in which VRRPv3 Advertisement packets are sent on an interface.

The **undo vrrp vrid version-3 send-packet-mode** command restores the default mode.

By default, VRRPv3 Advertisement packets are sent in **v3-only** mode.

Format

vrrp vrid *virtual-router-id* **version-3 send-packet-mode** { **v2-only** | **v3-only** | **v2v3-both** }

undo vrrp vrid *virtual-router-id* **version-3 send-packet-mode**

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the VRID of a VRRP group.	The value is an integer that ranges from 1 to 255.
v2-only	Indicates that only VRRPv2 Advertisement packets are sent.	-

Parameter	Description	Value
v3-only	Indicates that only VRRPv3 Advertisement packets are sent.	-
v2v3-both	Indicates that both VRRPv2 and VRRPv3 Advertisement packets are sent.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If devices in a VRRP group use different VRRP version numbers, the VRRP group may fail to negotiate the status. This is because a VRRPv2-enabled device can only receive VRRPv2 Advertisement packets and discards the received VRRPv3 Advertisement packets. You can set the mode in which VRRP Advertisement packets are sent on the VRRPv3-enabled device so that the VRRPv2-enabled and VRRPv3-enabled devices can negotiate the status.

Precautions

- Only VRRPv3 supports this command.
- If the **vrrp version-3 send-packet-mode** command is used in the system view and interface view simultaneously, the configuration in the interface view takes effect.

NOTE

If a large number of VRRP groups are configured, **v2v3-both** is not recommended.

Example

Set the mode in which VRRPv3 Advertisement packets are sent to **v2-only** on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] vrrp version v3
[HUAWEI] vrrp version-3 send-packet-mode v2-only
Warning: The globally configured packet sending mode will take effect for every VRRP backup
group.Continue?[Y/N]:y
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] vrrp vrid 24 version-3 send-packet-mode v2-only
```

Set the mode in which VRRPv3 Advertisement packets are sent to **v2-only** on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] vrrp version v3
[HUAWEI] vrrp version-3 send-packet-mode v2-only
Warning: The globally configured packet sending mode will take effect for every VRRP backup
group.Continue?[Y/N]:y
```

```
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] vrrp vrid 24 version-3 send-packet-mode v2-only
```

12.2.49 vrrp vrid virtual-ip

Function

The **vrrp vrid virtual-ip** command creates a VRRP group and assigns a virtual IP address to the group.

The **undo vrrp vrid virtual-ip** command deletes the virtual IP address of a VRRP group.

By default, no VRRP group is created.

Format

vrrp vrid *virtual-router-id* **virtual-ip** *virtual-address*

undo vrrp vrid *virtual-router-id* [**virtual-ip** *virtual-address*]

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the VRID of a VRRP group.	The value is an integer that ranges from 1 to 255.
virtual-ip *virtual-address*	Specifies the virtual IP address of a VRRP group.	The value is in dotted decimal notation.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In practice, hosts use the default gateway to communicate with external networks. As value-added services such as IPTV or video conferencing services are widely deployed, hosts may fail to communicate with external networks if the default gateway fails. Configuring dynamic routing protocols such as RIP, OSPF, or ICMP can improve system reliability. However, it is difficult to configure dynamic routing protocols and some hosts may not support dynamic routing protocols. VRRP virtualizes multiple routing devices into a virtual router without changing the networking. The virtual router IP address is configured as the default gateway address.

If users on a network have the same reliability requirements, configure multiple virtual IP addresses for a VRRP group. By doing this, one virtual IP address serves one separate user group, and the default gateway address remains consistent regardless of changes in VRRP device locations. A VRRP group can be assigned a maximum of 16 virtual IP addresses.

Precautions

The MAC address of the VBDIF must differ from the virtual MAC address of the VRRP group. (The last two bits of the VRRP virtual MAC address are determined by the VRID. For example, The VRID of the virtual router composed of SwitchA and SwitchB is 3, so the MAC address of the VRRP group is 00-00-5E-00-01-03).

If all the virtual IP addresses in a VRRP group are deleted, the VRRP group is deleted automatically.

For VRRP4 or VRRP6 groups configured on a device, each VRID can be bound to a maximum of 16 ports.

After the **vrrp vrid virtual-ip** command is run on an interface, when the ARP entries learned by the interface are aged, the device sends ARP aging probe packets with the source IP address being the interface's IP address. The virtual IP address of the interface is not used as the source IP address.

When VRRP and static ARP are configured simultaneously, note the following points:

- When VRRP is configured on a VLANIF interface or Ethernet interface, the IP address corresponding to the VLANIF interface or Ethernet interface in a static ARP entry cannot be set to the virtual IP address of a VRRP group. Otherwise, services cannot be forwarded between devices. For example, if a static ARP entry contains IP address 10.1.1.1, the IP address 10.1.1.1 cannot be used as the virtual IP address.
- When VRRP is configured on a VLANIF interface or Ethernet interface, the virtual IP address of a VRRP group cannot be used as the IP address corresponding to the VLANIF interface or Ethernet interface in a static ARP entry. Otherwise, services cannot be forwarded between devices. For example, if the VRRP group uses virtual IP address 10.1.1.1, the IP address 10.1.1.1 cannot be used in a static ARP entry.

NOTE

- VRRP groups must use different virtual IP addresses.
- Two devices in a VRRP group must be configured with the same VRID.
- VRRP groups on different interfaces of a device can be configured with the same VRID.
- A virtual IP address must be different from the IP address of a user host. If the user host IP address is the same as the virtual IP address, all packets on the local network segment are sent to the user host. As a result, data of this network segment cannot be forwarded correctly.

Example

Create a VRRP group on VLANIF 100 with ID 1 and virtual IP address 10.10.10.10.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] vrrp vrid 1 virtual-ip 10.10.10.10
```

Create a VRRP group with VRID 1 and virtual IP address 10.10.10.10 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] vrrp vrid 1 virtual-ip 10.10.10.10
```

12.2.50 vrrp6 nd send-mode simple

Function

The **vrrp6 nd send-mode simple** command enables a sub-interface for QinQ VLAN tag termination to send double-tagged ND packets carrying only the minimal inner VLAN ID when the VRRP status of the sub-interface in the Virtual Router Redundancy Protocol for IPv6 (VRRP6) backup group is master.

The **undo vrrp6 nd send-mode simple** command enables a sub-interface for QinQ VLAN tag termination to send double-tagged ND packets to all VLANs specified by the outer VLAN IDs and inner VLAN IDs when the VRRP status of the sub-interface in the VRRP6 backup group is master.

By default, double-tagged ND packets are sent to all VLANs specified by the outer VLAN IDs and inner VLAN IDs.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

vrrp6 nd send-mode simple

undo vrrp6 nd send-mode simple

Parameters

None

Views

Eth-Trunk sub-interface view, GE sub-interface view, MultiGE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

A sub-interface for QinQ VLAN tag termination sends double-tagged ND packets when the VRRP status of the sub-interface in the VRRP backup group is master. If there is a range for the inner VLAN IDs, the sub-interface sends ND packets to all VLANs in this range to update VRRP backup group's MAC address entry on a downstream switch, exposing a heavy burden on the system. To prevent this problem, you can use the **vrrp6 nd send-mode simple** command to allow an ND packet carrying only the minimal inner VLAN ID to be sent, reducing the number of ND packets to be sent.

NOTE

The **vrrp6 nd send-mode simple** command takes effect within VLANs specified only by inner VLAN IDs rather than outer VLAN IDs. For example, VLAN IDs in the outer tag range from 1 to 10 and VLAN IDs in the inner tag range from 1 to 10. After the **vrrp6 nd send-mode simple** command is run, ND packets carrying only inner VLAN 1 and outer VLAN IDs ranging from 1 to 10 are sent. 10 ND packets (10 outer VLAN IDs x 1 inner VLAN ID) are sent.

The **vrrp6 nd send-mode simple** command is configured only on a sub-interface for QinQ VLAN tag termination.

Example

Allow ND packets carrying only inner VLAN 1 to be sent.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet0/0/1.1
[HUAWEI-GigabitEthernet0/0/1.1] qinq termination pe-vid 5 ce-vid 1 to 10
[HUAWEI-GigabitEthernet0/0/1.1] quit
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet0/0/1.1
[HUAWEI-GigabitEthernet0/0/1.1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1.1] ipv6 address auto link-local
[HUAWEI-GigabitEthernet0/0/1.1] vrrp6 vrid 1 virtual-ip FE80::7 link-local
[HUAWEI-GigabitEthernet0/0/1.1] vrrp6 nd send-mode simple
```

12.2.51 vrrp6 un-check hop-limit

Function

The **vrrp6 un-check hop-limit** command disables the device from checking the TTL value in VRRP6 Advertisement packets.

The **undo vrrp6 un-check hop-limit** command enables the device to check the TTL value in VRRP6 Advertisement packets.

By default, the system checks the TTL value in VRRP6 Advertisement packets.

Format

vrrp6 un-check hop-limit

undo vrrp6 un-check hop-limit

Parameters

None

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, MultiGE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, MultiGE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

The device checks the TTL value in received VRRP6 Advertisement packets. If the TTL value of a VRRP6 Advertisement packet is not 255, the device discards the packet.

On certain networks, especially on a network where the device interworks with non-Huawei devices, valid packets may be discarded if TTL check is enabled. You can configure the device not to check the TTL value in VRRP6 Advertisement packets.

Example

Disable the device from checking the TTL value in VRRP6 Advertisement packets on VLANIF 100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] vrrp6 un-check hop-limit
```

Disable the device from checking the TTL value in VRRP6 Advertisement packets on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] vrrp6 un-check hop-limit
```

12.2.52 vrrp6 vrid preempt-mode disable

Function

The **vrrp6 vrid preempt-mode disable** command configures the device in a VRRP6 group in non-preemption mode.

The **undo vrrp6 vrid preempt-mode** command restores the default preemption mode.

By default, the device uses the immediate preemption mode.

Format

vrrp6 vrid *virtual-router-id* **preempt-mode disable**

undo vrrp6 vrid *virtual-router-id* **preempt-mode**

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the VRID of a VRRP6 group.	The value is an integer that ranges from 1 to 255.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, MultiGE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, MultiGE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To enable the device with higher priority in a VRRP6 group to be the master, set the preemption mode on the device. In non-preemption mode, as long as the master is working properly, the backup with higher priority cannot be the master.

NOTE

When non-preemption is disabled, the preemption delay is restored to 0 seconds immediately.

Prerequisites

The **vrrp6 vrid virtual-ip** command has been executed on an interface to create a VRRP6 group.

Example

Configure VRRP6 group 1 in non-preemption mode on the VLANIF interface.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] vrrp6 vrid 1 virtual-ip FE80::7 link-local
[HUAWEI-Vlanif100] vrrp6 vrid 1 preempt-mode disable
```

Configure VRRP6 group 1 in non-preemption mode on the Ethernet interface.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] vrrp6 vrid 1 virtual-ip FE80::7 link-local
[HUAWEI-GigabitEthernet0/0/1] vrrp6 vrid 1 preempt-mode disable
```

12.2.53 vrrp6 vrid preempt-mode timer delay

Function

The **vrrp6 vrid preempt-mode timer delay** command sets the preemption delay for the device in a VRRP6 group.

The **undo vrrp6 vrid preempt-mode timer delay** command restores the default preemption delay for the device in a VRRP6 group.

By default, the preemption delay is 0 seconds, indicating immediate preemption.

Format

vrrp6 vrid *virtual-router-id* **preempt-mode timer delay** *delay-value*

undo vrrp6 vrid *virtual-router-id* **preempt-mode timer delay**

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the VRID of a VRRP6 group.	The value is an integer that ranges from 1 to 255.
delay *delay-value*	Specifies the preemption delay.	The value is an integer that ranges from 0 to 3600, in seconds. The default value is 0.

Views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the backup in a VRRP6 group does not receive VRRP6 Advertisement packets from the master within a specified period of time, the backup becomes the master. On an unstable network, even if the master is working properly, the backup may not receive packets from the master because of network congestion. In this case, the VRRP6 group status will flap and traffic is lost. To prevent frequent switching of the VRRP6 group status, run the **vrrp6 vrid preempt-mode timer delay** command to set the preemption delay so that the backup becomes the master only after the delay expires.

Prerequisites

The **vrrp6 vrid virtual-ip** command has been executed to create a VRRP6 group.

Precautions

You are advised to set the preemption delay of the backup in a VRRP6 group to 0, configure the master in preemption mode, and set the preemption delay to be longer than 15s. These settings allow a period of time for status synchronization between the uplink and downlink on devices on an unstable network. If the preceding settings are not used, two masters coexist and user devices may learn an incorrect master address. As a result, traffic is interrupted.

- The preemption delay refers to the delay before the backup switches to the master. Therefore, the IP address owner is irrelevant to the preemption delay. After the IP address owner recovers, it becomes the master immediately without a delay.
- On a stable network, a short preemption delay is recommended. When the master is faulty, the backup can rapidly switch to the master. This prevents traffic loss. On an unstable network, a long preemption delay is recommended. This prevents traffic loss caused by frequent switching of the VRRP6 group status.

Example

Set the preemption delay of VRRP6 group 1 to 10 seconds on the VLANIF interface.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] vrrp6 vrid 1 virtual-ip FE80::7 link-local
[HUAWEI-Vlanif100] vrrp6 vrid 1 preempt-mode timer delay 10
```

Set the preemption delay of VRRP6 group 1 to 10 seconds on the Ethernet interface.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] vrrp6 vrid 1 virtual-ip FE80::7 link-local
[HUAWEI-GigabitEthernet0/0/1] vrrp6 vrid 1 preempt-mode timer delay 10
```

12.2.54 vrrp6 vrid priority

Function

The **vrrp6 vrid priority** command sets the priority of the device in a VRRP6 group.

The **undo vrrp6 vrid priority** command restores the default priority of the device in a VRRP6 group.

By default, the priority of the device in a VRRP6 group is 100.

Format

vrrp6 vrid *virtual-router-id* **priority** *priority-value*

undo vrrp6 vrid *virtual-router-id* **priority**

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the VRID of a VRRP6 group.	The value is an integer that ranges from 1 to 255.
priority *priority-value*	Specifies the priority of the device in a VRRP6 group.	The value is an integer that ranges from 1 to 254. A larger value indicates a higher priority.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, MultiGE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, MultiGE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure the device in a VRRP6 group as the default gateway, run the **vrrp6 vrid priority** command to specify the highest priority for the device so that the device can become the master.

Prerequisites

The **vrrp6 vrid virtual-ip** command has been executed to create a VRRP6 group.

Precautions

- Priority 0 is reserved in the system. Priority 255 is reserved for the IP address owner.
- When devices in a VRRP6 group have the same priority, the device that first changes to master state becomes the master. If devices attempt to be the master simultaneously, the device where the interface with the largest IP address is located becomes the master.

Example

Set the priority of the switch in VRRP6 group 2 to 120 on the VLANIF interface.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
```

```
[HUAWEI-Vlanif100] vrrp6 vrid 2 virtual-ip FE80::7 link-local
[HUAWEI-Vlanif100] vrrp6 vrid 2 priority 120
```

Set the priority of the switch in VRRP6 group 2 to 120 on the Ethernet interface.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] vrrp6 vrid 2 virtual-ip FE80::7 link-local
[HUAWEI-GigabitEthernet0/0/1] vrrp6 vrid 2 priority 120
```

12.2.55 vrrp6 vrid timer advertise

Function

The **vrrp6 vrid timer advertise** command sets the interval at which the master sends VRRP6 Advertisement packets.

The **undo vrrp6 vrid timer advertise** command restores the default interval at which the master sends VRRP6 Advertisement packets.

By default, the master sends VRRP6 Advertisement packets every 1 second.

Format

vrrp6 vrid *virtual-router-id* **timer advertise** *advertise-interval*

undo vrrp6 vrid *virtual-router-id* **timer advertise**

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the VRID of a VRRP6 group.	The value is an integer that ranges from 1 to 255.
advertise *advertise-interval*	Specifies the interval at which the master sends VRRP6 Advertisement packets.	The value is an integer that ranges from 100 to 4095, in centiseconds.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, MultiGE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, MultiGE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The master in a VRRP6 group sends VRRP6 Advertisement packets to backups at intervals to notify that it is working properly. If the backup with the highest priority does not receive any VRRP6 Advertisement packets from the master at the specified interval (usually, three times the interval for sending VRRP6 Advertisement packets), it considers the master faulty and becomes the master. The **vrrp6 vrid timer advertise** command sets the interval at which the master sends VRRP6 Advertisement packets.

Prerequisites

The **vrrp6 vrid virtual-ip** command has been executed on an interface to create a VRRP6 group.

Precautions

If a longer interval is used, backups in the same VRRP6 group cannot detect the fault on the master in a timely manner, causing packet loss. If a shorter interval is used, system resources are occupied. In addition, when network traffic is heavy or the network is unstable, backups may not receive packets after the Master_Down_Interval timer expires. As a result, the VRRP6 group status is incorrectly switched. Set the interval based on actual networking.

NOTE

- For VRRP for IPv4, set the same interval for sending VRRP Advertisement packets for members in a VRRP group to prevent multiple masters in the VRRP group.
- For VRRP for IPv6, even if you set different intervals for sending VRRP Advertisement packets for members in a VRRP6 group, there is only one master in a VRRP6 group.

Example

Set the interval at which the master in VRRP6 group 1 sends VRRP6 Advertisement packets to 200 centiseconds on the VLANIF interface.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] vrrp6 vrid 1 virtual-ip FE80::7 link-local
[HUAWEI-Vlanif100] vrrp6 vrid 1 timer advertise 200
```

Set the interval at which the master in VRRP6 group 1 sends VRRP6 Advertisement packets to 200 centiseconds on the Ethernet interface.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] vrrp6 vrid 1 virtual-ip FE80::7 link-local
[HUAWEI-GigabitEthernet0/0/1] vrrp6 vrid 1 timer advertise 200
```

12.2.56 vrrp6 vrid track admin-vrrp6 vrid

Function

The **vrrp6 vrid track admin-vrrp6 vrid** command binds a VRRP6 group to an mVRRP6 group.

The **undo vrrp6 vrid track admin-vrrp6** command unbinds a VRRP6 group from an mVRRP6 group.

By default, no VRRP6 group is bound to an mVRRP6 group.

Format

vrrp6 vrid *virtual-router-id1* **track admin-vrrp6 interface** *interface-type interface-number* **vrid** *virtual-router-id2* **unflowdown**

undo vrrp6 vrid *virtual-router-id1* **track admin-vrrp6**

Parameters

Parameter	Description	Value
vrid *virtual-router-id1*	Specifies the VRID of a VRRP6 group.	The value is an integer that ranges from 1 to 255.
vrid *virtual-router-id2*	Specifies the VRID of an mVRRP6 group.	The value is an integer that ranges from 1 to 255.
interface-type interface-number	Specifies the type and number of an interface configured with an mVRRP6 group.	-
unflowdown	Allows the interface where a VRRP6 group bound to an mVRRP6 group is configured to retain the Up state if the mVRRP6 group is in Backup or Initialize state.	-

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, MultiGE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, MultiGE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If multiple VRRP6 groups are configured on the device, each group sends VRRP6 Advertisement packets to maintain its state machine. As a result, a large number of VRRP6 Advertisement packets are generated, which occupy network bandwidth resources and cause CPU performance to deteriorate. To solve the problem, run the **vrrp6 vrid track admin-vrrp6 vrid** command to bind a VRRP6 group to an mVRRP6 group. After a VRRP6 group is bound to an mVRRP6 group, the VRRP6 group does not send VRRP6 Advertisement packets to negotiate the Master and Backup states. The mVRRP6 group determines the status of the bound VRRP6 group. This method greatly reduces the impact of VRRP6 Advertisement packets on network bandwidth and CPU performance.

This mode is used on a network where uplink and downlink traffic can be transmitted along different paths. **unflowdown** can be configured to allow the mVRRP6 group to determine the status of its bound VRRP6 group. Uplink traffic travels through the master and then reaches the upper-layer network, and downlink traffic travels through either the master or backup to reach users.

Prerequisites

A VRRP6 group and an mVRRP6 group have been created.

Precautions

The **vrrp6 vrid track admin-vrrp6 vrid** command can be used only on the interface where the bound VRRP6 group is configured. This command cannot be used on the interface where an mVRRP6 group is configured.

VRRP4 and VRRP6 can be configured on an interface simultaneously. However, there are limitations:

- A VRRP4 group can be bound to only an mVRRP4 group, and a VRRP6 group can be bound to only an mVRRP6 group.
- At most one VRRP4 group and one VRRP6 group can be configured on an interface. An interface cannot be configured with multiple VRRP4 or VRRP6 groups.

Example

Bind VRRP6 group 1 to mVRRP6 group 2 on the VLANIF interface.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] vrrp6 vrid 1 track admin-vrrp6 interface vlanif 11 vrid 2 unflowdown
```

Bind VRRP6 group 1 to mVRRP6 group 2 on the Ethernet interface.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] vrrp6 vrid 1 track admin-vrrp6 interface gigabitethernet 0/0/2 vrid 2
unflowdown
```

12.2.57 vrrp6 vrid track bfd-session

Function

The **vrrp6 vrid track bfd-session** command associates a VRRP6 group with a BFD session.

The **undo vrrp6 vrid track bfd-session** command disassociates a VRRP6 group from a BFD session.

By default, a VRRP6 group is not associated with a BFD session.

NOTE

Only the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

vrrp6 vrid *virtual-router-id* **track bfd-session** { *session-id* | **session-name** *bfd-configure-name* } [**increased** *value-increased* | **reduced** *value-reduced*]

undo vrrp6 vrid *virtual-router-id* **track bfd-session** [*session-id* | **session-name** *bfd-configure-name*]

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the VRID of a VRRP6 group.	The value is an integer that ranges from 1 to 255.
session-id	Specifies the local discriminator of the monitored BFD session.	The value is an integer that ranges from 1 to 8191.
session-name *bfd-configure-name*	Specifies the name of the monitored BFD session.	The value is a string of 1 to 15 case-insensitive characters without spaces. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
increased *value-increased*	Specifies the value by which the priority increases when the monitored BFD session becomes Down.	The value is an integer that ranges from 1 to 255. The maximum priority value is 254.
reduced *value-reduced*	Specifies the value by which the priority decreases when the monitored BFD session becomes Down.	The value is an integer that ranges from 1 to 255. The priority can decrease to 1. By default, when the monitored BFD session becomes Down, the VRRP6 priority decreases by 10.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, MultiGE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, MultiGE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Association between a VRRP6 group and a BFD session implements the following functions:

1. Rapid active/standby switchover: When the link of a VRRP6 group or the master is faulty, the backup becomes the master after a certain time (second level), causing packet loss. You can associate the VRRP6 group with a BFD session on the backup so that the BFD session can rapidly detect communication faults of the VRRP6 group. When the BFD session detects a fault, it notifies the VRRP6 group that the priority of the backup needs to be increased. Then an active/standby switchover is triggered immediately. This millisecond-level switchover reduces traffic loss. When the monitored BFD session recovers, the original priority of the device in the VRRP6 group is restored.
2. Monitoring the uplink: Because VRRP6 cannot detect faults on the uplink of a VRRP6 group, services are interrupted. You can associate the VRRP6 group with a BFD session on the master so that the BFD session monitors the uplink status of the master. When the BFD session detects a fault on the uplink, it notifies the VRRP6 group that the priority of the master needs to be decreased. Then an active/standby switchover is triggered immediately. This reduces the impact of the uplink fault on service forwarding. When the monitored BFD session recovers, the original priority of the device in the VRRP6 group is restored.

Prerequisites

A VRRP6 group has been created and a static BFD session or a static BFD session with automatically negotiated discriminators has been created.

Precautions

Currently, the device supports only association between VRRP6 and BFD for IPv4.

After a VRRP6 group is associated with a BFD session, the BFD session type cannot be modified. Before deleting the BFD session type, you must delete all original configurations.

After a VRRP6 group is associated with a BFD session, set an appropriate value of **increased** *value-increased* or **reduced** *value-reduced*. This setting ensures that an active/standby switchover is performed immediately when the monitored BFD session becomes Down.

Multiple VRRP6 groups can monitor a BFD session, and a VRRP6 group can monitor a maximum of eight BFD sessions simultaneously.

NOTE

When associating a VRRP6 group with a BFD session, note the following points:

- If an IPv6 address owner exists in the VRRP6 group, the VRRP6 group cannot monitor the BFD session.
- If **session-name** *bfd-configure-name* is specified, the VRRP6 group can be bound to only the static BFD session with automatically negotiated discriminators.
- If *session-id* is specified, the VRRP6 group can bind to only a static BFD session.

Example

Associate VRRP6 group 1 with the BFD session **hello** on VLANIF 100.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] bfd hello bind peer-ip 10.1.1.1 interface vlanif 100
[HUAWEI-bfd-session-hello] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] vrrp6 vrid 1 virtual-ip FE80::7 link-local
[HUAWEI-Vlanif100] vrrp6 vrid 1 virtual-ip FC00::100
[HUAWEI-Vlanif100] vrrp6 vrid 1 track bfd session-name hello reduced 40
```

Associate VRRP6 group 1 with the BFD session **hello** on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] bfd hello bind peer-ip 10.1.1.1 interface gigabitethernet 0/0/1
[HUAWEI-bfd-session-hello] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] vrrp6 vrid 1 virtual-ip FE80::7 link-local
[HUAWEI-GigabitEthernet0/0/1] vrrp6 vrid 1 virtual-ip FC00::100
[HUAWEI-GigabitEthernet0/0/1] vrrp6 vrid 1 track bfd session-name hello reduced 40
```

12.2.58 vrrp6 vrid track interface

Function

The **vrrp6 vrid track interface** command associates a VRRP6 group with an interface.

The **undo vrrp6 vrid track interface** command disassociates a VRRP6 group from an interface.

By default, a VRRP6 group is not associated with an interface.

Format

vrrp6 vrid *virtual-router-id* **track interface** *interface-type interface-number* [**increased** *value-increased* | **reduced** *value-reduced*]

undo vrrp6 vrid *virtual-router-id* **track interface** [*interface-type interface-number*]

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the VRID of a VRRP6 group.	The value is an integer that ranges from 1 to 255.
interface-type interface-number	Specifies the type and number of an interface monitored by a VRRP6 group. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
increased *value-increased*	Specifies the value by which the priority increases when the monitored interface becomes Down.	The value is an integer that ranges from 1 to 255. The maximum priority value is 254.
reduced *value-reduced*	Specifies the value by which the priority decreases when the monitored interface becomes Down.	The value is an integer that ranges from 1 to 255. The priority can decrease to 1. By default, when the monitored interface goes Down, the VRRP6 priority of the device decreases by 10.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, MultiGE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, MultiGE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

VRRP6 can only detect the status change of the interface on which a VRRP6 group is configured. VRRP6 cannot detect faults on the uplink interface of the master, causing service interruption. You can associate a VRRP6 group with a device interface that is not in the VRRP6 group. When the monitored interface is faulty, the priority of the master is reduced. This triggers an active/standby switchover and reduces the impact of services on the uplink interface. When the fault is rectified, the original master restores its priority and switches to the master to forward traffic.

Prerequisites

The **vrrp6 vrid virtual-ip** command has been executed on an interface to create a VRRP6 group.

Precautions

After a VRRP6 group is associated with an interface, set **increased** *value-increased* or **reduced** *value-reduced* to an appropriate value. This setting ensures that an active/standby switchover is performed immediately when the monitored interface becomes Down.

NOTE

- The master and backup in the VRRP6 group must work in preemption mode. It is recommended that the preemption delay be 0 on the backup and larger than 0 on the master.
- If the device is the IPv6 address owner (the virtual router IPv6 address is used as the actual interface address), you cannot associate a VRRP6 group with an interface.
- If the IPv4 protocol status on the monitored interface configured with an IPv4 address changes, a new master in the VRRP6 group is selected. If the IPv6 protocol status on the monitored interface configured with an IPv6 address changes, the VRRP6 group remains unchanged.

Example

Associate VRRP6 group 1 with VLANIF 100 and set **reduced** *value-reduced* to 50 when VLANIF 100 becomes Down.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 200
[HUAWEI-Vlanif200] vrrp6 vrid 1 virtual-ip FE80::7 link-local
[HUAWEI-Vlanif200] vrrp6 vrid 1 virtual-ip FC00::2
[HUAWEI-Vlanif200] vrrp6 vrid 1 track interface vlanif 100 reduced 50
```

Associate VRRP6 group 1 with GE0/0/2 and set reduced *value-reduced* to 50 when GE0/0/2 becomes Down.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] vrrp6 vrid 1 virtual-ip FE80::7 link-local
[HUAWEI-GigabitEthernet0/0/1] vrrp6 vrid 1 virtual-ip FC00::2
[HUAWEI-GigabitEthernet0/0/1] vrrp6 vrid 1 track interface gigabitethernet0/0/2 reduced 50
```

12.2.59 vrrp6 vrid virtual-ip

Function

The **vrrp6 vrid virtual-ip** command creates a VRRP6 group and assigns a virtual IPv6 address to the group.

The **undo vrrp6 vrid virtual-ip** command deletes the virtual IPv6 address of a VRRP6 group.

By default, no VRRP6 group is created.

Format

vrrp6 vrid *virtual-router-id* **virtual-ip** *virtual-ipv6-address* [**link-local**]

undo vrrp6 vrid *virtual-router-id* [**virtual-ip** *virtual-ipv6-address* [**link-local**]]

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the VRID of a VRRP6 group.	The value is an integer that ranges from 1 to 255.
virtual-ip *virtual-ipv6-address*	Specifies the virtual IPv6 address of a VRRP6 group.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
link-local	Indicates that a link-local address is used as the virtual IPv6 address of a VRRP6 group. The first virtual IPv6 address of a VRRP6 group must be a link-local address.	-

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, MultiGE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, MultiGE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In practice, hosts use the default gateway to communicate with external networks. As value-added services such as IPTV or video conferencing services are widely deployed, hosts may fail to communicate with external networks if the default gateway fails. Configuring dynamic routing protocols such as RIPng, OSPFv3, or ICMPv6 can improve system reliability. However, it is difficult to configure dynamic routing protocols and some hosts may not support dynamic routing protocols. VRRP6 virtualizes multiple routing devices into a virtual router without changing the networking. The virtual router IPv6 address is configured as the default gateway address.

If users on a network have the same reliability requirements, configure multiple virtual IPv6 addresses for a VRRP6 group. By doing this, one virtual IPv6 address serves one separate user group, and the default gateway address remains consistent regardless of changes in VRRP6 device locations. A VRRP6 group can be assigned a maximum of 16 virtual IPv6 addresses.

Precautions

For VRRP4 or VRRP6 groups configured on a device, each VRID can be bound to a maximum of 16 ports.

If all the virtual IPv6 addresses in a VRRP6 group are deleted, the VRRP6 group is deleted automatically.

NOTE

- The first virtual IPv6 address of a VRRP6 group must be a link-local address. That is, you must run the **vrrp6 vrid** *virtual-router-id* **virtual-ip** *virtual-ipv6-address* **link-local** command before assigning other virtual IPv6 addresses to the VRRP6 group.
- VRRP6 groups must use different virtual IP addresses.
- Two devices in a VRRP6 group must be configured with the same VRID.
- VRRP6 groups on different interfaces of a device can be configured with the same VRID.
- The VLANIF interface of a super VLAN does not support VRRP6.

Example

Configure a VRRP6 group on VLANIF 100 and configure the virtual IPv6 address FE80::7.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] vrrp6 vrid 1 virtual-ip FE80::7 link-local
```

Configure a VRRP6 group on GE0/0/1 and configure the virtual IPv6 address FE80::7.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] vrrp6 vrid 1 virtual-ip FE80::7 link-local
```

12.3 HSB Configuration Commands

12.3.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

12.3.2 bind-service

Function

The **bind-service** command binds an HSB service to an HSB group.

The **undo bind-service** command unbinds the HSB service from the HSB group.

By default, no HSB service is bound to an HSB group.

Format

bind-service *service-index*

undo bind-service *service-index*

Parameters

Parameter	Description	Value
service-index	Specifies the ID of an HSB service.	The value is fixed as 0.

Views

HSB group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An HSB group synchronizes backup information and responds to link status changes through the HSB channel established by the HSB service. To make the HSB group work properly, bind an HSB service to the HSB group.

Prerequisites

An HSB group has been configured.

Example

Bind HSB service 0 to an HSB group.

```
<HUAWEI> system-view
[HUAWEI] hsb-group 0
[HUAWEI-hsb-group-0] bind-service 0
```

12.3.3 display hsb statistics hsb-group

Function

The **display hsb statistics hsb-group** command displays statistics on processes of an HSB group.

Format

display hsb statistics hsb-group *group-index* **event**

Parameters

Parameter	Description	Value
group-index	Specifies the index of an HSB group.	The fixed value is 0.
event	Indicates process statistics.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display hsb statistics hsb-group** command displays statistics on processes. Two main processes are involved: negotiation process and switching process.

Example

Display statistics on processes of the HSB public mechanism.

```
<HUAWEI> display hsb statistics hsb-group 0 event
Hot Standby Statistic Event:
----------------------------------------------------------
Hot Standby Group Dealed Vrrp Group Record:
  Local_Vrrp Peer_Vrrp  Batch_Status Systime
  BACKUP     BACKUP     Ind          2019-8-23 11:55:2
  MASTER     BACKUP     Ind          2019-8-23 11:55:8

Hot Standby Group Event Record:
  Run Independent Event    : 0
  Realtime Sync Event      : 0
  Delete Event(Snd, Recv)  : 0, 0
  Add Event(Snd, Recv)     : 0, 0
  Switch Event(Snd, Recv)  : 0, 0
  Finish Status(Cur, Total): 0, 0

Hot Standby Group Process Record:
```

Table 12-25 Description of the display hsb statistics hsb-group command output

Item	Description
HSB Process/HSB Process ID	ID of an HSB process.
Hot Standby Statistic Event	Statistics about received and handled events of an HSB group.
Hot Standby Group Dealed Vrrp Group Record	Record of the VRRP group of which services are received and processed by the HSB group.
Local_Vrrp	Local VRRP group.
Peer_Vrrp	Remote VRRP group.
Batch_Status	Backup process status.
Systime	System time.
Hot Standby Group Event Record	Record of events notified by the backup service module and received events.
Run Independent Event	Number of events running independently.
Realtime Sync Event	Number of events synchronized in real time.
Delete Event(Snd, Recv)	Number of deleted events that are received or sent.
Add Event(Snd, Recv)	Number of added events that are received or sent.
Switch Event(Snd, Recv)	Number of switched events that are received or sent.
Finish Status(Cur, Total)	Number of current backup services or total number of backup services of which the backup process is complete.
Hot Standby Group Process Record	Statistics on backup processes of the HSB public mechanism.
Negotiate Start Entry	The master device starts to be negotiated.
Negotiate Has Started	Negotiating master and backup devices has started.
Negotiate Start Send Pkt Failed	Sending negotiation packets fails.
Negotiate Req Entry	Batch deletion of backup devices starts.
Negotiate Req Failed	The master device fails to send negotiation-start packets to the backup device.

Item	Description
Negotiate Req Batch Status Error	The backup process status is incorrect. The backup process status of the current backup group is not Independent.
Negotiate Req Vrrp Status Error	The VRRP group status is incorrect and is not Backup.
Negotiate Req Check Para Failed	The backup device checks that some backup parameters from the master device are invalid.
Negotiate Req Notify Event Failed	The backup device notifies that batch deleting backup services fails.
Negotiate Del Entry	Batch deleting firewall services on the backup device is complete.
Negotiate Del Batch Status Error	The backup device fails to check the negotiation process and is not none.
Negotiate Del Vrrp Status Error	The backup device fails to check the VRRP group status and is not Backup.
Negotiate Del Send Pkt Failed	The backup device fails to send batch deletion complete messages to the master device.
Negotiate Ack Entry	Batch backup on the master device starts.
Negotiate Ack Failed	The backup device notifies the master device that the negotiation end message fails to be sent.
Negotiate Ack Batch Status Error	The master device fails to check the negotiation process and is not Batch-Started.
Negotiate Ack Vrrp Status Error	The VRRP group status of the master device is incorrect and is not Master.
Negotiate Ack Notify Event Failed	The master device fails to notify batch backup events on the firewall forwarding plane.
Negotiate Add Entry	The master device receives a message indicating that batch backup on the firewall forwarding plane is complete.
Negotiate Add Batch Status Error	The master device fails to check the negotiation process and is not Batch-Adding.
Negotiate Add Vrrp Status Error	The master device fails to check the VRRP group status and is not Backup.

Item	Description
Negotiate Add Send Pkt Failed	The master device fails to send batch deletion complete messages to the backup device.
Negotiate End Entry	Negotiation ends.
Negotiate End Failed	The master device notifies the backup device that the negotiation end message fails to be sent.
Negotiate End Batch Status Error	The master device fails to check the negotiation process and is not Batch-Adding.
Negotiate End Vrrp Status Error	The VRRP group status is incorrect and is not Master.
Negotiate End Batch Backup Mid Count	Statistics about the services that indicate that batch backup ends and are received by the active device from the standby device.
Switch Start Entry	Switching starts.
Switch Has Started	Switch Has Started.
Switch Start Send Pkt Failed	Sending switching-start messages fails.
Switch Req Entry	The original master device responds to switching messages.
Switch Req Failed	The original backup device fails to initiate switching.
Switch Req Batch Status Error	The original master device fails to check the switching process status and is not Realtime.
Switch Req Notify Event Failed	The original master device fails to notify switching of backup services.
Switch Switching Entry	Switching is complete.
Switch Switching Batch Status Error	The original master device fails to check the switching process status and is not Switching.
Switch Switching Send Pkt Failed	The original backup service fails to send a message indicating that the switching is complete.
Switch Switching Vrrp Changed	During switching, the VRRP status of the original backup device changes.
Switch Switching Notify Vrrp Failed	During switching, the VRRP status of the backup device changes and is not Master. The change is notified to the remote device.
Switch End Entry	Switching ends.

Item	Description
Switch End Failed	The original backup device receives a message indicating the switching failure.
Switch End Batch Status Error	The original master device fails to check the switching process status and is not Switching.
Switch End Vrrp Changed	During switching, the VRRP status of the original backup device changes.
Switch End Notify Vrrp Failed	During switching, the VRRP status of the backup device changes and is not Backup. The change is notified to the remote device.
HSB Group Vrrp All Master	Number of times two master devices exist in a VRRP group.
HSB Group Vrrp All Backup	Number of times two backup devices exist in a VRRP group.
HSB Group Received All Master Event	Number of dual-active events received by the HSB group.
HSB Group Received All Backup Event	Number of dual-standby events received by the HSB group.
HSB Group Notify All Group Event Error	The HSB group fails to notify backup events of all VRRP groups.
HSB Group Notify One Group Event Error	The HSB group fails to notify backup events of a single VRRP group.
HSB Group Receive Group Event Error	The HSB group fails to receive a notification indicating that the backup service is complete.
HSB Group Vrrp State Change Event	VRRP group status change event.
HSB Group Vrrp State Received Event	Number of VRRP status events received by the HSB group.
HSB Group Vrrp State Dealed Event	Number of VRRP status change events processed and responded by the HSB group.
HSB Group Packet To Task Error	An error occurs when the HSB group delivers HSB service packets.
HSB Group Packet To Task Failed	The HSB group fails to deliver HSB service packets.
HSB Batch Backup Mid Error Count	Statistics about the IDs of the services that are processed incorrectly after batch backup ends.

12.3.4 display hsb statistics hsb-service

Function

The **display hsb statistics hsb-service** command displays statistics on packets or processes of the HSB public mechanism.

Format

display hsb statistics hsb-service *service-index* { **event** | **packet** }

Parameters

Parameter	Description	Value
service-index	Specifies the index of an HSB service.	The fixed value is 0.
packet	Indicates packet statistics.	-
event	Indicates process statistics.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display hsb statistics hsb-service** command displays statistics on received, sent, and discarded packets or processes of the HSB public mechanism.

Example

Display statistics on packets of the HSB public mechanism.

```
<HUAWEI> display hsb statistics hsb-service 0 packet
Hot Standby Service Packet Statistics:
---------------------------------------------------------
  Packet Sent      : 0
  Packet Received  : 0
  Packet ID Error : 0
  Packet Sent Dropped    : 0
  Packet Received Dropped : 0
---------------------------------------------------------
      Group and Group Register Module Packet:
   Group-ID/Module-ID  Packet Sent         Packet Recived
   0                    0                    0
   400c0000             0                    0
  ---------------------------------------------------------
```

Display statistics on processes of the HSB public mechanism.

```
<HUAWEI> display hsb statistics hsb-service 0 event
Hot Standby Service Process Record:
----------------------------------------------------------
  HSB Service Packet To Group Failed    : 0
  HSB Service Packet To Group Error     : 0
  HSB Service Packet To Task Error      : 0
  HSB Service Packet To Outer Error     : 0
  HSB Service Tunnel State Event        : 1
----------------------------------------------------------
```

Table 12-26 Description of the **display hsb statistics hsb-service** command output

Item	Description
Hot Standby Service Packet Statistics	Statistics on packets of the HSB public mechanism.
Packet Sent	Number of sent packets.
Packet Received	Number of received packets.
Packet ID Error	Packet loss times recorded in PKD ID detection when the HSB receives packets.
Packet Sent Dropped	Number of sent packets that are discarded.
Packet Received Dropped	Number of received packets that are discarded.
Group and Group Register Module Packet	Number of packets of the HSB group or of the module bound to the HSB group.
Group-ID/Module-ID	HSB group ID or module ID.
Hot Standby Service Process Record	Statistics on processes of the HSB public mechanism.
HSB Service Packet To Group Failed	An error occurs when the HSB service delivers HSB service packets to the HSB group.
HSB Service Packet To Group Error	Failure to deliver HSB service packets to the HSB group.
HSB Service Packet To Task Error	Failure to deliver HSB service packets to the backup service.
HSB Service Packet To Outer Error	Failure to deliver HSB service packets to the external module (HSB group or HSB service).
HSB Service Tunnel State Event	HSB service tunnel status event.

12.3.5 display hsb-group

Function

The **display hsb-group** command displays information about an HSB group.

Format

display hsb-group *group-index*

Parameters

Parameter	Description	Value
group-index	Specifies the ID of an HSB group.	The value is 0.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view information about an HSB group.

Example

Display information about HSB group 0.

```
<HUAWEI> display hsb-group 0
Hot Standby Group Information:
----------------------------------------------------------
  HSB-group ID                : 0
  Vrrp Group ID               : 2
  Vrrp Interface              : Vlanif100
  Service Index               : 0
  Group Vrrp Status           : Master
  Group Status                : Active
  Group Backup Process        : Realtime
  Backup State                : Ended
  Peer Group Device Name      : -
  Peer Group Software Version : -
  Group Backup Modules        : -
```

Table 12-27 Description of the **display hsb-group** command output

Item	Description
HSB-group ID	ID of an HSB group.

Item	Description
Vrrp Group ID	VRRP group ID.
Vrrp Interface	Interface configured with the VRRP group.
Service Index	HSB service ID.
Group Vrrp Status	Status of the VRRP group: ● Master ● Backup ● Initialize ● None
Group Status	HSB group status: ● Active ● Inactive ● Independent ● Switching
Group Backup Process	Backup process status: ● Independent: independent backup state ● Batch-Started: batch backup negotiation state ● Batch-Deleting: batch deletion state ● Batch-Delete-End: batch deletion end state ● Batch-Adding: batch backup state ● Realtime: real-time backup state ● Switching: switching state
Backup State	Backup status of the HSB group: ● Processing: Backup has been completed for the main core but is still ongoing for the sub core. ● Ended: Backup has been completed for both the main core and sub core. ● -: Backup has not been completed for the main core.
Peer Group Device Name	Device name corresponding to the peer HSB group.
Peer Group Software Version	Software version corresponding to the peer HSB group.

Item	Description
Group Backup Modules	Service module bound to the HSB group.

12.3.6 display hsb-service

Function

The **display hsb-service** command displays information about an HSB service.

Format

display hsb-service *service-index*

Parameters

Parameter	Description	Value
service-index	Specifies the ID of an HSB service.	The value is fixed as 0.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view information about an HSB service.

Example

Display the HSB service configuration.

```
<HUAWEI> display hsb-service 0
Hot Standby Service Information:
----------------------------------------------------------
  Local IP Address       : 192.168.4.1
  Peer IP Address        : 192.168.4.2
  Source Port            : 10245
  Destination Port       : 10245
  Keep Alive Times       : 5
  Keep Alive Interval    : 3
  Service State          : Not Valid
  Service Batch Modules  :
  Shared-key             : ******
----------------------------------------------------------
```

Table 12-28 Description of the **display hsb-service** command output

Item	Description
Local IP Address	IP address of the local device. To set this parameter, run the **service-ip-port** command.
Peer IP Address	IP address of the peer device. To set this parameter, run the **service-ip-port** command.
Source Port	Local port number. To set this parameter, run the **service-ip-port** command.
Destination Port	Destination port number. To set this parameter, run the **service-ip-port** command.
Keep Alive Times	Number of times that heartbeat packets are sent. To set this parameter, run the **service-keep-alive detect** command.
Keep Alive Interval	Interval for sending heartbeat packets. To set this parameter, run the **service-keep-alive detect** command.
Service State	Status of the HSB service: ● Connected ● Disconnected ● Not Valid
Service Batch Modules	Service modules bound to an HSB service.
Shared-key	Key used by the HSB devices. To set this parameter, run the **key** command.

12.3.7 display hsb-resource map

Function

The **display hsb-resource map** command displays HSB resource mapping information.

Format

display hsb-resource map

Parameters

None.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view mappings between HSB logical resources and interfaces, run the **display hsb-resource map** command.

Example

Display HSB resource mapping information.

```
<HUAWEI> display hsb-resource map
Hot Standby Backup interface map Information:
HSB-interface           Interface
----------------------------------------------------------
hsb-interface512        Vlanif100
hsb-interface1          GigabitEthernet0/0/1
----------------------------------------------------------
Total number: 2
```

Table 12-29 Description of the **display hsb-resource map** command output

Item	Description
Hot Standby Backup interface map Information	Mapping information of the HSB backup interface.
HSB-interface	HSB logical interface.
Interface	Interface name.
Total number	Total number of interface mappings.

12.3.8 display hsb-service-type dhcp hsb-group

Function

The **display hsb-service-type dhcp hsb-group** command displays information about the HSB group bound to DHCP servers.

Format

display hsb-service-type dhcp hsb-group

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display hsb-service-type dhcp hsb-group** command to view information about the HSB group bound to DHCP servers.

Example

Display information about the HSB group bound to DHCP servers.

```
<HUAWEI> display hsb-service-type dhcp hsb-group
DHCP HSB Group Information:
----------------------------------------------------------
   DHCP HSB Group : 0
----------------------------------------------------------
```

Table 12-30 Description of the **display hsb-service-type dhcp hsb-group** command output

Item	Description
DHCP HSB Group	ID of the HSB group.

12.3.9 hsb enable

Function

The **hsb enable** command enables hot standby (HSB) in an HSB group.

The **undo hsb enable** command disables HSB in an HSB group.

By default, HSB is disabled.

Format

hsb enable

undo hsb enable

Parameters

None.

Views

HSB group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An HSB group takes effect and notifies the service modules of status changes only after the HSB group is enabled. You need to run the **hsb enable** command to enable HSB in an HSB group after the HSB group configuration is complete.

Precautions

Do not run the **undo hsb enable** command when the master and backup devices are performing batch backup.

The master and backup devices must be the same device type and use the same software version. Otherwise, the HSB function may become unavailable.

Example

Enable HSB in HSB group 0.

```
<HUAWEI> system-view
[HUAWEI] hsb-group 0
[HUAWEI-hsb-group-0] hsb enable
```

12.3.10 hsb-group

Function

The **hsb-group** command creates an HSB group.

The **undo hsb-group** command deletes an HSB group.

By default, no HSB group is created.

Format

hsb-group *group-index*

undo hsb-group *group-index*

Parameters

Parameter	Description	Value
group-index	Specifies the ID of an HSB group.	The value is fixed as 0.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure HSB functions, create an HSB group first. An HSB group instructs service modules to perform batch backup, real-time backup, and status synchronization. An HSB group supports status negotiation and event notification functions, implementing service synchronization on master and backup devices.

Precautions

After HSB is enabled for an HSB group, an HSB service cannot be bound to the HSB group.

Example

Create HSB group 0.

```
<HUAWEI> system-view
[HUAWEI] hsb-group 0
[HUAWEI-hsb-group-0]
```

12.3.11 hsb-resource map

Function

The **hsb-resource map** command configures HSB resource mapping information.

The **undo hsb-resource map** command deletes HSB resource mapping information.

By default, no HSB resource mapping is configured.

Format

hsb-resource map interface *interface-type interface-number* **hsb-interface** *hsb-interface-number*

undo hsb-resource map interface *interface-type interface-number* **hsb-interface** *hsb-interface-number*

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of an interface: - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
hsb-interface *hsb-interface-number*	Specifies the index of an HSB logical interface.	The value is an integer in the range from 1 to 512.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

If the interface types and numbers on the active and standby devices are different, the standby device cannot back up interface-related entry information of the active device by default. As a result, services are interrupted after an active/ standby switchover. To solve this problem, run the **hsb-resource map** command on the active and standby devices to configure mappings between interfaces and HSB logical interfaces. The configuration will map interfaces of the active and standby devices to the same HSB logical interface so that the standby device can back up interface-related entry information of the active device based on the mappings.

Example

Configure mappings between interfaces and a specific HSB logical interface.

```
<HUAWEI> system-view
[HUAWEI] hsb-resource map interface vlanif 10 hsb-interface 1
```

12.3.12 hsb-service

Function

The **hsb-service** command creates an HSB service and displays the HSB service view.

The **undo hsb-service** command deletes an HSB service.

By default, no HSB service is created.

Format

hsb-service *service-index*

undo hsb-service *service-index*

Parameters

Parameter	Description	Value
service-index	Specifies the ID of an HSB service.	The fixed value is 0.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

An HSB service establishes an HSB channel for transmitting packets of other services and maintains the link status by notifying the HSB group of the faulty link. Only after an HSB group is bound to an HSB service, the HSB function can be implemented.

Example

Create HSB service 0.

```
<HUAWEI> system-view
[HUAWEI] hsb-service 0
[HUAWEI-hsb-service-0]
```

12.3.13 hsb-service-type dhcp hsb-group

Function

The **hsb-service-type dhcp hsb-group** command binds DHCP services to an HSB group.

The **undo hsb-service-type dhcp hsb-group** command unbinds DHCP services from an HSB group.

By default, DHCP services are not bound to an HSB group.

Format

hsb-service-type dhcp hsb-group *group-index*

undo hsb-service-type dhcp hsb-group *group-index*

Parameters

Parameter	Description	Value
group-index	Specifies the index of an HSB group.	The value is 0.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a DHCPv6 prefix delegation (PD) scenario, to ensure reachable routes between the DHCPv6 relay agent and terminals, you need to run the **hsb-service-type dhcp hsb-group** command to bind DHCP services to a specific HSB group. This configuration ensures that prefix routing information on the DHCPv6 relay agent can be backed up by the HSB group.

Prerequisites

An HSB group has been created using the **hsb-group** command.

Precautions

Services can be bound to an HSB group only before the HSB group is enabled.

This command applies only to the DHCPv6 PD scenario and must be configured on the DHCPv6 relay agent.

Example

Bind DHCP services to an HSB group.

```
<HUAWEI> system-view
[HUAWEI] hsb-group 0
[HUAWEI-hsb-group-0] quit
[HUAWEI] hsb-service-type dhcp hsb-group 0
```

12.3.14 key

Function

The **key** command configures the key used by the HSB devices.

The **undo key** command deletes the key used by the HSB devices.

By default, the key used by HSB devices is not configured.

Format

key cipher *key-string*

undo key

Parameters

Parameter	Description	Value
cipher *key-string*	Indicates the key used by the HSB devices.	The value can be a string of 48 characters in cipher text or a string of 8 to 16 characters in plain text.

Views

HSB service view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To ensure security of HSB information negotiation and service backup and prevent the attacks initiated by using bogus packets or modifying packets, run the **key** command to configure the key used by HSB devices. The key provides authentication and verification mechanisms.

Precautions

- Configuring a shared key for HSB devices is not recommended in a secure network environment, as this configuration will degrade the HSB performance.
- The **key** command must be configured before the **service-ip-port** command. Otherwise, the **key** configuration will fail.
- The two HSB devices must be configured with the same shared key. Inconsistent keys on two ends will cause frequent interruption of the HSB channel.

Example

Set the key used by HSB devices to **YsHsjx_202206**.

```
<HUAWEI> system-view
[HUAWEI] hsb-service 0
[HUAWEI-hsb-service-0] key cipher YsHsjx_202206
```

12.3.15 reset hsb statistics hsb-group

Function

The **reset hsb statistics hsb-group** command clears statistics on HSB processes.

Format

reset hsb statistics hsb-group *group-index* **event**

Parameters

Parameter	Description	Value
group-index	Specifies the index of an HSB group.	The value is fixed as 0.
event	Indicates process statistics.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Before collecting HSB statistics within a certain period, run this command to clear the existing HSB statistics. You can run this command to clear statistics about HSB processes. Two main processes are involved: HSB negotiation process and HSB switching process.

Example

Clear statistics about HSB processes.

```
<HUAWEI> reset hsb statistics hsb-group 0 event
```

12.3.16 reset hsb statistics hsb-service

Function

The **reset hsb statistics hsb-service** command clears statistics on packets or processes of the HSB public mechanism.

Format

reset hsb statistics hsb-service *service-index* { **packet** | **event** }

Parameters

Parameter	Description	Value
service-index	Specifies the index of an HSB service.	The value is fixed as 0.
packet	Indicates packet statistics.	-
event	Indicates process statistics.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Before collecting HSB statistics within a certain period, run this command to clear the existing HSB statistics. You can run this command to clear statistics on packets or processes of the HSB public mechanism.

Example

Clear statistics on packets of the HSB public mechanism.

```
<HUAWEI> reset hsb statistics hsb-service 0 packet
```

Clear statistics on processes of the HSB public mechanism.

```
<HUAWEI> reset hsb statistics hsb-service 0 event
```

12.3.17 service-ip-port

Function

The **service-ip-port** command configures the IP address and port number of an HSB channel.

The **undo service-ip-port** command deletes the IP address and port number of an HSB channel.

By default, the IP address and port number of an HSB channel are not configured.

Format

service-ip-port local-ip { *local-ipv4-address* | *local-ipv6-address* } **peer-ip** { *peer-ipv4-address* | *peer-ipv6-address* } **local-data-port** *local-port* **peer-data-port** *peer-port*

undo service-ip-port local-ip { *local-ipv4-address* | *local-ipv6-address* } **peer-ip** { *peer-ipv4-address* | *peer-ipv6-address* } **local-data-port** *local-port* **peer-data-port** *peer-port*

Parameters

Parameter	Description	Value
local-ip { *local-ipv4-address* | *local-ipv6-address* }	Specifies the local IPv4 or IPv6 address of the HSB service.	- *local-ipv4-address*: The value is in dotted decimal notation. - *local-ipv6-address*: The value is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
peer-ip { *peer-ipv4-address* | *peer-ipv6-address* }	Specifies the peer IPv4 or IPv6 address of the HSB service.	- *peer-ipv4-address*: The value is in dotted decimal notation. - *peer-ipv6-address*: The value is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
local-data-port *local-port*	Specifies the local port number of the HSB service.	The value is an integer that ranges from 10240 to 49152.
peer-data-port *peer-port*	Specifies the peer port number of the HSB service.	The value is an integer that ranges from 10240 to 49152.

Views

HSB service view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you create an HSB service using the **hsb-service** command, run the **service-ip-port** command to configure IP addresses and port numbers for the local and peer devices. When the configuration is complete, the HSB service establishes a Transmission Control Protocol (TCP) channel to transmit packets of other services and notifies service modules of link status changes.

Prerequisites

An HSB service has been created.

Precautions

It is recommended that the HSB channel be configured on an independent and highly reliable physical link.

If the command configuration fails to be restored, you cannot view the unrestored configuration information. In this case, you are advised to check whether the port is occupied by other services.

Example

Configure IP addresses and port numbers for the local and peer devices for the HSB service 0.

```
<HUAWEI> system-view
[HUAWEI] hsb-service 0
[HUAWEI-hsb-service-0] service-ip-port local-ip 192.168.1.1 peer-ip 192.168.1.2 local-data-port 10240
peer-data-port 10240
```

12.3.18 service-keep-alive detect

Function

The **service-keep-alive detect** command sets the retransmission times and interval of HSB packets.

The **undo service-keep-alive** command restores the default retransmission times and interval of HSB packets.

The default retransmission times is 5, and the default retransmission interval is 3 seconds.

Format

service-keep-alive detect retransmit *retransmit-times* **interval** *interval-value*

undo service-keep-alive [**detect retransmit** *retransmit-times* **interval** *interval-value*]

Parameters

Parameter	Description	Value
retransmit *retransmit-times*	Specifies the retransmission times of HSB packets.	The value is an integer that ranges from 1 to 20.
interval *interval-value*	Specifies the retransmission interval of HSB packets.	The value is an integer that ranges from 1 to 10, in seconds.

Views

HSB service view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An HSB service sends and retransmits HSB packets to prevent long TCP interruption that is not detected by the protocol stack. If a device does not receive an HSB packet from the peer device within the period (value of *retransmit-times* x value of *interval-value*), the local device receives a message indicating the exception and then re-establishes a channel to the peer.

Prerequisites

An HSB service has been configured.

Precautions

It is recommended that the product of the retransmission times of HSB packets multiplied by the retransmission interval of HSB packets be greater than or equal to the value of **Master_Down_Interval**. The value of **Master_Down_Interval** is calculated using the following formula: Master_Down_Interval = 3 x Advertisement_Interval + Skew_time, in seconds. For details, see **vrrp vrid timer advertise** and **vrrp6 vrid timer advertise**. It is recommended that the retransmission times and retransmission interval of HSB packets be set to their default values.

Example

Set the retransmission times of HSB service 0 to 5, and the retransmission interval to 1 second.

```
<HUAWEI> system-view
[HUAWEI] hsb-service 0
[HUAWEI-hsb-service-0] service-keep-alive detect retransmit 5 interval 1
```

12.3.19 track vrrp

Function

The **track vrrp** command binds an IPv4 VRRP group to an HSB group.

The **undo track vrrp** command unbinds an IPv4 VRRP group from an HSB group.

By default, no HSB group is bound to an IPv4 VRRP group.

Format

track vrrp vrid *virtual-router-id* **interface** *interface-type interface-number*

undo track vrrp [**vrid** *virtual-router-id* **interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the ID of an IPv4 VRRP group bound to an HSB group.	The value is an integer that ranges from 1 to 255.
interface *interface-type interface-number*	Specifies the type and number of the interface in an IPv4 VRRP group. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-

Views

HSB group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **track vrrp** command to bind a VRRP group to an HSB group. The HSB group negotiates the service status based on the VRRP status. By monitoring the changes in the bound HSB channel status and VRRP status, the HSB group instructs service modules to perform batch backup, real-time backup, and status synchronization.

Prerequisites

An HSB group has been configured.

Example

Bind VLANIF100 in IPv4 VRRP group 4 to HSB group 0.

```
<HUAWEI> system-view
[HUAWEI] hsb-group 0
[HUAWEI-hsb-group-0] track vrrp vrid 4 interface vlanif 100
```

12.3.20 track vrrp6

Function

The **track vrrp6** command binds an IPv6 VRRP group to an HSB group.

The **undo track vrrp6** command unbinds the IPv6 VRRP group from the HSB group.

By default, no IPv6 VRRP group is bound to an HSB group.

Format

track vrrp6 vrid *virtual-router-id* **interface** *interface-type interface-number*

undo track vrrp6 [**vrid** *virtual-router-id* **interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
vrid *virtual-router-id*	Specifies the ID of an IPv6 VRRP group bound to an HSB group.	The value is an integer that ranges from 1 to 255.
interface *interface-type interface-number*	Specifies the type and number of the interface in an IPv6 VRRP group. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

HSB group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the HSB service is used, you need to run this command to bind a VRRP group to an HSB group. The HSB group negotiates the service status based on the VRRP status. By monitoring the changes in the bound HSB channel status and

VRRP status, the HSB group instructs service modules to perform batch backup, real-time backup, and status synchronization.

Prerequisites

An HSB group has been configured.

Example

Bind IPv6 VRRP group 4 on VLANIF100 to HSB group 0.

```
<HUAWEI> system-view
[HUAWEI] hsb-group 0
[HUAWEI-hsb-group-0] track vrrp6 vrid 4 interface vlanif 100
```

12.4 DLDP Configuration Commands

12.4.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

12.4.2 display dldp

Function

The **display dldp** command displays the DLDP status of an interface or global DLDP status.

Format

display dldp [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays DLDP status of a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can use the **display dldp** command to view the DLDP status on the device.

Prerequisites

DLDP has been enabled globally using the **dldp enable** command.

DLDP has been enabled in the interface view using the **dldp enable** command.

Precaution

You can run the **display dldp** command to view DLDP status only after enabling DLDP globally using the **dldp enable** command.

Example

Display the DLDP status on the device.

```
<HUAWEI> display dldp
DLDP global status: enable
DLDP interval: 10s
DLDP work-mode: enhance
DLDP authentication-mode: sha, password is ******
DLDP unidirectional-shutdown: auto
DLDP delaydown-timer: 4s
The number of enabled ports is: 1
The number of global neighbors is: 1
The max number of global neighbors is: 512
Interface GigabitEthernet0/0/1
 DLDP port state: advertisement
 DLDP link state: up
 The neighbor number of the port is: 1.
   Neighbor mac address:80fb-0636-792d
   Neighbor port index:49
   Neighbor state:two way
   Neighbor aged time(s):16
```

Display the DLDP status on GE0/0/1.

```
<HUAWEI> display dldp interface gigabitethernet 0/0/1
Interface GigabitEthernet0/0/1
 DLDP port state: advertisement
 DLDP link state: up
 The neighbor number of the port is: 1.
   Neighbor mac address:0001-0001-0001
   Neighbor port index:26
   Neighbor state:two way
   Neighbor aged time(s):206
```

Table 12-31 Description of the display dldp command output

Item	Description
DLDP global status	Global DLDP status. The value can be: ● enable: DLDP is enabled. ● disable: DLDP is disabled. To enable DLDP, use the **dldp enable** command.
DLDP interval	Interval for sending the Advertisement packets, in seconds. To set the interval, use the **dldp interval** command.
DLDP work-mode	Working mode of DLDP. The value can be: ● enhance ● normal To set the working mode of DLDP, use the **dldp work-mode** command.
DLDP authentication-mode	Authentication mode of DLDP packets. The value can be: ● none: DLDP packets are not authenticated. ● simple: DLDP packets are authenticated using plain-text passwords. ● md5: DLDP packets are authenticated using MD5. ● sha: DLDP packets are authenticated using SHA2-256. To set DLDP authentication mode, use the **dldp authentication-mode** command.
DLDP unidirectional-shutdown	Interface shutdown mode. The value can be: ● manual: Interfaces are manually shut down. ● auto: Interfaces are automatically shut down. To set the interface shutdown mode, use the **dldp unidirectional-shutdown** command.

Item	Description
DLDP delaydown-timer	Delay of an interface's response to a Port-Down event, in seconds. To set the delay, use the **dldp delaydown-timer** command.
The number of enabled ports is	Number of interfaces on which DLDP is enabled on a device.
The number of global neighbors is	Number of DLDP neighbors.
The max number of global neighbors is	The max number of global DLDP neighbors.

Item	Description
DLDP port state	Current DLDP status of an interface. The value can be: ● inactive: DLDP is enabled but the link is Down. ● active: DLDP is enabled and the link is Up, or entries of neighbors have been cleared. ● advertisement: All neighbors have established bidirectional connections or have been in Active state for at least 5 seconds. The link in this state is stable. ● probe: The interface receives a packet from an unknown neighbor. The interface then sends a probe packet to check whether the link is a unidirectional link. When an interface enters this state, DLDP starts the probe timer and starts an echo timer for each neighbor to be detected. ● disable: DLDP detects a unidirectional link or a neighbor disappears when DLDP works in enhanced mode. An interface in this state receives and forwards only BPDUs, not user traffic. ● delaydown: When DLDP is in Active, Advertisement, or Probe state, it has not entered the Inactive state when receiving a Port-Down event. An interface in delaydown state retains the DLDP neighbor information and starts the DelayDown timer. ● loop: Indicates that a loop occurs on the interface because the Rx and Tx of an optical module are connected by the same optical fiber.
DLDP link state	Status of the interface. ● up ● down
The neighbor number of the port	Number of neighbors of an interface.
Neighbor mac address	MAC address of a peer device.

Item	Description
Neighbor port index	Index of a peer port.
Neighbor state	Peer status. - unknown - one way - two way
Neighbor aged time(s)	Time period after which a peer ages, in seconds.

12.4.3 display dldp statistics

Function

The **display dldp statistics** command displays the statistics about DLDP packets on an interface.

Format

display dldp statistics [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays the statistics about DLDP packets on a specified DLDP interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number. If no interface is specified, the statistics about DLDP packets on all DLDP interfaces are displayed. If an interface is specified, the statistics about DLDP packets on the specified interface are displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

If DLDP negotiation fails, you can use the **display dldp statistics** command to check the statistics about DLDP packets. This command can be used to display the statistics about DLDP packets after the statistics about DLDP packets are cleared using the **reset dldp statistics** command.

Prerequisites

DLDP has been enabled globally and on interfaces using the **dldp enable** command.

Example

Display the statistics about DLDP packets on the device.

```
<HUAWEI> display dldp statistics
Interface : GigabitEthernet0/0/1
 Packets sent: 15
 Packets received: 0
 Invalid packets received: 0
 Loop packets received: 0
 Authentication failed packets received: 0
 Valid packets received: 0
```

Display the statistics about DLDP packets on GE0/0/1.

```
<HUAWEI> display dldp statistics interface gigabitethernet 0/0/1
Interface : GigabitEthernet0/0/1
 Packets sent: 0
 Packets received: 0
 Invalid packets received: 0
 Loop packets received: 0
 Authentication failed packets received: 0
 Valid packets received: 0
```

Table 12-32 Description of the **display dldp statistics** command output

Item	Description
Interface	Name of the port on which DLDP is enabled.
Packets sent	Number of DLDP sent packets.
Packets received	Number of DLDP received packets.
Invalid packets received	Number of DLDP erroneous packets that are received.

Item	Description
Loop packets received	Number of DLDP loop packets that are received.
Authentication failed packets received	Number of DLDP received packets that fail to pass the authentication.
Valid packets received	Number of DLDP valid packets that are received.

12.4.4 dldp authentication-mode

Function

The **dldp authentication-mode** command configures a DLDP authentication mode.

The **undo dldp authentication-mode** command restores the default DLDP authentication mode.

By default, DLDP packets are not authenticated.

Format

dldp authentication-mode { **md5** *md5-password* | **simple** *simple-password* | **sha** *sha-password* | **none** }

undo dldp authentication-mode [**md5** *md5-password* | **simple** *simple-password* | **sha** *sha-password* | **none**]

Parameters

Parameter	Description	Value
md5 *md5-password*	Uses MD5 to authenticate DLDP packets exchanged between the interfaces on the local and neighbor devices. *md5-password* specifies the MD5 authentication password. **NOTE** The password is saved in the configuration file in cipher text for security.	The value is a string of 6 to 16 case-sensitive characters in plain text and consists of at least two of the following: lowercase letters, uppercase letters, digits, and special characters excluding question marks (?) and spaces. **NOTE** Ciphertext passwords with various lengths configured in an earlier version are also supported in the existing version.

Parameter	Description	Value
simple *simple-password*	Uses the plain text to authenticate DLDP packets exchanged between the interfaces on the local and neighbor devices. *simple-password* specifies the plain-text authentication password. **NOTE** The password is saved in the configuration file in cipher text for security.	The value is a string of 6 to 16 case-sensitive characters in plain text and consists of at least two of the following: lowercase letters, uppercase letters, digits, and special characters excluding question marks (?) and spaces. **NOTE** Ciphertext passwords with various lengths configured in an earlier version are also supported in the existing version.
none	Performs no authentication on DLDP packets exchanged between the interfaces on the local and neighbor devices.	-
sha *sha-password*	Uses SHA2-256 mode to authenticate DLDP packets exchanged between the interfaces on the local and neighbor devices. *sha-password* specifies the SHA2-256 authentication password. **NOTE** The password is saved in the configuration file in cipher text for security.	The value is a string of 6 to 16 case-sensitive characters in plain text and consists of at least two of the following: lowercase letters, uppercase letters, digits, and special characters excluding question marks (?) and spaces. **NOTE** Ciphertext passwords with various lengths configured in an earlier version are also supported in the existing version.

NOTE

For security purposes, you are advised to use SHA2-256 as the authentication algorithm of DLDP.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To ensure packet validity on an insecure network, users can configure one of the following authentication modes for DLDP packets:

- None: The sender sets the authentication key of the DLDP packets to all 0s and the authentication type field to 0. The receiver compares the authentication key and authentication type with those set on the local end. If the settings on the two ends are different, the receiver discards the DLDP packets.
- Plain text: The sender sets the authentication key of the DLDP packets to the plain-text password set on the local end and the authentication type field to 1. The receiver compares the authentication key and authentication type with those set on the local end. If the settings on the two ends are different, the receiver discards the DLDP packets.
- MD5: The sender sets the authentication key of the DLDP packets to the summary of the cipher text obtained from the password set on the local end using the MD5 algorithm, and sets the authentication type field to 2. The receiver compares the authentication key and authentication type with the summary of the cipher text obtained on the local end using the MD5 algorithm. If the settings on the two ends are different, the receiver discards the DLDP packets.
- SHA2-256 authentication: The sender sets the authenticator field of the DLDP packets to the digest of the cipher text obtained from the password set on the local end using the SHA2-256 algorithm, and sets the authentication type field to 3. The receiver compares the authenticator and authentication type with the digest of the cipher text obtained on the local end using the SHA2-256 algorithm. If the settings on the two ends are different, the receiver discards the DLDP packets.

When the device that uses MD5 authentication is upgraded from V200R001 or V200R002 to V200R008 or later, to ensure compatibility, upgrade the DLDP authentication mode to MD5-compatible. You can run the **undo dldp authentication-mode md5-compatible** command to cancel MD5-compatible authentication.

Prerequisites

DLDP has been enabled globally using the **dldp enable** command.

Precautions

If the **dldp authentication-mode** command is executed while DLDP is running, the local device deletes information about the DLDP neighbor device and triggers the neighbor device to clear information about the local device. In this way, the negotiation can be re-performed.

If the DLDP authentication mode is set, ensure that the local and neighbor devices are configured with the same DLDP authentication mode and password. If they use different DLDP authentication modes or passwords, DLDP packets cannot be authenticated. DLDP can work properly only when the two interfaces are authenticated.

Example

Configure simple authentication for DLDP packets exchanged between two devices. Set the SHA2-256 password to YsHsjx_202206.

```
<HUAWEI> system-view
[HUAWEI] dldp authentication-mode sha YsHsjx_202206
```

12.4.5 dldp compatible-mode enable

Function

The **dldp compatible-mode enable** command enables the DLDP compatible mode.

The **undo dldp compatible-mode enable** command disables the DLDP compatible mode.

By default, the DLDP compatible mode is disabled.

Format

dldp compatible-mode enable

undo dldp compatible-mode enable

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This configuration is required if the device works with the following Huawei switches to provide the DLDP function:

- S8500
- S7800
- S6500
- S5600 series

- S5100-EI
- S3900 series
- S3500 series
- S3100 series

Prerequisites

DLDP has been enabled globally using the **dldp enable** command.

Precautions

If two devices are connected by two cross-connected links, the DLDP compatible mode must be enabled or disabled on both the two interfaces.

If two devices are Huawei devices (not preceding models), the DLDP compatible mode must be enabled or disabled on both the two interfaces.

Example

Enable the DLDP compatible mode on interfaceGE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dldp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dldp enable
[HUAWEI-GigabitEthernet0/0/1] dldp compatible-mode enable
```

12.4.6 dldp compatible-mode local-mac

Function

The **dldp compatible-mode local-mac** command configures the switch to send DLDP packets containing source MAC addresses in the DLDP compatible mode.

The **undo dldp compatible-mode local-mac** command restores the source MAC addresses of the DLDP packets to the default MAC address.

By default, the MAC address of a DLDP packet is the system MAC address.

Format

dldp compatible-mode local-mac *mac-address*

undo dldp compatible-mode local-mac [*mac-address*]

Parameters

Parameter	Description	Value
mac-address	Specifies the source MAC address of the DLDP packets sent in the DLDP compatible mode.	The value is in H-H-H format. H contains 1 to 4 hexadecimal digits. **NOTE** The source MAC address cannot be a multicast MAC address, a broadcast MAC address, or a reserved address.

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run **dldp compatible-mode local-mac** command to configure the source MAC addresses for DLDP packets sent in DLDP compatible mode. This prevents the DLDP flapping due to discovery of multiple neighbors when the device needs to work with the following Huawei switches:

- S8500
- S7800
- S6500
- S5600 series switches
- S5100-EI
- S3900 series switches
- S3500 series switches
- S3100 series switches

Prerequisites

The DLDP compatible mode has been enabled using the **dldp compatible-mode enable** command.

Precautions

When the configuration is complete, the newly configured MAC address is used as the source MAC addresses of the sent DLDP packets.

Example

Set the source MAC address of the DLDP packets sent by interface GE0/0/1 in DLDP compatible mode to 00e0-fc12-0011.

```
<HUAWEI> system-view
[HUAWEI] dldp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dldp enable
[HUAWEI-GigabitEthernet0/0/1] dldp compatible-mode enable
[HUAWEI-GigabitEthernet0/0/1] dldp compatible-mode local-mac 00e0-fc12-0011
```

12.4.7 dldp delaydown-timer

Function

The **dldp delaydown-timer** command sets the timeout value of the DelayDown timer.

The **undo dldp delaydown-timer** command restores the default timeout value of the DelayDown timer.

The default timeout value of the DelayDown timer is 1 second.

Format

dldp delaydown-timer *time*

undo dldp delaydown-timer [*time*]

Parameters

Parameter	Description	Value
time	Specifies the timeout value of the DelayDown timer.	The value is an integer ranging from 1 to 5, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a DLDP interface in Active, Advertisement, or Probe state receives a Port-Down event, the interface enters Inactive state and clears the neighbor information. In some cases, the interface is Down for a short time. For example, failure of the Tx fiber on a port may cause jitter of optical signals on the Rx fiber, which makes the port Down and then Up again. To prevent the neighbor information from being deleted immediately in this case, the DLDP interface first enters the DelayDown state and starts the DelayDown timer. Before the DelayDown timer times out, the interface retains the neighbor information and responds to only Port-Up events. You can use the **dldp delaydown-timer** command to set the timeout value of the DelayDown timer.

- If the DLDP interface does not receive any Port-Up event when the DelayDown timer times out, the interface deletes the neighbor entry and enters the Inactive state.
- If the DLDP interface receives the Port-Up event before the DelayDown timer times out, the interface returns to the previous state.

Prerequisites

DLDP has been enabled globally using the **dldp enable** command.

Precautions

After the **dldp delaydown-timer** command is executed, the DLDP status is not affected by the Up/Down jitter within the timeout value of the DelayDown timer.

Example

Set the timeout value of the DelayDown timer to 2 seconds.

```
<HUAWEI> system-view
[HUAWEI] dldp enable
[HUAWEI] dldp delaydown-timer 2
```

12.4.8 dldp enable

Function

The **dldp enable** command enables DLDP.

The **undo dldp enable** command disables DLDP.

By default, DLDP is disabled globally and on each interface.

Format

dldp enable

undo dldp enable

Parameters

None

Views

System view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Sometimes unidirectional links occur on networks. On a unidirectional link, the local device can receive packets from the peer device at the link layer, but the peer device cannot receive packets from the local device. Unidirectional links result in problems such as loops on an STP topology.

DLDP is used to monitor the link status of optical fibers or copper twisted pairs. If a unidirectional link exists, DLDP automatically shuts down the interface or prompts users to manually shut down the interface to prevent network faults.

To enable DLDP, run the **dldp enable** command to globally enable DLDP and then run this command on the interface.

Prerequisites

DLDP takes effect only when the physical link is connected; therefore, securely connect optical fibers or copper twisted pairs before enabling DLDP.

Precautions

- After you enable DLDP using the **dldp enable** command in the system view, run this command again on the interfaces to enable DLDP so that the interfaces can properly transmit and receive DLDP packets.
- If DLDP is disabled in the system view, DLDP is disabled on all interfaces, and all the DLDP configurations are deleted, which cannot be restored.
- Unidirectional links can be detected only for GE optical modules.

Example

Enable DLDP globally.

```
<HUAWEI> system-view
[HUAWEI] dldp enable
```

Enable DLDP on interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dldp enable
```

12.4.9 dldp interval

Function

The **dldp interval** command sets the interval for sending Advertisement packets.

The **undo dldp interval** command restores the default interval for sending Advertisement packets.

The default interval for sending Advertisement packets is 5 seconds.

Format

dldp interval *interval*

undo dldp interval [*interval*]

Parameters

Parameter	Description	Value
interval	Specifies the interval for sending Advertisement packets.	The value is an integer ranging from 1 to 100, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Applicable Environment

An interface in Advertisement state sends Advertisement packets. DLDP creates a neighbor entry, starts the entry timer, and transits to the Probe state if the neighbor entry does not exist on the peer interface. DLDP updates the entry timer if the neighbor entry exists.

You can adjust the interval for sending Advertisement packets to allow DLDP to detect unidirectional links on different networks.

The interval for sending Advertisement packets must be smaller than one third of the STP convergence time.

- If the interval is too long, STP loops occur before a unidirectional link is shut down on a DLDP interface, which may lead to forwarding of many error packets.
- If the interval is too short, the traffic volume on the network increases.

Prerequisites

DLDP has been enabled globally using the **dldp enable** command.

Precautions

After the **dldp interval** command is executed, the local device running DLDP deletes information about the peer device and triggers the peer device to clear information about the local device. In this way, the negotiation can be re-performed.

Ensure that the interval for sending Advertisement packets is set to the same value on the local and peer devices connected through optical fibers or copper twisted pairs.

Example

Set the interval for sending Advertisement packets to 20 seconds on all DLDP interfaces.

```
<HUAWEI> system-view
[HUAWEI] dldp enable
[HUAWEI] dldp interval 20
```

12.4.10 dldp reset

Function

The **dldp reset** command resets the DLDP status of an interface so that the interface re-detects unidirectional links.

Format

dldp reset

Parameters

None

Views

System view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a unidirectional link is detected, the corresponding interface enters the Disable state. The system prompts you to shut down the interface or automatically sets the interface state to DLDP Down according to the configuration. To enable the interface to detect unidirectional links again, you can reset the DLDP status of the interface as follows:

- If the interface is shut down using the **shutdown (interface view)** command, run the **undo shutdown (interface view)** command to enable the interface to detect unidirectional links again. If the system automatically sets the interface state to DLDP Down, wait the interface to recover using the auto recovery mechanism after the link state becomes bidirectional using the auto recovery mechanism.

- Run the **dldp reset** command to restore the interface. The DLDP status of the interface after recovery depends on the physical status of the port. If the physical status is Down, the DLDP status of the interface changes to Inactive. If the physical status is Up, the DLDP status changes to Active.

You can reset the DLDP status globally or on the interfaces.

- When you run the **dldp reset** command in the interface view, the command takes effect only on this interface.
- When you run the **dldp reset** command in the system view, the command takes effect on all disabled interfaces.

Prerequisites

- If you run this command in the system view, ensure that DLDP has been enabled globally using the **dldp enable** command.
- If you run this command in the interface view, ensure that DLDP has been enabled globally and on the interfaces using the **dldp enable** command.

Example

Reset the DLDP status of all disabled interfaces.

```
<HUAWEI> system-view
[HUAWEI] dldp reset
```

Reset the DLDP status of disabled interfaceGE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dldp reset
```

12.4.11 dldp unidirectional-shutdown

Function

The **dldp unidirectional-shutdown** command sets the shutdown mode if DLDP detects a unidirectional link on an interface.

The **undo dldp unidirectional-shutdown** command restores the default shutdown mode if DLDP detects a unidirectional link on an interface.

By default, an interface is shut down automatically if DLDP detects a unidirectional link on the interface.

Format

dldp unidirectional-shutdown { **auto** | **manual** }

undo dldp unidirectional-shutdown [**auto** | **manual**]

Parameters

Parameter	Description	Value
auto	Specifies the automatic mode.	-

Parameter	Description	Value
manual	Specifies the manual mode. When the traffic is heavy or CPU usage is high, the manual shutdown mode is recommended.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When DLDP detects a unidirectional link on an interface, run the **dldp unidirectional-shutdown** command to configure the shutdown mode for the interface. The following shutdown modes are available:

- Manual mode: This mode can prevent DLDP from shutting down the port immediately when the network performance is poor. This leads to failure in packet forwarding. It is a compromise mode used to prevent interface shutdown due to incorrect judgment of the system. In this mode, DLDP detects unidirectional links, and the network administrator manually shuts down the interface. When the DLDP state machine detects a unidirectional link, the system sends trap messages to prompt the network administrator to shut down the interface. Then the DLDP state machine changes to the Disable state.
- Automatic mode: It is the default mode. When a unidirectional link is detected, the DLDP state machine changes to the Disable state, records the trap messages, and sets the interface status to Blocking.

Prerequisites

DLDP has been enabled globally using the **dldp enable** command.

Precautions

When the traffic is heavy or CPU usage is high, the manual shutdown mode is recommended.

Example

Configure DLDP to automatically shut down an interface when a unidirectional link is detected.

```
<HUAWEI> system-view
[HUAWEI] dldp enable
[HUAWEI] dldp unidirectional-shutdown auto
```

12.4.12 dldp work-mode

Function

The **dldp work-mode** command sets the working mode of DLDP.

The **undo dldp work-mode** command restores the default working mode of DLDP.

By default, the working mode of DLDP is enhance.

Format

dldp work-mode { **enhance** | **normal** }

undo dldp work-mode [**enhance** | **normal**]

Parameters

Parameter	Description	Value
enhance	Indicates enhance mode of DLDP.	-
normal	Indicates normal mode of DLDP.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A unidirectional link fault may be caused by cross connections of optical fibers or disconnection of one optical fiber. You can use the **dldp work-mode** command to set the working mode of DLDP to detect the preceding two types of unidirectional links.

DLDP can work in either of the following working modes:

- Normal: DLDP does not automatically detect a neighbor when aging out a neighbor entry. In this mode, the system can identify only unidirectional links caused by cross connections of optical fibers. When the aging timer of a neighbor times out, the local end deletes the entry of the neighbor and sends an Advertisement packet with an RSY tag.

- Enhance: DLDP automatically detects a neighbor when aging out a neighbor entry. In this mode, the system can identify unidirectional links caused by cross connections of optical fibers or disconnection of one optical fiber. In this mode, when the aging timer of a neighbor times out, the local end starts the enhance timer and consecutively sends eight Probe packets to detect the neighbor, at the rate of one packet per second. If the local end does not receive any Echo packet from the neighbor when the Echo timer times out, DLDP enters the Disable state.

Prerequisites

DLDP has been enabled globally using the **dldp enable** command.

Example

Set the working mode of DLDP to enhance.

```
<HUAWEI> system-view
[HUAWEI] dldp enable
[HUAWEI] dldp work-mode enhance
```

12.4.13 reset dldp statistics

Function

The **reset dldp statistics** command deletes the statistics about DLDP packets on an interface.

Format

reset dldp statistics [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type* *interface-number*	Deletes the statistics about DLDP packets on a specified DLDP interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number. If no interface is specified, the statistics about DLDP packets on all DLDP interfaces are deleted. If an interface is specified, the statistics about DLDP packets on the interface are deleted.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before collecting statistics about DLDP packets on an interface in a specified period, you can run the **reset dldp statistics** command to delete the existing DLDP packet statistics on the interface.

Precautions

The **reset dldp statistics** command deletes the statistics about DLDP packets. Exercise caution when running this command.

Example

Delete the statistics about DLDP packets on all DLDP interfaces.

```
<HUAWEI> reset dldp statistics
```

12.5 Smart Link And Monitor Link Configuration Commands

12.5.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

12.5.2 display monitor-link group

Function

The **display monitor-link group** command displays information about a specified Monitor Link group or all Monitor Link groups.

Format

display monitor-link group { **all** | *group-id* }

Parameters

Parameter	Description	Value
all	Displays information about all Monitor Link groups.	-
group-id	Displays information about the specified Monitor Link groups.	The value is an integer that ranges from 1 to 16.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After creating a Monitor Link group and adding uplink and downlink interfaces to the group, run this command to view the information about the group. The displayed information includes the name and status of each member interface.

Prerequisites

A Monitor Link group has been created using the **monitor-link group** command, and uplink and downlink interfaces have been added to the Monitor Link group using the **port** command.

Example

Display information about Monitor Link group 1.

```
<HUAWEI> display monitor-link group 1
Monitor Link group 1 information :
Recover-timer is 3 sec.
----------------------------------------------------------------------------------------------------
Member                 Role     State Last-up-time                    Last-down-time
----------------------------------------------------------------------------------------------------
GigabitEthernet0/0/1   UpLk     DOWN  0000/00/00 00:00:00 UTC+00:00      0000/00/00 00:00:00 UTC
+00:00
GigabitEthernet0/0/2   DwLk[1]  DOWN  0000/00/00 00:00:00 UTC+00:00      0000/00/00 00:00:00 UTC
+00:00
<HUAWEI> display monitor-link group 1
Monitor Link group 1 information :
Recover-timer is 3 sec.
----------------------------------------------------------------------------------------------------
Member                 Role     State Last-up-time                    Last-down-time
----------------------------------------------------------------------------------------------------
GigabitEthernet0/0/1   UpLk     DOWN  0000/00/00 00:00:00 UTC+00:00      0000/00/00 00:00:00 UTC
+00:00
GigabitEthernet0/0/2   UpLk     DOWN  0000/00/00 00:00:00 UTC+00:00      0000/00/00 00:00:00 UTC
+00:00
GigabitEthernet0/0/3   DwLk[1]  DOWN  0000/00/00 00:00:00 UTC+00:00      0000/00/00 00:00:00 UTC
+00:00
```

Table 12-33 Description of the display monitor-link group command output

Item	Description
Recover-timer	Wait-to-Restore time of the Monitor Link group, expressed in seconds. Use the **timer recover-time** command to set this parameter.
Member	Member interface of a Monitor Link group.
Role	Role of a member interface. ● UpLk: An uplink. ● DwLk[1]: A downlink. The number within the square brackets specifies a downlink ID.
State	Physical status of a member interface. ● UP: The member interface is in the Up state. ● DOWN: The number interface is in the Down state.

Item	Description
Last-up-time	Time when the member interface becomes Up for the last time. The format is YYYY/MM/DD HH:MM:SS UTC+HH:MM. If no record indicates that the interface is switched from Down to Up, the time is displayed as 0000/00/00 00:00:00 UTC +00:00.
Last-down-time	Time when the member interface becomes Down for the last time. The format is YYYY/MM/DD HH:MM:SS UTC+HH:MM. If no record indicates that the interface is switched from Up to Down, the time is displayed as 0000/00/00 00:00:00 UTC +00:00.

12.5.3 display monitor-link protocol-parameter group

Function

The **display monitor-link protocol-parameter group** command displays internal data of all Monitor Link groups or a specified Monitor Link group, including member interface information and Monitor Link configuration.

Format

display monitor-link protocol-parameter group { **all** | *group-id* }

Parameters

Parameter	Description	Value
all	Displays internal data of all Monitor Link groups.	-
group-id	Displays internal data of a specified Monitor Link group.	The value is an integer that ranges from 1 to 16.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

This command displays internal data of Monitor Link groups for diagnosis. You can use this command to check internal status data of a Monitor Link group.

Example

Display the internal data of Monitor Link group 1.

```
<HUAWEI> display monitor-link protocol-parameter group 1
MONITOR-LINK Group 1:
********************************
 *RecoverTime:        3 sec.
 *TimeCounter:        0 sec.
 *Uplink Info:
  IfIndex:            357(GigabitEthernet4/0/40/0/4)
  PortType:           2(MTLK_PORT_SWITCH)
  LinkStatus:         0(down)
  IFNET_S
   SMLK Group ID:     0
   MTLK Group ID:     1
   Role:              4(uplink)
 *Downlink 1 Info:
  IfIndex:            358(GigabitEthernet4/0/50/0/5)
  LinkStatus:         0(down)
  IsShutdown:         1(shutdown)
<HUAWEI> display monitor-link protocol-parameter group 1
MONITOR-LINK Group 1:
********************************
 *RecoverTime:        3 sec.
 *TimeCounter:        0 sec.
 *Uplink Info:
  IfIndex:            357(GigabitEthernet4/0/40/0/4)
  PortType:           2(MTLK_PORT_SWITCH)
  LinkStatus:         0(down)
  IFNET_S
   SMLK Group ID:     0
   MTLK Group ID:     1
   Role:              4(uplink)
 *Uplink Info:
  IfIndex:            358(GigabitEthernet4/0/50/0/5)
  PortType:           2(MTLK_PORT_SWITCH)
  LinkStatus:         0(down)
  IFNET_S
   SMLK Group ID:     0
   MTLK Group ID:     1
   Role:              4(uplink)
 *Downlink 1 Info:
  IfIndex:            359(GigabitEthernet4/0/60/0/6)
  LinkStatus:         0(down)
  IsShutdown:         1(shutdown)
```

Table 12-34 Description of the display monitor-link protocol-parameter group command output

Item	Description
MONITOR-LINK Group 1	ID of a Monitor Link group.

Item	Description
RecoverTime	Wait-to-restore (WTR) time of the Monitor Link group The WTR time can be set using the **timer recover-time** command.
TimeCounter	WTR timer counter value.
Uplink Info	Information about the uplink interface in the Monitor Link group.
IfIndex	Interface index.
PortType	Type of the interface. ● 0(MTLK_PORT_UNKOWN): invalid interface type ● 1(MTLK_PORT_SMLK): Smart Link group ● 2(MTLK_PORT_SWITCH): Ethernet or Eth-Trunk interface
LinkStatus	Link status of an interface: ● 0(down) ● 1(up)
IFNET_S	Mnemonic symbol, indicating information saved on an interface.
SMLK Group ID	ID of a Smart Link group.
MTLK Group ID	ID of a Monitor Link group.
Role	Role of an interface in the Monitor link group.
Ctrl Vlan	Control VLAN.
Password	Password of Flush packets.
Downlink 1 Info	Information about downlink interface 1.
IsShutdown	Whether the downlink interface is shut down.

12.5.4 display smart-link flush

Function

The **display smart-link flush** command displays information about received Flush packets.

Format

display smart-link flush

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display smart-link flush** command displays information about received Flush packets, which helps you learn about link switchover information and identify interface faults. To delete information about received Flush packets, run the **reset smart-link flush** command.

Precautions

The master and slave interfaces of the Smart Link group are both in Down state. When the master interface or slave interface becomes Up, statistics on Flush packets may be inaccurate.

Prerequisites

The downstream device has been enabled to send Flush packets using the **flush send** command and the local device has been enabled to receive Flush packets using the **smart-link flush receive** command.

Follow-up Procedure

If the current information about Flush packets is no longer needed, run the **reset smart-link flush** command to delete the information.

Example

Display information about the received Flush packets.

```
<HUAWEI> display smart-link flush
Receive flush packets count:              1191
Receive last flush interface:             GigabitEthernet0/0/1
Receive last flush packet time:           02:42:37 UTC+03:00 2009/11/27
Receive last flush packet source mac:     00e0-fc00-0140
Receive last flush packet control vlan ID: 311
```

Table 12-35 Description of the display smart-link flush command output

Item	Description
Receive flush packets count	Number of Flush packets received.
Receive last flush interface	Interface that receives the latest Flush packet.

Item	Description
Receive last flush packet time	Time when the latest Flush packet is received, in any of the following formats: - HH:MM:SS YYYY-MM-DD - HH:MM:SS UTC±HH:MM DST YYYY-MM-DD - HH:MM:SS UTC±HH:MM YYYY-MM-DD - HH:MM:SS DST YYYY-MM-DD UTC±HH:MM indicates that a time zone is configured using the **clock timezone** command; DST indicates that the daylight saving time is configured using **clock daylight-saving-time** command.
Receive last flush packet source mac	Source MAC address of the latest Flush packet received.
Receive last flush packet control vlan ID	Control VLAN ID of the latest Flush packet received.

12.5.5 display smart-link group

Function

The **display smart-link group** command displays information about all Smart Link groups or a specified Smart Link group.

Format

display smart-link group { **all** | *group-id* }

Parameters

Parameter	Description	Value
all	Displays information about all Smart Link groups.	-
group-id	Displays information about a specified Smart Link group.	The value is an integer that ranges from 1 to 16.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display smart-link group** command displays information about a Smart Link group, including member interfaces in the Smart Link group and link status. If a Smart Link group fails, you can find the cause of the fault according to the displayed information.

Prerequisites

A Smart Link group has been created by using the **smart-link group** command, and member interfaces have been added to the Smart Link group by using the **port** command.

Example

Display information about Smart Link group 1.

```
<HUAWEI> display smart-link group 1
Smart Link group 1 information :
  Smart Link group was enabled
  Load-Balance Instance: 5 7 9 to 10
  Protected-vlan reference-instance: 4 to 10
  DeviceID: 00e0-fc12-3456  Control-vlan ID: 1011
  Member                 Role   InstanceID State    Flush Count Last-Flush-Time
  --------------------------------------------------------------------------------

  GigabitEthernet0/0/1    Master 4         Inactive 0          0000/00/00 00:00:00 UTC+00:00
  GigabitEthernet0/0/1    Master 5         Active   0          0000/00/00 00:00:00 UTC+00:00
  GigabitEthernet0/0/1    Master 6         Inactive 0          0000/00/00 00:00:00 UTC+00:00
  GigabitEthernet0/0/1    Master 7         Active   0          0000/00/00 00:00:00 UTC+00:00
  GigabitEthernet0/0/1    Master 8         Inactive 0          0000/00/00 00:00:00 UTC+00:00
  GigabitEthernet0/0/1    Master 9         Active   0          0000/00/00 00:00:00 UTC+00:00
  GigabitEthernet0/0/1    Master 10        Active   0          0000/00/00 00:00:00 UTC+00:00
  GigabitEthernet0/0/2    Slave  4         Inactive 0          0000/00/00 00:00:00 UTC+00:00
  GigabitEthernet0/0/2    Slave  5         Active   0          0000/00/00 00:00:00 UTC+00:00
  GigabitEthernet0/0/2    Slave  6         Inactive 0          0000/00/00 00:00:00 UTC+00:00
  GigabitEthernet0/0/2    Slave  7         Active   0          0000/00/00 00:00:00 UTC+00:00
  GigabitEthernet0/0/2    Slave  8         Inactive 0          0000/00/00 00:00:00 UTC+00:00
  GigabitEthernet0/0/2    Slave  9         Active   0          0000/00/00 00:00:00 UTC+00:00
  GigabitEthernet0/0/2    Slave  10        Active   0          0000/00/00 00:00:00 UTC+00:00
```

Table 12-36 Description of the display smart-link group command output

Item	Description
Smart Link group	Whether a Smart Link group is enabled. ● enabled: The Smart Link group is enabled. ● disabled: The Smart Link group is disabled. Run the **smart-link enable** command to modify this parameter.

Item	Description
Wtr-time	WTR time of a Smart Link group. Run the **timer wtr** command to modify this parameter.
Link status	Interface on which the data streams of a Smart Link group are locked. ● lock: Data streams are locked on the master interface. ● force: Data streams are locked on the slave interface. Run the **smart-link** command to modify this parameter.
Load-Balance Instance	ID of the load balancing instance. Run the **load-balance instance** command to modify this parameter.
Protected-vlan reference-instance	ID of the protection VLAN instance. Run the **protected-vlan reference-instance** command to modify this parameter.
DeviceID	MAC address of the local device.
Control-vlan ID	Control VLAN ID of a Smart Link group. Run the **flush send** command to modify this parameter.
Member	Member interfaces added to a Smart Link group. Run the **port** command to modify this parameter.
Role	Role of a member interface in a Smart Link group. ● Master: master interface ● Slave: slave interface Run the **port** command to modify this parameter.
InstanceID	Protection instance ID. Run the **protected-vlan reference-instance** command to modify this parameter. If **protected-vlan reference-instance** is not configured, instance 0 and all instances created by **instance** are displayed.

Item	Description
State	Status of a member interface. ● Active: The member interface is forwarding packets. ● Inactive: The member interface is blocked. ● Unknown: The status of the member interface is unknown (for example, the Smart Link group is disabled or no member interface is added to the group).
Flush Count	Number of Flush packets sent.
Last-Flush-Time	Time when the latest Flush packet is sent. The format is YYYY/MM/DD HH:MM:SS UTC+HH:MM. If no Flush packet has ever been sent, the time is displayed as 0000/00/00 00:00:00 UTC+00:00.

12.5.6 display smart-link protocol-parameter group

Function

The **display smart-link protocol-parameter group** command displays internal data of all Smart Link groups or a specified Smart Link group, including member interface information and Smart Link configuration.

Format

display smart-link protocol-parameter group { **all** | *group-id* }

Parameters

Parameter	Description	Value
all	Displays internal data of all Smart Link groups.	-
group-id	Displays internal data of a specified Smart Link group.	The value is an integer that ranges from 1 to 16.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

This command displays internal data of Smart Link groups for diagnosis. You can use this command to check internal status data of a Smart Link group.

Example

Display the internal data of Smart Link group 1.

```
<HUAWEI> display smart-link protocol-parameter group 1
SMART-LINK Group 1:
********************************
 *Master Port Info:
  IfIndex:            0()
  PortStatus:         1(unknown)
  LinkStatus:         0(down)
  IFNET_S
   SMLK Group ID:      0
   MTLK Group ID:      0
   Role:              0(invalid)
   Ctrl Vlan:          0
   Password:
 *Slave Port Info:
  IfIndex:            0()
  PortStatus:         1(unknown)
  LinkStatus:         0(down)
  IFNET_S
   SMLK Group ID:      0
   MTLK Group ID:      0
   Role:              0(invalid)
   CTRL Vlan:          0
   Password:
 *FSM Info:
  CurrentState:       0(Idle)
  TransEvent:         0(Invalid)
  TransIfIndex:       0()
 *Other Config:
  Lock|Force:         0(unknown)
  WtrTime:            60 sec.
  RevertEnable:       0(disable)
  GroupActive:        0(inactive)
  MTLK Uplink:        0
  RvtTimeCounter:     0 sec.
 *Flush Send Info:
  CTRL Vlan:          0
  Password:
 *1AG Event Info:
  Event Type:         0
```

Table 12-37 Description of the display smart-link protocol-parameter group command output

Item	Description
SMART-LINK Group 1	ID of a Smart Link group.
Master Port Info	Information about the master interface in the Smart Link group.
IfIndex	Interface index.

Item	Description
PortStatus	Physical status of an interface: - 1(unknown) - 2(active) - 3(inactive)
LinkStatus	Link status of an interface: - 0(down) - 1(up)
IFNET_S	Mnemonic symbol, indicating information saved on an interface.
SMLK Group ID	ID of a Smart Link group.
MTLK Group ID	ID of a Monitor Link group.
Role	Role of a member interface in a Smart Link group: - 0(invalid) - 1(master) - 2(slave)
Ctrl Vlan	Control VLAN. When the device sends Flush packets, run the **flush send** command to specify this parameter. When the device receives Flush packets, run the **smart-link flush receive** command to specify this parameter.
Password	Password of Flush packets. When the device sends Flush packets, run the **flush send** command to specify this parameter. When the device receives Flush packets, run the **smart-link flush receive** command to specify this parameter.
Slave Port Info	Information about a slave interface.
FSM Info	Finite state machine (FSM) information.
CurrentState	Current state of the state machine: - 0(Idle) - 1(Init) - 2(Master) - 3(Slave) - 0(MultiIdle) (used in load balancing scenarios)

Item	Description
TransEvent	Latest state machine transition event.
TransIfIndex	Index of the interface where the latest state machine transition event occurs.
Other Config	Other configuration.
Lock|Force	Interface where data streams are locked. ● lock: indicates that data streams are locked on the master interface. ● force: indicates that data streams are locked on the slave interface.
WtrTime	Wait-to-restore (WTR) time of a Smart Link group. The WTR time can be changed using the **timer wtr** command.
RevertEnable	Whether revertive switching is enabled. To configure the revertive switching function, run the **restore enable** command.
GroupActive	Whether the current Smart Link group is enabled.
MTLK Uplink	Uplink interface of a Monitor Link group.
RvtTimeCounter	WTR timer counter.
Flush Send Info	Information about Flush packets.
1AG Event Info	802.1ag event information.
Event Type	Type of an 802.1ag event.

12.5.7 flush send

Function

The **flush send** command enables a Smart Link group to send Flush packets.

The **undo flush send** command disables a Smart Link group from sending Flush packets.

By default, a Smart Link group is disabled from sending Flush packets.

Format

flush send control-vlan *vlan-id* [**password** { **simple** | **sha** } *password*]

undo flush send [**control-vlan** *vlan-id* [**password** { **simple** | **sha** } *password*]]

Parameters

Parameter	Description	Value
control-vlan *vlan-id*	Specifies the control VLAN ID of the Flush packets to be sent.	The value is an integer that ranges from 1 to 4094.
password simple	Indicates that the Flush packets sent from the Smart Link group contain a password in plain text. **NOTE** The password is saved in the configuration file in cipher text for security.	-
password sha	Indicates that the Flush packets sent from the Smart Link group contain an SHA2-256-encrypted password. **NOTE** The password is saved in the configuration file in cipher text for security.	-
password	Specifies the password carried in Flush packets.	The value is a string of 8 to 16 case-sensitive characters in plain text and consists of at least two of the following: lowercase letters, uppercase letters, digits, and special characters excluding question marks (?) and spaces.

Views

Smart Link group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a switchover occurs between the master and slave links in a Smart Link group, the existing forwarding entries do not apply to the new topology. All the

MAC address entries and ARP entries on the network need to be updated. Therefore, the Smart Link group sends Flush packets to request other devices to update their MAC address tables and ARP tables.

The **flush send** command enables a Smart Link group to send Flush packets and sets the encryption mode, control VLAN ID, and password for Flush packets.

Prerequisites

A Smart Link group has been created using the **smart-link group** command.

Follow-up Procedure

Run the **smart-link flush receive** command on the upstream device interface to enable the interface to receive Flush packets. Ensure that the control VLAN ID and password set for the Flush packets received by the upstream device are the same as those set for the Flush packets sent by the local device. That is, the control VLAN ID and password in Flush packets sent by a device must be the same as those in Flush packets received by the device.

Precautions

- The specified control VLAN exists on the device. If it does not exist, the Flush packets fail to send.
- The control VLAN cannot be the VLAN mapped by a VBST dynamic instance.
- The control VLAN must be in the protected instance list configured by the **protected-vlan reference-instance** command.
- The Flush packets mentioned here are used only for communication between Huawei S series switches and CE series switches. Other manufacturers may define the Flush packet format differently. The peer device must be enabled to receive Flush packets.
- The original encryption mode and password are deleted after you run this command to configure the new ones.
- For security purposes, you are advised to use SHA2-256 as the authentication algorithm of Smart Link.
- The original password cannot be retrieved after it is encrypted using the SHA2-256 algorithm. If you forget your password, configure a new password.

Example

Enable Smart Link group 1 to send Flush packets with control VLAN ID 100 and password YsHsjx_202206.

```
<HUAWEI> system-view
[HUAWEI] smart-link group 1
[HUAWEI-smlk-group1] flush send control-vlan 100 password sha YsHsjx_202206
```

12.5.8 load-balance instance

Function

The **load-balance instance** command sets the load-balancing instances for a Smart Link group.

The **undo load-balance instance** command deletes load-balancing instances for a Smart Link group.

Format

load-balance instance { *instance-id1* [**to** *instance-id2*] } &<1-10> **slave**

undo load-balance instance { **all** | { *instance-id1* [**to** *instance-id2*] } &<1-10> [**slave**] }

Parameters

Parameter	Description	Value
instance-id1 [**to** *instance-id2*]	Specifies ID of a Smart Link instance. ● *instance-id1* specifies the first instance ID. The value is an integer that ranges from 0 to 4094. ● **to** *instance-id2* specifies the last instance ID. The value of *instance-id2* is an integer that ranges from 0 to 4094. The value of *instance-id2* must be greater than the value of *instance-id1*. The *instance-id1* and *instance-id2* parameters identify a range of instances. If **to** *instance-id2* is not specified, only one instance specified by *instance-id1* is configured.	-
slave	Indicates that the slave interface sends packets of the specified Smart Link instances.	-
all	Deletes all load-balancing instances of a Smart Link group.	-

Views

Smart Link group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If load balancing is not configured for a Smart Link group, only the active link transmits data traffic and the standby link is idle.

The **load-balance instance** command implements load balancing in a Smart Link group. When both links in the Smart Link group are Up, the standby link transmits the traffic from the VLANs mapping the specified instances.

The instances specified in the command are Multiple Spanning Tree Protocol (MSTP) instances. Each instance maps a range of VLANs. Multiple instances can be bound to the standby link to implement load balancing.

Prerequisites

A Smart Link group has been created using the **smart-link group** command, and VLANs have been mapped to the specified instances using the **instance** command.

Follow-up Procedure

After configuring load balancing in a Smart Link group, you can use the **display smart-link group** command to verify the configuration.

Precautions

- The VLANs mapping the instances in the command cannot be used as the control VLAN ID of Flush packets sent by the local device.
- Before you run the **load-balance instance** command in a Smart Link group, the Smart Link group must be disabled.
- The load balancing instance specified by the **load-balance instance** command must be in the protected instance list by the **protected-vlan reference-instance** command.

Example

Configure load balancing in Smart Link group 3. Configure the standby link to transmit the traffic from the VLANs mapping the instance 1.

```
<HUAWEI> system-view
[HUAWEI] smart-link group 3
[HUAWEI-smlk-group3] load-balance instance 1 slave
```

12.5.9 monitor-link group

Function

The **monitor-link group** command creates a Monitor Link group and displays the Monitor Link group view. If the specified Monitor Link group exists, the command directly displays the Monitor Link group view.

The **undo monitor-link group** command deletes a Monitor Link group.

By default, no Monitor Link group exists.

Format

monitor-link group *group-id*

undo monitor-link group *group-id*

Parameters

Parameter	Description	Value
group-id	Specifies the ID of a Monitor Link group.	The value is an integer that ranges from 1 to 16.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Monitor Link extends link redundancy of Smart Link. It synchronizes the downlink interface status with the uplink interface status so that the downstream device can be notified quickly when the uplink interface fails. The downstream device then triggers a link switchover in the Smart Link group. This prevents packet loss caused by the uplink interface failure. Before using the Monitor Link group, you must create a Monitor Link group and enter the Monitor Link group view.

Follow-up Procedure

Add uplink and downlink interfaces to the created Monitor Link group.

Precautions

Before deleting a Monitor Link group that has member interfaces, run the **undo port** command to delete all the member interfaces.

Example

Create Monitor Link group 1.

```
<HUAWEI> system-view
[HUAWEI] monitor-link group 1
[HUAWEI-mtlk-group1]
```

Delete Monitor Link group 2.

```
<HUAWEI> system-view
[HUAWEI] undo monitor-link group 2
```

12.5.10 port (Monitor Link group view)

Function

The **port** command adds an interface to a Monitor Link group and specifies the link connected to the interface as an uplink or a downlink.

The **undo port** command deletes an uplink or a downlink interface from a Monitor Link group.

By default, a Monitor Link group has no member interface.

Format

port *interface-type interface-number* { **downlink** [*downlink-id*] | **uplink** }

undo port [*interface-type interface-number*] { **downlink** *downlink-id* | **uplink** }

undo port all

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of the interface to be added to a Monitor Link group. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
downlink [*downlink-id*]	Configures the current interface as a downlink interface and specifies the downlink ID.	The value is an integer that ranges from 1 to 512. If the *downlink-id* parameter is not specified, the system allocates an ID to the interface in an ascending order.
uplink	Configures the current interface as an uplink interface.	-
all	Deletes all member interfaces from a Monitor Link group.	-

Views

Monitor Link group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A Monitor Link group consists of an uplink interface or two uplink interfaces and several downlink interfaces. If the uplink interface fails, the Monitor Link group automatically disables all the downlink interfaces. After configuring a Monitor Link group, add uplink and downlink interfaces to the group. The Monitor Link group then can synchronize the downlink interface status with the uplink interface status.

Prerequisites

A Monitor Link group has been created by using the **monitor-link group** command.

Precautions

A Monitor Link group supports a maximum of two uplink interfaces (physical interfaces, Eth-Trunk interfaces, or a combination of them) or one Smart Link group.

The uplink interface status determines the downlink interface status.

- If there is only one uplink interface and the uplink interface is in Up state in the Monitor Link group or the uplink interface changes from the Down state to the Up state in the group, all downlink interfaces go Up. If there are two uplink interfaces and both of them are Down, all downlink interfaces are shut down. If only one uplink interface is Down, the downlink interfaces are Up.
- If there is only one uplink interface and the uplink interface is deleted from the Monitor Link group or the uplink interface changes from the Up state to the Down state in the group, all downlink interfaces are shut down. If there are two uplink interfaces and only one of them is Down, all downlink interfaces are shut down.

If an uplink interface exists in the Monitor Link group, run the **undo port** command to delete this interface before adding a new one.

An interface cannot be added to a Monitor Link group in the following situations:

- The interface has been added to an Eth-Trunk.
- The interface has been added to a Smart Link group.
- The interface has been added to another Monitor Link group.

Example

Add GE0/0/1 to Monitor Link group 1 and specify this interface as the uplink interface.

```
<HUAWEI> system-view
[HUAWEI] monitor-link group 1
[HUAWEI-mtlk-group1] port gigabitethernet 0/0/1 uplink
```

Add GE0/0/2 to a Monitor Link group and specify this interface as the downlink interface and the link ID as 1.

```
<HUAWEI> system-view
[HUAWEI] monitor-link group 1
[HUAWEI-mtlk-group1] port gigabitethernet 0/0/2 downlink 1
```

12.5.11 port (Smart Link group view)

Function

The **port** command adds an interface to a Smart Link group and specifies the interface as the master or slave interface.

The **undo port** command deletes a master or slave interface from a Smart Link group.

By default, a Smart Link group has no member interface.

Format

port *interface-type interface-number* { **master** | **slave** }

undo port *interface-type interface-number* { **master** | **slave** }

undo port { **all** | **master** | **slave** }

Parameters

Parameter	Description	Value
interface-type interface-number	• *interface-type* specifies the interface type. • *interface-number* specifies the interface number.	-
master	Specifies an interface as a master interface.	-
slave	Specifies an interface as a slave interface.	-
all	Deletes all the interfaces in a Smart Link group.	-

Views

Smart Link group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The Smart Link function implements link redundancy and rapid link status transition on a dual-homed network. When a device is connected to upstream devices by two uplink interfaces, one link is blocked and functions as the backup of the other link. When the active link fails, traffic is switched to the other link. To implement the Smart Link function, create a Smart Link group and add two interfaces to the Smart Link group, one as the master interface, and the other as the slave interface. The master interface is in active state; the slave interface is in inactive state.

Prerequisites

A Smart Link group has been created using the **smart-link group** command. The Spanning Tree Protocol (STP) has been disabled on the interfaces to be added to the Smart Link group by using the **stp disable** command.

Follow-up Procedure

Run the **smart-link enable** command to enable the Smart Link group. Run the **flush send** command to enable the Smart Link group to send Flush packets, and run the **smart-link flush receive** command on the upstream device interface to enable the interface to receive Flush packets.

Precautions

If port security is also configured, packets will be discarded when the number of MAC addresses learned by an interface reaches the upper limit. In this case, Smart Link Flush packets may fail to be received. To prevent this, you are advised not to use both Smart Link and port security.

Before adding a new master or slave interface to a Smart Link group, delete the previous one from the Smart Link group.

The slave interface is blocked when the Smart Link group is enabled.

An interface can be added to only one Smart Link group.

If an interface has been added to a Smart Link group, the following configurations cannot be performed on the interface. If any of the following configurations is performed on an interface, the interface cannot be added to a Smart Link group:

- RRPP, SEP, or ERPS
- STP
- Adding an interface to an Eth-Trunk
- Adding an interface to a Monitor Link group
- Adding an interface to another Smart Link group
- Service loopback (for an Eth-Trunk)

Example

Add GE0/0/1 to Smart Link group 1 and specify the interface as the master interface.

```
<HUAWEI> system-view
[HUAWEI] smart-link group 1
[HUAWEI-smlk-group1] port gigabitethernet 0/0/1 master
```

12.5.12 protected-vlan reference-instance

Function

The **protected-vlan reference-instance** command configures the protection instances for a Smart Link group.

The **undo protected-vlan reference-instance** command deletes the protection instances of a Smart Link group.

Format

protected-vlan reference-instance { *instance-id1* [**to** *instance-id2*] }&<1-10>

undo protected-vlan reference-instance { **all** | { *instance-id1* [**to** *instance-id2*] }&<1-10> }

Parameters

Parameter	Description	Value
instance-id1 [**to** *instance-id2*]	Specifies the protection instance ID of a Smart Link group. ● *instance-id1* specifies the first instance ID. The value is an integer that ranges from 0 to 4094. ● **to** *instance-id2* specifies the last instance ID. The value of *instance-id2* is an integer that ranges from 0 to 4094. The value of *instance-id2* cannot be smaller than the value of *instance-id1*. The *instance-id1* and *instance-id2* parameters identify a range of protection instances. If **to** *instance-id2* is not specified, only the protection instance specified by *instance-id1* is configured.	-
all	Specifies IDs for deleting all protection instances of a Smart Link group.	-

Views

Smart Link group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **protected-vlan reference-instance** command enables Smart Link to transmit or block the data packets from the VLAN mapping the protection instances. The Smart Link function takes effect only on the VLANs mapping the protection instances. The **protected-vlan reference-instance** command enables users to unbind some VLANs from protection instances. Transmitting the data from these VLANs is not restricted by Smart Link.

Prerequisites

A Smart Link group has been created using the **smart-link group** command, and VLANs have been mapped to the specified instances using the **instance** command.

Precautions

Before you run the **protected-vlan reference-instance** command in a Smart Link group, the Smart Link group must be disabled.

The instances specified in the **protected-vlan reference-instance** command cannot be the VBST dynamic instances.

The Smart Link function takes effect only on the VLANs mapped to the protection instances. Therefore, the users' service data VLANs and VLANs mapped to load-balancing instances must be contained in the VLANs mapped to protection instances.

The VLANs not mapped to protection instances may cause network storms.

Example

Set the protection instance ID of a Smart Link group to 10.

```
<HUAWEI> system-view
[HUAWEI] smart-link group 1
[HUAWEI-smlk-group1] protected-vlan reference-instance 10
```

12.5.13 reset smart-link flush

Function

The **reset smart-link flush** command clears statistics about Flush packets.

Format

reset smart-link flush

Parameters

None

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To collect the statistics in a specified period, you can run the **reset smart-link flush** command to clear historical data before collecting the statistics. For example, a Smart Link group sends a large number of Flush packets after a failover occurs. You can view the Flush packet statistics to locate the fault. After locating the fault, you can use the **reset smart-link flush** command to clear the statistics so that you can collect new statistics for fault location when another failover occurs.

Precautions

The cleared statistics cannot be restored. Run the **display smart-link flush** command to view Flush packet statistics before clearing the statistics.

Example

Clear statistics about Flush packets.

```
<HUAWEI> reset smart-link flush
```

12.5.14 restore enable

Function

The **restore enable** command enables the revertive switching of a Smart Link group.

The **undo restore enable** command disables the revertive switching of a Smart Link group.

By default, the revertive switching of a Smart Link group is disabled.

Format

restore enable

undo restore enable

Parameters

None

Views

Smart Link group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the active link in a Smart Link group fails, traffic is switched to the standby link. The original active link remains blocked after recovery. To enable the original active link to transmit traffic, enable the revertive switching function in the Smart Link group. Traffic is switched back to the original active link when the WTR timer expires.

Prerequisites

A Smart Link group has been created using the **smart-link group** command.

Follow-up Procedure

By default, the WTR timer is 60 seconds. You can run the **timer wtr** command to change the value.

Precautions

- Link switching is performed only when both member interfaces in the Smart Link group are in Up state.
- Do not run the **undo restore enable** command during revertive switching because this will cause a revertive switching failure.

Example

Enable the revertive switching of Smart Link group 1.

```
<HUAWEI> system-view
[HUAWEI] smart-link group 1
[HUAWEI-smlk-group1] restore enable
```

12.5.15 smart-link

Function

The **smart-link** command enables a Smart Link group to lock data streams and specifies the locking interface.

The **undo smart-link** command disables a Smart Link group from locking data streams.

By default, a Smart Link group is disabled from locking data streams.

Format

smart-link { **force** | **lock** }

undo smart-link { **force** | **lock** }

Parameters

Parameter	Description	Value
force	Locks data streams on the slave interface.	-
lock	Locks data streams on the master interface.	-

Views

Smart Link group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Run the **smart-link** command to lock data streams on the master or slave link. During the maintenance, the active link in the Smart Link group needs to be inspected. To prevent the inspection from affecting normal services, configure the data stream policy for the Smart Link group. Then the device forcibly locks data streams to the standby link and switches them back to the active link after the inspection is complete.

Prerequisites

The Smart Link group has been enabled by using the **smart-link enable** command.

Precautions

After data streams are locked on a specified link, traffic cannot be switched to the other link even the specified link fails.

The **lock** and **force** keywords are mutually exclusive and only one of them can be entered each time. The **lock** keyword takes precedence over the **force** keyword. If you specify **force** and then **lock**, data streams are locked on the master interface. If you specify **lock** first, the configuration fails when you specify **force** in the command.

Example

Smart Link group 1 is configured to lock data streams and lock data streams on the slave interface.

```
<HUAWEI> system-view
[HUAWEI] smart-link group 1
[HUAWEI-smlk-group1] smart-link enable
[HUAWEI-smlk-group1] smart-link force
```

12.5.16 smart-link enable

Function

The **smart-link enable** command enables a Smart Link group.

The **undo smart-link enable** command disables a Smart Link group.

By default, a Smart Link group is disabled.

Format

smart-link enable

undo smart-link enable

Parameters

None

Views

Smart Link group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A Smart Link group takes effect and blocks the slave interface only after it is enabled. After the Smart Link group is disabled, the slave interface is unblocked.

After creating a Smart Link group and adding interfaces to the group, you must enable the Smart Link group to make it effective.

Precautions

After a Smart Link group is enabled, the slave interface is blocked only if the master and slave interfaces are both in Up state.

Example

Enable Smart Link group 1.

```
<HUAWEI> system-view
[HUAWEI] smart-link group 1
[HUAWEI-smlk-group1] smart-link enable
```

12.5.17 smart-link flush receive

Function

The **smart-link flush receive** command enables an interface to receive Flush packets and specifies the control VLAN ID and password for Flush packets.

The **undo smart-link flush receive** command disables an interface from receiving Flush packets.

By default, an interface rejects Flush packets.

Format

smart-link flush receive control-vlan { { *vlan-id* } &<1-10> [**password** { **simple** | **sha** } *password*] | **all** }

undo smart-link flush receive [**control-vlan** { *vlan-id* | **all** }] (interface view)

undo smart-link flush receive (port group view)

Parameters

Parameter	Description	Value
control-vlan *vlan-id*	Specifies the control VLAN ID of Flush packets that can be received.	The value is an integer that ranges from 1 to 4094.
password simple	Indicates that the password for sending Flush packets is in plain text. **NOTE** The password is saved in the configuration file in cipher text for security.	-
password sha	Indicates that Flush packets sent from the Smart Link group contain an SHA2-256-encrypted password. **NOTE** The password is saved in the configuration file in cipher text for security.	-
password	Specifies the password carried in Flush packets.	The value is a string of 8 to 16 case-sensitive characters in plain text and consists of at least two of the following: lowercase letters, uppercase letters, digits, and special characters excluding question marks (?) and spaces.
all	Indicates that all control VLANs allow Flush packets.	-

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, Eth-Trunk interface view and port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a switchover occurs between the master and slave links in a Smart Link group, the existing forwarding entries do not apply to the new topology. All the MAC address entries and ARP entries on the network need to be updated. The Smart Link group sends Flush packets to notify upstream devices of the topology change. Upstream devices can update their MAC address entries and ARP entries only if they are enabled to receive Flush packets. If a device rejects Flush packets, it cannot forward packets correctly after a link failover occurs in the Smart Link group.

Precautions

- The Flush packets mentioned here are used only for communication between Huawei CE series and S series switches. Other manufacturers may define different Flush packet formats.
- The **smart-link flush receive** command does not add member interfaces of the Smart Link group to the control VLAN. You need to configure the member interfaces to allow the control VLAN. The interface accepts a Flush packet only if the control VLAN ID and password in the packet are the same as those configured on the local interface.
- A maximum of 256 control VLANs used to receive Flush packets can be configured on an interface.
- The original encryption mode and password are deleted after you run this command to configure the new ones. If the control VLAN ID is changed, the password must be reconfigured.
- For security purposes, you are advised to use SHA2-256 as the authentication algorithm of Smart Link.
- If the password is encrypted in the SHA2-256 mode, it cannot be retrieved. Set a new password after the original one is lost.

Example

Enable GE0/0/1 to receive Flush packets with control VLAN ID 100 and password **YsHsjx_202206**.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] smart-link flush receive control-vlan 100 password sha YsHsjx_202206
```

12.5.18 smart-link flush receive password

Function

The **smart-link flush receive password** command specifies an encryption mode and a password for Flush packets on all interfaces.

The **undo smart-link flush receive password** command deletes the encryption mode and a password for Flush packets on all interfaces.

By default, no encryption mode or password is configured for Flush packets on all interfaces.

Format

smart-link flush receive password { **simple** | **sha** } *password*

undo smart-link flush receive password

Parameters

Parameter	Description	Value
simple	Indicates that the password for sending Flush packets is in plain text. **NOTE** The password is saved in the configuration file in cipher text for security.	-
sha	Indicates that the password for sending Flush packets is in SHA2-256 mode. **NOTE** The password is saved in the configuration file in cipher text for security.	-
password	Specifies the password carried in Flush packets.	The value is a string of 8 to 16 case-sensitive characters in plain text and consists of at least two of the following: lowercase letters, uppercase letters, digits, and special characters excluding question marks (?) and spaces.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **smart-link flush receive password** command to specify an encryption mode and a password for Flush packets on all interfaces.

Prerequisites

The downstream device has been enabled to send Flush packets by using the **flush send** command.

Precautions

- The password configured in a control VLAN on an interface that is enabled to receive flush packets takes precedence over the password configured globally. If the password on an interface is not configured, the interface configured globally is used.
- For security purposes, you are advised to use SHA2-256 as the authentication algorithm of Smart Link.

Example

Specify YsHsjx_202206 for Flush packets.

```
<HUAWEI> system-view
[HUAWEI] smart-link flush receive password sha YsHsjx_202206
```

12.5.19 smart-link hold-time

Function

The **smart-link hold-time** command sets the holdtime for reporting the Interface-Up or Interface-Down event in a Smart Link group.

The **undo smart-link hold-time** command deletes the holdtime for reporting the Interface-Up or Interface-Down event in a Smart Link group.

By default, a port-Up or port-Down event is reported immediately.

Format

smart-link hold-time *hold-time*

undo smart-link hold-time [*hold-time*]

Parameters

Parameter	Description	Value
hold-time	Specifies the holdtime for reporting the Interface-Up or Interface-Down event in a Smart Link group.	The value is an integer that ranges from 0 to 60, in 100 ms.

Views

Smart Link group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If services are frequently switched between links in a Smart Link group because of temporary link disconnection, packets may be lost and system performance deteriorates. To prevent frequent switchover caused by temporary link disconnection, run the **smart-link hold-time** command to set the holdtime for reporting an Interface-Up or Interface-Down event. When the member interfaces of the Smart Link group alternate between Up and Down, the Smart Link group waits until the holdtime expires, and then triggers a switchover.

Prerequisites

A Smart Link group has been created using the **smart-link group** command.

Precautions

If you run the **smart-link hold-time** command multiple times in the same Smart Link group view, only the latest configuration takes effect.

Example

Set the holdtime of Smart Link failover in Smart Link group 1 to 300 ms.

```
<HUAWEI> system-view
[HUAWEI] smart-link group 1
[HUAWEI-smlk-group1] smart-link hold-time 3
```

12.5.20 smart-link group

Function

The **smart-link group** command creates a Smart Link group and enters the Smart Link group view. If the Smart Link group already exists, you can enter the Smart Link group view directly.

The **undo smart-link group** command deletes a Smart Link group that already exists.

By default, no Smart Link group is created on the device.

Format

smart-link group *group-id*

undo smart-link group *group-id*

Parameters

Parameter	Description	Value
group-id	Specifies a Smart Link group ID.	The value is an integer that ranges from 1 to 16.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The Smart Link function implements link backup and rapid switchover on a dual-homed network. To use the Smart Link function, you must create a Smart Link group first.

Follow-up Procedure

After creating a Smart Link group, perform the following actions:

1. Configure master and slave interfaces in the Smart Link group.
2. Enable the Smart Link group to send Flush packets.
3. Enable the Smart Link group.

Precautions

Run the **undo port** command to delete all the member interfaces before deleting a Smart Link group that has member interfaces.

Example

Create Smart Link group 1.

```
<HUAWEI> system-view
[HUAWEI] smart-link group 1
[HUAWEI-smlk-group1]
```

12.5.21 smart-link group uplink

Function

The **smart-link group uplink** command adds a Smart Link group to a Monitor Link group as the uplink interface.

The **undo smart-link group uplink** command deletes a Smart Link group from a Monitor Link group.

Format

smart-link group *group-id* **uplink**

undo smart-link group *group-id* **uplink**

Parameters

Parameter	Description	Value
group-id	Specifies a Smart Link group ID.	The value is an integer that ranges from 1 to 16.

Views

Monitor Link group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Cascading of Smart Link and Monitor Link improves link backup reliability. When the uplink interface is a Smart Link group, the uplink interface is considered faulty and the Monitor Link group forcibly disables the downlink interfaces only if both the master and slave interfaces of the Smart Link group are in Inactive or Down state.

Prerequisites

A Smart Link group has been created using the **smart-link group** command.

Precautions

A Smart Link group can be added to only one Monitor Link group.

A Smart Link can function only as the uplink interface in a Monitor Link group.

When the uplink interface fails, all the downlink interfaces in the Monitor Link group are shut down.

Before adding a Smart Link group to a Monitor Link group, delete the previous uplink interface from the Monitor Link group.

Example

Add Smart Link group 1 to Monitor Link group 2 as the uplink interface.

```
<HUAWEI> system-view
[HUAWEI] monitor-link group 2
[HUAWEI-mtlk-group2] smart-link group 1 uplink
```

12.5.22 smart-link link-switch send-broadcast enable

Function

The **smart-link link-switch send-broadcast enable** command enables a device to send broadcast packets to trigger the peer device to re-learn MAC addresses.

The **undo smart-link link-switch send-broadcast enable** command cancels the configuration.

By default, the function of sending broadcast packets to trigger the peer device to re-learn MAC addresses is disabled.

NOTE

Only the S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

smart-link link-switch send-broadcast enable

undo smart-link link-switch send-broadcast enable

Parameters

None

Views

Smart Link group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a Smart Link interface is connected to a non-Huawei device that does not support Smart Link and the active link goes Down, MAC address information on the network cannot be quickly updated. In this case, you can run this command to enable a device to send broadcast packets to trigger the peer device to re-learn MAC addresses.

Prerequisites

This function takes effect only when Smart Link is enabled and the master and slave interfaces are configured.

Example

Enable the function of sending broadcast packets for Smart Link group 1.

```
<HUAWEI> system-view
[HUAWEI] smart-link group 1
```

```
[HUAWEI-smlk-group1] smart-link enable
[HUAWEI-smlk-group1] smart-link link-switch send-broadcast enable
```

12.5.23 smart-link manual switch

Function

The **smart-link manual switch** command enables the device to switch services from the active link to the standby link in a Smart Link group.

Format

smart-link manual switch

Parameters

None

Views

Smart Link group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the active link in a Smart Link group fails, traffic is switched to the standby link. The original active link remains blocked after recovery. Generally, a stable link is used as the active link. Therefore, after the original active link recovers, you can perform the following operations to switch traffic back to this link:

- Enable the revertive switching of a Smart Link group. The system performs switching after the revertive switching timer times out.
- Run the **smart-link manual switch** command to switch traffic back.

However, the minimum revertive switching time is 30s, and the default value is 60s. You can run the **smart-link manual switch** command to manually switch traffic back to the active link.

Prerequisites

To implement an active/standby switchover between links, ensure that:

- The active interface and standby interface exist and are both in Up state.
- Traffic is not blocked on either interface by using the **smart-link** command.

Precautions

Millisecond-level packet loss will occur during the switchover.

Example

Perform an active/standby switchover between links of Smart Link group 1.

```
<HUAWEI> system-view
[HUAWEI] smart-link group 1
[HUAWEI-smlk-group1] smart-link manual switch
```

12.5.24 smart-link { vpls-notify | vll-notify } enable

Function

The **smart-link** { **vpls-notify** | **vll-notify** } **enable** command enables an interface to notify the VPLS/VLL module when the interface receives a Flush packet.

The **undo smart-link** { **vpls-notify** | **vll-notify** } **enable** command cancels the configuration.

By default, an interface does not notify the VPLS/VLL module when receiving a Flush packet.

NOTE

Only the S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730S-H, S6730-H, S5731-S, S5731S-S, S6730-S, and S6730S-S support this command.

Format

smart-link { **vpls-notify** | **vll-notify** } **enable**

undo smart-link { **vpls-notify** | **vll-notify** } **enable**

Parameters

Parameter	Description	Value
vpls-notify	Enables an interface to notify the VPLS module when receiving Flush packets.	-
vll-notify	Enables an interface to notify the VLL module when receiving Flush packets.	-

Views

GE interface view, MultiGE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a customer edge (CE) device is dual homed to a VPLS or VLL network through VLANIF interfaces or dot1q sub-interfaces of a provider edge (PE) device, associate Smart Link with VPLS on the corresponding physical interfaces of the PE device. If the VLANIF interfaces or dot1q sub-interfaces are bound to VSI or VLL run the **smart-link flush receive** and **smart-link { vpls-notify | vll-notify } enable** commands on the corresponding physical interfaces. Then the physical interfaces can notify the VPLS or VLL module when receiving a Flush packet. The VPLS or VLL module then deletes the MAC addresses learned from the VSI or VLL bound to the VLANIF interfaces or dot1q sub-interfaces, and sends messages to remote devices, instructing them to update MAC address entries.

Prerequisites

The VPLS or VLL configuration has been completed on the backbone network. The Smart Link configuration has been completed on the CE interfaces connected to the PE device. The VLANIF interfaces or dot1q sub-interfaces of the PE device connected to the CE device have been bound to VSI or VLL. The physical interfaces connected to the CE device have been enabled to accept Flush packets by using the **smart-link flush receive** command.

Precautions

You can associate Smart Link with VPLS or VLL only when a CE device is connected to the VPLS or VLL network through VLANIF interfaces or dot1q sub-interfaces of a PE device. Smart Link cannot be associated with VPLS or VLL when the CE device is connected to the VPLS or VLL network through physical interfaces.

Example

Enable XGE0/0/1 to notify the VPLS module when the interface receives a Flush packet.

```
<HUAWEI> system-view
[HUAWEI] interface xgigabitethernet 0/0/1
[HUAWEI-XGigabitEthernet0/0/1] smart-link vpls-notify enable
```

12.5.25 timer recover-time

Function

Using the **timer recover-time** command, you can set the wait to restore (WTR) time of a Monitor Link group.

Using the **undo timer recover-time** command, you can restore the default WTR time of a Monitor Link group.

By default, the WTR time of a Monitor Link group is 3 seconds.

Format

timer recover-time *recover-time*

undo timer recover-time [*recover-time*]

Parameters

Parameter	Description	Value
recover-time	Specifies the WTR time of a Monitor Link group.	The value is an integer that ranges from 3 to 60, in seconds. The default value is 3.

Views

Monitor Link group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the downlink interface status changes frequently in a Monitor Link group because of temporary uplink disconnection, packets are lost and system performance deteriorates. To prevent frequent failover caused by temporary link disconnection, you can use the **timer recover-time** command to set the WTR time of the Monitor Link group. The Monitor Link group does not restore downlink interfaces immediately after the uplink interface recovers. The downlink interfaces become Up until the WTR time expires.

recover-time indicates the internal switching time of a Monitor Link group. That is, the system starts the interface Up operation after the internal switching time is reached. The actual interface Up time is also affected by the interface Up performance.

Prerequisites

A Monitor Link group has been created by using the **monitor-link group** command.

Example

Set the WTR time to 6 seconds for Monitor Link group 1.

```
<HUAWEI> system-view
[HUAWEI] monitor-link group 1
[HUAWEI-mtlk-group1] timer recover-time 6
```

12.5.26 timer wtr

Function

The **timer wtr** command sets the WTR time of a Smart Link group.

The **undo timer wtr** command restores the default WTR time of a Smart Link group.

By default, the WTR time of a Smart Link group is 60 seconds.

Format

timer wtr *wtr-time*

undo timer wtr [*wtr-time*]

Parameters

Parameter	Description	Value
wtr-time	Specifies the WTR time.	The value is an integer that ranges from 30 to 1200, in seconds. The default WTR time is 60 seconds.

Views

Smart Link group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the active link in a Smart Link group fails, traffic is switched to the standby link. The original active link remains blocked after recovery. To enable the original active link to transmit traffic, enable the revertive switching function in the Smart Link group. Traffic is switched back to the original active link when the WTR timer expires.

Precautions

If the network is unstable or has no requirement for the transmission delay, set a longer WTR time to prevent frequent switching.

Example

Set the WTR time to 120 seconds for Smart Link group 1.

```
<HUAWEI> system-view
[HUAWEI] smart-link group 1
[HUAWEI-smlk-group1] timer wtr 120
```

12.6 MAC Swap Loopback Configuration Commands

12.6.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

12.6.2 display loopback swap-mac information

Function

The **display loopback swap-mac information** command displays the MAC swap loopback configuration.

Format

display loopback swap-mac information

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

To ensure a successful loopback test, use this command to check the loopback configuration before the loopback test. After the loopback test is complete, use this command to view the number of loopback test packets and the number of discarded test packets, and compare them with the number of packets sent from the tester to check network performance.

Pre-configuration Tasks

The local MAC swap loopback function has been configured by using the **loopback local swap-mac** command or the local MAC swap loopback function has been configured by using the **loopback remote swap-mac** command.

Example

Display the MAC swap loopback configuration.

Models excluding the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S:

```
<HUAWEI> display loopback swap-mac information
  Loopback type              : local
  Loopback state             : running
  Loopback test time(s)      : 60
  Loopback interface         : GigabitEthernet0/0/1
  Loopback output interface : GigabitEthernet0/0/2
  Loopback source MAC        : 0001-0001-0001
  Loopback destination MAC  : 0002-0002-0002
  Loopback vlan              : 10
  Loopback inner vlan        : 0
  Loopback packets           : 0
  Drop packets               : 3
```

S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S:

```
<HUAWEI> display loopback swap-mac information
  Loopback type              : remote
  Loopback state             : running
  Loopback test time(s)      : 60
  Loopback interface         : GigabitEthernet0/0/1
  Loopback output interface : GigabitEthernet0/0/2
```

Table 12-38 Description of the display loopback swap-mac information command output

Item	Description
Loopback type	Type of the MAC swap loopback test: - local: local MAC swap loopback test - remote: remote MAC swap loopback test Run the following commands to configure loopback type. **loopback local swap-mac** **loopback remote swap-mac**
Loopback state	Status of the MAC swap loopback function: - running: The MAC swap loopback function is enabled. - stop: The MAC swap loopback function is disabled. Run the following commands to configure loopback state. **loopback swap-mac**
Loopback test time(s)	Timeout period of the loopback test. If the value is none, the loopback test timeout function is disabled.

Item	Description
Loopback interface	Interface where the loopback test is performed.
Loopback output interface	Outbound interface that sends test packets back to the tester.
Loopback source MAC	Source MAC address of test packets.
Loopback destination MAC	Destination MAC address of test packets.
Loopback vlan	VLAN ID of test packets.
Loopback inner vlan	Inner VLAN ID of test packets.
Loopback packets	Number of received loopback packets.
Drop packets	Number of discarded packets. This field is displayed only when a local MAC swap loopback test is performed.

12.6.3 loopback local swap-mac

Function

The **loopback local swap-mac** command enables local MAC swap loopback.

The **undo loopback local swap-mac** command disables local MAC swap loopback.

By default, local MAC swap loopback is disabled on an interface.

NOTE

The S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S500, S5735-S-I, S5735S-S, and S5735-S do not support this command.

Format

loopback local swap-mac source-mac *source-mac-address* **dest-mac** *dest-mac-address* **vlan** *vlan-id* [**inner-vlan** *inner-vlan-id*] **interface** *interface-type interface-number* [**timeout** { *time-value* | **none** }]

undo loopback local swap-mac

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **inner-vlan** *inner-vlan-id* parameter.

Parameters

Parameter	Description	Value
source-mac *source-mac-address*	Specifies the source MAC address of test packets.	The value is in H-H-H format. An H is a hexadecimal number of 1 to 4 digits. The source and destination MAC addresses must be unicast MAC addresses.
dest-mac *dest-mac-address*	Specifies the destination MAC address of test packets.	The value is in H-H-H format. An H is a hexadecimal number of 1 to 4 digits. The source and destination MAC addresses must be unicast MAC addresses.
vlan *vlan-id*	Specifies the VLAN ID of test packets.	The value is an integer that ranges from 1 to 4094.
inner-vlan *inner-vlan-id*	Specifies the inner VLAN ID of test packets.	The value is an integer that ranges from 1 to 4094.
interface *interface-type interface-number*	Specifies the outbound interface that sends loopback packets back to the tester. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
timeout *time-value*	Specifies the timeout period of a loopback test. If the **loopback swap-mac start** command is run to enable MAC swap loopback, a MAC swap loopback test stops after the timeout period of the loopback test expires.	The value is an integer that ranges from 5 to 300, in seconds. The default value is 60.

Parameter	Description	Value
timeout none	Indicates that the loopback test timeout function is disabled. If the **loopback swap-mac start** command is run to enable MAC swap loopback, a MAC swap loopback test cannot automatically stop after its timeout period expires. Instead, you must run the **loopback swap-mac stop** command to manually stop the MAC swap loopback test.	-

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before using the Switch to provide services for users, perform a local MAC swap loopback test on the Switch to check whether the Switch can provide services properly. This test checks connectivity and QoS CAR of the network between the Switch downlink interface and a remote device. The local MAC swap loopback test can also check whether VLAN mapping and VLAN stacking are configured successfully on the downlink interface.

A local MAC swap loopback test checks connectivity and performance of the network between a tester and a tested switch, and performance of the tested switch.

In a local MAC swap loopback test, a tester sends test packets to the Switch. When test packets reach the downlink interface, the Switch swaps the source and destination MAC addresses of test packets and sends the packets back to the tester through a specified outbound interface.

Follow-up Procedure

Run the **loopback swap-mac start** command to enable the MAC swap loopback function.

Precautions

NOTICE

When a local loopback test is performed on an interface, all services on the interface are interrupted.

- An Eth-Trunk interface in LACP mode does not support the local MAC swap loopback function. An Eth-Trunk member interface does not support the MAC swap loopback function.
- Before enabling the local MAC swap loopback function, you need to run the **undo stp enable** command to disable STP on the interface.
- The port is not a Layer 3 port. If the port is a Layer 3 port, run the **portswitch** command to switch the port to the Layer 2 mode.
- If a large number of test packets are sent, test packets occupy bandwidth of other services on the interface that sends test packets.

Example

Configure local MAC swap loopback.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] loopback local swap-mac source-mac 00e0-fc00-0085 dest-mac 00e0-
fc00-1004 vlan 100 interface gigabitethernet 0/0/2
```

12.6.4 loopback remote swap-mac

Function

The **loopback remote swap-mac** command enables remote MAC swap loopback.

The **undo loopback remote swap-mac** command disables remote MAC swap loopback.

By default, remote MAC swap loopback is disabled on an interface.

Format

Models excluding the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S500, S5735-S-I, S5735S-S, and S5735-S:

loopback remote swap-mac source-mac *source-mac-address* **dest-mac** *dest-mac-address* **vlan** *vlan-id* [**inner-vlan** *inner-vlan-id*] [**timeout** { *time-value* | **none** }]

undo loopback remote swap-mac

S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S500, S5735-S-I, S5735S-S, and S5735-S:

loopback remote swap-mac [**timeout** { *time-value* | **none** }]

undo loopback remote swap-mac

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **inner-vlan** *inner-vlan-id* parameter.

Parameters

Parameter	Description	Value
source-mac *source-mac-address*	Specifies the source MAC address of test packets.	The value is in H-H-H format. An H is a hexadecimal number of 1 to 4 digits. The source and destination MAC addresses must be unicast MAC addresses.
dest-mac *dest-mac-address*	Specifies the destination MAC address of test packets.	The value is in H-H-H format. An H is a hexadecimal number of 1 to 4 digits. The source and destination MAC addresses must be unicast MAC addresses.
vlan *vlan-id*	Specifies the VLAN ID of test packets.	The value is an integer that ranges from 1 to 4094.
inner-vlan *inner-vlan-id*	Specifies the inner VLAN ID of test packets.	The value is an integer that ranges from 1 to 4094.
timeout *time-value*	Specifies the timeout period of a loopback test. If the **loopback swap-mac start** command is run to enable MAC swap loopback, a MAC swap loopback test stops after the timeout period of the loopback test expires.	The value is an integer that ranges from 5 to 300, in seconds. The default value is 60.

Parameter	Description	Value
timeout none	Indicates that the loopback test timeout function is disabled. If the **loopback swap-mac start** command is run to enable MAC swap loopback, a MAC swap loopback test cannot automatically stop after its timeout period expires. Instead, you must run the **loopback swap-mac stop** command to manually stop the MAC swap loopback test.	-

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before using the Switch to provide services for users, perform a remote MAC swap loopback test to check whether the Switch can provide services properly. This test checks connectivity and performance of the network between the Switch uplink interface and a remote device. The remote MAC swap loopback test can also check whether VLAN mapping and VLAN stacking are configured successfully on the uplink interface.

A remote MAC swap loopback test checks connectivity and performance of the network between a tester and a tested switch but does not check performance of the tested switch.

In a remote MAC swap loopback test, a tester sends test packets to the Switch. When test packets reach the uplink interface, the Switch swaps the source and destination MAC addresses of test packets and sends the packets back to the tester through this interface.

Follow-up Procedure

Run the **loopback swap-mac start** command to enable the MAC swap loopback function.

Precautions

- An Eth-Trunk interface supports the MAC swap loopback function but an Eth-Trunk member interface does not.
- The port is not a Layer 3 port. If the port is a Layer 3 port, run the **portswitch** command to switch the port to the Layer 2 mode.
- The **loopback remote swap-mac** and **single-fiber enable** commands cannot be used on the same interface.
- If the switch does not receive any test packet within the timeout period after the remote MAC swap loopback test starts, perform the test again. And then run the **loopback swap-mac start** command.
- If **timeout none** is specified in the command, you can perform a loopback test at any time until the MAC swap loopback function is disabled by using the **loopback swap-mac stop** command.

Example

Configure remote MAC swap loopback.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] loopback remote swap-mac source-mac xxxx-xxxx-xxxx dest-mac xxxx-xxxx-xxxx vlan 100
```

12.6.5 loopback swap-mac

Function

The **loopback swap-mac** command enables or disables the MAC swap loopback function.

By default, the MAC swap loopback function is disabled.

Format

loopback swap-mac { **start** | **stop** }

Parameters

Parameter	Description	Value
start	Enables the MAC swap loopback function.	-
stop	Disables the MAC swap loopback function.	-

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Both local and remote loopback tests deteriorate network performance. To minimize impact of a loopback test, enable the MAC swap loopback function when the loopback test begins and disable it immediately after the loopback test is complete.

A MAC swap loopback test stops when you disable the MAC swap loopback function or the loopback test times out. To perform the loopback test again, run the **loopback swap-mac start** command.

Pre-configuration Tasks

The local MAC swap loopback function has been configured by using the **loopback local swap-mac** command or the local MAC swap loopback function has been configured by using the **loopback remote swap-mac** command.

Precautions

An Eth-Trunk interface supports the MAC swap loopback function but an Eth-Trunk member interface does not.

An Eth-Trunk interface in LACP mode does not support the local MAC swap loopback function.

To ensure service provisioning on the interface, disable the MAC swap loopback function immediately after the loopback test is complete.

The **loopback swap-mac** command is a one-time command and is not saved in the configuration file.

Example

Enable the MAC swap loopback function.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] loopback swap-mac start
```

12.7 EFM Configuration Commands

12.7.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

12.7.2 clear mgr inactive-configuration slot

Function

The **clear mgr inactive-configuration slot** command deletes the inactive Ethernet OAM configurations from the switch that does not register.

Format

clear mgr inactive-configuration slot *slot-id* [**card** *card-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies the slot ID of a switch that does not register.	The value is an integer and the value range depends on device model.
card *card-id*	Specifies the offline card ID.	The value is an integer and the value range depends on device model.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

After a subcard has been replaced, using the **clear mgr inactive-configuration slot** command deletes the configurations of the subcard that does not register if these configurations do not need to be saved.

Running the **clear mgr inactive-configuration slot** command can delete the inactive configurations.

Before using this command, note the following points:

- When the device is in the CSS, ensure that the specified card on which configurations are to be deleted does not register.
- Ensure that the specified subcard on which configurations are to be deleted does not register.

Example

Delete the configurations of the card that does not register in slot 1.

```
<HUAWEI> system-view
[HUAWEI] clear mgr inactive-configuration slot 1
Warning: The inactive oam-mgr configuration related to the interfaces of the slot or card will be deleted
and cannot be restored, continue? [Y/N]:y
Info: Operation succeeded.
```

12.7.3 display efm

Function

The **display efm** command displays the EFM configuration on an interface.

Format

display efm { **all** | **interface** *interface-type interface-number* }

Parameters

Parameter	Description	Value
all	Displays the EFM configuration on all the interfaces enabled with EFM.	-
interface-type interface-number	Displays the EFM configuration of a specified interface. • *interface-type* specifies the interface type. • *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

To view the EFM configuration on the device, run the **display efm** command.

- If **all** is specified, all EFM configuration is displayed.
- If **interface** *interface-type interface-number* is specified, the EFM configuration of a specified interface is displayed.

Prerequisites

EFM has been enabled globally using the **efm enable** command.

Example

Display the EFM configuration on GigabitEthernet0/0/1.

```
<HUAWEI> display efm interface gigabitethernet 0/0/1
 Item                          Value
 ----------------------------------------------------
 Interface:                     GigabitEthernet0/0/1
 EFM Enable Flag:               enable
 Mode:                          active
 Loopback IgnoreRequest:        no
 OAMPDU MaxSize:                128
 OAMPDU Timeout:                5000

 ErrFramePeriodNotification:    disable
 ErrFramePeriodPeriod:          200000
 ErrFramePeriodThreshold:       1
 Loopback Remain Time:          1189
```

Table 12-39 Description of the display efm command output

Item	Description
Interface	Interface name.
EFM Enable Flag	Whether EFM is enabled on an interface: - disable: indicates that EFM is disabled on an interface. - enable: indicates that EFM is enabled on an interface. To enable or disable EFM on an interface, run the **efm enable** command.
Mode	Operation mode of EFM on an interface: - active: indicates that EFM works in active mode. - passive: indicates that EFM works in passive mode. To set the operation mode of EFM on an interface, run the **efm mode** command.

Item	Description
Loopback IgnoreRequest	Whether loopback requests from the remote end are ignored: - yes: Loopback requests from the remote end are ignored. - no: Loopback requests from the remote end are processed. To set the parameter, run the **efm loopback ignore-request** command.
OAMPDU MaxSize	Maximum size of an EFM OAMPDU on an interface. The value ranges from 64 to 1518, in bytes. The default value is 128 bytes. To set the maximum size of an EFM OAMPDU on an interface, run the **efm packet max-size** command.
OAMPDU Timeout	Timeout interval at which an interface receives EFM OAMPDUs. The value is an integer that ranges from 3000 to 30000, in milliseconds. It must be an integer multiple of 1000. The default value is 5000 ms. To set the timeout interval at which an interface receives EFM OAMPDUs, run the **efm timeout** command.
OAMPDU Interval	Timeout interval at which an interface sends EFM OAMPDUs. The value is fixed as 1000, in milliseconds.
Parser	Parser: - forward: device is forwarding non-OAMPDUs to the lower sublayer. - loopback: device is looping back non-OAMPDUs to lower sublayer. - discard: device is discarding non-OAMPDUs.
Multiplexer	Multiplexer: - forward: device is forwarding non-OAMPDUs to higher sublayer. - discard: device is discarding non-OAMPDUs.

Item	Description
ErrCodeNotification	Whether detection of EFM errored codes is enabled: ● disable: indicates that detection of EFM errored codes is disabled. ● enable: indicates that detection of EFM errored codes is enabled. To enable or disable the detection of EFM errored codes, run the **efm error-code notification enable** command.
ErrCodePeriod	Period for detecting EFM errored codes on an interface. The value ranges from 1 to 60, in seconds. The default value is 1s. To set the period for detecting EFM errored codes on an interface, run the **efm error-code period** command.
ErrCodeThreshold	Threshold for detecting EFM errored codes on an interface. The value ranges from 0 to 65535. The default value is 1. To set the threshold for detecting EFM errored codes on an interface, run the **efm error-code threshold** command.
ErrFrameNotification	Whether detection of EFM errored frames is enabled: ● disable: indicates that detection of EFM errored frames is disabled. ● enable: indicates that detection of EFM errored frames is enabled. To enable or disable the detection of EFM errored frames, run the **efm error-frame notification enable** command.
ErrFramePeriod	Period for detecting EFM errored frames on an interface. The value ranges from 1 to 60, in seconds. The default value is 1s. To set the period for detecting EFM errored frames on an interface, run the **efm error-frame period** command.
ErrFrameThreshold	Threshold for detecting EFM errored frames on an interface. The value ranges from 0 to 65535. The default value is 1. To set the threshold for detecting EFM errored frames on an interface, run the **efm error-frame threshold** command.

Item	Description
ErrFrameSecondNotification	Whether detection of EFM errored frame seconds is enabled: - disable: indicates that detection of EFM errored frame seconds is disabled. - enable: indicates that detection of EFM errored frame seconds is enabled. To enable or disable the detection of EFM errored frame seconds, run the **efm error-frame-second notification enable** command.
ErrFrameSecondPeriod	Period for detecting EFM errored frame seconds on an interface. The value ranges from 10 to 900, in seconds. The default value is 60s. To set the period for detecting EFM errored frame seconds on an interface, run the **efm error-frame-second period** command.
ErrFrameSecondThreshold	Threshold for detecting EFM errored frame seconds on an interface. The value ranges from 0 to 900. The default value is 1. To set the threshold for detecting EFM errored frame seconds on an interface, run the **efm error-frame-second threshold** command.
Hold Up Time	Value of the EFM faulty-state holdup timer. The value ranges from 0 to 50, in seconds. The default value is 0. To set the value of the EFM faulty-state holdup timer, run the **efm holdup-timer** command.
ThresholdEvtTriggerErrDown	Whether a threshold crossing event is associated with an interface: - disable: A threshold crossing event is not associated with an interface. - enable: A threshold crossing event is associated with an interface. To set the parameter, run the **efm threshold-event trigger error-down** command.

Item	Description
TriggerIfDown	Whether an interface is blocked when the interface detects a fault on the link between the local and peer interfaces: - disable: The system does not block an interface when detecting a fault on the link between the local and peer interfaces. - enable: The system blocks an interface when detecting a fault on the link between the local and peer interfaces. To set the parameter, run the **efm trigger if-down** command.
TriggerMacRenew	Whether the MAC address entry on an interface is updated when the interface detects a fault on the link between the local and peer interfaces: - disable: The system does not update the MAC address entry when detecting a fault on the link between the local and peer interfaces. - enable: The system updates the MAC address entry when detecting a fault on the link between the local and peer interfaces. To set the parameter, run the **efm trigger mac-renew** command.
Remote MAC	MAC address of the remote interface. The value -- indicates that the system cannot obtain the MAC address of the remote interface.
Remote EFM Enable Flag	Whether EFM is enabled on the remote interface: - disable: indicates that EFM is disabled on the remote interface. - enable: indicates that EFM is enabled on the remote interface. - --: indicates that the system cannot obtain the EFM status on the remote device.
Remote Mode	Operation mode of EFM on the remote interface: - active: indicates that EFM works in active mode. - passive: indicates that EFM works in passive mode. - --: indicates that the system cannot obtain the operation mode of EFM on the remote device.
Remote MaxSize	Maximum size of an OAMPDU on the remote interface, in bytes. The value -- indicates that the system cannot obtain the maximum size of an OAMPDU on the remote interface.

Item	Description
Remote Loopback IgnoreRequest	Whether the remote interface ignores loopback requests from the local end: ● --: The system cannot obtain the mode in which the remote interface processes loopback requests from the local end. ● yes: The remote interface ignores loopback requests from the local end. ● no: The remote interface processes loopback requests from the local end.
Remote State	Active/Standby information of the peer device. The value -- indicates that the system cannot obtain the active/standby information of the peer device.
Remote Parser	Remote parser: ● forward: device is forwarding non-OAMPDUs to the lower sublayer. ● discard: device is discarding non-OAMPDUs.
Remote Multiplexer	Remote Multiplexer: ● forward: device is forwarding non-OAMPDUs to higher sublayer. ● loopback: device is looping back non-OAMPDUs to lower sublayer. ● discard: device is discarding non-OAMPDUs.
ErrFramePeriodNotification	Whether detection of EFM errored frame periods is enabled: ● disable: indicates that detection of EFM errored frame periods is disabled. ● enable: indicates that detection of EFM errored frame periods is enabled.
ErrFramePeriodPeriod	Period for detecting errored frame periods on the interface. The value is an integer that ranges from 20000 to 4294967295. The default value is 200000.
ErrFramePeriodThreshold	Threshold for detecting errored frame periods on the interface. The value is an integer that ranges from 0 to 900. The default value is 1.

Item	Description
Loopback Remain Time	Remaining time of remote loopback: - --: The interface does not send a remote loopback request. - Never Timeout: The interface sends a remote loopback request. The value of **timeout** is 0, indicating that the interface is always in remote loopback state. - Loopback Remain Time: The interface sends a remote loopback request, and the timeout interval of remote loopback is specified.

12.7.4 display efm link-event local

Function

The **display efm link-event local** command displays statistics about local link events.

Format

display efm link-event local { **all** | **interface** *interface-type interface-number* }

Parameters

Parameter	Description	Value
all	Displays statistics about local link events of all interfaces.	-
interface-type interface-number	Displays statistics about local link events of a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After error code detection, error frame detection, or error frame second detection is configured, you can run the **display efm link-event local** command to view statistics about local link events.

Precautions

After the **display efm link-event local** command is run, a hyphen (-) is displayed if error code detection, error frame detection, or error frame second detection is not configured in the interface view.

Example

Displays statistics about local link events on GigabitEthernet0/0/1.

```
<HUAWEI> display efm link-event local interface gigabitethernet 0/0/1
Item                    Value
----------------------------------------------------
Interface:              GigabitEthernet0/0/1
-------------------------
Errored-code
Errors:                 0
Error Running Total :     0
Event Running Total :     0
-------------------------
Errored-frame
Errors:                 0
Error Running Total :     0
Event Running Total :     0
-------------------------
Errored-frame-period
Errors:                 0
Error Running Total :     0
Event Running Total :     0
-------------------------
Errored-frame-seconds
Errors:                 0
Error Running Total :     0
Event Running Total :     0
```

Table 12-40 Description of the display efm link-event local command output

Item	Description
Interface	Interface enabled with EFM.
Errored-code	Information about error code.
Errored-frame	Information about error frame.
Errored-frame-period	Information about error frame period.
Errored-frame-seconds	Information about error frame second.
Errors	Number of currently detected error codes, error frames, error frame period, or error frame seconds.
Error Running Total	Total number of detected error codes, error frames, error frame period, or error frame seconds.

Item	Description
Event Running Total	Count of detected error codes, error frames, error frame period, or error frame seconds.

12.7.5 display efm session

Function

The **display efm session** command displays information about an EFM session between the specified interface and the peer.

Format

display efm session { **all** | **interface** *interface-type interface-number* }

Parameters

Parameter	Description	Value
all	Displays information about EFM sessions between all interfaces configured with EFM and the peers.	-
interface-type interface-number	Displays information about the EFM session between the specified interface and the peer. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

To check whether an EFM session configured on a device is negotiated successfully, run the **display efm session** command. The command output includes the EFM status and timeout interval of a loopback test.

- If **all** is specified, information about all EFM sessions configured on the device is displayed.
- If **interface** *interface-type interface-number* is specified, information about EFM sessions configured on a specified interface is displayed.

Prerequisites

EFM has been enabled globally using the **efm enable** command.

Example

Display information about EFM sessions between all interfaces and the peers.

```
<HUAWEI> display efm session all
Interface              EFM State              Loopback Timeout
----------------------------------------------------------------------
GigabitEthernet0/0/1      discovery                   --
```

Table 12-41 Description of the display efm session command output

Item	Description
Interface	Interface name.
EFM State	EFM protocol status on the interface: ● disabled: The EFM protocol is disabled on the interface. ● discovery: The interface is in OAM discovery state. ● detect: The interface is in Detect state. ● loopback (control): The interface initiates remote loopback and discards the packets looped back. ● loopback (be controlled): The interface responds to remote loopback.
Loopback Timeout	Timeout interval of a loopback test.

12.7.6 display test-packet result

Function

The **display test-packet result** command displays information about sent test packets.

Format

display test-packet result

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After remote loopback is enabled and the **test-packet start** command is used to configure a device to send test packets, the **display test-packet result** command can be used to view information about sent test packets. You can determine link performance based on the information about test packets.

Example

Display information about sent test packets.

```
<HUAWEI> display test-packet result
 TestResult             Value
--------------------------------------------------------
 PacketsSend :            5
 PacketsReceive :          5
 PacketsLost :            0
 BytesSend :              320
 BytesReceive :            320
 BytesLost :             0
 StartTime :             06-13-2012 14:44:13 UTC+03:00
 EndTime :               06-13-2012 14:44:14 UTC+03:00
```

Table 12-42 Description of the display test-packet result command output

Item	Description
PacketsSend	Number of sent test packets.
PacketsReceive	Number of received test packets.
PacketsLost	Number of discarded test packets.
BytesSend	Total length of sent test packets, in bytes.
BytesReceive	Total length of received test packets, in bytes.
BytesLost	Total length of discarded test packets, in bytes.
StartTime	Start time test packets are sent.
EndTime	End time test packets are sent.

12.7.7 efm enable

Function

The **efm enable** command enables EFM globally or on an interface.

The **undo efm enable** command disables EFM globally or on an interface.

By default, EFM is disabled globally. That is, EFM is disabled on all interfaces.

Format

efm enable

undo efm enable

Parameters

None

Views

System view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before using EFM functions, you must enable EFM globally.

After EFM is enabled on an interface, the interface starts to send OAMPDUs to perform point-to-point EFM link detection. EFM link detection can be implemented between two interfaces only after EFM is enabled on the peer interface.

Precautions

When you use the **undo efm enable** command to disable EFM globally, the device deletes all EFM configurations. When the device is implementing remote loopback and sending a great deal of test packets, running the **undo efm enable** command will cause packets to be forwarded.

NOTE

Eth-Trunks do not support EFM.

Example

Enable EFM globally.

```
<HUAWEI> system-view
[HUAWEI] efm enable
Info: Operation succeeded.
```

Enable EFM on Layer 2 interface GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] efm enable
Info: Operation succeeded.
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm enable
Info: Operation succeeded.
```

Enable EFM on Layer 3 interface GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] efm enable
Info: Operation succeeded.
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] efm enable
Info: Operation succeeded.
```

12.7.8 efm error-code notification enable

Function

The **efm error-code notification enable** command enables an interface to detect EFM errored codes.

The **undo efm error-code notification enable** command disables an interface from detecting EFM errored codes.

By default, an interface is not enabled to detect EFM errored codes.

Format

efm error-code notification enable

undo efm error-code notification enable

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Monitoring Ethernet links is difficult if network performance deteriorates while traffic is being transmitted over physical links. Link monitoring is used to detect link layer faults in various environments. After EFM link monitoring is configured, the device queries statistics about the physical layer data of the interface management module to monitor the quality of the link connected to an interface. EFM link monitoring implements the following functions:

- Reports an alarm when the number of errored codes detected during a specified detection interval exceeds the preset threshold.
- Reports an alarm when the number of errored frames detected during a specified detection interval exceeds the preset threshold.

- Reports an alarm when the number of errored frame seconds detected during a specified interval exceeds the preset threshold.

The **efm error-code notification enable** command enables an interface to detect EFM errored codes. The local device considers a link faulty if the number of detected errored codes within the detection interval reaches or exceeds the preset threshold. Then the local device generates an alarm, reports the alarm to the NMS, and sends an OAMPDU to notify the peer device of the link failure.

Prerequisites

EFM has been enabled globally and on an interface using the **efm enable** command.

Example

Enable Layer 2 interface GigabitEthernet0/0/1 to detect errored codes.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm enable
[HUAWEI-GigabitEthernet0/0/1] efm error-code notification enable
Info: Operation succeeded.
```

Enable Layer 3 interface GigabitEthernet0/0/1 to detect errored codes.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] efm enable
[HUAWEI-GigabitEthernet0/0/1] efm error-code notification enable
Info: Operation succeeded.
```

12.7.9 efm error-code period

Function

The **efm error-code period** command sets the period for detecting EFM errored codes on an interface.

The **undo efm error-code period** command restores the default period for detecting EFM errored codes on an interface.

By default, the period for detecting EFM errored codes on an interface is 1s.

Format

efm error-code period *period*

undo efm error-code period

Parameters

Parameter	Description	Value
period	Specifies the period for detecting EFM errored codes.	The value is an integer that ranges from 1 to 60, in seconds. The default value is 1s.

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **efm error-code period** *period* command is run to set the period for detecting EFM errored codes, run the **efm error-code notification enable** command to enable an interface to detect EFM errored codes. When the number of detected errored codes during the period reaches or exceeds a preset threshold, the local device generates an alarm and notifies the peer device of the alarm event.

Prerequisites

EFM has been enabled globally using the **efm enable** command.

Example

Set the period for detecting EFM errored codes on Layer 2 interface GigabitEthernet0/0/1 to 20s.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm error-code period 20
Info: Operation succeeded.
```

Set the period for detecting EFM errored codes on Layer 3 interface GigabitEthernet0/0/1 to 20s.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] efm error-code period 20
Info: Operation succeeded.
```

12.7.10 efm error-code threshold

Function

The **efm error-code threshold** command sets the threshold for detecting EFM errored codes on an interface.

The **undo efm error-code threshold** command restores the default threshold for detecting EFM errored codes on an interface.

By default, the threshold for detecting EFM errored codes on an interface is 1.

Format

efm error-code threshold *threshold*

undo efm error-code threshold

Parameters

Parameter	Description	Value
threshold	Specifies the threshold for detecting EFM errored codes.	The value is an integer that ranges from 0 to 65535. The default value is 1. The value 0 is not recommended.

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **efm error-code period** *period* command is executed to set the period for detecting EFM errored codes, run the **efm error-code threshold** *threshold* command to set the threshold for detecting errored codes. Run the **efm error-code notification enable** command to enable an interface to detect EFM errored codes. When the number of detected errored codes during the period reaches or exceeds the threshold specified by *threshold*, the local device generates an alarm and notifies the peer device of the alarm event.

Prerequisites

EFM has been enabled globally using the **efm enable** command.

Example

Set the threshold for detecting EFM errored codes on Layer 2 interfaceGigabitEthernet0/0/1 to 100.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm error-code threshold 100
Info: Operation succeeded.
```

Set the threshold for detecting EFM errored codes on Layer 3 interface GigabitEthernet0/0/1 to 100.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] efm error-code threshold 100
Info: Operation succeeded.
```

12.7.11 efm error-frame notification enable

Function

The **efm error-frame notification enable** command enables an interface to detect EFM errored frames.

The **undo efm error-frame notification enable** command disables an interface from detecting EFM errored frames.

By default, an interface is not enabled to detect EFM errored frames.

Format

efm error-frame notification enable

undo efm error-frame notification enable

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

2: Configuration level

Usage Guidelines

Usage Scenario

Monitoring Ethernet links is difficult if network performance deteriorates while traffic is being transmitted over physical links. Link monitoring is used to detect link layer faults in various environments. After EFM link monitoring is configured, the device queries statistics about the physical layer data of the interface management module to monitor the quality of the link connected to an interface. EFM link monitoring implements the following functions:

- Reports an alarm when the number of errored codes detected during a specified detection interval exceeds the preset threshold.
- Reports an alarm when the number of errored frames detected during a specified detection interval exceeds the preset threshold.
- Reports an alarm when the number of errored frame seconds detected during a specified interval exceeds the preset threshold.

The **efm error-frame notification enable** command enables an interface to detect EFM errored frames. The local device considers a link faulty if the number of detected errored frames within the detection interval reaches or exceeds the preset threshold. Then the local device generates an alarm, reports the alarm to the NMS, and sends an OAMPDU to notify the peer device of the link failure.

Prerequisites

EFM has been enabled globally and on an interface using the **efm enable** command.

Example

Enable Layer 2 interfaceGigabitEthernet0/0/1 to detect errored frames.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm enable
[HUAWEI-GigabitEthernet0/0/1] efm error-frame notification enable
Info: Operation succeeded.
```

Enable Layer 3 interface GigabitEthernet0/0/1 to detect errored frames.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] efm enable
[HUAWEI-GigabitEthernet0/0/1] efm error-frame notification enable
Info: Operation succeeded.
```

12.7.12 efm error-frame period

Function

The **efm error-frame period** command sets the period for detecting EFM errored frames on an interface.

The **undo efm error-frame period** command restores the default period for detecting EFM errored frames on an interface.

By default, the period for detecting EFM errored frames on an interface is 1s.

Format

efm error-frame period *period*

undo efm error-frame period

Parameters

Parameter	Description	Value
period	Specifies the period for detecting EFM errored frames.	The value is an integer that ranges from 1 to 60, in seconds. The default value is 1s.

Views

Usage Guidelines

Usage Scenario

After the **efm error-code period** *period* command is run to set the period for detecting EFM errored frames on an interface, run the **efm error-frame notification enable** command to enable an interface to detect EFM errored frames. When the number of detected errored frames during the period reaches or exceeds a preset threshold, the local device generates an alarm and notifies the peer device of the alarm event.

Prerequisites

EFM has been enabled globally using the **efm enable** command.

Example

Set the period for detecting EFM errored frames on Layer 2 interface GigabitEthernet0/0/1 to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm error-frame period 20
Info: Operation succeeded.
```

Set the period for detecting EFM errored frames on Layer 3 interface GigabitEthernet0/0/1 to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] efm error-frame period 20
Info: Operation succeeded.
```

12.7.13 efm error-frame threshold

Function

The **efm error-frame threshold** command sets the threshold for detecting EFM errored frames on an interface.

The **undo efm error-frame threshold** command restores the default threshold for detecting EFM errored frames on an interface.

By default, the threshold for detecting EFM errored frames on an interface is 1.

Format

efm error-frame threshold *threshold*

undo efm error-frame threshold

Parameters

Parameter	Description	Value
threshold	Specifies the threshold for detecting EFM errored frames.	The value is an integer that ranges from 0 to 65535. The default value is 1. The value 0 is not recommended.

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

Usage Scenario

Monitoring Ethernet links is difficult if network performance deteriorates while traffic is being transmitted over physical links. Link monitoring is used to detect link layer faults in various environments. After EFM link monitoring is configured, the device queries statistics about the physical layer data of the interface management module to monitor the quality of the link connected to an interface. EFM link monitoring implements the following functions:

- Reports an alarm when the number of errored codes detected during a specified detection interval exceeds the preset threshold.
- Reports an alarm when the number of errored frames detected during a specified detection interval exceeds the preset threshold.
- Reports an alarm when the number of errored frame seconds detected during a specified interval exceeds the preset threshold.

The **efm error-frame-second notification enable** command enables an interface to detect EFM errored frame seconds. The local device considers a link faulty if the number of detected errored frame seconds within the detection interval reaches or exceeds the preset threshold. Then the local device generates an alarm, reports the alarm to the NMS, and sends an OAMPDU to notify the peer device of the link failure.

Prerequisites

EFM has been enabled globally and on an interface using the **efm enable** command.

Example

Enable Layer 2 interface GigabitEthernet0/0/1 to detect errored frame seconds.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm enable
[HUAWEI-GigabitEthernet0/0/1] efm error-frame-second notification enable
Info: Operation succeeded.
```

Enable Layer 3 interface GigabitEthernet0/0/1 to detect errored frame seconds.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] efm enable
[HUAWEI-GigabitEthernet0/0/1] efm error-frame-second notification enable
Info: Operation succeeded.
```

12.7.15 efm error-frame-second period

Function

The **efm error-frame-second period** command sets the period for detecting EFM errored frame seconds on an interface.

The **undo efm error-frame-second period** command restores the default period for detecting EFM errored frame seconds on an interface.

By default, the period for detecting EFM errored frame seconds on an interface is 60s.

Format

efm error-frame-second period *period*

undo efm error-frame-second period

Parameters

Parameter	Description	Value
period	Specifies the period for detecting EFM errored frame seconds.	The value is an integer that ranges from 10 to 900, in seconds. The default value is 60s.

Usage Guidelines

Usage Scenario

After the **efm error-frame-second period** *period* command is executed to set the threshold for detecting EFM errored frame seconds on an interface, run the **efm error-frame-second threshold** *threshold* command to set the threshold for detecting errored frame seconds. Run the **efm error-frame-second notification enable** command to enable an interface to detect EFM errored frame seconds. When the number of detected errored frame seconds during the period reaches or exceeds the threshold specified by *threshold*, the local device generates an alarm and notifies the peer device of the alarm event.

Prerequisites

EFM has been enabled globally using the **efm enable** command.

Example

Set the threshold for detecting EFM errored frame seconds on Layer 2 interface GigabitEthernet0/0/1 to 10.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm error-frame-second threshold 10
Info: Operation succeeded.
```

Set the threshold for detecting EFM errored frame seconds on Layer 3 interface GigabitEthernet0/0/1 to 10.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] efm error-frame-second threshold 10
Info: Operation succeeded.
```

12.7.17 efm holdup-timer

Function

The **efm holdup-timer** command sets the value of the EFM faulty-state holdup timer on an interface.

The **undo efm holdup-timer** command restores the default value interval of the EFM faulty-state holdup timer on an interface.

By default, the value of the EFM faulty-state holdup timer is 0s.

Format

efm holdup-timer *time*

undo efm holdup-timer

Parameters

Parameter	Description	Value
time	Specifies the value of the EFM faulty-state holdup timer on an interface.	The value is an integer that ranges from 0 to 50, in seconds. The default value is 0.

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **efm trigger if-down** command is used to associate EFM with an interface, run the **efm holdup-timer** command to set the value of the EFM faulty-state holdup timer for connectivity faults detected by EFM. The faulty state remains unchanged within the value of the holdup timer. EFM does not detect whether the connectivity fault is cleared until the faulty-state holdup timer expires.

After the failed link recovers, EFM works as follows:

- If *time* is not specified, EFM immediately changes the link status to Up.
- If *time* is specified, EFM changes the link status to Up only after the time specified by *time* expires. This prevents the link from frequently alternating between Up and Down.

Prerequisites

EFM has been enabled globally and on interfaces using the **efm enable** command.

It is recommended that you run the **efm trigger if-down** command to associate EFM with an interface before running the **efm holdup-timer** command to set the value of EFM faulty-state holdup timer on the interface. Otherwise, the holdup timer does not take effect.

Example

Set the value of EFM faulty-state holdup timer on GigabitEthernet0/0/1 to 10s.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm enable
[HUAWEI-GigabitEthernet0/0/1] efm trigger if-down
[HUAWEI-GigabitEthernet0/0/1] efm holdup-timer 10
```

12.7.18 efm loopback

Function

The **efm loopback** command configures an interface to initiate or end an EFM remote loopback.

Format

efm loopback { **start** [**timeout** *timeout*] | **stop** }

Parameters

Parameter	Description	Value
start	Initiate an EFM remote loopback.	-
timeout *timeout*	Specifies the timeout interval of an EFM remote loopback.	The value is an integer that ranges from 0 to 1000, in minutes. The default value is 20. The value 0 indicates that no timeout interval is set. That is, the interface remains in remote loopback state.
stop	Ends an EFM remote loopback.	-

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

NOTE

The S6735-S, S6720-EI and S6720S-EI can only initiate EFM OAM remote loopback requests.

Usage Scenario

EFM remote loopback is used to locate link failures and test the link quality. After remote loopback is enabled, configure the local device to send test packets to the peer device. Based on the statistics about sent and received test packets, you can check connectivity and performance of a specified link.

- If **start** is specified, an interface on the local device sends a remote loopback message to the peer device. After receiving the message, the peer device enters the loopback state. In loopback state, the peer sends back all received packets, except EFM OAMPDUs, to the local device through the interface that has received these packets.
- If **stop** is specified, an interface on the local device sends a remote loopback stop message to the peer device. After receiving the message, the peer device exits from the loopback state.
- If remote loopback is left enabled, the remote device keeps looping back service data, causing a service interruption. To prevent this problem, a capability can be configured to disable remote loopback automatically after a specified timeout interval. By default, the timeout interval for remote loopback is 20 minutes. The remote loopback test stops after 20 minutes. You can set the timeout interval to 0 to keep a link in remote loopback state.

NOTE

The link in remote loopback state will not forward service data. Therefore, execute caution when you set the timeout interval to 0.

Prerequisites

- EFM has been enabled and is in detect state.
- The device has been configured to work in active mode using the **efm mode active** command.

Precautions

After remote loopback is enabled, all packets except EFM OAMPDUs are looped back on the remote device. EFM OAM remote loopback must be implemented on the link that does not need to forward service data. Otherwise, service data forwarding is affected.

Remote loopback is implemented successfully only when EFM protocols at the local end and the peer are in handshake state and EFM at the local end works in active mode. You can use the **display efm session** command to check whether EFM OAM protocols on the local interface and the peer are in handshake state.

Example

Configure Layer 2 interface GigabitEthernet0/0/1 to initiate an EFM OAM remote loopback.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm enable
[HUAWEI-GigabitEthernet0/0/1] efm loopback start
```

Set the timeout interval for an EFM OAM remote loopback on Layer 2 interface GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm enable
[HUAWEI-GigabitEthernet0/0/1] efm loopback start timeout 10
```

Configure Layer 2 interface GigabitEthernet0/0/1 to stop an EFM OAM remote loopback.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm enable
[HUAWEI-GigabitEthernet0/0/1] efm loopback stop
```

Configure Layer 3 interface GigabitEthernet0/0/1 to initiate an EFM OAM remote loopback.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] efm enable
[HUAWEI-GigabitEthernet0/0/1] efm loopback start
```

Set the timeout interval for an EFM OAM remote loopback on Layer 3 interface GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] efm loopback start timeout 10
```

Configure Layer 3 interface GigabitEthernet0/0/1 to stop an EFM OAM remote loopback.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] efm loopback stop
```

12.7.19 efm loopback ignore-request

Function

The **efm loopback ignore-request** command enables an interface to ignore loopback requests sent by the remote end.

The **undo efm loopback ignore-request** command restores the default setting for the loopback function on an interface.

By default, an interface supports remote loopback. After receiving a loopback request from a remote end, the interface enters the loopback state.

Format

efm loopback ignore-request

undo efm loopback ignore-request

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Remote loopback is used to monitor link quality and locate link faults. Periodic loopback detection helps detect network faults in a timely manner.

If an interface is in loopback state, the interface loops back all received traffic, causing service interruption and imposing attacks. To solve this problem, run the

efm loopback ignore-request command to enable the interface to reject the remote Ethernet OAM loopback request carried in a Loopback Control OAMPDU sent by a remote interface.

Prerequisites

EFM has been enabled globally and on an interface using the **efm enable** command and the interface is not in loopback state.

Precautions

After the **efm loopback ignore-request** command is run, the interface will discard an OAMPDU carrying a remote loopback request.

Example

Enable Layer 2 interface GigabitEthernet0/0/1 to ignore loopback requests sent by a specified remote interface.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm loopback ignore-request
```

Enable Layer 3 interface GigabitEthernet0/0/1 to ignore loopback requests sent by a specified remote interface.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] efm loopback ignore-request
```

12.7.20 efm mode

Function

The **efm mode** command configures the working mode of EFM on an interface.

The **undo efm mode** command restores the default working mode of EFM on an interface.

By default, EFM on an interface works in active mode.

Format

efm mode { **active** | **passive** }

undo efm mode

Parameters

Parameter	Description	Value
active	Indicates that EFM on an interface works in active mode.	-
passive	Indicates that EFM on an interface works in passive mode.	-

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

EFM supports two connection modes: active and passive. By setting the working mode of EFM OAM, you can configure whether a device can send or receive a specified type of EFM OAMPDU. **Table 12-43** describes the differences between the active and passive modes.

Table 12-43 Capabilities for processing OAMPDUs in active and passive modes

Event	Active Mode	Passive Mode
Initiate a connection request by sending an Information OAMPDU during the discovery process	Supported	Not supported
Respond to a connection request during the discovery process	Supported	Supported
Send Information OAMPDUs	Supported	Supported
Send Event Notification OAMPDUs	Supported	Supported
Send Loopback Control OAMPDUs	Supported	Not supported
Respond to Loopback Control OAMPDUs	Supported (The remote EFM entity must work in active mode.)	Supported

Precautions

- The working mode of EFM can be set on an interface only after EFM is enabled globally and before EFM is enabled on the interface. The working mode of EFM on an interface cannot be changed after EFM is enabled on the interface. Before changing the working mode of EFM on an interface, run the **undo efm enable** command to disable EFM on the interface.

- An EFM connection can only be initiated by an OAM entity working in active mode. An OAM entity working in passive mode waits to receive a connection request from its peer entity.
- Two OAM entities both working in passive mode cannot establish an EFM connection between them.

Example

Configure EFM OAM on Layer 2 interface GigabitEthernet0/0/1 to work in passive mode.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm mode passive
```

Configure EFM OAM on Layer 3 interface GigabitEthernet0/0/1 to work in passive mode.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] efm mode passive
```

12.7.21 efm packet max-size

Function

The **efm packet max-size** command sets the maximum size of an EFM OAMPDU on an interface. All EFM OAMPDUs that exceed the maximum size on an interface are discarded as invalid packets.

The **undo efm packet max-size** command restores the default maximum size of an EFM OAMPDU on an interface.

By default, the maximum size of an EFM OAMPDU on an interface is 128 bytes.

Format

efm packet max-size *size*

undo efm packet max-size

Parameters

Parameter	Description	Value
size	Specifies the maximum size of an EFM OAMPDU. The size contains the length of Layer 2 frame header and the length of the cyclic redundancy check (CRC) field.	The value is an integer that ranges from 64 to 1518, in bytes. The default value is 128 bytes.

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **efm packet max-size** command to adjust the maximum size of an EFM OAMPDU so that non-Huawei devices can communicate.

Prerequisites

EFM has been enabled globally using the **efm enable** command.

Precautions

The local device and the peer determine the actual value of the maximum size of an EFM OAMPDU through negotiation. The smaller maximum size of an EFM OAMPDU set on the local interface or the peer is used.

Example

Set the maximum size of an EFM OAMPDU on Layer 2 interface GigabitEthernet0/0/1 to 120 bytes.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm packet max-size 120
```

Set the maximum size of an EFM OAMPDU on Layer 3 interface GigabitEthernet0/0/1 to 120 bytes.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] efm packet max-size 120
```

12.7.22 efm src-mac

Function

The **efm src-mac** command configures an interface or bridge MAC address as the source MAC address in an OAMPDU.

The **undo efm src-mac** command restores the default configuration.

By default, a bridge MAC address is used as the source MAC address in an OAMPDU.

Format

efm src-mac { **port** | **bridge** }

undo efm src-mac

Parameters

Parameter	Description	Value
port	Configures an interface MAC address as the source MAC address in an OAMPDU.	-
bridge	Configures a bridge MAC address as the source MAC address in an OAMPDU.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

OAMPDUs support interface or bridge MAC addresses as source MAC addresses. You can run the **efm src-mac** command to configure an interface or bridge MAC address as the source MAC address in an OAMPDU before enabling EFM globally.

Example

Configure an interface MAC address as the source MAC address in an OAMPDU.

```
<HUAWEI> system-view
[HUAWEI] efm src-mac port
```

12.7.23 efm timeout

Function

The **efm timeout** command sets the timeout interval at which EFM OAMPDUs are received.

The **undo efm timeout** command restores the default timeout interval.

By default, the timeout interval at which EFM OAMPDUs are received is 5000 milliseconds.

Format

efm timeout *timeout-value*

undo efm timeout

Parameters

Parameter	Description	Value
timeout-value	Specifies the timeout interval at which an interface receives EFM OAMPDUs.	The value is an integer that ranges from 3000 to 30000, in milliseconds. The step is 1000 milliseconds. The default value is 5000 milliseconds.

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By setting the timeout interval at which OAMPDUs are received, you can change the time required for connectivity fault detection.

Prerequisites

EFM OAM has been enabled globally but is not enabled on an interface.

Precautions

After the timeout interval expires, the EFM OAM protocol switches back to the discovery state. Ensure that interfaces on both ends of a link use the same timeout interval. Otherwise, EFM session negotiation may fail, or the EFM session may flap.

After EFM OAM is enabled on an interface, the timeout interval cannot be changed.

- A shorter timeout interval indicates a shorter time required for connectivity fault detection.
- A longer timeout interval indicates a longer time required for connectivity fault detection.

Example

Set the timeout interval at which EFM OAMPDUs are received on Layer 2 interface GigabitEthernet0/0/1 to 3000 ms.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm timeout 3000
```

Set the timeout interval at which EFM OAMPDUs are received on Layer 3 interface GigabitEthernet0/0/1 to 3000 ms.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] efm timeout 3000
```

12.7.24 efm threshold-event trigger error-down

Function

The **efm threshold-event trigger error-down** command associates an EFM threshold crossing event with an interface.

The **undo efm threshold-event trigger error-down** command disassociates an EFM threshold crossing event from an interface.

By default, a threshold crossing event is not associated with an interface.

Format

efm threshold-event trigger error-down

undo efm threshold-event trigger error-down

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When link monitoring is configured for an interface on a link, the link is considered unavailable, if the number of errored frames, errored codes, or errored frame seconds detected by the interface reaches or exceeds the threshold within a period. In this case, you can run the **efm threshold-event trigger error-down** command to associate a threshold crossing event with an interface so that the system sets the administrative state of the interface to Down. As a result, all services on the interface are interrupted.

Prerequisites

EFM has been enabled on an interface using the **efm enable** command.

Follow-up Procedure

Configure the interface to go administratively Up by using either of the following methods:

- Run the **error-down auto-recovery** command to set the auto-recovery delay before an interface goes administratively Up.
- Run the **shutdown** command and then the **undo shutdown** command to restore the administrative state of the interface to Up.

Example

Associate a threshold crossing event with Layer 2 interface GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm enable
[HUAWEI-GigabitEthernet0/0/1] efm threshold-event trigger error-down
```

Associate a threshold crossing event with Layer 3 interface GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] efm enable
[HUAWEI-GigabitEthernet0/0/1] efm threshold-event trigger error-down
```

12.7.25 efm trigger clear-arp vlan

Function

The **efm trigger clear-arp vlan** command clears an ARP entry corresponding to a VLANIF interface.

The **undo efm trigger clear-arp vlan** command cancels the configuration.

By default, an interface does not clear an ARP entry.

Format

efm trigger clear-arp vlan *vlan-id*

undo efm trigger clear-arp vlan *vlan-id*

Parameters

Parameter	Description	Value
vlan-id	Specifies the VLAN ID in an ARP entry.	The value is an integer that ranges from 1 to 4094.

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

NOTE

The **efm trigger clear-arp vlan** command takes effect only on Layer 2 Ethernet interfaces.

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When detecting a fault, the EFM module notifies the OAM management module of the fault. The OAM management module searches the EFM fault relationship table based on the interface number and VLAN ID, and then clears the ARP entry that corresponds to the VLANIF interface.

Prerequisites

EFM has been enabled globally and on an interface using the **efm enable** command.

Example

Enable GigabitEthernet0/0/1 in VLAN 10 to clear ARP entries.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm enable
[HUAWEI-GigabitEthernet0/0/1] efm trigger clear-arp vlan 10
```

12.7.26 efm trigger error-down

Function

The **efm trigger error-down** command associates an error event with an interface.

The **undo efm trigger error-down** command disassociates an error event from an interface.

By default, an error event is not associated with an interface.

Format

efm { **critical-event** | **dying-gasp** | **link-fault** | **timeout** } **trigger error-down**

undo efm { **critical-event** | **dying-gasp** | **link-fault** | **timeout** } **trigger error-down**

Parameters

Parameter	Description	Value
critical-event	Indicates an unspecified critical event. It usually refers to a fault on the interface associated with MGR.	-
dying-gasp	Indicates an unrecoverable failure. It usually refers to device restart or power-off.	-
link-fault	Indicates a physical link fault. It usually refers to a fault on an interface.	-
timeout	Indicates the timeout interval at which EFM OAMPDUs are received.	-

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When EFM OAM associated with an interface detects a connectivity fault on a link, the protocol status of the interface goes Down. The interface goes Up after the faulty link recovers.

After the **efm trigger error-down** command is used, the administrative status of the interface goes Down when EFM OAM detects remote **critical-event**, **dying-gasp**, or **link-fault** events, or local **timeout** event. Traffic will not be switched back after the faulty link recovers. Check link quality before switching traffic back to the original link.

Prerequisites

EFM OAM has been enabled globally and on an interface using the **efm enable** command.

Follow-up Procedure

When the protocols status of an interface goes Down because error events are associated with the interface. The protocol status of the interface will not go Up even if the faulty link recovers. In this case, perform either of the following operations:

- Run the **restart (interface view)** command to restart the interface.
- Run the **shutdown (interface view)** and **undo shutdown (interface view)** commands to manually restore the interface.

- Run the **undo efm trigger error-down** command to disable association between error events and an interface.

To configure the shutdown interface to go Up automatically, run the **error-down auto-recovery cause efm-remote-failure interval** *interval-value* command in the system view to enable an interface to go Up and set a recovery delay before the interface enters the error-down state. The interface goes Up automatically after the delay.

Precautions

An interface can be associated with various types of error events. For example, if both **efm critical-event trigger error-down** and **efm dying-gasp trigger error-down** are used, the protocol status of the interface becomes Down when the device receives EFM OAM packets indicating **critical-event** or **dying-gasp** faults.

- Dying Gasp fault notification function supports models such as **Table 12-44** shows.

Table 12-44 Models that support Dying Gasp fault notification

Device Series	Model Unless otherwise specified: • The models listed in the table can send Dying Gasp messages to the remote device and send Dying Gasp alarms (EFM_1.3.6.1.4.1.2011.5.25.136.1.6.5_hwDot3ahEfmNonThresholdEvent) to the NMS. • All interfaces of the device can send Dying Gasp fault notification.
S5720-LI	All models support except S5720-16X-PWH-LI-AC, S5720-28P-LI-AC, S5720-28P-PWR-LI-AC, S5720-28X-PWH-LI-AC, S5720-52P-LI-AC, S5720-52P-PWR-LI-AC, S5720-52X-PWR-LI-ACF
S5720S-LI	S5720S-12TP-LI-AC, S5720S-12TP-PWR-LI-AC, S5720S-28TP-PWR-LI-ACL, and S5720S-28X-LI-24S-AC NOTE • They can send Dying Gasp messages to the remote device only, but cannot send Dying Gasp alarms to the NMS. • A maximum of 30 interfaces can send Dying Gasp messages.
S5720I-SI	All models
S5735-L	All models
S5735S-L	All models support except S5735S-L48P4S-A and S5735S-L48P4X-A
S5735-L1	S5735-L24P4X-A1, S5735-L24T4X-A1, S5735-L24T4X-D1, S5735-L24T4X-QA1, S5735-L32ST4X-A1, S5735-L32ST4X-D1, S5735-L48T4X-A1, S5735-L8P4X-A1, and S5735-L8T4X-A1 support

Device Series	Model **Unless otherwise specified:** **● The models listed in the table can send Dying Gasp messages to the remote device and send Dying Gasp alarms (EFM_1.3.6.1.4.1.2011.5.25.136.1.6.5_hwDot3ahEfmNonThresholdEvent) to the NMS.** **● All interfaces of the device can send Dying Gasp fault notification.**
S5735S-L1	S5735S-L32ST4X-A1 support
S5735S-L-M	All models
S5735-L-I	All models
S500-32ST4X	S500-32ST4X support

- The **efm critical-event trigger error-down** command is used and the remote interface associated with MGR goes Down. The local device will set the protocol status of the corresponding interface to Down after receiving an EFM OAM packet indicating a **critical-event** fault.
- The **efm dying-gasp trigger error-down** command is used and the board where the remote interface resides is reset or the system restarts. The local device will set the protocol status of the corresponding interface to Down after receiving an EFM OAM packet indicating a **dying-gasp** fault.
- The **efm link-fault trigger error-down** command is used and the physical link of the remote device is faulty. The local device will set the protocol status of the corresponding interface to Down after receiving an EFM OAM packet indicating a **link-fault** fault.
- The **efm timeout trigger error-down** command is used on the local device. The local device will set the protocol status of the corresponding interface to Down if it does not receive packets from the remote device in a specified period of time (5s by default).

NOTE

The **efm trigger if-down** and **efm trigger error-down** commands cannot be used simultaneously, and the **efm trigger mac-renew** and **efm trigger error-down** commands cannot be used simultaneously.

Example

Associate **dying-gasp** faults with Layer 2 interface GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm enable
[HUAWEI-GigabitEthernet0/0/1] efm dying-gasp trigger error-down
```

Associate **dying-gasp** faults with Layer 3 interface GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] efm enable
[HUAWEI-GigabitEthernet0/0/1] efm dying-gasp trigger error-down
```

12.7.27 efm trigger if-down

Function

The **efm trigger if-down** command associates EFM with an interface.

The **undo efm trigger if-down** command disassociates EFM from an interface.

By default, EFM OAM is not associated with any interface.

Format

efm trigger if-down

undo efm trigger if-down

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

EFM can be associated with interfaces. On a scenario with primary and backup links, if EFM detects a fault on the primary link, it will set the protocol status of the associated interface to ETHOAM Down, speeding up routing convergence. Traffic can be fast switched to the backup link.

Prerequisites

EFM has been enabled globally and on an interface, and is in detect state.

Precautions

If EFM is associated with an interface and detects a link fault, the protocol status of the interface becomes ETHOAM Down, and no packet except EFM OAMPDUs can be forwarded by the interface, and all Layer 2 and Layer 3 services are blocked. Therefore, associating EFM with an interface may greatly affect services. When the interface detects link recovery using EFM, the interface can forward all packets and unblocks Layer 2 and Layer 3 services.

If Layer 2 and Layer 3 services are blocked due to a misoperation, run the **undo efm trigger if-down** command in the interface view to restore services.

Example

Associate EFM with Layer 2 interface GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm enable
[HUAWEI-GigabitEthernet0/0/1] efm trigger if-down
```

Associate EFM with Layer 3 interface GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] efm enable
[HUAWEI-GigabitEthernet0/0/1] efm trigger if-down
```

12.7.28 efm trigger mac-renew

Function

The **efm trigger mac-renew** command configures the device to clear the MAC address table on a physical interface.

The **undo efm trigger mac-renew** command cancels the configuration.

By default, an interface is not enabled to clear the MAC address table.

Format

efm trigger mac-renew

undo efm trigger mac-renew

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view

NOTE

The **efm trigger mac-renew** command takes effect only on Layer 2 Ethernet interfaces.

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When you need to configure the device to clear the MAC address table on a physical interface, run the **efm trigger mac-renew** command.

Precautions

EFM has been enabled globally and on an interface using the **efm enable** command.

NOTE

The **efm trigger mac-renew** and **efm trigger if-down** commands cannot be used simultaneously on an interface.

Example

Configure GigabitEthernet0/0/1 to delete the corresponding MAC entry after a fault notification is received.

```
<HUAWEI> system-view
[HUAWEI] efm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] efm enable
[HUAWEI-GigabitEthernet0/0/1] efm trigger mac-renew
```

12.7.29 oam-bind efm interface efm interface

Function

The **oam-bind efm interface efm interface** command enables bidirectional fault notification between EFM modules.

The **undo oam-bind efm interface efm interface** command cancels the configuration.

By default, bidirectional transmission of information about a fault between EFM OAM sessions is not configured.

NOTE

Only the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, and S6720S-S support this function.

Format

oam-bind efm interface *interface-type interface-number* **efm interface** *interface-type interface-number*

undo oam-bind efm interface *interface-type interface-number* **efm interface** *interface-type interface-number*

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and the number of an interface configured with bidirectional fault notification between EFM modules. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

OAM management view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If EFM is deployed at both sides of a device, associate EFM modules on the device to ensure reliable service transmission.

Association between EFM and EFM is bidirectional. EFM modules notify each other of faults.

The following commands are used to associate EFM modules:

- **oam-bind efm interface efm interface**
- **oam-bind ingress efm interface egress efm interface**

Choose the preceding commands in different scenarios according to **Table 12-45**.

Table 12-45 Association between EFM modules

Scenario	Configuration Solution 1	Configuration Solution 2
Bidirectional fault notification between EFM modules	Run the **oam-bind efm interface efm interface** command.	Use the following commands: ● Run the **oam-bind ingress efm interface egress efm interface** command to configure EFM for the link at one side of the device to notify EFM for the link at the other side of the device of faults. **ingress efm interface** *interface-type interface-number* specifies the EFM-capable interface on the link at one side of the device, and **egress efm interface** *interface-type interface-number* specifies the EFM-capable interface on the link at the other side of the device. ● Run the **oam-bind ingress efm interface egress efm interface** command to configure EFM for the link at one side of the device to notify EFM for the link at the other side of the device of faults. **ingress efm interface** *interface-type interface-number* specifies the EFM-capable interface on the link at one side of the device, and **egress efm interface** *interface-type interface-number* specifies the EFM-capable interface on the link at the other side of the device.

Scenario	Configuration Solution 1	Configuration Solution 2
Unidirectional fault notification between EFM sessions	Choose either of the following commands based on the transmission direction: ● Run the **oam-bind ingress efm interface egress efm interface** command to configure EFM for the link at one side of the device to notify EFM for the link at the other side of the device of faults. **ingress efm interface** *interface-type interface-number* specifies the EFM-capable interface on the link at one side of the device, and **egress efm interface** *interface-type interface-number* specifies the EFM-capable interface on the link at the other side of the device. ● Run the **oam-bind ingress efm interface egress efm interface** command to configure EFM for the link at one side of the device to notify EFM for the link at the other side of the device of faults. **ingress efm interface** *interface-type interface-number* specifies the EFM-capable interface on the link at one side of the device, and **egress efm interface** *interface-type interface-number* specifies the EFM-capable interface on the link at the other side of the device.	None

Prerequisites

The following conditions must be met:

- EFM OAM has been enabled on specified interfaces.
- Two EFM OAM sessions have been associated with each other. When an EFM OAM session is associated with another EFM OAM session, the EFM OAM session cannot be associated with other EFM OAM sessions.

Example

Configure bidirectional fault notification between EFM OAM sessions.

```
<HUAWEI> system-view
[HUAWEI] oam-mgr
[HUAWEI-oam-mgr] oam-bind efm interface gigabitethernet0/0/1 efm interface gigabitethernet0/0/2
```

12.7.30 oam-bind efm interface trigger if-down interface

Function

The **oam-bind efm interface trigger if-down interface** command enables bidirectional fault notification between EFM and an interface.

The **undo oam-bind efm interface trigger if-down interface** command cancels the configuration.

By default, bidirectional transmission of information about a fault between EFM OAM and an interface is not configured.

Format

oam-bind efm interface *interface-type1 interface-number1* **trigger if-down interface** *interface-type2 interface-number2*

undo oam-bind efm interface *interface-type1 interface-number1* **trigger if-down interface** *interface-type2 interface-number2*

Parameters

Parameter	Description	Value
interface-type1 interface-number1	Specifies the type and number of the interface enabled with EFM. ● *interface-type1* specifies the interface type. ● *interface-number1* specifies the interface number.	-
interface-type2 interface-number2	Specifies the type and number of the interface bound to an EFM session. ● *interface-type2* specifies the interface type. ● *interface-number2* specifies the interface number.	-

Views

OAM management view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Association between EFM and an interface in the OAM management view is bidirectional:

- After EFM OAM detects a fault, the OAM module notifies the interface associated with EFM OAM of the fault. Then the interface goes Down. After EFM detects that the fault is rectified, the OAM module notifies the interface associated with EFM OAM. Then the interface goes Up.
- After the interface goes Down, the OAM module notifies EFM OAM of the interface Down event.
- A physical interface associated with EFM cannot be the one that EFM monitors. If EFM is associated with a physical interface that it monitors, the link is locked.

The following commands are used to configure association between EFM and an interface in the OAM management view:

- **oam-bind efm interface trigger if-down interface**
- **oam-bind interface efm interface trigger if-down**
- **oam-bind ingress efm interface trigger if-down egress interface**
- **oam-bind ingress interface egress efm interface trigger if-down**

Table 12-46 describes the implementation of association between EFM and an interface.

Table 12-46 Association between EFM and an EFM-incapable interface

Scenario	Configuration Solution 1	Configuration Solution 2
Bidirectional fault notification between EFM and an interface	Choose either of the following commands (the two commands have the same function): ● To specify an EFM OAM session first, run the **oam-bind efm interface trigger if-down interface** command. ● To specify an interface first, run the **oam-bind interface efm interface trigger if-down** command. **NOTE** After configuring bidirectional fault notification between EFM and an interface, run the **display current-configuration** command to view the current configuration. The **display current-configuration** command displays **oam-bind ingress interface egress efm interface trigger if-down** and **oam-bind ingress efm interface trigger if-down egress interface** commands, but does not display the **oam-bind efm interface trigger if-down interface** or **oam-bind interface efm interface trigger if-down** command. The displayed commands configure reverse transmission directions of fault information.	Run the following commands at a random order: ● **oam-bind ingress efm interface trigger if-down egress interface** ● **oam-bind ingress interface egress efm interface trigger if-down**
Unidirectional fault notification between EFM and an interface	Choose either of the following commands based on the transmission direction: ● To configure EFM OAM to report faults to an interface, run the **oam-bind ingress efm interface trigger if-down egress interface** command. ● To configure an interface to report faults to EFM OAM, run the **oam-bind ingress interface egress efm interface trigger if-down** command.	None

Precautions

When configuring bidirectional fault notification between EFM and an interface, pay attention to the following points:

- EFM has been enabled on the interface specified by **efm interface** *interface-type1 interface-number1*.

- EFM and an interface are associated with each other. After an interface is associated with an EFM session, the interface cannot be associated with other EFM sessions. Similarly, when EFM is bound to an interface, EFM cannot be bound to other interfaces.

Example

Configure bidirectional fault notification between an EFM session and GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] oam-mgr
[HUAWEI-oam-mgr] oam-bind efm interface gigabitethernet 0/0/1 trigger if-down interface
gigabitethernet 0/0/2
```

12.7.31 oam-bind ingress efm interface egress efm interface

Function

The **oam-bind ingress efm interface egress efm interface** command enables an EFM OAM session to report faults to another EFM OAM session.

The **undo oam-bind ingress efm interface egress efm interface** command disables an EFM OAM session from reporting faults to another EFM OAM session.

By default, unidirectional transmission of information about a fault from one EFM OAM session to another EFM OAM session is not configured.

NOTE

Only the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, and S6720S-S support this function.

Format

oam-bind ingress efm interface *interface-type1 interface-number1* **egress efm interface** *interface-type2 interface-number2*

undo oam-bind ingress efm interface *interface-type1 interface-number1* **egress efm interface** *interface-type2 interface-number2*

Parameters

Parameter	Description	Value
interface-type1 interface-number1	Specifies the type and number of the interface enabled with EFM OAM. ● *interface-type1* specifies the interface type. ● *interface-number1* specifies the interface number.	-

Parameter	Description	Value
interface-type2 interface-number2	Specifies the type and number of the interface bound to an EFM OAM session. • *interface-type2* specifies the interface type. • *interface-number2* specifies the interface number.	-

Usage Guidelines

Usage Scenario

If EFM is deployed at both sides of a device, associate EFM modules on the device to ensure reliable service transmission.

Association between EFM and EFM is bidirectional. EFM modules notify each other of faults.

The following commands are used to associate EFM modules:

- **oam-bind efm interface efm interface**
- **oam-bind ingress efm interface egress efm interface**

Choose the preceding commands in different scenarios according to **Table 12-47**.

Table 12-47 Association between EFM modules

Scenario	Configuration Solution 1	Configuration Solution 2
Bidirectional fault notification between EFM modules	Run the **oam-bind efm interface efm interface** command.	Use the following commands: ● Run the **oam-bind ingress efm interface egress efm interface** command to configure EFM for the link at one side of the device to notify EFM for the link at the other side of the device of faults. **ingress efm interface** *interface-type interface-number* specifies the EFM-capable interface on the link at one side of the device, and **egress efm interface** *interface-type interface-number* specifies the EFM-capable interface on the link at the other side of the device. ● Run the **oam-bind ingress efm interface egress efm interface** command to configure EFM for the link at one side of the device to notify EFM for the link at the other side of the device of faults. **ingress efm interface** *interface-type interface-number* specifies the EFM-capable interface on the link at one side of the device, and **egress efm interface** *interface-type interface-number* specifies the EFM-capable interface on the link at the other side of the device.

Scenario	Configuration Solution 1	Configuration Solution 2
Unidirectional fault notification between EFM sessions	Choose either of the following commands based on the transmission direction: ● Run the **oam-bind ingress efm interface egress efm interface** command to configure EFM for the link at one side of the device to notify EFM for the link at the other side of the device of faults. **ingress efm interface** *interface-type interface-number* specifies the EFM-capable interface on the link at one side of the device, and **egress efm interface** *interface-type interface-number* specifies the EFM-capable interface on the link at the other side of the device. ● Run the **oam-bind ingress efm interface egress efm interface** command to configure EFM for the link at one side of the device to notify EFM for the link at the other side of the device of faults. **ingress efm interface** *interface-type interface-number* specifies the EFM-capable interface on the link at one side of the device, and **egress efm interface** *interface-type interface-number* specifies the EFM-capable interface on the link at the other side of the device.	None

Precautions

Ingress EFM OAM reports faults to egress EFM OAM.

Example

Configure an EFM OAM session to report faults to another EFM OAM session.

```
<HUAWEI> system-view
[HUAWEI] oam-mgr
```

```
[HUAWEI-oam-mgr] oam-bind ingress efm interface gigabitethernet 0/0/1 egress efm interface
gigabitethernet 0/0/2
```

12.7.32 oam-bind ingress efm interface trigger if-down egress interface

Function

The **oam-bind ingress efm interface trigger if-down egress interface** command enables EFM to report faults to an interface.

The **undo oam-bind ingress efm interface trigger if-down egress interface** command cancels the configuration.

By default, unidirectional transmission of information about a fault from EFM OAM to an interface is not configured.

Format

oam-bind ingress efm interface *interface-type1 interface-number1* **trigger if-down egress interface** *interface-type2 interface-number2*

undo oam-bind ingress efm interface *interface-type1 interface-number1* **trigger if-down egress interface** *interface-type2 interface-number2*

Parameters

Parameter	Description	Value
interface-type1 interface-number1	Specifies the type and number of the interface enabled with EFM. • *interface-type1* specifies the interface type. • *interface-number1* specifies the interface number.	-
interface-type2 interface-number2	Specifies the type and number of the interface bound to an EFM session. • *interface-type2* specifies the interface type. • *interface-number2* specifies the interface number.	-

Views

OAM management view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Association between EFM and an interface in the OAM management view is bidirectional:

- After EFM OAM detects a fault, the OAM module notifies the interface associated with EFM OAM of the fault. Then the interface goes Down. After EFM detects that the fault is rectified, the OAM module notifies the interface associated with EFM OAM. Then the interface goes Up.
- After the interface goes Down, the OAM module notifies EFM OAM of the interface Down event.
- A physical interface associated with EFM cannot be the one that EFM monitors. If EFM is associated with a physical interface that it monitors, the link is locked.

The following commands are used to configure association between EFM and an interface in the OAM management view:

- **oam-bind efm interface trigger if-down interface**
- **oam-bind interface efm interface trigger if-down**
- **oam-bind ingress efm interface trigger if-down egress interface**
- **oam-bind ingress interface egress efm interface trigger if-down**

Table 12-48 describes the implementation of association between EFM and an interface.

Table 12-48 Association between EFM and an EFM-incapable interface

Scenario	Configuration Solution 1	Configuration Solution 2
Bidirectional fault notification between EFM and an interface	Choose either of the following commands (the two commands have the same function): - To specify an EFM OAM session first, run the **oam-bind efm interface trigger if-down interface** command. - To specify an interface first, run the **oam-bind interface efm interface trigger if-down** command. **NOTE** After configuring bidirectional fault notification between EFM and an interface, run the **display current-configuration** command to view the current configuration. The **display current-configuration** command displays **oam-bind ingress interface egress efm interface trigger if-down** and **oam-bind ingress efm interface trigger if-down egress interface** commands, but does not display the **oam-bind efm interface trigger if-down interface** or **oam-bind interface efm interface trigger if-down** command. The displayed commands configure reverse transmission directions of fault information.	Run the following commands at a random order: - **oam-bind ingress efm interface trigger if-down egress interface** - **oam-bind ingress interface egress efm interface trigger if-down**

Scenario	Configuration Solution 1	Configuration Solution 2
Unidirectional fault notification between EFM and an interface	Choose either of the following commands based on the transmission direction: ● To configure EFM OAM to report faults to an interface, run the **oam-bind ingress efm interface trigger if-down egress interface** command. ● To configure an interface to report faults to EFM OAM, run the **oam-bind ingress interface egress efm interface trigger if-down** command.	None

Precautions

Before enabling EFM to report faults to an interface, pay attention to the following points:

- EFM has been enabled on the interface specified by **efm interface** *interface-type2 interface-number2*.
- EFM and the interface are associated with each other. After an interface is associated with an EFM session, the interface cannot be associated with other EFM sessions. Similarly, when EFM is bound to an interface, EFM cannot be bound to other interfaces.

Ingress EFM reports faults to the specified interface.

Example

Configure EFM to report a fault to GigabitEthernet0/0/2.

```
<HUAWEI> system-view
[HUAWEI] oam-mgr
[HUAWEI-oam-mgr] oam-bind ingress efm interface gigabitethernet 0/0/1 trigger if-down egress
interface gigabitethernet 0/0/2
```

12.7.33 oam-bind ingress interface egress efm interface trigger if-down

Function

The **oam-bind ingress interface egress efm interface trigger if-down** command enables an interface to report faults to EFM OAM.

The **undo oam-bind ingress interface egress efm interface trigger if-down** command cancels the configuration.

By default, unidirectional transmission of information about a fault from an interface to EFM OAM is disabled.

Format

oam-bind ingress interface *interface-type1 interface-number1* **egress efm interface** *interface-type2 interface-number2* **trigger if-down**

undo oam-bind ingress interface *interface-type1 interface-number1* **egress efm interface** *interface-type2 interface-number2* **trigger if-down**

Parameters

Parameter	Description	Value
interface-type1 interface-number1	Specifies the type and number of the interface enabled with EFM. ● *interface-type1* specifies the interface type. ● *interface-number1* specifies the interface number.	-
interface-type2 interface-number2	Specifies the type and number of the interface bound to an EFM OAM session. ● *interface-type2* specifies the interface type. ● *interface-number2* specifies the interface number.	-

Views

OAM management view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an inward MEP is configured, bidirectional association between EFM and an EFM-incapable interface of a device can be configured in the OAM management view. This ensures that service traffic can be switched to the backup link if the primary link fails.

Association between EFM and an interface in the OAM management view is bidirectional:

- After EFM OAM detects a fault, the OAM module notifies the interface associated with EFM OAM of the fault. Then the interface goes Down. After EFM detects that the fault is rectified, the OAM module notifies the interface associated with EFM OAM. Then the interface goes Up.
- After the interface goes Down, the OAM module notifies EFM OAM of the interface Down event.

The following commands are used to configure association between EFM and an interface in the OAM management view:

- **oam-bind efm interface trigger if-down interface**
- **oam-bind interface efm interface trigger if-down**
- **oam-bind ingress efm interface trigger if-down egress interface**
- **oam-bind ingress interface egress efm interface trigger if-down**

Table 12-49 describes the implementation of association between EFM and an interface.

Table 12-49 Association between EFM and an EFM-incapable interface

Scenario	Configuration Solution 1	Configuration Solution 2
Bidirectional fault notification between EFM and an interface	Choose either of the following commands (the two commands have the same function): - To specify an EFM OAM session first, run the **oam-bind efm interface trigger if-down interface** command. - To specify an interface first, run the **oam-bind interface efm interface trigger if-down** command. **NOTE** After configuring bidirectional fault notification between EFM and an interface, run the **display current-configuration** command to view the current configuration. The **display current-configuration** command displays **oam-bind ingress interface egress efm interface trigger if-down** and **oam-bind ingress efm interface trigger if-down egress interface** commands, but does not display the **oam-bind efm interface trigger if-down interface** or **oam-bind interface efm interface trigger if-down** command. The displayed commands configure reverse transmission directions of fault information.	Run the following commands at a random order: - **oam-bind ingress efm interface trigger if-down egress interface** - **oam-bind ingress interface egress efm interface trigger if-down**
Unidirectional fault notification between EFM and an interface	Choose either of the following commands based on the transmission direction: - To configure EFM OAM to report faults to an interface, run the **oam-bind ingress efm interface trigger if-down egress interface** command. - To configure an interface to report faults to EFM OAM, run the **oam-bind ingress interface egress efm interface trigger if-down** command.	None

Configuration Impact

After an interface goes Down, the status of the associated EFM OAM session does not change. However, the device configured with association sends a message to inform the peer of the fault and triggers the peer to generate an alarm.

Precautions

Before enabling an interface to report faults to EFM OAM, pay attention to the following points:

- EFM has been enabled on the interface specified by **efm interface** *interface-type2 interface-number2*.
- EFM and an interface are associated with each other. After an interface is associated with an EFM session, the interface cannot be associated with other EFM sessions. Similarly, when EFM is bound to an interface, EFM cannot be bound to other interfaces.

The ingress interface reports faults to egress EFM.

Example

Configure GigabitEthernet0/0/1 to report a fault to EFM.

```
<HUAWEI> system-view
[HUAWEI] oam-mgr
[HUAWEI-oam-mgr] oam-bind ingress interface gigabitethernet 0/0/1 egress efm interface
gigabitethernet 0/0/2 trigger if-down
```

12.7.34 oam-bind interface efm interface trigger if-down

Function

The **oam-bind interface efm interface trigger if-down** command enables bidirectional transmission of fault messages between an interface and EFM OAM.

The **undo oam-bind interface efm interface trigger if-down** command cancels the configuration.

By default, bidirectional transmission of information about a fault between an interface and EFM OAM is not configured.

Format

oam-bind interface *interface-type1 interface-number1* **efm interface** *interface-type2 interface-number2* **trigger if-down**

undo oam-bind interface *interface-type1 interface-number1* **efm interface** *interface-type2 interface-number2* **trigger if-down**

Parameters

Parameter	Description	Value
interface-type1 interface-number1	Specifies the type and number of the interface enabled with EFM. ● *interface-type1* specifies the interface type. ● *interface-number1* specifies the interface number.	-
interface-type2 interface-number2	Specifies the type and number of the interface bound to an EFM session. ● *interface-type2* specifies the interface type. ● *interface-number2* specifies the interface number.	-

Usage Guidelines

Usage Scenario

If an inward MEP is configured, bidirectional association between EFM and an EFM-incapable interface of a device can be configured in the OAM management view. This ensures that service traffic can be switched to the backup link if the primary link fails.

Association between EFM and an interface in the OAM management view is bidirectional:

- After EFM OAM detects a fault, the OAM module notifies the interface associated with EFM OAM of the fault. Then the interface goes Down. After EFM detects that the fault is rectified, the OAM module notifies the interface associated with EFM OAM. Then the interface goes Up.
- After the interface goes Down, the OAM module notifies EFM OAM of the interface Down event.

The following commands are used to configure association between EFM and an interface in the OAM management view:

- **oam-bind efm interface trigger if-down interface**
- **oam-bind interface efm interface trigger if-down**
- **oam-bind ingress efm interface trigger if-down egress interface**
- **oam-bind ingress interface egress efm interface trigger if-down**

Table 12-50 describes the implementation of association between EFM and an interface.

Table 12-50 Association between EFM and an EFM-incapable interface

Scenario	Configuration Solution 1	Configuration Solution 2
Bidirectional fault notification between EFM and an interface	Choose either of the following commands (the two commands have the same function): - To specify an EFM OAM session first, run the **oam-bind efm interface trigger if-down interface** command. - To specify an interface first, run the **oam-bind interface efm interface trigger if-down** command. **NOTE** After configuring bidirectional fault notification between EFM and an interface, run the **display current-configuration** command to view the current configuration. The **display current-configuration** command displays **oam-bind ingress interface egress efm interface trigger if-down** and **oam-bind ingress efm interface trigger if-down egress interface** commands, but does not display the **oam-bind efm interface trigger if-down interface** or **oam-bind interface efm interface trigger if-down** command. The displayed commands configure reverse transmission directions of fault information.	Run the following commands at a random order: - **oam-bind ingress efm interface trigger if-down egress interface** - **oam-bind ingress interface egress efm interface trigger if-down**
Unidirectional fault notification between EFM and an interface	Choose either of the following commands based on the transmission direction: - To configure EFM OAM to report faults to an interface, run the **oam-bind ingress efm interface trigger if-down egress interface** command. - To configure an interface to report faults to EFM OAM, run the **oam-bind ingress interface egress efm interface trigger if-down** command.	None

Prerequisites

Basic EFM OAM functions have been configured.

Precautions

When configuring bidirectional transmission of fault messages between EFM and an interface, pay attention to the following points:

- EFM has been enabled on the interface specified by **efm interface** *interface-type2 interface-number2*.
- EFM and the interface are associated with each other. After an interface is associated with an EFM session, the interface cannot be associated with other EFM sessions. Similarly, when EFM is bound to an interface, EFM cannot be bound to other interfaces.
- Association between EFM and an EFM-capable interface and association between EFM and an EFM-incapable interface cannot be configured together.
- A physical interface associated with EFM cannot be the one that EFM monitors. If EFM is associated with a physical interface that it monitors, the link is locked.

Example

Configure bidirectional transmission of fault messages between EFM and GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] oam-mgr
[HUAWEI-oam-mgr] oam-bind interface gigabitethernet 0/0/1 efm interface gigabitethernet 0/0/2
trigger if-down
```

12.7.35 oam-mgr

Function

The **oam-mgr** command displays the OAM management view.

The **undo oam-mgr** command exits from the OAM management view.

Format

oam-mgr

undo oam-mgr

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

CFM can advertise fault information to interfaces or protocol modules. Ethernet OAM fault advertisement is implemented by an OAM manager, application modules, and detection modules. An OAMMGR module associates one module with another. A detection module monitors link status and network performance. If a detection module detects a fault, it instructs the OAMMGR module to notify an application module or another detection module of the fault. After receiving the notification, the application or detection module takes measures to prevent a communication interruption or service quality deterioration. Run the **oam-mgr** command to display the MGR view before associating the CFM module and other modules.

Example

Enter the OAM management view.

```
<HUAWEI> system-view
[HUAWEI] oam-mgr
[HUAWEI-oam-mgr]
```

12.7.36 test-packet start

Function

The **test-packet start** command configures the device to send test packets.

Format

test-packet start interface *interface-type interface-number* [**-c** *count* | **-s** *size*] *

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the outbound interface of test packets. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
-c *count*	Specifies the number of test packets to be sent.	The value is an integer that ranges from 1 to 65535. The default value is 5.
-s *size*	Specifies the length of a test packet.	The value is an integer that ranges from 64 to 1518, in bytes. The default value is 64 bytes.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After remote loopback is enabled on the device, run the **test-packet start** command on an interface in active mode to configure the device to send test packets. Then check link connectivity and performance based on returned test packets.

Press **Ctrl+C** to stop sending test packets. After using this command to send test packets, use the **display test-packet result** command to view the test result.

Precautions

During test packet transmission, parameters of sent test packets cannot be changed.

Example

Send test packets from outbound interface GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] test-packet start interface gigabitethernet 0/0/1
```

12.8 CFM Configuration Commands

12.8.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

12.8.2 active time

Function

The **active time** command sets the RMEP activation time.

The **undo active time** command deletes the RMEP activation time.

By default, the RMEP activation time is 0 seconds.

Format

active time *time*

undo active time

Parameters

Parameter	Description	Value
time *time*	Specifies the RMEP activation time.	The value ranges from 0 to 600, in seconds.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you run the **remote-mep ccm-receive enable** command to enable the local device to receive CCMs from an RMEP in the same MA, the local device generates an RMEP connectivity fault alarm in the following situations:

- A connectivity fault is detected between the local MEP and the RMEP using CC.
- The physical link works normally between the local MEP and the RMEP. The remote device is not configured with a MEP when connectivity check is performed or the MEP configuration is later than connectivity check. In this case, if the local MEP does not receive the CCM from the RMEP in consecutive three intervals for sending CCMs, the local device considers that a connectivity fault occurs between the local MEP and the RMEP.

  The RMEP connectivity fault alarm is generated incorrectly. To solve the problem, set the RMEP activation time.

Precautions

IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007.

If the RMEP activation time is set on the local device that is enabled to receive CCMs from a certain RMEP, the local device can receive CCMs at the configured RMEP activation time. That is, the activation time is the time reserved for configuring the RMEP.

At the RMEP activation time, if the local MEP does not receive any CCMs in three consecutive sending intervals, a connectivity fault occurs between the local MEP and the RMEP. Then the local device generates an alarm about the RMEP connectivity fault.

If the local device uses the default RMEP activation time, the local MEP receives CCMs from the RMEP immediately after the local device is enabled to receive CCMs from the RMEP.

NOTE

The RMEP activation time takes effect only for subsequent RMEPs in an MA, but is invalid for existing RMEPs in the MA.

Example

Set the RMEP activation time to 30s.

```
<HUAWEI> system-view
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] active time 30
```

12.8.3 alarm finish time

Function

The **alarm finish time** command sets the clear alarm anti-jitter time.

The **undo alarm finish time** command restores the default clear alarm anti-jitter time.

By default, the clear alarm anti-jitter time is 10000 ms.

Format

alarm finish time *time*

undo alarm finish time

Parameters

Parameter	Description	Value
time *time*	Specifies the clear alarm anti-jitter time.	The value ranges from 0 to 30000, in milliseconds. The step is 500, for example, the anti-jitter time can be 500, 1000, or 1500.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When detecting a link fault or link recovery, CFM will send an alarm to the NMS. If CFM frequently detects a link fault or link recovery, alarm flapping occurs. To suppress alarm flapping, run the **alarm finish time** command to set the clear alarm anti-jitter time. This prevents the NMS or system from being affected by frequently reported alarms.

Precautions

IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007.

When detecting link recovery, CFM compares the current link recovery time with the last time the fault was generated. CFM sends an alarm to the NMS only when the time difference is not smaller than the clear alarm anti-jitter time.

Example

Set the clear alarm anti-jitter time to 2000 ms.

```
<HUAWEI> system-view
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] alarm finish time 2000
```

12.8.4 alarm occur time

Function

The **alarm occur time** command sets the alarm anti-jitter time.

The **undo alarm occur time** command restores the default alarm anti-jitter time.

By default, the alarm anti-jitter time is 2500 ms.

Format

alarm occur time *time*

undo alarm occur time

Parameters

Parameter	Description	Value
time *time*	Specifies the alarm anti-jitter time.	The value ranges from 0 to 30000, in milliseconds. The step is 500, for example, the anti-jitter time can be 500, 1000, or 1500.

IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007.

When detecting a fault, CFM compares the current fault generation time with the last time the fault was rectified. CFM sends an alarm to the NMS only when the time difference is not smaller than the alarm anti-jitter time.

Example

Set the alarm anti-jitter time to 2000 ms.

```
<HUAWEI> system-view
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] alarm occur time 2000
```

12.8.5 alarm rdi track-action disable

Function

The **alarm rdi track-action disable** command disables CFM from being triggered when an RDI alarm is generated.

The **undo alarm rdi track-action disable** command enables CFM to be triggered when an RDI alarm is generated.

By default, CFM is triggered when an RDI alarm is generated.

Format

alarm rdi track-action oam-mgr disable

undo alarm rdi track-action oam-mgr disable

Parameters

Parameter	Description	Value
oam-mgr	Indicates that CFM is associated with another feature in the OAM management view.	-

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When CFM is associated with other functions such as EFM and the device receives an RDI alarm, run the **alarm rdi track-action disable** command to disable CFM from being triggered.

Prerequisites

An MD has been created using the **cfm md** *md-name* command, and an MA has been created using the **ma** *ma-name* command.

Example

Disable CFM from being triggered in the OAM MGR view when an RDI alarm is generated.

```
<HUAWEI> system-view
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] alarm rdi track-action oam-mgr disable
```

12.8.6 alarm suppression track-action oam-mgr enable

Function

The **alarm suppression track-action oam-mgr enable** command configures the function of disabling the MGR module from being notified upon processing of LOC alarms in scenarios where both LOC clear alarms and RDI fault alarms exist.

The **undo alarm suppression track-action oam-mgr enable** command disables this function.

By default, this function is disabled on a device.

Format

alarm suppression track-action oam-mgr enable

undo alarm suppression track-action oam-mgr enable

Parameters

None

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In scenarios where both LOC clear alarms and RDI fault alarms are generated on a device, to prevent link flapping, you can configure the device not to notify the MGR module upon processing of LOC clear alarms. Instead, the device reports LOC clear alarms when processing RDI fault alarms.

Precautions

You are advised to run this command only in scenarios where CFM is associated with an interface bidirectionally. Otherwise, fault recovery performance may be affected.

Example

Disable the MGR module from being notified of LOC clear alarms in scenarios where both LOC clear alarms and RDI fault alarms are generated on a device.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] alarm suppression track-action oam-mgr enable
```

12.8.7 ccm-interval

Function

The **ccm-interval** command sets the interval at which a Maintenance Association End Point (MEP) sends or detects Continuity Check Messages (CCMs) in an MA.

The **undo ccm-interval** command restores the default interval.

By default, a MEP in an MA sends or detects CCMs every 1000 ms.

Format

ccm-interval *interval*

undo ccm-interval

Parameters

Parameter	Description	Value
interval	Specifies the interval at which a MEP sends or detects CCMs.	The value is an integer, in milliseconds. The value is as follows: - S6735-S, S6720-EI and S6720S-EI: 100, 1000, or 10000 - S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S: 3.3, 10, 100, 1000, or 10000 To use the value of 3.3 or 10, first run the **set service-mode** command to configure the device to work in enhanced mode. - SS1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, and S6720S-S: 1000 or 10000

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To set the interval at which a MEP in an MA sends or detects CCMs, use this command.

Precautions

All the MEPs in an MA must send or detect CCMs at the same interval.

The interval at which CCMs are sent or detected cannot be changed on the device in an MA if one of the following operations is performed:

- The device is enabled to send CCMs using the **mep ccm-send enable** command.
- The device is enabled to receive CCMs using the **remote-mep ccm-receive enable** command.

The **undo mep ccm-send** or **undo mep ccm-receive** command must be run before the interval is reconfigured.

Example

Set the interval for sending or detecting CCMs to 1000 ms within the MA **ma1** where the device is not enabled to send or receive CCMs.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] ccm-interval 1000
```

Set the interval for sending or detecting CCMs to 1000 ms within the MA **ma1** where the device is enabled to send and receive CCMs.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] undo mep ccm-send enable
[HUAWEI-md-md1-ma-ma1] undo remote-mep ccm-receive enable
[HUAWEI-md-md1-ma-ma1] ccm-interval 1000
```

12.8.8 cfm default md

Function

The **cfm default md** command creates the default MD.

The **undo cfm default md** command deletes the default MD.

By default, the default MD is not created.

Format

cfm default md [**level** *level*]

undo cfm default md

Parameters

Parameter	Description	Value
level *level*	Specifies the level of the default MD.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher MD priority. By default, the level of the default MD is 7 (highest level).

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To identify and locate faults on an MP or a link in an MD, create the default MD.

Precautions

IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007.

The level of the default MD must be higher than that of all MDs to which MEPs configured on the local device belong. In addition, the default MD must be of the same level as the higher-level MD. The default MD transmits higher-level CCMs and creates MIPs to send LTR messages.

On the device configured with the default MD, a MIP can be created based on the default MD in the MA that is not associated with a VLAN. The interface where the default MD is configured generates a MIP based on the MIP creation rule.

To modify the MD level, delete the default MD and reconfigure it.

Prerequisites

CFM has been enabled globally using the **cfm enable (system view)** command.

Example

Create the default MD at level 6.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm default md level 6
```

12.8.9 cfm destination-mac

Function

The **cfm destination-mac** command configures the destination MAC address of a CCM.

The **undo cfm destination-mac** command restores the default setting.

As defined in IEEE 802.1ag/Draft 7.0, the default destination MAC address of a CCM is 0180-C2FF-FFF0.

Format

cfm destination-mac *mac-address*

undo cfm destination-mac

Parameters

Parameter	Description	Value
mac-address	Specifies the destination MAC address of a CCM.	The value is in the format of H-H-H. A MAC address must start with 0180-c2 and end with 0, and the last three bytes must be greater than 2F. The default value is 0180-C2FF-FFF0.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

No specific multicast MAC address is defined in IEEE 802.1ag/Draft 7.0, so devices of different vendors may send CCMs with different multicast MAC addresses. To allow devices of different vendors to interconnect, you must use the same multicast MAC address on these devices. Otherwise, CCMs cannot be transmitted between these devices.

Prerequisites

- The **cfm enable** command has been run to enable CFM globally.
- The **cfm version draft7** command has been run to switch the Ethernet CFM version to IEEE 802.1ag Draft 7.

Example

Set the destination MAC address of a CCM to 0180-C210-FFF0.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm version draft7
[HUAWEI] cfm destination-mac 0180-c210-fff0
```

12.8.10 cfm enable (system view)

Function

The **cfm enable** command enables Connectivity Fault Management (CFM) globally.

The **undo cfm enable** command disables CFM globally.

By default, CFM is disabled globally.

Format

cfm enable

undo cfm enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To identify and locate faults on links, enable CFM globally.

Precautions

After you use the **undo cfm enable** command to disable CFM globally, the device automatically deletes all the CFM configurations, including the configurations of MDs, MAs, MEPs, MIPs, and RMEPs.

All the configuration commands related to the CFM function are valid only after CFM is enabled globally.

Example

Enable CFM globally.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
```

12.8.11 cfm if-down trigger ccm-send-stop

Function

The **cfm if-down trigger ccm-send-stop** command triggers the MEP on an interface to stop sending CCMs when the interface goes Down.

The **undo cfm if-down trigger ccm-send-stop** command restores the default configuration.

By default, the MEP on an interface is not triggered to stop sending CCMs when the interface goes Down.

Format

cfm if-down trigger ccm-send-stop

undo cfm if-down trigger ccm-send-stop

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Figure 12-1 VLAN stacking scenario with an inward-facing MEP configured

As shown in **Figure 12-1**, in a VLAN stacking scenario with an inward-facing MEP configured, a VLL is configured between Switch1 and Switch2, 802.1ag detection is configured between Switch2 and Switch3, and the MEP on Switch3 is inward-facing. If the interface where the MEP resides goes Down, to prevent the MEP from continuing to send CCMs so that other services can detect the fault information detected by CC, run the **cfm if-down trigger ccm-send-stop** command in the interface view.

Prerequisites

Run the **cfm enable** command to enable CFM globally.

Example

Trigger the MEP on GE 0/0/1 to stop sending CCMs when the interface goes Down.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] cfm if-down trigger ccm-send-stop
```

12.8.12 cfm md

Function

The **cfm md** command creates an MD and displays the MD view, or displays the view of an existing MD.

The **undo cfm md** command deletes an MD.

Format

cfm md *md-name* [**format** { **no-md-name** | **dns** *dns-md-format-name* | **mac-address** *mac-md-format-name* | **string** *string-md-format-name* }] [**level** *level*]

undo cfm md [*md-name*]

Parameters

Parameter	Description	Value
md *md-name*	Specifies the name of an MD.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). The name of an MD on a device must be unique. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
no-md-name	Indicates that the MA ID field of a sent packet does not contain an MD name.	-
dns *dns-md-format-name*	Specifies the DNS name used as the MD name carried in packets.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?).
mac-address *mac-md-format-name*	Specifies an MD name carried in packets, in the format of H-H-H:U<0-65535>, for example, 0001-0001-0001:1.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?).
string *string-md-format-name*	Specifies an ASCII MD name.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?).
level *level*	Specifies the level of an MD.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher MD priority. The default value is 0.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure CFM to identify and locate faults on links, use this command to create an MD.

Precautions

All the CFM-enabled devices of an ISP can be added to the same MD.

NOTE

When 802.1ag packets in a low-level MD enter a high-level MD, the 802.1ag packets will be discarded. 802.1ag packets in a high-level MD can traverse a low-level MD. 802.1ag packets in an MD cannot traverse the MD of the same level.

Only IEEE Standard 802.1ag-2007 supports **format**, **no-md-name**, **dns** *dns-md-format-name*, **mac-address** *mac-md-format-name*, and **string** *string-md-format-name*.

The MD name format can be specified during the MD configuration, as defined in IEEE Standard 802.1ag-2007. Each MD can be configured with only one name format and one level. You can use the **cfm md** command to enter the view of the existing MD but cannot change the name format and level of the existing MD. To change the name format and level of the existing MD, delete the MD and then use the **cfm md** command to create a new MD.

As defined in IEEE 802.1ag Draft 7, after creating an MD, you cannot use the **cfm md** command to change the level of the MD. To change the level of the MD, you need to delete the MD and then create an MD again.

When an MD is deleted, a device automatically deletes all the configurations of MAs, MEPs, MIPs, and RMEPs within the MD.

The MA, MEP, and RMEP must be created within an MD, so you must create an MD before creating the MA, MEP, and RMEP.

Prerequisites

CFM has been enabled globally using the **cfm enable (system view)** command.

Example

Create an MD named **mdcustomer** at level 4.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md mdcustomer level 4
```

Change the level of **mdcustomer** from 4 to 6.

```
<HUAWEI> system-view
[HUAWEI] undo cfm md mdcustomer
```

```
Warning: Deleting the MD(s) will delete all information about the MA(s). Continue?[Y/N]:y
[HUAWEI] cfm md mdcustomer level 6
```

Create an MD named **mdcustomer** at level 4, with the MD name in **no-md-name** format.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md mdcustomer format no-md-name level 4
```

12.8.13 cfm mip

Function

The **cfm mip level** command creates a MIP on an interface.

The **undo cfm mip** command deletes a MIP on an interface.

By default, no MIP is created.

Format

cfm mip level *level-value*

undo cfm mip

Parameters

Parameter	Description	Value
level *level-value*	Specifies the level of a MIP.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To identify and locate faults on an MP or a link in an MD, create a MIP in the MD.

A MIP is located inside the MD. It can process and respond to CCMs, but cannot send CCMs. When a MIP receives a packet carrying a level higher than its own, the MIP does not process the packet and forwards it along the original path. A MIP forwards only the packet in which the level is lower than or equal to its own.

If a MIP is created and an MP performs LB or LT, the MIP will reply with LBMs or LTMs to identify and locate faults for the MP or link in the MD.

A MIP can be created manually or automatically:

- The **cfm mip level** *level-value* command can be used to manually create a MIP. This configuration is simple, but it is difficult to manage many MIPs and configuration errors may occur.
- The **mip create-type (MD view)** command can be used to define the rule for creating a MIP and enable the device to automatically create a MIP based on the rule. Configuring creation rules is complex, but properly configured rules ensure correct MIP settings.

Prerequisites

CFM has been enabled globally using the **cfm enable (system view)** command.

Precautions

Only IEEE Std 802.1ag-2007 supports the manual MIP configuration.

Example

Create a MIP at level 4.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] cfm mip level 4
```

12.8.14 cfm portid-tlv type

Function

The **cfm portid-tlv type** command sets the portid-tlv type for trace packets.

The **undo cfm portid-tlv type** command restores the default portid-tlv type for trace packets.

By default, the portid-tlv type in trace packets is in character string format.

Format

cfm portid-tlv type { **interface-name** | **local** }

undo cfm portid-tlv type

Parameters

Parameter	Description	Value
interface-name	Indicates that the portid-tlv type is in character string format.	-
local	Indicates that the portid-tlv type is in Huawei proprietary format.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When using the trace function, you need to specify the type of inbound and outbound interface names. You can use the **cfm portid-tlv type** command to set the type of interface names.

Precautions

NOTE

IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007. Before using the **cfm portid-tlv type** command, you must use the **cfm version** command to set the Ethernet CFM version to IEEE Standard 802.1ag-2007.

Vendors may use different TLV types. To implement interworking between Huawei and non-Huawei devices, configure **interface-name** to specify the interface name type in character string format.

If all the devices running on the entire network are Huawei data communications devices, to interwork with devices running different versions, configure **local** to specify the interface name type in Huawei proprietary format.

Example

Configure the portid-tlv type in character string format.

```
<HUAWEI> system-view
[HUAWEI] cfm portid-tlv type interface-name
```

12.8.15 cfm protocol

Function

The **cfm protocol** command configures the EtherType value of a CCM.

The **undo cfm protocol** command restores the default setting.

As defined in IEEE 802.1ag/Draft 7, the default EtherType value of a CCM is 0xBBB0.

Format

cfm protocol *ethertype-value*

undo cfm protocol

Parameters

Parameter	Description	Value
ethertype-value	Specifies the EtherType value of a CCM.	The value is an integer that ranges from 0600 to FFFF. The default value is BBB0.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

No specific protocol type is defined in IEEE 802.1ag/Draft 7, so devices of different vendors may use different protocols to encapsulate CCMs. To allow devices of different vendors to interwork with each other, you must run the **cfm protocol** command to configure the same protocol types on these devices. Otherwise, these devices cannot communicate.

NOTE

You must run the **cfm enable** command to enable CFM globally before configuring the protocol type.

Example

Set the EtherType value of a CCM to 0900.

```
<HUAWEI> system-view
[HUAWEI] cfm protocol 0900
```

12.8.16 cfm trigger if-down

Function

The **cfm trigger if-down** command associates Ethernet CFM with an interface.

The **undo cfm trigger if-down** command disassociates Ethernet CFM from an interface.

By default, an interface is not associated with Ethernet CFM.

Format

cfm md *md-name* **ma** *ma-name* **remote-mep mep-id** *mep-id* **trigger if-down**

undo cfm md *md-name* **ma** *ma-name* **remote-mep mep-id** *mep-id* **trigger if-down**

Parameters

Parameter	Description	Value
md *md-name*	Specifies the name of an MD in an MA.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
ma *ma-name*	Specifies the name of an MA.	The value is a string of 1 to 43 characters without spaces, hyphens (-), and question marks (?). The total length of the names of the MA and MD must be within 44 characters. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
remote-mep mep-id *mep-id*	Specifies ID of an RMEP.	The value is an integer that ranges from 1 to 8191.

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

CFM can be associated with interfaces. On a scenario with active and standby links, when CFM detects a fault on the active link, the OAM management module shuts down the interface and enables the interface 7 seconds later. This speeds up route convergence. In addition, traffic can be fast switched to the standby link.

Precautions

An interface can be bound to only one RMEP. To modify the association between the interface and the RMEP, delete the current configuration and then configure the new association.

Prerequisites

An outward-facing MEP has been created in the specified MA and the MEP has been created on the interface.

Example

Associate Ethernet CFM with GigabitEthernet0/0/1. The MD name, MA name, and RMEP ID are **md1**, **ma1**, and 2 respectively.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] cfm md md1 ma ma1 remote-mep mep-id 2 trigger if-down
```

12.8.17 cfm trigger clear-arp vlan

Function

The **cfm trigger clear-arp vlan** command clears an ARP entry corresponding to a VLANIF interface.

The **undo cfm trigger clear-arp vlan** command cancels the configuration.

By default, an interface is disabled from clearing an ARP entry.

Format

cfm md *md-name* **ma** *ma-name* **trigger clear-arp vlan** *vlan-id*

undo cfm md *md-name* **ma** *ma-name* **trigger clear-arp vlan** *vlan-id*

Parameters

Parameter	Description	Value
md *md-name*	Specifies the name of an MD in an MA.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
ma *ma-name*	Specifies the name of an MA.	The value is a string of 1 to 43 characters without spaces, hyphens (-), and question marks (?). The total length of the names of the MA and MD must be within 44 characters. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
vlan *vlan-id*	Specifies the VLAN ID in an ARP entry.	The value is an integer that ranges from 1 to 4094.

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When detecting a fault, the CM module notifies the OAM management module of the fault. The OAM management module searches the CM fault relationship table based on the interface number and VLAN ID, and then clears the ARP entry that corresponds to the VLANIF interface.

Precautions

Before associating Ethernet CFM with an interface, you must create an outward-facing MEP in the specified MA and ensure that the MEP is on the interface.

Prerequisites

CFM has been enabled globally using the **cfm enable (system view)** command.

Example

Enable GigabitEthernet0/0/1 to clear an ARP entry matching VLANIF 10 after receiving a fault notification.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] cfm md md1 ma ma1 trigger clear-arp vlan 10
```

12.8.18 cfm trigger vlan mac-renew

Function

The **cfm trigger vlan mac-renew** command clears MAC address entries of a range of VLANs associated with Ethernet CFM after Ethernet CFM detects a fault.

The **undo cfm trigger vlan mac-renew** command cancels the configuration.

Format

cfm trigger vlan { { *vlan-id* [**to** *vlan-id*] } &<1-10> } **mac-renew**

undo cfm trigger vlan { { *vlan-id* [**to** *vlan-id*] } &<1-10> } **mac-renew**

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
vlan-id	Specifies the ID of a VLAN.	The value is an integer that ranges from 1 to 4094.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **cfm trigger vlan mac-renew** command is run, CFM deletes MAC address entries of a range of configured VLANs when detecting a fault so that services can be switched between links.

Precautions

A maximum of 10 VLAN ranges can be configured. The VLAN ranges cannot overlap.

When CFM detects a fault in a VLAN associated with the MA in the range specified in this command, the MAC address entries of this VLAN are deleted. If a fault is detected in a VLAN out of the specified range, the MAC address entries of this VLAN are not deleted.

If the **cfm trigger vlan mac-renew** command is run multiple times, MAC addresses of VLANs specified by the commands are deleted.

Example

Configure the device to clear MAC address entries of VLANs 100 to 200 after CFM detects a fault.

```
<HUAWEI> system-view
[HUAWEI] cfm trigger vlan 100 to 200 mac-renew
```

12.8.19 cfm version

Function

The **cfm version** command switches an Ethernet CFM version between IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007.

The **undo cfm version** command restores the default Ethernet CFM version.

By default, IEEE Standard 802.1ag-2007 is enabled on a device.

Format

cfm version { **draft7** | **standard** }

undo cfm version

Parameters

Parameter	Description	Value
draft7	Indicates IEEE 802.1ag Draft 7.	-
standard	Indicates IEEE Standard 802.1ag-2007.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You need to switch IEEE 802.1ag between the two versions when the device supports both IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007.

Precautions

To ensure that CFM works properly, all devices on the entire network must run IEEE 802.1ag of the same version. During switching between IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007, all 802.1ag functions are unavailable. You can run the **cfm enable (system view)** command to enable CFM globally only after all devices use the same IEEE 802.1ag version.

Example

Switch IEEE Standard 802.1ag-2007 to IEEE 802.1ag Draft 7.

```
<HUAWEI> system-view
[HUAWEI] cfm version draft7
```

12.8.20 display cfm default md

Function

The **display cfm default md** command displays information about the default MD.

Format

display cfm default md

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can use the **display cfm default md** command to view information about the level of the default MD, MIP creation rule, Sender ID TLV type, and IDs of VLANs associated with the default MD.

Prerequisites

CFM has been enabled globally using the **cfm enable (system view)** command.

Precautions

IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007.

Example

Display information about the default MD.

```
<HUAWEI> display cfm default md
Level   MIP-Create-type   SenderID TLV-type   VLAN-List
-------------------------------------------------------------------------------------
7       default           defer               100 to 200 2049
```

Table 12-51 Description of the **display cfm default md** command output

Item	Description
Level	Level of the default MD. The value ranges from 0 to 7. A higher level represents a higher priority of the default MD.
MIP-Create-type	MIP creation rule: ● default ● explicit ● none
SenderID TLV-type	Type of the Sender ID TLV filled in the CCM: ● none ● chassis ● manage ● chassisManage ● defer
VLAN-List	IDs of VLANs associated with the default MD.

12.8.21 display cfm error-info

Function

The **display cfm error-info** command displays the incorrect configuration of the specified error type.

Format

display cfm error-info error-type unexpected-mep [**md** *md-name* **ma** *ma-name* **mep-id** *mep-id*]

Parameters

Parameter	Description	Value
error-type unexpected-mep	Indicates the error about an unexpected MEP ID.	-

Parameter	Description	Value
md *md-name*	Specifies the name of an MD.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). The name of an MD is unique. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
ma *ma-name*	Specifies the name of an MA.	The value is a string of 1 to 43 characters without spaces, hyphens (-), and question marks (?). The total length of the names of the MA and MD must be within 44 characters. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
mep-id *mep-id*	Specifies the ID of a MEP. The ID identifies a MEP. The MEP ID must be unique in an MA and in a VLAN.	The value is an integer that ranges from 1 to 8191.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

If CFM cannot work properly, run the **display cfm error-info** command to check received CCMs with unknown MEP IDs. The information helps diagnose a fault.

- If no parameter is configured in the **display cfm error-info** command, the device displays CCMs with unexpected MEP IDs received by all MEPs.

- If an MD name, an MA name, or a MEP ID is specified, the device displays CCMs with unexpected MEP IDs received by a specified MEP.

Prerequisites

CFM has been enabled globally using the **cfm enable (system view)** command.

Precautions

IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007.

Example

Display information about received CCMs with unexpected MEP IDs saved on the device.

```
<HUAWEI> display cfm error-info error-type unexpected-mep
 The total number of unexpected MEPs is : 1
--------------------------------------------------
 MD Name            : md
 Level              : 0
 MA Name            : ma
 MEP ID             : 1
 Unexpected MEP List:
 Unexpected MEP ID  : 2
 MAC Address        : 00e0-fc44-81a4
```

Table 12-52 Description of the **display cfm error-info** command output

Item	Description
MD Name	MD name in CCMs.
Level	Level of an MA.
MA Name	MA name in CCMs.
MEP ID	ID of a MEP in CCMs.
Unexpected MEP List	Unexpected MEP information.
Unexpected MEP ID	Unexpected MEP ID.
MAC Address	MAC address in CCMs.

12.8.22 display cfm ma

Function

The **display cfm ma** command displays detailed information about an MA.

Format

display cfm ma [**md** *md-name* [**ma** *ma-name*]]

Parameters

Parameter	Description	Value
md *md-name*	Displays detailed MA information in a specified MD. *md-name* specifies the name of the MD. If the parameter is not specified, detailed information about all MAs in all MDs is displayed.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
ma *ma-name*	Displays detailed information about the specified MA. *ma-name* specifies the name of the MA. If *md-name* is specified but this parameter is not specified, detailed information about all the MAs in the specified MD is displayed.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.

Usage Guidelines

Usage Scenario

After an MA is configured or CFM cannot work properly, use the **display cfm ma** command to check the MA configuration and the number of MEPs and RMEPs in the MA.

Example

Display detailed information about the MA named **ma1** in the MD named **md1**.

```
<HUAWEI> display cfm ma md md1 ma ma1
 MD Name             : md1
 MD Name Format      : string
 Level               : 0
 MIP Create-type     : none
 SenderID TLV-type   : defer
 MA Name             : ma1
 MA Name Format      : string
```

```
 Interval           : 1000
 Priority           : 7
 VLAN ID            : --
 VSI Name           : --
 L2VC ID            : --
 MEP Number         : 1
 RMEP Number        : 1
 Suppressing Alarms : No
 Sending AIS Packet : No
 Interface TLV      : disabled
 RDI Track-action   : all-enabled
```

Display detailed information about all the MAs in the specified MD.

```
<HUAWEI> display cfm ma md md1
The total number of MAs is : 2
--------------------------------------------------
 MD Name            : md1
 MD Name Format     : string
 Level              : 0
 MIP Create-type    : none
 SenderID TLV-type  : defer
 MA Name            : ma1
 MA Name Format     : string
 Interval           : 1000
 Priority           : 7
 VLAN ID            : --
 VSI Name           : --
 L2VC ID            : --
 MEP Number         : 1
 RMEP Number        : 1
 Suppressing Alarms : No
 Sending AIS Packet : No
 Interface TLV      : disabled
 RDI Track-action   : all-enabled
 MD Name            : md1
 MD Name Format     : string
 Level              : 0
 MIP Create-type    : none
 SenderID TLV-type  : defer
 MA Name            : ma2
 MA Name Format     : string
 Interval           : 1000
 Priority           : 7
 VLAN ID            : --
 VSI Name           : --
 L2VC ID            : --
 MEP Number         : 1
 RMEP Number        : 1
  Suppressing Alarms : No
 Sending AIS Packet : No
 Interface TLV      : disabled
 RDI Track-action   : all-enabled
```

Display detailed information about all the MAs in the MD named **md** in **no-md-name** format.

```
<HUAWEI> display cfm ma md md
The total number of MAs is : 2
--------------------------------------------------
 MD Name            : md
 MD Name Format     : string
 Level              : 0
 MIP Create-type    : none
 SenderID TLV-type  : defer
 MA Name            : ma
 MA Name Format     : no-md-name
 Interval           : 1000
 Priority           : 7
 VLAN ID            : --
```

```
VSI Name           : --
L2VC ID            : --
MEP Number         : 0
RMEP Number        : 1
Suppressing Alarms : No
Sending AIS Packet : No
Interface TLV      : disabled
RDI Track-action   : all-enabled

MD Name            : md
MD Name Format     : string
Level              : 0
MIP Create-type    : none
SenderID TLV-type  : defer
MA Name            : ma
MA Name Format     : no-md-name
Interval           : 1000
Priority           : 7
VLAN ID            : --
VSI Name           : --
L2VC ID            : --
MEP Number         : 0
RMEP Number        : 1
Suppressing Alarms : No
Sending AIS Packet : No
Interface TLV      : disabled
RDI Track-action   : all-enabled
```

Table 12-53 Description of the **display cfm ma** command output

Item	Description
MD Name	Name of the MD. To set the name of the MD, run the **cfm md** command.
MD Name Format	Format of the MD name: ● no-md-name ● dns ● mac-address ● string To set the format of the MD name, run the **cfm md** command.
Level	MD level. The value ranges from 0 to 7. To set the MD level, run the **cfm md** command.
MIP Create-type	MIP creation rule: ● default ● explicit ● none To set the MIP creation rule, run the **mip create-type** or **mip create-type** command.

Item	Description
SenderID TLV-type	Type of the Sender ID TLV filled in the CCM: - none - chassis - manage - chassisManage - defer To set the type of the Sender ID TLV filled in the CCM, run the **senderid-tlv-type** command.
MA Name	Name of the MA. To set the name of the MA, run the **ma** command.
MA Name Format	Format of the MA name: - icc-based - string To set the format of the MA name, run the **ma** command.
Interval	Interval at which CCMs are sent in an MA. To set the interval at which CCMs are sent in an MA, run the **ccm-interval** command.
Priority	802.1p priority of CFM packets in an MA. The value ranges from 0 to 7. A larger value indicates a higher priority. The default value is 7. To set the 802.1p priority of CFM packets in an MA, run the **packet-priority** command.
VLAN ID	ID of the VLAN associated with an MA. To set the ID of the VLAN associated with an MA, run the **map** command.
VSI Name	Name of the VSI associated with an MA.
L2VC ID	ID of the L2VC associated with an MA.
MEP Number	Number of MEPs in an MA.
RMEP Number	Number of RMEPs in an MA.

Item	Description
Suppressing Alarms	Whether the device is enabled to suppress alarms.
Sending AIS Packet	Whether the device is sending AIS PDUs.
Interface TLV	Whether the CCM TLV is enabled: ● disabled ● enabled
RDI Track-action	Whether the device is RDI Track-action.

12.8.23 display cfm md

Function

The **display cfm md** command displays MD information, including the MD name and level.

Format

display cfm md [*md-name*]

Parameters

Parameter	Description	Value
md *md-name*	Specifies the name of an MD. If *md-name* is not specified, information about all MDs created on the device is displayed.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can use the **display cfm md** command to view MD information, including the MD level, MD name format, MIP creation rule in the MD, and Sender ID TLV type. In addition, you can view brief information about MAs in the MD, such as the MA name, interval at which CCMs are sent, ID of the VLAN associated with the MA, and name of the VSI associated with the MA. If *md-name* is not specified, information about all the created MDs is displayed.

Example

Display information about the MD named **mdcustomer** on the device running IEEE Standard 802.1ag-2007.

```
<HUAWEI> display cfm md mdcustomer
 MD Name            : mdcustomer
 MD Name Format     : string
 Level              : 0
 MIP Create-type    : none
 SenderID TLV-type  : defer
 MA list            :
        MA Name            : ma
        MA Name Format     : string
        Interval           : 1000
        VLAN ID            : 100
        VSI Name           : --
        L2VC ID            : --
```

Table 12-54 Description of the **display cfm md** command output

Item	Description
MD Name	Name of the MD. To set the name of the MD, run the **cfm md** command.
MD Name Format	Format of the MD name: ● no-md-name ● dns ● mac-address ● string To set the format of the MD name, run the **cfm md** command.
Level	Level of the MD. The value ranges from 0 to 7. A higher level indicates a higher priority. To set the level of the MD, run the **cfm md** command.

Item	Description
MIP Create-type	MIP creation rule: - default - explicit - none To set the MIP creation rule, run the **mip create-type** command.
SenderID TLV-type	Type of the Sender ID TLV in the CCM: - none - chassis - manage - chassisManage - defer To set the type of the Sender ID TLV in the CCM, run the **senderid-tlv-type** command.
MA list	Information about MAs in the MD.
MA Name	Name of the MA. To set the MAs in the MD, run the **ma** command.
MA Name Format	Format of the MA name: - icc-based - string To set the format of the MA name, run the **ma** command.
Interval	Interval at which CCMs are sent. To set the interval at which CCMs are sent, run the **ccm-interval** command.
VLAN ID	ID of the VLAN associated with an MA. To set the ID of the VLAN associated with an MA, run the **map** command.
VSI Name	Name of the VSI associated with an MA. The switch does not support this function.
L2VC ID	ID of the L2VC associated with an MA. The switch does not support this function.

12.8.24 display cfm mep

Function

The **display cfm mep** command displays information about a MEP in a specified MD and MA.

Format

display cfm mep [**md** *md-name* [**ma** *ma-name* [**mep-id** *mep-id*]]]

Parameters

Parameter	Description	Value
md *md-name*	Displays information about MEPs in a specified MD. *md-name* specifies the name of the MD. If this parameter is not specified, information about MEPs in all MDs and MAs on the device is displayed.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?).
ma *ma-name*	Displays information about MEPs in a specified MA. *ma-name* specifies the name of the MA. If this parameter is not specified, information about MEPs in all the MAs of a specified MD is displayed.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?).
mep-id *mep-id*	Displays information about a specified MEP. *mep-id* specifies the ID of the MEP.	The value is an integer that ranges from 1 to 8191.

Usage Guidelines

Usage Scenario

After a MEP is configured or CFM cannot work properly, use the **display cfm mep** command to check the MEP configuration.

Example

Display information about the MEP with an ID of 10 in the MA named **ma1** of the MD named **md1**.

```
<HUAWEI> display cfm mep md md1 ma ma1 mep-id 10
```

```
 MD Name            : md1
 MD Name Format     : string
 Level              : 0
 MA Name            : ma1
 MEP ID             : 2
 VLAN ID            : --
 VSI Name           : --
 L2VC ID            : --
 Interface Name     : GigabitEthernet0/0/1
 CCM Send           : enabled
 Direction          : outward
 MAC Address        : 00e0-fc03-0161
 MEP Pe-vid         : --
 MEP Ce-vid         : --
 MEP Vid            : --
 Alarm Status       : LOC
 Alarm AIS          : enabled
 Alarm RDI          : enabled
```

Display information about all MEPs in the MA named **ma1** of the MD named **md1**.

```
<HUAWEI> display cfm mep md md1 ma ma1
The total number of MEPs is : 1
--------------------------------------------------
 MD Name            : md1
 MD Name Format     : string
 Level              : 0
 MA Name            : ma1
 MEP ID             : 2
 VLAN ID            : --
 VSI Name           : --
 L2VC ID            : --
 Interface Name     : GigabitEthernet0/0/1
 CCM Send           : enabled
 Direction          : outward
 MAC Address        : 00e0-fc03-0161
 MEP Pe-vid         : --
 MEP Ce-vid         : --
 MEP Vid            : --
 Alarm Status       : LOC
 Alarm AIS          : enabled
 Alarm RDI          : enabled
```

Display information about all MEPs in the MD named **md1**.

```
<HUAWEI> display cfm mep md md1
The total number of MEPs is : 2
--------------------------------------------------
 MD Name            : md1
 MD Name Format     : string
 Level              : 0
 MA Name            : ma1
 MEP ID             : 2
 VLAN ID            : --
 VSI Name           : --
 L2VC ID            : --
 Interface Name     : GigabitEthernet0/0/1
 CCM Send           : enabled
 Direction          : outward
 MAC Address        : 00e0-fc03-0161
 MEP Pe-vid         : --  MEP Ce-vid         : --  MEP Vid            : --  Alarm Status       : LOC  Alarm AIS          :
enabled  Alarm RDI          : enabled
 MD Name            : md1
 MD Name Format     : string
 Level              : 0
 MA Name            : ma2
 MEP ID             : 4
 VLAN ID            : --
 VSI Name           : --
```

```
L2VC ID            : --
Interface Name     : GigabitEthernet0/0/2

Direction          : outward
MAC Address        : 00e0-fc03-0161
MEP Pe-vid         : --
MEP Ce-vid         : --
MEP Vid            : --
Alarm Status       : LOC
Alarm AIS          : enabled
Alarm RDI          : enabled
```

Table 12-55 Description of the **display cfm mep** command output

Item	Description
MD Name	Name of the MD. To set the name of the MD, run the **cfm md** command.
MD Name Format	Format of the MD name: - no-md-name - dns - mac-address - string To set the format of the MD name, run the **cfm md** command.
Level	Level of the MD. The value ranges from 0 to 7. A higher level indicates a higher priority of the MD. To set the MD level, run the **cfm md** command. **NOTE** If the level of a MEP on an intermediate node is higher than or equal to that on the source node, run the **cfm md** command to decrease the level of the MEP on the intermediate node to be lower than that on the source node.
MA Name	Name of the MA. To set the name of the MA, run the **ma** command.
MEP ID	ID of the MEP. To set the ID of the MEP, run the **mep mep-id** command.
VLAN ID	ID of the VLAN associated with an MA. To set the ID of the VLAN associated with an MA, run the **map** command.
VSI Name	Name of the VSI associated with an MA.
L2VC ID	ID of the L2VC associated with an MA.

Item	Description
Interface Name	Interface where a MEP is configured. If a MEP is based on VLANIF interfaces, this field is displayed as --.
CCM Send	Whether the MEP is enabled to send CCMs: - enabled: The MEP is enabled to send CCMs. - disabled: The MEP is disabled from sending CCMs. To set the parameter, run the **mep ccm-send enable** command.
Direction	Type of the MEP: - inward: indicates an inward-facing MEP. An inward-facing MEP broadcasts 802.1ag packets in the VLAN associated with the MA, but does not send 802.1ag packets to the interface where the MEP is configured. - outward: indicates an outward-facing MEP. An outward-facing MEP sends 802.1ag packets through an interface on which the MEP is configured. **NOTE** If the MEP direction is incorrect, run the **mep mep-id** command to configure a correct direction.
MAC Address	MAC address of the MEP.
MEP Pe-vid	Outer VLAN ID of the QinQ interface where the MEP is configured.
MEP Ce-vid	Inner VLAN ID of the QinQ interface where the MEP is configured.
MEP Vid	VLAN ID of the Dot1q interface where the MEP is configured.
Alarm Status	Alarm type: - unexpectedMEP: The MEP receives CCMs with an unexpected flag. - mismerge: The MEG ID in received CCMs is different from that configured for the MEP. - unexpectedPeriod: The interval in the received CCMs is different from the configured interval. - unexpectedMAC: The MEP MAC address in the received CCM is different from at least one MAC address of the RMEP. - LOC: At least one session between the MEP and an RMEP is terminated. - RDI: The MEP receives CCMs with the RDI.

Item	Description
Alarm AIS	Whether the alarm reporting function of a specific alarm indication signal (AIS) is enabled: - enable - disable
Alarm RDI	Whether the alarm reporting function of a specific remote defect indication (RDI) is enabled: - enable - disable

12.8.25 display cfm mip

Function

The **display cfm mip** command displays MIP information.

Format

display cfm mip [**interface** *interface-type interface-number* | **level** *level*]

Parameters

Parameter	Description	Value
level *level*	Displays information about a MIP of a specified level. *level* specifies the level of the MIP.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher level.
interface-type interface-number	Displays MIP information on a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can use the **display cfm mip** command to check MIPs, interfaces where MIPs are configured, and levels of the MIPs on the device.

Precautions

If **level** *level* and **interface** *interface-type interface-number* are not specified, information about all MIPs on the device is displayed.

Example

Display information about all MIPs.

```
<HUAWEI> display cfm mip
Interface Name              Level      MAC
-------------------------------------------------------
GigabitEthernet0/0/1          0         00e0-fc02-377f
GigabitEthernet0/0/1          0         00e0-fc02-375f
```

Display information about the MIP at level 7.

```
<HUAWEI> display cfm mip level 7
Interface Name              Level      MAC
-------------------------------------------------------
GigabitEthernet0/0/1          7         00e0-fc02-367f
GigabitEthernet0/0/1          7         00e0-fc02-365f
```

Display information about MIPs on GigabitEthernet0/0/1.

```
<HUAWEI> display cfm mip interface gigabitethernet 0/0/1
Interface Name              Level      MAC
-------------------------------------------------------
GigabitEthernet0/0/1          0        00e0-fc02-368f
```

Display information about MIPs on the GigabitEthernet0/0/1.

```
<HUAWEI> display cfm mip interface gigabitethernet 0/0/1
Info: The MIP does not exist.
```

Table 12-56 Description of the **display cfm mip** command output

Item	Description
Interface Name	Name of the interface where a MIP is configured.
Level	Level of the MIP. The value ranges from 0 to 7. A larger value indicates a higher priority. To set the level of the MIP, run the **cfm mip** command.
MAC	MAC address of the MIP.

12.8.26 display cfm mp-info

Function

The **display cfm mp-info** command displays information about CFM objects on a specified interface or in a VLAN.

Format

display cfm mp-info [**interface** *interface-type interface-number*] [**level** *md-level*] [**inward** | **outward**] [**vlan** *vlanid* | **no-associated-vlan**]

Parameters

Parameter	Description	Value
interface-type interface-number	Displays CFM information on a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
level *md-level*	Specifies the level of an MD.	The value is an integer that ranges from 0 to 7. By default, the value is 0.
inward	Indicates the inward-facing MEP. An inward-facing MEP sends 802.1ag packets through all interfaces in a VLAN associated with an MA, except the interface on which the MEP is configured. That is, the inward-facing MEP broadcasts 802.1ag packets in the VLAN associated with the MA.	-
outward	Indicates the outward-facing MEP. An outward-facing MEP sends 802.1ag packets through an interface on which the MEP is configured.	-
vlan *vlanid*	Displays CFM information in a specified VLAN.	The value is an integer that ranges from 1 to 4094.
no-associated-vlan	Indicates the MP that is not associated with a VLAN.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can use the **display cfm mp-info** command to view information about CFM objects and the relationship between MPs on the interface so that you can configure MEPs correctly.

Prerequisites

CFM has been enabled globally using the **cfm enable (system view)** command.

Precautions

IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007.

Multiple MEPs can be configured and multiple MIPs can be generated on an interface; however, the levels of MEPs or MIPs must be the same. If the configuration is incorrect, CCM leak occurs or LBR or LTR messages cannot be sent correctly.

Example

Display information about the specified interface, MD level, MEP type, and VLAN.

```
<HUAWEI> display cfm mp-info interface gigabitethernet 0/0/1
The total number of MPs is : 1
The number of MEPs is : 1. The number of MIPs is : 0.
--------------------------------------------------
 MD Name            : md1
 MD Name Format     : string
 Level              : 0
 MA Name            : ma2
 MEP ID             : 4
 VLAN ID            : --
 VSI Name           : --
 L2VC ID            : --
 Interface Name     : GigabitEthernet0/0/1
 CCM Send           : enabled
 Direction          : outward
 MAC Address        : 00e0-fc03-0161
 MEP Pe-vid         : --
 MEP Ce-vid         : --
 MEP Vid            : --
 Alarm Status       : LOC
 Alarm AIS          : enabled
 Alarm RDI          : enabled
```

Table 12-57 Description of the **display cfm mp-info** command output

Item	Description
Interface Name	Name of the interface.
MD Name	Name of the MD. To set the name of the MD, run the **cfm md** command.
MD Name Format	Format of the MD name: - no-md-name - dns - mac-address - string To set the format of the MD name, run the **cfm md** command.
Level	Level of the MD, MA, or MP. The value ranges from 0 to 7. A higher level indicates a higher priority. To set the MD level, run the **cfm md** command.
MA Name	Name of the MA. To set the name of the MA, run the **ma** command.
MEP ID	ID of the MEP. To set the ID of the MEP, run the **mep mep-id** command.
CCM Send	Whether the MEP is enabled to send CCMs: - enabled - disabled To set the parameter, run the **mep ccm-send enable** command.
Direction	Type of the MEP: - inward - outward To set the type of the MEP, run the **mep mep-id** command.
VLAN ID	ID of the VLAN associated with an MA. To set the ID of the VLAN associated with an MA, run the **map** command.
VSI Name	Name of the VSI associated with an MA.
L2VC ID	ID of the L2VC associated with an MA.

Item	Description
MAC Address	MAC address of the MEP or MIP. **NOTE** An MP's MAC address can be a bridge MAC address or the MAC address of the interface where the MP is configured. The MAC address depends on the configured MP address model: ● If the shared MP address model is configured, an MP uses a bridge MAC address as its own MAC address. ● If the independent MP address model is configured, an MP uses the MAC address of the interface where the MP is configured.
MEP Pe-vid	VLAN ID in the outer tag of a VLAN frame.
MEP Ce-vid	VLAN ID in the inner tag of a VLAN frame.
MEP Vid	ID of a VLAN.
Alarm Status	Type of alarm: ● unexpectedMEGLevel: The MD level carried in a CCM sent by the RMEP was different from that specified on the MEP. ● unexpectedMEP: The trap about inconsistency between the MD level carried in a CCM sent by the RMEP and that specified on the MEP was cleared. ● mismerge: An MD or MA name carried in a CCM sent by the RMEP was different from that specified on the MEP. ● unexpectedPeriod: The CCM interval carried in a CCM sent by the RMEP was different from that specified on the MEP. ● unexpectedMAC: The source MAC address carried in a CCM sent by the RMEP was different from the RMEP's MAC address specified on the MEP. ● LOC: At least one session between the MEP and an RMEP is terminated. ● exceptionalMACstatus: TLV information carried in a CCM sent by the RMEP within a specified interval showed that the interface connecting the RMEP to the MEP became abnormal. ● RDI: The RMEP sent a CCM carrying the RDI flag with the value of 1 to the MEP.
Alarm AIS	Whether the alarm reporting function of a specific alarm indication signal (AIS) is enabled: ● enable ● disable

Item	Description
Alarm RDI	Whether the alarm reporting function of a specific remote defect indication (RDI) is enabled: ● enable ● disable

12.8.27 display cfm remote-mep

Function

The **display cfm remote-mep** command displays information about RMEPs in a specified MD and MA.

Format

display cfm remote-mep md *md-name* **ma** *ma-name* **mep-id** *mep-id*

display cfm remote-mep [**md** *md-name* [**ma** *ma-name*]] [**cfm-state** { **up** | **down** | **disable** }]

Parameters

Parameter	Description	Value
md *md-name*	Displays information about RMEPs in a specified MD. *md-name* specifies the name of the MD. If this parameter is not specified, information about RMEPs in all MDs and MAs on the device is displayed.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphen (-), and question mark (?).
ma *ma-name*	Displays information about RMEPs in a specified MA. *ma-name* specifies the name of the MA. If this parameter is not specified, information about RMEPs in all MAs in a specified MD is displayed.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphen (-), and question mark (?).
mep-id *mep-id*	Displays information about a specified RMEP. *mep-id* specifies the ID of the RMEP.	The value is an integer that ranges from 1 to 8191.
cfm-state	Displays RMEP information based on the CFM status.	-

Parameter	Description	Value
up	Displays information about RMEPs in Up state.	-
down	Displays information about RMEPs in Down state.	-
disable	Displays information about RMEPs in disabled state.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After an RMEP is configured or CFM cannot work properly, use the **display cfm remote-mep** command to check the RMEP configuration, including:

- Name and level of the MD
- Name of the MA and VLAN associated with the MA
- ID of the RMEP
- MAC address of the RMEP
- Whether the MEP is enabled to receive CCMs from the RMEP
- Alarm status

You can specify **cfm-state** to view RMEP information in the specified CFM state.

Example

Display information about the RMEP with an ID of 50 in the MA named **ma1** within the MD named **md1**.

```
<HUAWEI> display cfm remote-mep md md1 ma ma1 mep-id 50
 MD Name            : md1
 Level              : 0
 MA Name            : ma1
 RMEP ID            : 5
 VLAN ID            : --
 VSI Name           : --
 L2VC ID            : --
 MAC                : --
 CCM Receive        : enabled
 Trigger-If-Down    : enabled
 CFM Status         : down
 Alarm Status       : LOC
 Interface TLV      : --
 Connect Status     : up
```

Display information about all RMEPs in the MA named **ma1** within the MD named **md1**.

```
<HUAWEI> display cfm remote-mep md md1 ma ma1
The total number of RMEPs is : 1
The status of RMEPs : 0 up, 1 down, 0 disable
--------------------------------------------------
 MD Name            : md1
 Level              : 0
 MA Name            : ma1
 RMEP ID            : 5
 VLAN ID            : --
 VSI Name           : --
 L2VC ID            : --
 MAC                : --
 CCM Receive        : enabled
 Trigger-If-Down    : enabled
 CFM Status         : down
 Alarm Status       : LOC
 Interface TLV      : --
 Connect Status     : up
```

Display information about all RMEPs configured on the device.

```
<HUAWEI> display cfm remote-mep
The total number of RMEPs is : 1
The status of RMEPs : 0 up, 0 down, 1 disable
--------------------------------------------------
 MD Name            : md
 Level              : 0
 MA Name            : ma
 RMEP ID            : 1
 VLAN ID            : --
 VSI Name           : --
 L2VC ID            : --
 MAC                : --
 CCM Receive        : disabled
 Trigger-If-Down    : disabled
 CFM Status         : disabled
 Alarm Status       : none
 Interface TLV      : --
 Connect Status     : up
```

Display information about all RMEPs in Down state.

```
<HUAWEI> display cfm remote-mep cfm-state down
The total number of RMEPs is : 2
The status of RMEPs : 0 up, 2 down, 0 disable
--------------------------------------------------
 MD Name            : md
 Level              : 0
 MA Name            : ma
 RMEP ID            : 1111
 VLAN ID            : 1111
 VSI Name           : --
 L2VC ID            : --
 MAC                : --
 CCM Receive        : enabled
 Trigger-If-Down    : disabled
 CFM Status         : down
 Alarm Status       : none
 Interface TLV      : --
 Connect Status     : up

 MD Name            : md1
 Level              : 0
 MA Name            : ma1
 RMEP ID            : 2
 VLAN ID            : 100
 VSI Name           : --
```

```
L2VC ID            : --
MAC                : 00e0-fc41-5410
CCM Receive        : enabled
Trigger-If-Down    : disabled
CFM Status         : down
Alarm Status       : LOC
Interface TLV      : --
Connect Status     : up
```

Table 12-58 Description of the display cfm remote-mep command output

Item	Description
The total number of RMEPs is	Number of RMEPs.
MD Name	Name of the MD.
Level	Level of the MD. The value ranges from 0 to 7. A higher level indicates a higher priority of the MD.
MA Name	Name of the MA.
RMEP ID	ID of the RMEP.
VLAN ID	ID of the VLAN associated with an MA.
VSI Name	Name of the VSI associated with an MA.
L2VC ID	ID of the VC.
MAC	MAC address of the RMEP. **NOTE** An RMEP's MAC address can be a bridge MAC address or the MAC address of the interface where the RMEP is configured. The MAC address depends on the configured MP address model: ● If the shared MP address model is configured, an RMEP uses a bridge MAC address as its own MAC address. ● If the independent MP address model is configured, an RMEP uses the MAC address of the interface where the RMEP is configured.
CCM Receive	Whether the MEP is enabled to receive CCMs from the RMEP: ● disabled: The MEP is disabled from receiving CCMs from the RMEP. ● enabled: The MEP is enabled to receive CCMs from the RMEP. To configure the CCM reception function, run the **remote-mep ccm-receive enable** command.

Item	Description
Trigger-If-Down	Whether the block/unblock function is configured on the interface: - disable: indicates that the block/unblock function is disabled on the interface for the RMEP. - enable: indicates that the block/unblock function is enabled on the interface for the RMEP. When a MEP detects a connectivity fault between the MEP and the RMEP in the same MA, the system blocks the interface on which the MEP is configured and then unblocks it. To configure the block/unblock function, run the **cfm trigger if-down** command.
CFM Status	CFM status: - up: indicates that CC works properly. - down: No MEP is configured on the device or the interface where the MEP is configured is unavailable. The reason why the interface is unavailable is one of the following: The subcard is not installed or has been restarted. The Eth-Trunk has no member interface or all member interfaces are Down. - disable: indicates that CFM is not configured, that is, the MEP is not enabled to send CCMs and the RMEP is not enabled to receive CCMs.
Alarm Status	CFM alarm status: - unexpectedPeriod: The interval carried in a CCM sent by the RMEP is different from that configured on the MEP. - unexpectedMAC: The source MAC address carried in a CCM sent by the RMEP is different from the RMEP's MAC address configured on the MEP. - LOC: The session is terminated. - exceptionalMACstatus: TLV information carried in a CCM sent by the RMEP within a specified interval indicates that the interface connecting the RMEP to the MEP is abnormal. - RDI: The MEP receives CCMs with RDI. - none: No alarm is generated. **NOTE** If the device is configured with no MEP but an RMEP, the CFM status is Down. However, no alarm is generated. That is, the field is none.

Item	Description
Interface TLV	Status of an interface type-length-value (TLV). The value can be: - - -: The default value is 0. No TLV status is available on the interface. - up: The interface status is Up, and the interface can transmit packets. - down: The interface status is Down, and the interface cannot transmit packets. - testing: The TLV status of the interface is testing. - unknown: The interface status is unknown. - dormant: The interface is blocked and is waiting for an external event. - notPresent: Information about the interface components is lost. - lowerLayerDown: The lower layer status of the interface is Down. **NOTE** - The packets carrying the interface TLV field with the value Up or Down can be sent. - The received packets carrying the interface TLV field with any value can be parsed.
Connect Status	The connect status of RMEP: - none: Detection is not started on the RMEP. - start: The RMEP is configured, but the remote device does not receive valid CCMs within the timeout period. - up: The physical link is working properly, and the remote device can receive correct CCMs. - down: The local device cannot receive correct CCMs.

12.8.28 display mip create-type

Function

The **display mip create-type** command displays MIP creation rules globally or on a specified interface.

Format

display mip create-type [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface-type interface-number	Displays MIP creation rules on a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number. If this parameter is not specified, MIP creation rules on a device are displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE 802.1ag Draft 7.

After MIP creation rules are configured using the **mip create-type (system view)** command or CFM does not work properly, use the **display mip create-type** command to check MIP creation rules.

Example

Display MIP creation rules on GigabitEthernet0/0/1.

```
<HUAWEI> display mip create-type interface gigabitethernet 0/0/1
Interface Name              MIP Create-Type  MIP Create-Type On Interface
---------------------------------------------------------------------------
GigabitEthernet0/0/1          default          --
```

Table 12-59 Description of the **display mip create-type** command output

Item	Description
Interface Name	Name of the interface.
MIP Create-Type	MIP creation rule on the device: - default: A MIP can be created on the interface without a higher-level MEP and a lower-level MIP. - explicit: A MIP can be created on an interface with a lower-level MEP but without a higher-level MEP or a lower-level MIP. - none: No MIP is created automatically.

Item	Description
MIP Create-Type On Interface	MIP creation rule on an interface: ● default: A MIP can be created on the interface without a higher-level MEP and a lower-level MIP. ● explicit: A MIP can be created on an interface with a lower-level MEP but without a higher-level MEP or a lower-level MIP. ● none: No MIP is created automatically. ● --: The MIP creation rule on an interface is the same as that on the device.

12.8.29 display oam global configuration

Function

The **display oam global configuration** command displays the global configuration of Ethernet OAM.

Format

display oam global configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can use the **display oam global configuration** command to check the global configuration of Ethernet OAM, including:

- Whether Ethernet CFM is enabled globally
- Whether GMAC ping is enabled
- Whether GMAC trace is enabled
- Whether EFM OAM is enabled globally

- Ethernet CFM version information
- MP address model

Precautions

IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007.

NOTE

Run the **cfm version** command to switch Ethernet CFM 802.1ag between IEEE 802.1ag Draft 7 and IEEE Std 802.1ag-2007.

Example

Display the global configuration of Ethernet OAM on the device.

```
<HUAWEI> display oam global configuration
Global Configuration                         Value
-------------------------------------------------------
CFM Status                                  enabled
Ping MAC Status                               disabled
Trace MAC Status                              disabled
CFM MAC-tunnel MIP Trace Status                       disabled
EFM Status                                  enabled
CFM Protocol                                standard
CFM MP-address-model                               bridge
```

Table 12-60 Description of the **display oam global configuration** command output

Item	Description
CFM Status	Whether Ethernet CFM is enabled globally: ● disabled: Ethernet CFM is disabled globally. ● enabled: Ethernet CFM is enabled globally. To configure the parameter, run the **cfm enable** command.
Ping MAC Status	Whether GMAC ping is enabled: ● disabled: GMAC ping is disabled. ● enabled: GMAC ping is enabled. To configure the parameter, run the **ping mac enable** command.
Trace MAC Status	Whether GMAC trace is enabled: ● disabled: GMAC trace is disabled. ● enabled: GMAC trace is enabled. To configure the parameter, run the **trace mac enable** command.

Item	Description
CFM MAC-tunnel MIP Trace Status	Whether the intermediate node in the MAC tunnel is enabled to respond to MAC trace messages: - disabled: The intermediate node in the MAC tunnel is disabled from responding to MAC trace messages. - enabled: The intermediate node in the MAC tunnel is enabled to respond to MAC trace messages. **NOTE** The switch does not support this parameter.
EFM Status	Whether EFM OAM is enabled globally: - disabled: EFM OAM is disabled globally. - enabled: EFM OAM is enabled globally. To configure the parameter, run the **efm enable** command.
CFM Protocol	Ethernet CFM version. - standard: IEEE Standard 802.1ag-2007. - bbb0: IEEE 802.1ag Draft 7. To configure the parameter, run the **cfm version** command.
CFM MP-address-model	MP address model: - bridge: shared MP address model - individual: independent MP address model **NOTE** Currently, only the shared MP address model is supported.

12.8.30 ma

Function

The **ma** command creates an MA in an MD and displays the MA view, or directly displays view of an existing MA.

The **undo ma** command deletes an MA.

Format

MD view, MA view:

ma *ma-name* [**format** { **icc-based** *iccbased-ma-format-name* | **string** *ma-format-name* }]

MD view:

undo ma [*ma-name*]

Parameters

Parameter	Description	Value
ma-name	Specifies the name of an MA. The name of an MA in an MD is unique.	The value is a string of 1 to 43 characters without spaces, hyphens (-), and question marks (?). The total length of the names of the MA and MD must be within 44 case-sensitive characters. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
icc-based *iccbased-ma-format-name*	Specifies an ICC-based MA name carried in CCMs to be sent. ITU carrier codes (ICCs) are assigned to network operators or service providers and maintained by ITU-T Telecommunication Standardization Bureau (TSB) in compliance with ITU-T M.1400 Recommendation.	The value is a string of 1 to 13 case-sensitive characters without spaces, hyphens (-), and question marks (?).
string *ma-format-name*	Specifies a string-based MA name carried in CCMs to be sent.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?).

Views

MD view, MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, services are deployed based on VLANs on a network. If CFM is required to monitor link connectivity, run the **ma** *ma-name* command to create an MA. Then CFM can be implemented in the MA.

Prerequisites

An MD has been created using the **cfm md** *md-name* command.

Precautions

- When an MA is deleted, the device automatically deletes all MEPs and RMEPs in the MA, stops CC, and clears MA-related alarms.
- An ICC-based MA can only be configured in the MD with the MD name in **no-md-name** format.

Example

Create an MA named **ma1**.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1]
```

12.8.31 map

Function

The **map** command associates a VLAN with an MA.

The **undo map** command disassociates a VLAN from an MA.

By default, an MA is not associated with any VLAN.

Format

map vlan *vlan-id*

undo map vlan

Parameters

Parameter	Description	Value
vlan-id	Specifies the ID of a VLAN.	The value is an integer that ranges from 1 to 4094.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Ethernet CFM detects connectivity faults in each MA. After an MA is associated with a VLAN, Ethernet CFM can detect connectivity faults in the VLAN.

Precautions

If CFM is used to detect connectivity faults between two directly connected devices, the MA does not need to be associated with a VLAN.

An MA can be associated with only one VLAN.

NOTICE

You can create or delete the association between an MA and a VLAN only when no MEP or RMEP is configured in the MA.

Before changing the VLAN associated with an MA, use the **undo map** command to disassociate the MA from the VLAN.

Example

Associate an MA with VLAN 10. The MA is not associated with any VLAN before the configuration.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 10
```

12.8.32 mep mep-id

Function

The **mep mep-id** command creates a MEP.

The **undo mep mep-id** command deletes a MEP.

Format

mep mep-id *mep-id* **interface** *interface-type interface-number* [**pe-vid** *pe-vid* **ce-vid** *ce-vid*] { **inward** | **outward** }

undo mep mep-id *mep-id*

Parameters

Parameter	Description	Value
mep-id *mep-id*	Specifies the ID of a MEP. The ID identifies a MEP. The MEP ID must be unique in an MA and in a VLAN.	The value is an integer that ranges from 1 to 8191.
interface-type interface-number	Specifies the type and number of the interface where a MEP is configured. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
pe-vid *pe-vid*	Specifies the outer VLAN ID of a PE.	The value is a decimal integer that ranges from 1 to 4094.
ce-vid *ce-vid*	Specifies the inner VLAN ID of a CE.	The value is a decimal integer that ranges from 1 to 4094.
inward	Indicates an inward-facing MEP. An inward-facing MEP sends 802.1ag packets through all interfaces in a VLAN associated with an MA, except the interface on which the MEP is configured. That is, the inward-facing MEP broadcasts 802.1ag packets in the VLAN associated with the MA.	-
outward	Indicates an outward-facing MEP. An outward-facing MEP sends 802.1ag packets through an interface on which the MEP is configured.	-

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To create a MEP, run the **mep mep-id** command.

Precautions

Inward- and outward-facing MEPs are classified based on the scope where 802.1ag packets are sent.

The MEP level of the associated VLAN must be greater than the MEP level of the non-associated VLAN based on the same physical interface or Eth-Trunk member interface. The MEP level is determined by the MD level. You can run the **cfm md** *md-name* command to configure the MD level.

The requirements for the number and type of MEPs created in an MA are as follows:

- The inward- and outward-facing MEPs cannot coexist.
- You can create multiple inward-facing interface-based MEPs but only one outward-facing interface-based MEP. Only one inward-facing interface-based MEP can be created on an interface.

Example

Create an inward-facing MEP on GigabitEthernet0/0/1 in MA **ma1** of MD **md1** and set the MEP ID to 15.

```
<HUAWEI> system-view
[HUAWEI] vlan 100
[HUAWEI-vlan100] port gigabitethernet 0/0/1
[HUAWEI-vlan100] quit
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 100
[HUAWEI-md-md1-ma-ma1] mep mep-id 15 interface gigabitethernet 0/0/1 inward
```

12.8.33 mep alarm disable

Function

The **mep alarm disable** command disables a MEP from reporting alarms.

The **undo mep alarm disable** command enables a MEP to report alarms.

By default, a MEP is enabled to report alarms.

Format

mep mep-id *mep-id* **alarm** { **rdi** | **ais** } **disable**

undo mep mep-id *mep-id* **alarm** { **rdi** | **ais** } **disable**

NOTE

Only the S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support **ais**.

Parameters

Parameter	Description	Value
mep-id *mep-id*	Specifies the ID of a MEP. A MEP ID identifies a MEP. Each MEP must have a unique ID in an MA or a VLAN.	The value is an integer that ranges from 1 to 8191.
alarm rdi	Disables a MEP from reporting remote defect indication (RDI) alarms.	-
alarm ais	Disables a MEP from reporting AIS alarms.	-

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an NMS manages many MEPs on a network, it may receive a large number of RDI and AIS alarms. To reduce such alarms, you can disable the MEPs from reporting alarms. After a MEP is disabled from reporting of RDI or AIS alarms, AIS or RDI alarms of this MEP are no longer sent to the NMS. This reduces the load of the NMS and local device.

Prerequisites

The following operations have been performed:

1. Run the **cfm md** command to create an MD.
2. Run the **ma** command to create an MA.
3. Run the **mep mep-id** command to create a MEP.

Example

Disable MEP 1 in the MA **ma1** of the MD **md1** from reporting RDI alarms.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 100
[HUAWEI-md-md1-ma-ma1] mep mep-id 1 alarm rdi disable
```

12.8.34 mep ccm-send enable

Function

The **mep ccm-send enable** command enables a MEP in an MA to send CCMs.

The **undo mep ccm-send enable** command disables a MEP in an MA from sending CCMs.

By default, a MEP is disabled from sending CCMs.

Format

mep ccm-send [**mep-id** *mep-id*] **enable**

undo mep ccm-send [**mep-id** *mep-id*] **enable**

Parameters

Parameter	Description	Value
mep-id *mep-id*	Specifies the ID of a MEP. If this parameter is not specified, all the MEPs in the MA are enabled to send CCMs or disabled from sending CCMs.	The value of *mep-id* is an integer that ranges from 1 to 8191.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you use the **mep mep-id** command to configure a MEP, use this command to enable the MEP to send CCMs.

Precautions

The interval at which CCMs are sent or received cannot be modified on the device in an MA if one of the following operations is performed:

- The **mep ccm-send enable** command is run to enable a MEP in an MA to send CCMs.
- The **remote mep ccm-receive enable** command is run to enable a MEP in an MA to receive CCMs.

The **undo mep ccm-send enable** or **remote mep ccm-receive enable** command must be run before the interval is reconfigured.

Example

Enable MEP 10 in the MA named **ma1** to send CCMs.

```
<HUAWEI> system-view
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] mep ccm-send mep-id 10 enable
```

12.8.35 mip create-type (MD view)

Function

The **mip create-type** command configures a MIP creation rule in an MD or the default MD.

The **undo mip create-type** command restores the default MIP creation rule in an MD or the default MD.

By default, the MIP creation rule in an MD or the default MD is **none**. That is, MIPs are not created.

Format

mip create-type { **default** | **explicit** | **none** }

undo mip create-type

Parameters

Parameter	Description	Value
default	Indicates that a MIP can be created on the interface without a higher-level MEP and a lower-level MIP. In this mode, MIPs can be created when no MEP is configured on the interface.	-
explicit	Indicates that a MIP can be created on an interface with a lower-level MEP but without a higher-level MEP or a lower-level MIP. In this mode, a MIP can be created on an interface only when a lower-level MEP has been configured on this interface.	-
none	Indicates that the MIP creation rule on an interface is none, that is, a MIP is not created automatically.	-

Views

MD view, default MD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When all devices in an MD are enabled to send CCMs, MEPs send CCMs periodically. If a MEP receives no CCMs from an RMEP within three consecutive intervals for sending CCMs, a connectivity fault between the MEP and RMEP occurs. A MIP needs to be used to locate the fault.

Precautions

IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007.

After the MIP creation rule is set in an MD or the default MD, all interfaces in the MD or default MD use this rule to create a MIP.

If the MIP creation rule is **default** or **explicit**, the device creates a MIP automatically according to the rule.

NOTE

The **mip create-type** command can be used only on the Layer 2 interfaces to which the MD or default MD belongs.

Example

Set the MIP creation rule to **none** in the MD named **customer**.

```
<HUAWEI> system-view
[HUAWEI] cfm md customer level 1
[HUAWEI-md-customer] mip create-type none
```

Set the MIP creation rule to **default** in the default MD.

```
<HUAWEI> system-view
[HUAWEI] cfm default md
[HUAWEI-default-md] mip create-type default
```

12.8.36 mip create-type (system view)

Function

The **mip create-type** command configures a MIP creation rule on the device or a specified interface.

The **undo mip create-type** command restores the default MIP creation rule on a specified interface.

By default, the MIP creation rule on the device is **none** and all the interfaces use this rule to generate MIPs.

Format

mip create-type { **default** | **explicit** | **none** } [**interface** *interface-type interface-number*]

undo mip create-type [[**default** | **explicit** | **none**] **interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
default	Indicates that the MIP creation rule on an interface is **default**. That is, a MIP can be created on the interface without a higher-level MEP and a lower-level MIP. In this mode, MIPs can be created when no MEP is configured on the interface.	-
explicit	Indicates that the MIP creation rule on an interface is **explicit**. That is, a MIP can be created on an interface with a lower-level MEP but without a higher-level MEP or a lower-level MIP. In this mode, a MIP can be created on an interface only when a lower-level MEP has been configured on this interface.	-
none	Indicates that the MIP creation rule on an interface is **none**. That is, a MIP is not created automatically.	-
interface-type interface-number	Specifies the type and number of an interface where a MIP creation rule is configured. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number. If this parameter is not specified, the MIP creation rule takes effect globally.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure a MIP creation rule on the device, run the **mip create-type** command.

Precautions

NOTE

The command is only applicable to IEEE 802.1ag Draft 7.

If the MIP creation rule is **default** or **explicit**, the device creates a MIP automatically according to the rule.

Generally, you need to configure MIP nodes only when the 802.1ag MAC ping or trace operation is performed on a non-MEP node in an MA.

Prerequisites

CFM has been enabled globally using the **cfm enable (system view)** command.

Example

Set the MIP creation rule to **default** on GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] mip create-type default interface gigabitethernet 0/0/1
```

12.8.37 oam-bind cfm md ma efm interface

Function

The **oam-bind cfm md ma efm interface** command configures EFM and Ethernet CFM to report faults to each other.

The **undo oam-bind cfm md ma efm interface** command cancels the configuration.

By default, EFM OAM and Ethernet CFM are not configured to report faults to each other.

Format

oam-bind cfm md *md-name* **ma** *ma-name* **efm interface** *interface-type interface-number*

undo oam-bind cfm md *md-name* **ma** *ma-name* **efm interface** *interface-type interface-number*

NOTE

This command is not supported by only the SS1720GW-E, and S1720GWR-E.

Parameters

Parameter	Description	Value
md-name	Specifies the name of an MD.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
ma-name	Specifies the name of an MA.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). The total length of the names of the MA and MD must be within 44 characters. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
interface-type interface-number	Specifies the type and number of an Ethernet interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number. The interface must have been enabled with EFM OAM.	-

Views

Usage Guidelines

Usage Scenario

If EFM is deployed at one side and CFM is deployed at another side of a device, associate EFM with CFM on the device so that EFM and CFM can report faults to each other.

Association between EFM and CFM is bidirectional:

- When EFM detects a link fault, it will notify CFM of the fault.
- When CFM detects a link fault, it will notify EFM of the fault.

The following commands are used to associate EFM with CFM:

- **oam-bind cfm md ma efm interface**
- **oam-bind ingress cfm md ma egress efm interface**
- **oam-bind ingress efm interface egress cfm md ma**

Select the preceding commands in different scenarios according to **Table 12-61**.

Table 12-61 Association between EFM and CFM

Scenario	Configuration Solution 1	Configuration Solution 2
Bidirectional fault notification between EFM and CFM	The **oam-bind cfm md ma efm interface** command is used to configure EFM and CFM to report faults to each other.	Run the following commands at a random order (each command configures fault transmission in a single direction): - The **oam-bind ingress efm interface egress cfm md ma** command is used to configure EFM to report faults to CFM. - The **oam-bind ingress cfm md ma egress efm interface** command is used to configure CFM to report faults to EFM.
Unidirectional fault notification between EFM and CFM	Select either of the following commands based on the transmission direction: - Run the **oam-bind ingress efm interface egress cfm md ma** command to configure EFM to report faults to CFM. - Run the **oam-bind ingress cfm md ma egress efm interface** command to configure CFM to report faults to EFM.	None

Prerequisites

The MD and MA have been created and EFM has been enabled on the specified interface.

Precautions

The binding between an Ethernet CFM module and an interface is one-to-one. That is, when an Ethernet CFM module is bound to an interface, the Ethernet CFM module cannot be bound to other interfaces.

Example

Configure EFM and CFM to report faults to each other through the GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] oam-mgr
[HUAWEI-oam-mgr] oam-bind cfm md mdcustomer ma customer efm interface gigabitethernet 0/0/1
```

12.8.38 oam-bind cfm md ma trigger if-down interface

Function

The **oam-bind cfm md ma trigger if-down interface** command enables Ethernet CFM and an interface to report faults to each other.

The **undo oam-bind cfm md ma trigger if-down interface** command cancels the configuration.

By default, Ethernet CFM and an interface are not configured to report faults to each other.

Format

oam-bind cfm md *md-name* **ma** *ma-name* **trigger if-down interface** *interface-type interface-number*

undo oam-bind cfm md *md-name* **ma** *ma-name* **trigger if-down interface** *interface-type interface-number*

Parameters

Parameter	Description	Value
md *md-name*	Specifies the name of an MD.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
ma *ma-name*	Specifies the name of an MA.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). The total length of the names of the MA and MD must be within 44 characters. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
if-down	Indicates that an interface goes Down when Ethernet CFM on the interface detects a fault.	-

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of the interface bound to CFM. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-

Views

OAM management view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To associate CFM with an interface, run the **oam-bind cfm md ma trigger if-down interface** command.

Precautions

Before configuring CFM and an interface to report faults to each other, pay attention to the following points:

- The MD and MA related to the Ethernet CFM module must have been created.
- The binding between an Ethernet CFM module and an interface is one-to-one. That is, when an Ethernet CFM module is bound to an interface, the Ethernet CFM module cannot be bound to other interfaces.
- A physical interface associated with CFM cannot be monitored by CFM. If CFM is associated with a physical interface monitored by itself, the link is locked.

Configure unidirectional or bidirectional transmission of fault information between Ethernet CFM and an interface. You may use the following commands when associating Ethernet CFM with an interface:

- **oam-bind cfm md ma trigger if-down interface**
- **oam-bind interface cfm md ma trigger if-down**
- **oam-bind ingress cfm md ma egress interface**
- **oam-bind ingress interface egress cfm md ma trigger if-down**

Select the preceding commands in different scenarios according to **Table 12-62**.

Table 12-62 Association between Ethernet CFM and an interface

Scenario	Configuration Solution 1	Configuration Solution 2
Faults need to be transmitted bidirectionally between Ethernet CFM and an interface.	Select either of the following commands (the two commands have the same function): ● If you prefer to specify the MD and MA before the interface, use the **oam-bind cfm md ma trigger if-down interface** command. ● If you prefer to specify the interface before the MD and MA, use the **oam-bind interface cfm md ma trigger if-down** command. **NOTE** After configuring Ethernet CFM and an interface to report faults to each other, run the **display current-configuration** command to check the configuration. The command output displays the **oam-bind ingress cfm md ma egress interface** and **oam-bind ingress interface egress cfm md ma trigger if-down** commands, but does not display the **oam-bind cfm md ma trigger if-down interface** or **oam-bind interface cfm md ma trigger if-down** command. The displayed commands configure reverse directions of fault transmission.	Run the following commands at a random order (each command configures fault transmission in a single direction): ● **oam-bind ingress cfm md ma egress interface** ● **oam-bind ingress interface egress cfm md ma trigger if-down**
Faults need to be transmitted unidirectionally between Ethernet CFM and an interface.	Select either of the following commands based on the transmission direction: ● To configure Ethernet CFM to report faults to an interface, use the **oam-bind ingress cfm md ma egress interface** command. ● To configure an interface to report faults to Ethernet CFM, use the **oam-bind ingress interface egress cfm md ma trigger if-down** command.	None

Example

Configure Ethernet CFM to report faults to the GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] oam-mgr
[HUAWEI-oam-mgr] oam-bind cfm md md1 ma ma1 trigger if-down interface gigabitethernet 0/0/1
```

12.8.39 oam-bind ingress cfm md ma egress interface

Function

The **oam-bind ingress cfm md ma egress interface** command configures Ethernet CFM to report faults to an interface.

The **undo oam-bind ingress cfm md ma egress interface** command cancels the configuration.

By default, Ethernet CFM is not configured to report faults to an interface.

Format

oam-bind ingress cfm md *md-name* **ma** *ma-name* **trigger if-down egress interface** *interface-type interface-number*

undo oam-bind ingress cfm md *md-name* **ma** *ma-name* **trigger if-down egress interface** *interface-type interface-number*

Parameters

Parameter	Description	Value
md *md-name*	Specifies the name of an MD.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
ma *ma-name*	Specifies the name of an MA.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). The total length of the names of the MA and MD must be within 44 characters. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
if-down	Indicates that an interface goes Down when Ethernet CFM on the interface detects a fault.	-

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of the interface bound to CFM. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-

None

Example

Configure CFM to report faults to the GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] oam-mgr
[HUAWEI-oam-mgr] oam-bind ingress cfm md md1 ma ma1 trigger if-down egress interface
gigabitethernet 0/0/1
```

12.8.40 oam-bind ingress cfm md ma egress sep segment

Function

The **oam-bind ingress cfm md ma egress sep segment** command configures CFM to report faults to a SEP segment.

The **undo oam-bind ingress cfm md ma egress sep segment** command cancels the configuration.

By default, CFM is not configured to report faults to a SEP segment.

Format

oam-bind ingress cfm md *md-name* **ma** *ma-name* **egress sep segment** *segment-id* **interface** *interface-type interface-number*

undo oam-bind ingress cfm md *md-name* **ma** *ma-name* **egress sep segment** *segment-id* **interface** *interface-type interface-number*

Parameters

Parameter	Description	Value
ingress egress	Configures CFM to report faults to a SEP segment.	-
md *md-name*	Specifies the name of an MD.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
ma *ma-name*	Specifies the name of an MA.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). The total length of the names of the MA and MD must be within 44 characters. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
segment *segment-id*	Specifies the ID of a SEP segment.	The value is an integer that ranges from 1 to 1024.

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an Ethernet interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number. The Ethernet interface must have been added to the SEP segment.	-

Views

OAM management view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To associate CFM with SEP, run the **oam-bind ingress cfm md ma egress sep segment** command.

Precautions

When a device running SEP at the access layer connects to the aggregation layer, pay attention to the following points:

- When a fault occurs at the access layer, configure topology change notification so that the aggregation layer can detect the fault at the access layer. Devices in the SEP segment can update their MAC address tables and ARP tables in a timely manner.
- If a fault occurs at the aggregation layer, associate SEP with Ethernet CFM on the device between the access layer and aggregation layer so that the access layer can detect the fault at the aggregation layer. Devices at the access layer can update their MAC address tables and ARP tables.

Prerequisites

This command can take effect only when the following configurations are completed:

- Run the **cfm enable (system view)** command to enable CFM globally.
- Run the **cfm md** command in the system view to create an MD.
- Run the **ma** command in the MD view to create an MA.
- Run the **mep mep-id** command in the MA view to create a MEP.

- Run the **remote-mep** command in the MA view to create an RMEP.
- Run the **mep ccm-send enable** command in the MA view to enable the local MEP in the MA to send CCMs.
- Run the **remote-mep ccm-receive enable** command in the MA view to enable the MEP to receive CCMs from the RMEP in the same MA.
- The interface specified in this command has been added to the SEP segment.

Example

Configure CFM to report faults to SEP segment 10.

```
<HUAWEI> system-view
[HUAWEI] oam-mgr
[HUAWEI-oam-mgr] oam-bind ingress cfm md md1 ma ma1 egress sep segment 10 interface
gigabitethernet 0/0/1
```

12.8.41 oam-bind ingress cfm md ma egress efm interface

Function

The **oam-bind ingress cfm md ma egress efm interface** command configures Ethernet CFM to report faults to EFM OAM.

The **undo oam-bind ingress cfm md ma egress efm interface** command cancels the configuration.

By default, Ethernet CFM is not configured to report faults to EFM OAM.

Format

oam-bind ingress cfm md *md-name* **ma** *ma-name* **egress efm interface** *interface-type interface-number*

undo oam-bind ingress cfm md *md-name* **ma** *ma-name* **egress efm interface** *interface-type interface-number*

NOTE

This command is not supported by only the SS1720GW-E, and S1720GWR-E.

Parameters

Parameter	Description	Value
md-name	Specifies the name of an MD.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?).

Parameter	Description	Value
ma-name	Specifies the name of an MA.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). The total length of the names of the MA and MD must be within 44 characters.
interface-type interface-number	Specifies the type and number of an Ethernet interface. • *interface-type* specifies the interface type. • *interface-number* specifies the interface number. The interface must have been enabled with EFM OAM.	-

Bidirectional fault notification between EFM and CFM	The **oam-bind cfm md ma efm interface** command is used to configure EFM and CFM to report faults to each other.	Run the following commands at a random order (each command configures fault transmission in a single direction): - The **oam-bind ingress efm interface egress cfm md ma** command is used to configure EFM to report faults to CFM. - The **oam-bind ingress cfm md ma egress efm interface** command is used to configure CFM to report faults to EFM.
Unidirectional fault notification between EFM and CFM	Select either of the following commands based on the transmission direction: - Run the **oam-bind ingress efm interface egress cfm md ma** command to configure EFM to report faults to CFM. - Run the **oam-bind ingress cfm md ma egress efm interface** command to configure CFM to report faults to EFM.	None

Prerequisites

The MD and MA have been created and EFM has been enabled on the specified interface.

Example

Configure EFM to report faults to CFM through the GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] oam-mgr
[HUAWEI-oam-mgr] oam-bind ingress efm interface gigabitethernet 0/0/1 egress cfm md mdcustomer
ma customer
```

12.8.43 oam-bind ingress interface egress cfm md ma trigger if-down

Function

The **oam-bind ingress interface egress cfm md ma trigger if-down** command configures an interface to report faults to Ethernet CFM.

The **undo oam-bind ingress interface egress cfm md ma trigger if-down** command cancels the configuration.

By default, an interface is not configured to report faults to Ethernet CFM.

Format

oam-bind ingress interface *interface-type interface-number* **egress cfm md** *md-name* **ma** *ma-name* **trigger if-down**

undo oam-bind ingress interface *interface-type interface-number* **egress cfm md** *md-name* **ma** *ma-name* **trigger if-down**

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
md *md-name*	Specifies the name of an MD.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
ma *ma-name*	Specifies the name of an MA.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). The total length of the names of the MA and MD must be within 44 characters. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
if-down	Indicates that the OAM management module notifies Ethernet CFM of the fault and Ethernet CFM notifies the remote end of the fault when an interface goes Down.	-

Views

OAM management view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To associate an interface with CFM, run the **oam-bind ingress interface egress cfm md ma trigger if-down** command.

Precautions

If CFM is associated with an interface on a device and a device interface goes Down, the OAM management module notifies Ethernet CFM of the fault and Ethernet CFM notifies the remote end of the fault.

Prerequisites

Unidirectional fault transmission from an interface to Ethernet CFM can be configured only when the following requirements are met:

- The MD and MA related to the Ethernet CFM module must have been created.
- The binding between an Ethernet CFM module and an interface is one-to-one. That is, when an Ethernet CFM module is bound to an interface, the Ethernet CFM module cannot be bound to other interfaces.
- A physical interface associated with CFM cannot be the one that CFM monitors. If CFM is associated with a physical interface that it monitors, the link is locked.

Configure unidirectional or bidirectional fault transmission between Ethernet CFM and an interface. You may use the following commands when associating Ethernet CFM with an interface:

- **oam-bind cfm md ma trigger if-down interface**
- **oam-bind interface cfm md ma trigger if-down**
- **oam-bind ingress cfm md ma egress interface**
- **oam-bind ingress interface egress cfm md ma trigger if-down**

Select the preceding commands in different scenarios according to **Table 12-66**.

Table 12-66 Association between Ethernet CFM and an interface

Scenario	Configuration Solution 1	Configuration Solution 2
Faults need to be transmitted bidirectionally between Ethernet CFM and an interface.	Select either of the following commands (the two commands have the same function): - If you prefer to specify the MD and MA before the interface, use the **oam-bind cfm md ma trigger if-down interface** command. - If you prefer to specify the interface before the MD and MA, use the **oam-bind interface cfm md ma trigger if-down** command. **NOTE** After configuring Ethernet CFM and an interface to report faults to each other, run the **display current-configuration** command to check the configuration. The command output displays the **oam-bind ingress cfm md ma egress interface** and **oam-bind ingress interface egress cfm md ma trigger if-down** commands, but does not display the **oam-bind cfm md ma trigger if-down interface** or **oam-bind interface cfm md ma trigger if-down** command. The displayed commands configure reverse transmission directions of fault information.	Run the following commands at a random order (each command configures fault transmission in a single direction): - **oam-bind ingress cfm md ma egress interface** - **oam-bind ingress interface egress cfm md ma trigger if-down**
Faults need to be transmitted unidirectionally between Ethernet CFM and an interface.	Select either of the following commands based on the transmission direction: - To configure Ethernet CFM to report faults to an interface, use the **oam-bind ingress cfm md ma egress interface** command. - To configure an interface to report faults to Ethernet CFM, use the **oam-bind ingress interface egress cfm md ma trigger if-down** command.	None

Example

Configure Ethernet CFM to report faults to the GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] oam-mgr
[HUAWEI-oam-mgr] oam-bind ingress interface gigabitethernet 0/0/1 egress cfm md md1 ma ma1
trigger if-down
```

12.8.44 oam-bind interface cfm md ma trigger if-down

Function

The **oam-bind interface cfm md ma trigger if-down** command configures an interface and Ethernet CFM to report faults to each other.

The **undo oam-bind interface cfm md ma trigger if-down** command cancels the configuration.

By default, an interface and Ethernet CFM are not configured to report faults to each other.

Format

oam-bind interface *interface-type interface-number* **cfm md** *md-name* **ma** *ma-name* **trigger if-down**

undo oam-bind interface *interface-type interface-number* **cfm md** *md-name* **ma** *ma-name* **trigger if-down**

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
md *md-name*	Specifies the name of an MD.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
ma *ma-name*	Specifies the name of an MA.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). The total length of the names of the MA and MD must be within 44 characters. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
if-down	Indicates that the OAM management module notifies Ethernet CFM of the fault and Ethernet CFM notifies the remote end of the fault when an interface goes Down.	-

Views

OAM management view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To associate an interface with CFM, run the **oam-bind interface cfm md ma trigger if-down** command.

Precautions

Before configuring CFM and an interface to report faults to each other, pay attention to the following points:

- The MD and MA related to the Ethernet CFM module must have been created.
- The binding between an Ethernet CFM module and an interface is one-to-one. That is, when an Ethernet CFM module is bound to an interface, the Ethernet CFM module cannot be bound to other interfaces.
- A physical interface associated with CFM cannot be monitored by CFM. If CFM is associated with a physical interface monitored by itself, the link is locked.

Configure unidirectional or bidirectional fault transmission between Ethernet CFM and an interface. You may use the following commands when associating Ethernet CFM with an interface:

- **oam-bind cfm md ma trigger if-down interface**
- **oam-bind interface cfm md ma trigger if-down**
- **oam-bind ingress cfm md ma egress interface**
- **oam-bind ingress interface egress cfm md ma trigger if-down**

Select the preceding commands in different scenarios according to **Table 12-67**.

Table 12-67 Association between Ethernet CFM and an interface

Scenario	Configuration Solution 1	Configuration Solution 2
Faults need to be transmitted bidirectionally between Ethernet CFM and an interface.	Select either of the following commands (the two commands have the same function): • If you prefer to specify the MD and MA before the interface, use the **oam-bind cfm md ma trigger if-down interface** command. • If you prefer to specify the interface before the MD and MA, use the **oam-bind interface cfm md ma trigger if-down** command. **NOTE** After configuring Ethernet CFM and an interface to report faults to each other, run the **display current-configuration** command to check the configuration. The command output displays the **oam-bind ingress cfm md ma egress interface** and **oam-bind ingress interface egress cfm md ma trigger if-down** commands, but does not display the **oam-bind cfm md ma trigger if-down interface** or **oam-bind interface cfm md ma trigger if-down** command. The displayed commands configure reverse directions of fault transmission.	Run the following commands at a random order (each command configures fault transmission in a single direction): • **oam-bind ingress cfm md ma egress interface** • **oam-bind ingress interface egress cfm md ma trigger if-down**

Scenario	Configuration Solution 1	Configuration Solution 2
Faults need to be transmitted unidirectionally between Ethernet CFM and an interface.	Select either of the following commands based on the transmission direction: ● To configure Ethernet CFM to report faults to an interface, use the **oam-bind ingress cfm md ma egress interface** command. ● To configure an interface to report faults to Ethernet CFM, use the **oam-bind ingress interface egress cfm md ma trigger if-down** command.	None

Example

Enable the GigabitEthernet0/0/1 to report faults to Ethernet CFM.

```
<HUAWEI> system-view
[HUAWEI] oam-mgr
[HUAWEI-oam-mgr] oam-bind interface gigabitethernet 0/0/1 cfm md md1 ma ma1 trigger if-down
```

12.8.45 oam-mgr

Function

The **oam-mgr** command displays the OAM management view.

The **undo oam-mgr** command exits from the OAM management view.

Format

oam-mgr

undo oam-mgr

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

CFM can advertise fault information to interfaces or protocol modules. Ethernet OAM fault advertisement is implemented by an OAM manager, application modules, and detection modules. An OAMMGR module associates one module with another. A detection module monitors link status and network performance. If a detection module detects a fault, it instructs the OAMMGR module to notify an application module or another detection module of the fault. After receiving the notification, the application or detection module takes measures to prevent a communication interruption or service quality deterioration. Run the **oam-mgr** command to display the MGR view before associating the CFM module and other modules.

Example

Enter the OAM management view.

```
<HUAWEI> system-view
[HUAWEI] oam-mgr
[HUAWEI-oam-mgr]
```

12.8.46 packet-priority

Function

The **packet-priority** command sets the 802.1p priority of 802.1ag packets in an MA.

The **undo packet-priority** command restores the default 802.1p priority of 802.1ag packets in an MA.

Format

packet-priority *priority*

undo packet-priority

Parameters

Parameter	Description	Value
priority	Specifies the 802.1p priority of 802.1ag packets.	The value is an integer that ranges from 0 to 7. The default value is 7. A larger value indicates a higher priority.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The 802.1ag packets are the Continuity Check Message (CCM), Loopback Message (LBM), Loopback Reply (LBR), Linktrace Message (LTM), and Linktrace Reply (LTR).

The 802.1ag packets with different 802.1p priorities are transmitted differently on networks. You can use this command to change the transmission quality of 802.1ag packets on networks.

Example

Set the 802.1p priority of 802.1ag packets in an MA to 3.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] packet-priority 3
```

12.8.47 ping mac-8021ag

Function

The **ping mac-8021ag** command enables 802.1ag MAC ping to detect connectivity faults between a MEP and an RMEP or a MIP in an MA.

Format

All views except the MA view:

ping mac-8021ag mep mep-id *mep-id* **md** *md-name* **ma** *ma-name* { **mac** *mac-address* | **remote-mep mep-id** *mep-id* } [**-c** *count* | **interface** *interface-type interface-number* | **-s** *packetsize* | **-t** *timeout* | **-p** *priority-value*] *

MA view

ping mac-8021ag mep mep-id *mep-id* { **md** *md-name* **ma** *ma-name* { **mac** *mac-address* | **remote-mep mep-id** *mep-id* } | **mac** *mac-address* | **remote-mep mep-id** *mep-id* } [**-c** *count* | **interface** *interface-type interface-number* | **-s** *packetsize* | **-t** *timeout* | **-p** *priority-value*] *

Parameters

Parameter	Description	Value
mep mep-id *mep-id*	Specifies the ID of a MEP. The MEP must have been created using the **mep mep-id** command.	The value is an integer that ranges from 1 to 8191.

Parameter	Description	Value
md *md-name*	Specifies the name of an MD.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?).
ma *ma-name*	Specifies the name of an MA.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). The total length of the names of the MA and MD must be within 44 characters.
mac *mac-address*	Specifies the MAC address of the destination node. The destination node can be a MEP or MIP. *mac-address* specifies the MP's MAC address. **NOTE** An MP's MAC address can be a bridge MAC address or the MAC address of the interface where the MP is configured. The MAC address depends on the configured MP address model: ● If the shared MP address model is configured, an MP uses a bridge MAC address as its own MAC address. ● If the independent MP address model is configured, an MP uses the MAC address of the interface where the MP is configured.	The value is in H-H-H format. An H is a hexadecimal number of 1 to 4 digits. The value cannot be a broadcast or multicast MAC address.
remote-mep mep-id *mep-id*	Specifies the ID of an RMEP.	The value is an integer that ranges from 1 to 8191.
-c *count*	Specifies the number of ping attempts.	The value is an integer that ranges from 1 to 4294967295. The default value is 5.

Parameter	Description	Value
interface-type interface-number	Specifies the outbound interface on the local device for sending ping packets. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
-s *packetsize*	Specifies the size of a ping packet.	The value is an integer that ranges from 95 to 9000, in bytes. The default value is 95.
-t *timeout*	Specifies the timeout interval for waiting for a response packet.	The value is an integer that ranges from 1 to 65535, in milliseconds. The default value is 2000 ms.
-p *priority-value*	Specifies the priority of ping packets.	The value is an integer that ranges from 0 to 7. The default value is the same as the 802.1p priority of 802.1ag packets specified in the MA view.

Views

All views

Default Level

0: Visit level

Usage Guidelines

Usage Scenario

Similar to ping, 802.1ag MAC ping enables the local device to send test packets and wait for a response to check whether the destination device is reachable. In addition, the ping operation time can be calculated at the transmit end for network performance analysis.

A device is usually configured with multiple MDs and MAs. To accurately detect connectivity of a link between two or more devices, perform either of the following operations:

- Run the **ping mac-8021ag** command in the MA view.
  - Run the **ping mac-8021ag** command without **md** *md-name* **ma** *ma-name* specified to check connectivity of links in a specified MA.
  - Run the **ping mac-8021ag** command with **md** *md-name* and **ma** *ma-name* specified to check connectivity of links based on the configured MA and MD.
- Run the **ping mac-8021ag** command in all views except the MA view to check connectivity of links based on the configured MA and MD.

Prerequisites

- The MA has been associated with a VLAN.
- The MEP has been configured in the MA.

Precautions

802.1ag MAC ping is initiated by the local MEP in the MA and destined for a MEP or a MIP of the same level on other devices. The source node and the destination node can be located in different MAs.

If the outbound interface is specified, it cannot be configured with an inward-facing MEP.

Example

Ping the MIP with a bridge MAC address of 00e0-fc00-0204 twice on the MEP in **ma1** and set the size of ping packets to 112 bytes.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] ping mac-8021ag mep mep-id 1 mac 00e0-fc00-0204 -c 2 -s 112
Pinging 00e0-fc00-0204 with 112 bytes of data:
Reply from 00e0-fc00-0204: bytes = 112 time = 9ms
Reply from 00e0-fc00-0204: bytes = 112 time = 11ms
Packets: Sent = 2, Received = 2, Lost = 0  <0% Lost >
Minimum = 9ms, Maximum = 11ms, Average = 10ms
```

Table 12-68 Description of the **ping mac-8021ag** command output

Item	Description
Reply from 00e0-fc00-0204: bytes = 112 time = 9ms	Size and response time of ping packets sent by the destination device. When the response time is less than 1 ms, "time < 1ms" is displayed.
Packets: Sent = 2, Received = 2, Lost = 0 <0% Lost >	Number of sent ping packets, number of received reply packets, and number and percentage of discarded packets.
Minimum	Minimum round-trip time (RTT).
Maximum	Maximum RTT.
Average	Average RTT.

12.8.48 remote-mep

Function

The **remote-mep** command configures an RMEP in an MA.

The **undo remote-mep** command deletes an RMEP from an MA.

Format

remote-mep mep-id *mep-id* [**mac** *mac-address*]

undo remote-mep mep-id *mep-id*

Parameters

Parameter	Description	Value
mep-id *mep-id*	Specifies the ID of an RMEP.	The value is an integer that ranges from 1 to 8191.
mac *mac-address*	Specifies the MAC address of an RMEP.	The value is in H-H-H format. An H is a hexadecimal number of 1 to 4 digits.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure an RMEP, use this command.

Precautions

To detect CFM connectivity faults between a device and an RMEP in an MA, complete the following tasks:

- Run the **remote-mep** command to configure an RMEP in an MA.
- Run the **remote-mep ccm-receive enable** command to enable the MEP to receive CCMs from the RMEP.

To modify the bridge MAC address of the RMEP, you must delete the RMEP from an MA and then reconfigure the RMEP.

The RMEP ID must be different from the MEP ID configured on a local interface.

NOTICE

- If multiple MEPs exist in an MA, the configured RMEP corresponds to multiple MEPs.
- If one MEP exists in an MA, one or more configured RMEPs correspond to one MEP.

Example

Configure RMEP 10 in **ma1** on the device with the bridge MAC address of 00e0-fc00-0204.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] remote-mep mep-id 10 mac 00e0-fc00-0204
```

12.8.49 remote-mep ccm-receive enable

Function

The **remote-mep ccm-receive enable** command enables a MEP on the device to receive CCMs from an RMEP in the same MA or MAC tunnel.

The **undo remote-mep ccm-receive enable** command cancels the configuration.

By default, a MEP does not receive CCMs from an RMEP.

Format

remote-mep ccm-receive [**mep-id** *mep-id*] **enable**

undo remote-mep ccm-receive [**mep-id** *mep-id*] **enable**

Parameters

Parameter	Description	Value
mep-id *mep-id*	Enables a MEP to receive CCMs from the specified RMEP. If this parameter is not specified, a MEP can receive CCMs from all RMEPs in the same MA.	The value is an integer that ranges from 1 to 8191.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **remote-mep ccm-receive enable** command enables a MEP on the device to receive CCMs from an RMEP in the same MA or MAC tunnel.

Precautions

The interval at which CCMs are sent or detected cannot be changed on the device in an MA if one of the following operations is performed:

- The device is enabled to send CCMs using the **mep ccm-send enable** command.
- The device is enabled to receive CCMs using the **remote-mep ccm-receive enable** command.

The **undo mep ccm-send enable** or **undo remote mep ccm-receive enable** command must be run before the interval is reconfigured.

Prerequisites

A MEP and an RMEP have been created in the MA.

Example

Enable the device to receive CCMs from RMEP 10 in **ma1**.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] remote-mep mep-id 10 mac 00e0-fc00-0204
[HUAWEI-md-md1-ma-ma1] remote-mep ccm-receive mep-id 10 enable
```

12.8.50 senderid-tlv-type

Function

The **senderid-tlv-type** command sets the type of the Sender ID TLV in CFM packets.

The **undo senderid-tlv-type** command restores the default type of the Sender ID TLV in CFM packets.

By default, the type of the Sender ID TLV is **defer**.

Format

senderid-tlv-type { **none** | **chassis** | **manage** | **chassis-manage** | **defer** }

undo senderid-tlv-type

Parameters

Parameter	Description	Value
none	Indicates that a sent CFM packet does not contain the Sender ID TLV.	-
chassis	Indicates that a sent CFM packet contains the chassis ID.	-
manage	Indicates that a sent CFM packet contains the management address.	-
chassis-manage	Indicates that a sent CFM packet contains the chassis ID and management address.	-
defer	Indicates that the content of the Sender ID TLV is determined by the MD object.	-

Views

MD view, default MD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can use the **senderid-tlv-type** command to configure the type of the Sender ID TLV in CFM packets in the MD view or default MD view.

Example

Set the type of the Sender ID TLV to **manage**.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm default md
[HUAWEI-default-md] senderid-tlv-type manage
```

12.8.51 trace mac-8021ag

Function

The **trace mac-8021ag** command enables 802.1ag MAC trace to detect connectivity faults between a MEP and an RMEP or a MIP in an MA.

Format

All views except the MA view:

trace mac-8021ag mep mep-id *mep-id* **md** *md-name* **ma** *ma-name* { **mac** *mac-address* | **remote-mep mep-id** *mep-id* } [**interface** *interface-type interface-number* | **-t** *timeout* | **ttl** *ttl*] *

MA view:

trace mac-8021ag mep mep-id *mep-id* { **md** *md-name* **ma** *ma-name* { **mac** *mac-address* | **remote-mep mep-id** *mep-id* } | **mac** *mac-address* | **remote-mep mep-id** *mep-id* } [**interface** *interface-type interface-number* | **-t** *timeout* | **ttl** *ttl*] *

Parameters

Parameter	Description	Value
mep mep-id *mep-id*	Specifies the ID of a MEP. The MEP must have been created using the **mep mep-id** command.	The value is an integer that ranges from 1 to 8191.
md *md-name*	Specifies the name of an MD.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
ma *ma-name*	Specifies the name of an MA.	The value is a string of 1 to 43 case-sensitive characters without spaces, hyphens (-), and question marks (?). The total length of the names of the MA and MD must be within 44 characters. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
mac *mac-address*	Specifies the MAC address of the destination node. The destination node can be a MEP or MIP. *mac-address* specifies the MP's MAC address. The value is in H-H-H format. An H is a hexadecimal number of 1 to 4 digits. The value cannot be a broadcast or multicast MAC address. **NOTE** An MP's MAC address can be a bridge MAC address or the MAC address of the interface where the MP is configured. The MAC address depends on the configured MP address model: - If the shared MP address model is configured, an MP uses a bridge MAC address as its own MAC address. - If the independent MP address model is configured, an MP uses the MAC address of the interface where the MP is configured.	-
remote-mep mep-id *mep-id*	Specifies the ID of an RMEP.	The value is an integer that ranges from 1 to 8191.

Parameter	Description	Value
interface-type interface-number	Specifies the outbound interface on the local device for sending LTMs. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number. This parameter must be specified if the forwarding entry of the destination node does not exist in the MAC address table or there is more than one interface in a VLAN.	-
-t *timeout*	Specifies the timeout interval for waiting for an LTR.	The value is an integer that ranges from 1 to 65535, in milliseconds. The default value is 2000 ms.
ttl *ttl*	Specifies the maximum hop of LTMs.	The value is an integer that ranges from 1 to 255. The default value is 64.

Views

Usage Guidelines

Usage Scenario

Similar to traceroute (tracert for short), 802.1ag MAC trace tests the path between the local device and the destination device or locates failure points by sending test packets and receiving reply packets.

A device is usually configured with multiple MDs and MAs. To locate failure points or detect connectivity of a link between one MEP to another MEP or a MIP in the same MA, perform either of the following operations:

- Run the **trace mac-8021ag** command in the MA view.

  - Run the **trace mac-8021ag** command without **md** *md-name* and **ma** *ma-name* specified to test the actual forwarding patch and locate failure points in a specified MA.
  - Run the **md** *md-name* **ma** *ma-name* command with **md** *md-name* and **ma** *ma-name* specified to test the actual forwarding patch and locate failure points based on the configured MA and MD.
- Run the **trace mac-8021ag md** *md-name* **ma** *ma-name* command in all views except the MA view to test the actual forwarding patch and locate failure points based on the configured MA and MD.

Prerequisites

- The MA has been associated with a VLAN.
- The MEP has been configured in the MA.

Precautions

A MEP initiates an 802.1ag MAC trace test to monitor reachability of the MEP's or MIP's destination address. These nodes have the same level and can be located in the same MA or different MAs.

If the outbound interface is specified, it cannot be configured with an inward-facing MEP.

Example

Trace the MEP with the MAC address of aa99-6600-5600 from the MEP in the MA **macustomer**, with the TTL of 64.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md mdcustomer
[HUAWEI-md-mdcustomer] ma macustomer
[HUAWEI-md-mdcustomer-ma-macustomer] trace mac-8021ag mep mep-id 1 mac aa99-6600-5600 ttl
64
Tracing the route to aa99-6600-5600 over a maximum of 64 hops:
--------------------------------------------------------------------------------
 Hops  Ingress Mac        Ingress Port              Ingress Action      Relay Action
       Egress Mac         Egress Port               Egress Action       Ismep
---------------------------------------------------------------------------------
1      00e0-fc01-3302     Vlanif0/0/1     IngOK              RlyFDB
       00e0-fce2-36db     Vlanif0/0/1     EgrOK              NoMep
```

Table 12-69 Description of the **trace mac-8021ag** command output

Item	Description
Hops	Number of hops.
Ingress Mac	MAC address of the inbound interface for receiving LTMs on the intermediate node or destination node.
Ingress Port	Inbound interface for receiving LTMs on the intermediate node or destination node.

Item	Description
Ingress Action	Action taken by the inbound interface to process LTMs: ● IngOK: The inbound interface forwards LTMs successfully. ● If this field is empty, the inbound interface fails to forward LTMs.
Reply Action	Action taken by the device to process LTMs: ● RlyFDB: The device forwards LTMs to the next hop device. ● RlyHit: The device forwards LTMs to the destination device.
Egress Mac	MAC address of the outbound interface for forwarding LTMs on the intermediate node.
Egress Port	Outbound interface for forwarding LTMs on the intermediate node.
Egress Action	Action taken by the outbound interface to process LTMs: ● EgrOK: The outbound interface forwards LTMs successfully. ● If this field is empty, the outbound interface does not or fails to forward LTMs.
Ismep	Whether the mode of the outbound interface is a MEP: ● NoMep: no ● IsMep: yes

12.8.52 vlan (default MD view)

Function

The **vlan** command creates a VLAN in the default MD.

The **undo vlan** command deletes a VLAN from the default MD.

Format

vlan { *vlan-id1* [**to** *vlan-id2*] }&<1-10>

undo vlan { *vlan-id1* [**to** *vlan-id2*] }&<1-10>

Parameters

Parameter	Description	Value
vlan-id1	Specifies the start VLAN ID.	The value is an integer that ranges from 1 to 4094.
vlan-id2	Specifies the end VLAN ID.	The value is an integer that ranges from 1 to 4094. The value of *vlan-id2* must be greater than or equal to the value of *vlan-id1*.

Views

Default MD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you run the **vlan** command in the default MD view, all the interfaces in the specified VLAN can generate MIPs based on the configured MIP creation rule in the default MD.

Precautions

IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007.

If the **vlan** command is run multiple times, all configurations take effect.

NOTE

The specified VLAN cannot be associated with any MA.

Example

Associate VLAN 100 to VLAN 200 with the default MD.

```
<HUAWEI> system-view
[HUAWEI] cfm default md
[HUAWEI-default-md] vlan 100 to 200
```

12.9 Y.1731 Configuration Commands

12.9.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

12.9.2 ais enable

Function

The **ais enable** command enables alarm indication signal (AIS) in an MA.

The **undo ais enable** command disables AIS in an MA.

By default, AIS is disabled.

NOTE

Only the S6730-S, S6730S-S, S6730-H, S6730S-H, S6720S-S, S6720-EI, S6720S-EI, S6735-S, S5731-S, S5731S-H, S5731S-S, S5732-H, S5731-H, S5735S-H, S5736-S, S5735-S-I, S5735S-S, S500, S5720I-SI and S5735-S support this command.

Format

ais enable

undo ais enable

Parameters

None

Views

MD view, MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In MD nesting scenarios, if a MEP in a low-level MD detects a fault, the MEP sends a trap to the NMS. After a certain period, a MEP in the MD of a higher level also detects the fault and sends the same trap to the NMS. Enable the AIS function in low-level and high-level MDs to suppress the MEP of the high-level MD from sending traps to the NMS.

Precautions

The **ais enable** command can be used on only the device running IEEE Standard 802.1ag-2007.

When the device processes many AIS packets, the CPU usage will become high. When the device is enabled with AIS, it is recommended that nestling layers in an

MD should be reduced and the number of interfaces associated with VLANs in an MA should be reduced.

Prerequisites

An MD has been created using the **cfm md** command and an MA has been created using the **ma** command.

Example

Create an MD named **md1**, create an MA named **ma1** in the MD, and enable the AIS function in **ma1**.

```
<HUAWEI> system-view
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] ais enable
```

12.9.3 ais interval

Function

The **ais interval** command sets the interval at which a MEP in an MA sends AIS PDUs to a MEP in a high-level MA.

The **undo ais interval** command restores the default interval.

By default, the interval at which AIS PDUs are sent is 1s.

NOTE

Only the S6730-S, S6730S-S, S6730-H, S6730S-H, S6720S-S, S6720-EI, S6720S-EI, S6735-S, S5731-S, S5731S-H, S5731S-S, S5732-H, S5731-H, S5735S-H, S5736-S, S5735-S-I, S5735S-S, S500, S5720I-SI and S5735-S support this command.

Format

ais interval *interval-value*

undo ais interval

Parameters

Parameter	Description	Value
interval-value	Specifies the interval at which AIS PDUs are sent.	The value is an integer that ranges from 1 to 60, in seconds.

Views

MA view

2: Configuration level

Usage Guidelines

Usage Scenario

In MD nesting scenarios, if a MEP in a low-level MD detects a fault, the MEP sends a trap to the NMS. After a certain period, a MEP in the MD of a higher level also detects the fault and sends the same trap to the NMS. You can enable the AIS function in low-level and high-level MDs to suppress the MEP of the high-level MD from sending traps to the NMS. After AIS is enabled, set the interval at which AIS PDUs are sent according to the networking.

Precautions

The **ais interval** command can be used on only the device running IEEE Standard 802.1ag-2007.

Prerequisites

An MD has been created using the **cfm md** command, an MA has been created using the **ma** command, and AIS has been enabled using the **ais enable** command.

Example

Create an MD named **md1**, create an MA named **ma1** in the MD, and set the interval at which AIS PDUs are sent in **ma1** to 60s.

```
<HUAWEI> system-view
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] ais interval 60
```

12.9.4 ais level

Function

The **ais level** command sets the level of AIS PDUs to be sent by a MEP in an MA.

The **undo ais level** command deletes the level of AIS PDUs to be sent by a MEP in an MA.

NOTE

Only the S6730-S, S6730S-S, S6730-H, S6730S-H, S6720S-S, S6720-EI, S6720S-EI, S6735-S, S5731-S, S5731S-H, S5731S-S, S5732-H, S5731-H, S5735S-H, S5736-S, S5735-S-I, S5735S-S, S500, S5720I-SI and S5735-S support this command.

Format

ais level *level-value*

undo ais level

Parameters

Parameter	Description	Value
level-value	Specifies the level of AIS PDUs to be sent.	The value is an integer that ranges from 0 to 7.

Usage Scenario

In MD nesting scenarios, if a MEP in a low-level MD detects a fault, the MEP sends a trap to the NMS. After a certain period, a MEP in the MD of a higher level also detects the fault and sends the same trap to the NMS. You can enable the AIS function in low-level and high-level MDs to suppress the MEP of the high-level MD from sending traps to the NMS. After AIS is enabled, set the level of AIS PDUs to be sent according to the networking.

Precautions

The **ais level** command can be used on only the device running IEEE Standard 802.1ag-2007.

Prerequisites

An MD has been created using the **cfm md** command, an MA has been created using the **ma** command, and AIS has been enabled using the **ais enable** command.

Example

Create an MD named **md1**, create an MA named **ma1** in the MD, and set the level of AIS PDUs to be sent to 2 in **ma1**.

```
<HUAWEI> system-view
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] ais level 2
```

12.9.5 ais link-status

Function

The **ais link-status** command configures AIS to monitor interfaces.

The **undo ais link-status** command cancels the configuration.

By default, AIS does not monitor any interface.

NOTE

Only the S6730-S, S6730S-S, S6730-H, S6730S-H, S6720S-S, S6720-EI, S6720S-EI, S6735-S, S5731-S, S5731S-H, S5731S-S, S5732-H, S5731-H, S5735S-H, S5736-S, S5735-S-I, S5735S-S, S500, S5720I-SI and S5735-S support this command.

Format

ais link-status interface *interface-type interface-number*

undo ais link-status interface *interface-type interface-number*

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the interface to be monitored by AIS. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In MD nesting scenarios, if a MEP in a low-level MD detects a fault, the MEP sends a trap to the NMS. After a certain period, a MEP in the MD of a higher level also detects the fault and sends the same trap to the NMS. You can enable the AIS function in low-level and high-level MDs to suppress the MEP of the high-level MD from sending traps to the NMS. To speed up AIS PDU transmission, run the **ais link-status** command to configure AIS to monitor interfaces. In this manner, a MEP sends an AIS PDU immediately after the monitored interface goes Down. The MEP does not need to wait for the timeout of CCMs. In addition, the MEP in a high-level MD is suppressed from sending the same trap to the NMS.

NOTE

Both inward- and outward-facing MEPs can receive AIS PDUs in MD scenarios.

Precautions

The **ais link-status** command can be used on only the device running IEEE Standard 802.1ag-2007.

Prerequisites

An MD has been created using the **cfm md** command, an MA has been created using the **ma** command, and AIS has been enabled using the **ais enable** command.

Example

Create an MD named **md1**, create an MA named **ma1** in the MD, and configure AIS to monitor an interface in **ma1**.

```
<HUAWEI> system-view
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] ais link-status interface gigabitethernet 0/0/1
```

12.9.6 ais suppress-alarm

Function

The **ais suppress-alarm** command enables alarm suppression on the device.

The **undo ais suppress-alarm** command disables alarm suppression on the device.

By default, alarm suppression is disabled on the device.

NOTE

Only the S6730-S, S6730S-S, S6730-H, S6730S-H, S6720S-S, S6720-EI, S6720S-EI, S6735-S, S5731-S, S5731S-H, S5731S-S, S5732-H, S5731-H, S5735S-H, S5736-S, S5735-S-I, S5735S-S, S500, S5720I-SI and S5735-S support this command.

Format

ais suppress-alarm

undo ais suppress-alarm

Parameters

None

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In MD nesting scenarios, after a MEP in a high-level MD receives an AIS PDU, the MEP does not send an alarm to the NMS. If the MEP does not receive any AIS PDU within the period 3.5 times as long as the interval at which AIS PDUs are sent, the alarm suppression function is disabled automatically on the local device.

- If a MEP detects a link fault and sends an alarm to the NMS before receiving an AIS PDU, run the **ais suppress-alarm** command to enable the alarm suppression function. The MEP sends only an alarm indicating that the link fault is rectified if the MEP detects that the link fault is rectified.
- If a MEP does not detect a link fault before receiving an AIS PDU, after the **ais suppress-alarm** command is used to enable the alarm suppression function, the MEP does not send an alarm to the NMS if the MEP detects a link fault.

Precautions

The **ais suppress-alarm** command can be used on only the device running IEEE Standard 802.1ag-2007.

Prerequisites

An MD has been created using the **cfm md** command, an MA has been created using the **ma** command, and AIS has been enabled using the **ais enable** command.

Example

Create an MD named **md1**, create an MA named **ma1** in the MD, and enable alarm suppression in **ma1**.

```
<HUAWEI> system-view
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] ais suppress-alarm
```

12.9.7 ais vlan

Function

The **ais vlan** command sets the range of VLANs to which the MEP of an MA sends AIS PDUs.

The **undo ais vlan** command cancels the configuration.

NOTE

Only the S6730-S, S6730S-S, S6730-H, S6730S-H, S6720S-S, S6720-EI, S6720S-EI, S6735-S, S5731-S, S5731S-H, S5731S-S, S5732-H, S5731-H, S5735S-H, S5736-S, S5735-S-I, S5735S-S, S500, S5720I-SI and S5735-S support this command.

Format

ais vlan vid { *low-vid* [**to** *high-vid*] } &<1-10> **mep** *mep-id*

ais vlan pe-vid *pe-vid* **ce-vid** { *low-ce-vid* [**to** *high-ce-vid*] } &<1-10> **mep** *mep-id*

undo ais vlan vid { *low-vid* [**to** *high-vid*] } &<1-10> **mep** *mep-id*

undo ais vlan pe-vid *pe-vid* **ce-vid** { *low-ce-vid* [**to** *high-ce-vid*] } &<1-10> **mep** *mep-id*

undo ais vlan [**vid** | **pe-vid** *pe-vid*] **mep** *mep-id*

Parameters

Parameter	Description	Value
pe-vid *pe-vid*	Specifies the VLAN ID in the outer tag of a VLAN frame.	The value is an integer that ranges from 1 to 4094.
ce-vid *low-ce-vid*	Specifies the lower limit of the VLAN ID in the inner tag of a VLAN frame.	The value is an integer that ranges from 1 to 4094.
high-ce-vid	Specifies the upper limit of the VLAN ID in the inner tag of a VLAN frame.	The value is an integer that ranges from 1 to 4094.
vid *low-vid*	Specifies the lower limit of the VLAN ID in an AIS PDU.	The value is an integer that ranges from 1 to 4094.
high-vid	Specifies the upper limit of the VLAN ID in an AIS PDU.	The value is an integer that ranges from 1 to 4094.
mep *mep-id*	Specifies the ID of a MEP. The ID identifies a MEP. The MEP ID must be unique in an MA and in a VLAN.	The value is an integer that ranges from 1 to 8191.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **ais vlan** command to set the range of VLANs to which the AIS PDUs to be sent. This prevents the MEP from sending AIS PDUs to all VLANs and reduces the load of the system.

Precautions

The **ais vlan** command can be used on only the device running IEEE Standard 802.1ag-2007.

If the **ais vlan** command is run more than once, all configurations take effect.

Prerequisites

An MD has been created using the **cfm md** command, an MA has been created using the **ma** command, and AIS has been enabled using the **ais enable** command.

Example

Create an MD named **md1**, create an MA named **ma1** in the MD, and set the outer VLAN ID in outgoing AIS PDUs to 10 and set the inner VLAN ID range to 1 to 100.

```
<HUAWEI> system-view
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] ais vlan pe-vid 10 ce-vid 1 to 100 mep 1
```

Create an MD named **md1**, create an MA named **ma1** in the MD, and set the range of VLANs to which AIS PDUs are to be sent to 1 to 100 in **ma1**.

```
<HUAWEI> system-view
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] ais vlan vid 1 to 100 mep 1
```

12.9.8 delay-measure one-way continual

Function

The **delay-measure one-way continual** command configures proactive one-way frame delay measurement.

The **undo delay-measure one-way continual** command cancels the configuration.

By default, proactive one-way frame delay measurement is not configured in an MA.

Format

delay-measure one-way continual send mep *mep-id* { **mac** *mac-address* | **remote-mep** *mep-id* } **interval** { **1000** | **10000** | **30000** | **60000** | **150000** | **300000** }

undo delay-measure one-way continual send [**mep** *mep-id*]

Parameters

Parameter	Description	Value
mep *mep-id*	Specifies the ID of a MEP.	The value is an integer in the range from 1 to 8191.
mac *mac-address*	Specifies the MAC address of an RMEP.	-
remote-mep *mep-id*	Specifies the ID of an RMEP.	The value is an integer in the range from 1 to 8191.
interval { **1000** | **10000** | **30000** | **60000** | **150000** | **300000** }	Specifies the interval at which DM frames are sent.	The value is 1000, 10000, 30000, 60000, 150000, and 300000, in milliseconds.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Proactive OAM indicates that OAM actions are carried out continuously.

One-way frame delay measurement is implemented between two MEPs by exchanging DM frames. A MEP periodically sends DM frames carrying TxTimeStampf. After receiving a DM frame, the RMEP parses TxTimeStampf and compares this value with RxTimef (the time when the 1DM frame was received). The RMEP calculates the one-way frame delay based on these values using the following formula: Frame delay = RxTimef - TxTimeStampf

When clocks of the MEPs at both ends of a link are synchronized, the **delay-measure one-way continual** command can be used to implement proactive one-way frame delay measurement for a VLAN.

To implement proactive one-way frame delay measurement, specify the RMEP ID or destination MAC address, and interval at which DM frames are sent:

- If the local MEP has not learned the RMEP MAC address, you must specify the destination MAC address for frame delay measurement.
- If the local MEP has learned the RMEP MAC address, you can specify the RMEP ID for frame delay measurement.

Prerequisites

The command takes effect only after the following configurations are completed:

- Run the **cfm version standard** command in the system view to specify IEEE Standard 802.1ag-2007 for CFM.
- Run the **cfm enable (system view)** command to enable CFM globally.
- Run the **cfm md** command in the system view to create an MD.
- Run the **ma** command in the MD view to create an MA.
- Run the **mep mep-id** command in the MA view to create an inward-facing MEP.

If **remote-mep** *mep-id* is specified in the **delay-measure one-way continual** command, the following configurations must be completed:

- Run the **remote-mep** command in the MA view to create an RMEP.
- Run the **mep ccm-send enable** command in the MA view to enable the local MEP in the MA to send CCMs.
- Run the **remote-mep ccm-receive enable** command in the MA view to enable the MEP to receive CCMs from the RMEP in the same MA.

Precautions

- IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007.
- One-way frame delay measurement can be implemented only after the MEP synchronizes the time with its RMEP.

If the configuration changes during on-demand statistics, you can view only the pre-change statistics results. You are advised to run the command for on-demand statistics again for query.

Example

In a VLAN, enable proactive one-way frame delay measurement and set the destination MAC address to 01-22-33 and the interval at which DM frames are sent to 1000 ms.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 2
[HUAWEI-md-md1-ma-ma1] delay-measure one-way continual send mep 1 mac 01-22-33 interval 1000
```

In a VLAN, enable proactive one-way frame delay measurement and set the RMEP ID to 2 and the interval at which DM frames are sent to 1000 ms.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 2
[HUAWEI-md-md1-ma-ma1] delay-measure one-way continual send mep 1 remote-mep 2 interval
1000
```

12.9.9 delay-measure one-way continual receive

Function

The **delay-measure one-way continual receive** command configures the RMEP to receive DM frames to implement proactive one-way frame delay measurement.

The **undo delay-measure one-way continual receive** command cancels the configuration.

By default, the RMEP enabled with proactive one-way frame delay measurement in an MA is not configured to receive DM frames.

Format

delay-measure one-way continual receive mep *mep-id*

undo delay-measure one-way continual receive [**mep** *mep-id*]

Parameters

Parameter	Description	Value
mep *mep-id*	Specifies the ID of a MEP.	The value is an integer that ranges from 1 to 8191.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command is used in the VLAN scenario to enable the RMEP to receive DM frames to implement proactive one-way frame delay measurement.

Prerequisites

The command takes effect only after the following configurations are completed:

- Run the **cfm version standard** command in the system view to specify IEEE Standard 802.1ag-2007 for CFM.
- Run the **cfm enable (system view)** command to enable CFM globally.
- Run the **cfm md** command in the system view to create an MD.
- Run the **ma** command in the MD view to create an MA.
- Run the **mep mep-id** command in the MA view to create an inward-facing MEP.

Precautions

After the configuration is complete, the remote device can receive DMMs to implement proactive one-way frame delay measurement.

IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007.

Example

Configure the RMEP to receive DM frames in a VLAN.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md2
[HUAWEI-md-md2] ma ma2
[HUAWEI-md-md2-ma-ma2] map vlan 2
[HUAWEI-md-md2-ma-ma2] mep mep-id 2 interface gigabitethernet 0/0/1 inward
[HUAWEI-md-md2-ma-ma2] delay-measure one-way continual receive mep 2
```

12.9.10 delay-measure one-way send

Function

The **delay-measure one-way send** command configures on-demand one-way frame delay measurement.

By default, on-demand one-way frame delay measurement is not configured in an MA.

Format

delay-measure one-way send mep *mep-id* { **mac** *mac-address* | **remote-mep** *mep-id* } **interval** { **1000** | **10000** } **count** *count-value*

Parameters

Parameter	Description	Value
mac *mac-address*	Specifies the MAC address of an RMEP.	-
remote-mep *mep-id*	Specifies the ID of an RMEP.	The value is an integer that ranges from 1 to 8191.
interval	Specifies the interval at which DM frames are sent.	The value is 1000 or 10000, in milliseconds.
count *count-value*	Specifies the one-way frame delay measurement count. **NOTE** *count-value* must be configured. There is no default value.	The value is an integer that ranges from 1 to 60.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On-demand OAM indicates that OAM actions are initiated by manual configuration in a limited period of time. On-demand OAM may cause singular or periodic OAM actions during the diagnostic period. DM frames can be used for on-demand OAM to test the link delay.

One-way frame delay measurement is implemented between two MEPs by exchanging DM frames. A MEP periodically sends DM frames carrying

TxTimeStampf. After receiving a DM frame, the RMEP parses TxTimeStampf and compares this value with RxTimef (the time when the 1DM frame was received). The RMEP calculates the one-way frame delay based on these values using the following formula: Frame delay = RxTimef - TxTimeStampf

Prerequisites

The command takes effect only after the following configurations are completed:

- Run the **cfm version standard** command in the system view to specify IEEE Standard 802.1ag-2007 for CFM.
- Run the **cfm enable (system view)** command to enable CFM globally.
- Run the **cfm md** command in the system view to create an MD.
- Run the **ma** command in the MD view to create an MA.
- In a VLAN, outward-facing MEPs are supported. Perform the following operation to create a MEP in the MA view:
  - Run the **mep mep-id** command with *outward* specified to create an outward-facing MEP.

If **remote-mep** *mep-id* is specified in the **delay-measure one-way mep** command, the following configurations must be completed:

- Run the **remote-mep** command in the MA view to create an RMEP.
- Run the **mep ccm-send enable** command in the MA view to enable the local MEP in the MA to send CCMs.
- Run the **remote-mep ccm-receive enable** command in the MA view to enable the MEP to receive CCMs from the RMEP in the same MA.

Precautions

- One-way frame delay measurement can be implemented only after the MEP synchronizes the time with its RMEP.
- To implement one-way frame delay measurement, specify the RMEP ID or destination MAC address, interval at which DM frames are sent, and measurement count:
  - If the local MEP has not learned the RMEP MAC address, you must specify the destination MAC address for one-way frame delay measurement.
  - If the local MEP has learned the RMEP MAC address, you can specify the RMEP ID for one-way frame delay measurement.
- IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007.

If the configuration changes during on-demand statistics, you can view only the pre-change statistics results. You are advised to run the command for on-demand statistics again for query.

Example

In a VLAN, enable one-way frame delay measurement and set the destination MAC address to 01-22-33, interval at which DM frames are sent to 10000 ms, and measurement count to 60.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 2
[HUAWEI-md-md1-ma-ma1] delay-measure one-way send mep 1 mac 01-22-33 interval 10000 count 60
```

In a VLAN, enable one-way frame delay measurement and set the RMEP ID to 2, interval at which DM frames are sent to 10000 ms, and measurement count to 60.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 2
[HUAWEI-md-md1-ma-ma1] delay-measure one-way send mep 1 remote-mep 2 interval 10000 count
60
```

12.9.11 delay-measure one-way receive

Function

The **delay-measure one-way receive** command enables the RMEP to receive DM frames to implement one-way frame delay measurement.

The **undo delay-measure one-way receive** command cancels the configuration.

By default, the RMEP is not enabled to receive DM frames.

Format

delay-measure one-way receive mep *mep-id*

undo delay-measure one-way receive [**mep** *mep-id*]

Parameters

Parameter	Description	Value
mep *mep-id*	Specifies the ID of a MEP.	The value is an integer that ranges from 1 to 8191.

Views

MA view

Default Level

Usage Guidelines

Usage Scenario

This command is used in a VLAN to enable the RMEP to receive DM frames to implement one-way frame delay measurement.

Prerequisites

The command takes effect only after the following configurations are completed:

- Run the **cfm version standard** command in the system view to specify IEEE Standard 802.1ag-2007 for CFM.
- Run the **cfm enable (system view)** command to enable CFM globally.
- Run the **cfm md** command in the system view to create an MD.
- Run the **ma** command in the MD view to create an MA.
- Run the **mep mep-id** command in the MA view to create an inward-facing MEP.

Precautions

IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007.

Example

Configure the RMEP to receive DM frames in a VLAN.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md3
[HUAWEI-md-md3] ma ma3
[HUAWEI-md-md3-ma-ma3] map vlan 10
[HUAWEI-md-md3-ma-ma3] mep mep-id 3 interface gigabitethernet 0/0/1 inward
[HUAWEI-md-md3-ma-ma3] delay-measure one-way receive mep 3
```

12.9.12 delay-measure one-way threshold

Function

The **delay-measure one-way threshold** command sets the alarm threshold for one-way frame delay measurement.

The **undo delay-measure one-way threshold** command cancels the configuration.

Format

delay-measure one-way threshold *threshold-value*

undo delay-measure one-way threshold

Parameters

Parameter	Description	Value
threshold-value	Specifies the alarm threshold for one-way frame delay measurement.	The value is an integer that ranges from 1 to 4294967295, in microseconds.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **delay-measure one-way threshold** command sets an alarm threshold for one-way frame delay measurement between a MEP and an RMEP. When the one-way frame delay exceeds the alarm threshold, an alarm is generated.

Precautions

IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007.

This command is applicable to VLANs.

NOTE

Before setting the alarm threshold, you must correctly configure the MD and MA.

Example

Set the alarm threshold for one-way frame delay measurement in the VLAN to 10.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 100
[HUAWEI-md-md1-ma-ma1] delay-measure one-way threshold 10
```

12.9.13 delay-measure two-way continual

Function

The **delay-measure two-way continual** command configures proactive two-way frame delay measurement.

The **undo delay-measure two-way continual** command cancels the configuration.

By default, proactive two-way frame delay measurement is not configured in an MA.

Format

delay-measure two-way continual send mep *mep-id* { **mac** *mac-address* | **remote-mep** *mep-id* } **interval** { **1000** | **10000** | **30000** | **60000** | **150000** | **300000** }

undo delay-measure two-way continual send [**mep** *mep-id*]

Parameters

Parameter	Description	Value
mep *mep-id*	Specifies the ID of a MEP.	The value is an integer that ranges from 1 to 8191.
mac *mac-address*	Specifies the MAC address of an RMEP.	-
remote-mep *mep-id*	Specifies the ID of an RMEP.	The value is an integer that ranges from 1 to 8191.
interval { **1000** | **10000** | **30000** | **60000** | **150000** | **300000** }	Specifies the interval at which DMMs frames are sent.	The value is 1000, 10000, 30000, 60000, 150000, and 300000, in milliseconds.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Proactive OAM indicates that OAM actions are carried out continuously.

Two-way frame delay measurement is performed by a local MEP to send a DMM to its RMEP and then receive a DMR from the RMEP. After the two-way frame delay measurement is configured, a MEP periodically sends DMMs carrying TxTimeStampf (the time when the DMM was sent). After receiving the DMM, the RMEP replies with a DMR. The DMR carries RxTimeStampf (the time when the DMM was received) and TxTimeStampb (the time when the DMR was sent). The value in every field of the DMM is copied to the DMR except that the source and destination MAC addresses were interchanged. Upon receiving the DMR, the MEP calculates the two-way frame delay by using the following formula: Frame delay = (RxTimeb - TxTimeStampf) - (TxTimeStampb - RxTimeStampf)

When clocks of the MEPs at both ends of a link are not synchronized, the **delay-measure two-way continual** command can be used to implement proactive two-way frame delay measurement for a VLAN.

To implement proactive two-way frame delay measurement, you need to specify the RMEP ID or destination MAC address, interval at which DMMs are sent, and measurement count:

- If the local MEP has not learned the RMEP MAC address, you must specify the destination MAC address for two-way frame delay measurement.

- If the local MEP has learned the RMEP MAC address, you can specify the RMEP ID for two-way frame delay measurement.

Prerequisites

The command takes effect only after the following configurations are completed:

- Run the **cfm version standard** command in the system view to specify IEEE Standard 802.1ag-2007 for CFM.
- Run the **cfm enable (system view)** command to enable CFM globally.
- Run the **cfm md** command in the system view to create an MD.
- Run the **ma** command in the MD view to create an MA.
- Run the **mep mep-id** command with *inward* specified in the MA view to create an inward-facing MEP.

If **remote-mep** *mep-id* is specified in the **delay-measure two-way continual** command, the following configurations need to be completed in addition to the preceding configurations:

- Run the **remote-mep** command in the MA view to create an RMEP.
- Run the **mep ccm-send enable** command in the MA view to enable the local MEP in the MA to send CCMs.
- Run the **remote-mep ccm-receive enable** command in the MA view to enable the MEP to receive CCMs from the RMEP in the same MA.

Precautions

IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007.

Example

In a VLAN, enable proactive two-way frame delay measurement and set the destination MAC address to 01-22-33 and the interval at which DMMs are sent to 30s.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 2
[HUAWEI-md-md1-ma-ma1] delay-measure two-way continual send mep 1 mac 01-22-33 interval
30000
```

In a VLAN, enable proactive two-way frame delay measurement and set the RMEP ID to 2 and the interval at which DMMs are sent to 30s.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 2
[HUAWEI-md-md1-ma-ma1] delay-measure two-way continual send mep 1 remote-mep 2 interval
30000
```

12.9.14 delay-measure two-way continual send test-id

Function

The **delay-measure two-way continual send test-id** command configures two-way proactive frame delay measurement (DM).

The **undo delay-measure two-way continual send test-id** command deletes the configuration.

By default, two-way proactive frame DM is not configured in an MA.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

delay-measure two-way continual send test-id *test-id* **interval** { **1000** | **10000** | **15000** | **30000** } [**packet-size** *packet-size*]

undo delay-measure two-way continual send test-id *test-id*

Parameters

Parameter	Description	Value
test-id	Specifies the ID of a test instance.	The value is an integer ranging from 1 to 4294967295.
interval { **1000** | **10000** | **15000** | **30000** }	Specifies the interval at which DMMs are sent.	Enumerated value, in milliseconds: ● 1000 ● 10000 ● 15000 ● 30000
packet-size *packet-size*	Specifies the size of the sent packets.	The value is an integer ranging from 64 to 1518, in bytes. The default value is 64.

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In VLAN scenarios, to implement two-way proactive frame DM, run the **delay-measure two-way continual** command. This command does not take effect in point-to-multipoint link scenarios. To implement two-way proactive frame DM for point-to-multipoint links, run the **delay-measure two-way continual send test-id** command.

Prerequisites

A test instance has been created using the **test-id** command in the MA view.

Precautions

The **delay-measure two-way continual send test-id** and **delay-measure two-way continual** commands are mutually exclusive.

Example

Configure two-way proactive frame DM with the test instance of 1 and DMM transmission interval of 30s.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 100
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] set service-mode enhanced
Warning: This command will effect forward performance. Continue? [Y/N]:y
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 100
[HUAWEI-md-md1-ma-ma1] mep mep-id 1 interface gigabitethernet 0/0/1 inward
[HUAWEI-md-md1-ma-ma1] remote-mep mep-id 2
[HUAWEI-md-md1-ma-ma1] mep ccm-send enable
[HUAWEI-md-md1-ma-ma1] remote-mep ccm-receive enable
[HUAWEI-md-md1-ma-ma1] test-id 1 mep 1 remote-mep 2
[HUAWEI-md-md1-ma-ma1] delay-measure two-way continual send test-id 1 interval 30000
```

12.9.15 delay-measure two-way delay-threshold test-id

Function

The **delay-measure two-way delay-threshold test-id** command configures alarm thresholds for two-way proactive frame delay measurement (DM).

The **undo delay-measure two-way delay-threshold test-id** command deletes the alarm thresholds configured for two-way proactive frame DM.

By default, no alarm thresholds are configured for two-way proactive frame DM.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

delay-measure two-way delay-threshold test-id *test-id* **upper-limit** *upper-limit* **lower-limit** *lower-limit*

undo delay-measure two-way delay-threshold test-id *test-id* [**upper-limit** *upper-limit* **lower-limit** *lower-limit*]

Parameters

Parameter	Description	Value
test-id	Specifies the ID of a test instance.	The value is an integer ranging from 1 to 4294967295.
upper-limit *upper-limit*	Specifies an upper alarm threshold for two-way proactive frame DM.	The value is an integer ranging from 0 to 4294967295, in microseconds.
lower-limit *lower-limit*	Specifies a lower alarm threshold for two-way proactive frame DM.	The value is an integer ranging from 0 to 4294967295, in microseconds. The lower alarm threshold must be less than the upper alarm threshold.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure upper and lower alarm thresholds for two-way proactive frame DM that monitors link quality, run the **delay-measure two-way delay-threshold test-id** command. After configuring upper and lower alarm thresholds, you can obtain data (such as the number of times that a threshold-crossing event occurs) within a sampling period to monitor network performance.

Prerequisites

A test instance has been created using the **test-id** command in the MA view.

Precautions

Thresholds can be configured only for two-way proactive frame DM and cannot be configured for two-way on-demand frame DM.

Example

Set lower and upper alarm thresholds for two-way proactive frame DM in VLAN scenarios to 200 microseconds and 400 microseconds, respectively.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 100
[HUAWEI-GigabitEthernet0/0/1] quit
```

```
[HUAWEI] set service-mode enhanced
Warning: This command will effect forward performance. Continue? [Y/N]:y
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 100
[HUAWEI-md-md1-ma-ma1] mep mep-id 1 interface gigabitethernet 0/0/1 inward
[HUAWEI-md-md1-ma-ma1] remote-mep mep-id 2
[HUAWEI-md-md1-ma-ma1] mep ccm-send enable
[HUAWEI-md-md1-ma-ma1] remote-mep ccm-receive enable
[HUAWEI-md-md1-ma-ma1] test-id 1 mep 1 remote-mep 2
[HUAWEI-md-md1-ma-ma1] delay-measure two-way delay-threshold test-id 1 upper-limit 400 lower-limit 200
```

12.9.16 delay-measure two-way send

Function

The **delay-measure two-way send** command configures on-demand two-way frame delay measurement.

By default, on-demand two-way frame delay measurement is not configured in an MA.

Format

delay-measure two-way send mep *mep-id* { **mac** *mac-address* | **remote-mep** *mep-id* } **interval** { **1000** | **10000** } **count** *count-value*

Parameters

Parameter	Description	Value
mep *mep-id*	Specifies the ID of a MEP.	The value is an integer that ranges from 1 to 8191.
mac *mac-address*	Specifies the MAC address of an RMEP.	-
remote-mep *mep-id*	Specifies the ID of an RMEP.	The value is an integer that ranges from 1 to 8191.
interval	Specifies the interval at which DMMs are sent.	The value is 1000 or 10000, in milliseconds.
count *count-value*	Specifies the number of sent DMMs.	The value is an integer that ranges from 1 to 60.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On-demand OAM indicates that OAM actions are initiated by manual configuration in a limited period of time. On-demand OAM may cause singular or periodic OAM actions during the diagnostic period. DM frames can be used for on-demand OAM to test the link delay.

Two-way frame delay measurement is performed by a local MEP to send a DMM to its RMEP and then receive a DMR from the RMEP. After the two-way frame delay measurement is configured, a MEP periodically sends DMMs carrying TxTimeStampf (the time when the DMM was sent). After receiving the DMM, the RMEP replies with a DMR. The DMR carries RxTimeStampf (the time when the DMM was received) and TxTimeStampb (the time when the DMR was sent). The value in every field of the DMM is copied to the DMR except that the source and destination MAC addresses were interchanged. Upon receiving the DMR, the MEP calculates the two-way frame delay by using the following formula: Frame delay = (RxTimeb - TxTimeStampf) - (TxTimeStampb - RxTimeStampf)

Prerequisites

The command takes effect only after the following configurations are completed:

- Run the **cfm version standard** command in the system view to specify IEEE Standard 802.1ag-2007 for CFM.
- Run the **cfm enable (system view)** command to enable CFM globally.
- Run the **cfm md** command in the system view to create an MD.
- Run the **ma** command in the MD view to create an MA.

If **remote-mep** *mep-id* is specified in this command, the following configurations need to be completed in addition to the preceding configurations:

- Run the **remote-mep** command in the MA view to create an RMEP.
- Run the **mep ccm-send enable** command in the MA view to enable the local MEP in the MA to send CCMs.
- Run the **remote-mep ccm-receive enable** command in the MA view to enable the MEP to receive CCMs from the RMEP in the same MA.

Precautions

- IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007.
- To implement on-demand two-way frame delay measurement, you need to specify the RMEP ID or destination MAC address, interval at which DMMs are sent, and measurement count:
  - If the local MEP has not learned the RMEP MAC address, you must specify the destination MAC address for two-way frame delay measurement.
  - If the local MEP has learned the RMEP MAC address, you can specify the RMEP ID for two-way frame delay measurement.

If the configuration changes during on-demand statistics, you can view only the pre-change statistics results. You are advised to run the command for on-demand statistics again for query.

Example

In a VLAN, enable on-demand two-way frame delay measurement and set the destination MAC address to 01-22-33, interval at which DMMs are sent to 10000 ms, and measurement count to 60.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 100
[HUAWEI-md-md1-ma-ma1] delay-measure two-way send mep 1 mac 01-22-33 interval 10000 count
60
```

In a VLAN, enable on-demand two-way frame delay measurement and set the RMEP ID to 2, interval at which DMMs are sent to 10000 ms, and measurement count to 60.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 100
[HUAWEI-md-md1-ma-ma1] delay-measure two-way send mep 1 remote-mep 2 interval 10000 count
60
```

12.9.17 delay-measure two-way receive

Function

The **delay-measure two-way receive** command enables the RMEP to receive DMMs to implement two-way frame delay measurement.

The **undo delay-measure two-way receive** command cancels the configuration.

By default, the RMEP in an MA is not enabled to receive DMMs.

Format

delay-measure two-way receive mep *mep-id*

undo delay-measure two-way receive [**mep** *mep-id*]

Parameters

Parameter	Description	Value
mep *mep-id*	Specifies the ID of a MEP.	The value is an integer that ranges from 1 to 8191.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command is used to enable the RMEP to receive DMMs to implement proactive or on-demand two-way frame delay measurement. This command is used in a VLAN where an outward-facing MEP is configured with two-way frame delay measurement.

Prerequisites

The command takes effect only after the following configurations are completed:

- Run the **cfm version standard** command in the system view to specify IEEE Standard 802.1ag-2007 for CFM.
- Run the **cfm enable (system view)** command to enable CFM globally.
- Run the **cfm md** command in the system view to create an MD.
- Run the **ma** command in the MD view to create an MA.
- Run the **remote-mep** command in the MA view to create an RMEP.

Precautions

IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007.

Example

Enable the RMEP to receive DMMs in the MA **ma1** and MD **md1**, with the VLAN ID as 100.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 100
[HUAWEI-md-md1-ma-ma1] mep mep-id 1 interface gigabitethernet 0/0/1 outward
[HUAWEI-md-md1-ma-ma1] delay-measure two-way receive mep 1
```

12.9.18 delay-measure two-way receive test-id

Function

The **delay-measure two-way receive test-id** command enables a Remote Maintenance Association End Point (RMEP) to receive Delay Measure Messages (DMMs) for two-way frame delay measurement (DM).

The **undo delay-measure two-way receive test-id** command disables an RMEP from receiving DMMs for two-way frame DM.

By default, the RMEP in a Maintenance Association (MA) is disabled from receiving DMMs.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

delay-measure two-way receive test-id *test-id*

undo delay-measure two-way receive [**test-id** *test-id*]

Parameters

Parameter	Description	Value
test-id	Specifies the ID of a test instance.	The value is an integer ranging from 1 to 4294967295.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After running the **delay-measure two-way continual send test-id** or **delay-measure two-way send test-id** command to enable a MEP to send DMMs for two-way frame DM, run the **delay-measure two-way receive test-id** command to enable the RMEP to receive DMMs.

Prerequisites

A test instance has been created using the **test-id** command in the MA view.

Precautions

The **delay-measure two-way receive test-id** and **delay-measure two-way receive** commands are mutually exclusive.

Example

Enable the RMEP to receive DMMs for two-way frame DM with the test instance of 1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 100
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] set service-mode enhanced
Warning: This command will effect forward performance. Continue? [Y/N]:y
[HUAWEI] cfm enable
```

```
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 100
[HUAWEI-md-md1-ma-ma1] mep mep-id 1 interface gigabitethernet 0/0/1 inward
[HUAWEI-md-md1-ma-ma1] remote-mep mep-id 2
[HUAWEI-md-md1-ma-ma1] test-id 1 mep 1 remote-mep 2
[HUAWEI-md-md1-ma-ma1] delay-measure two-way receive test-id 1
```

12.9.19 delay-measure two-way send test-id

Function

The **delay-measure two-way send test-id** command configures on-demand two-way frame delay measurement based on the test instance.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

delay-measure two-way send test-id *test-id* **interval** { **1000** | **10000** } **count** *count* [**packet-size** *packet-size*]

Parameters

Parameter	Description	Value
test-id	Specifies the ID of a test instance.	The value is an integer ranging from 1 to 4294967295.
interval { **1000** | **10000** }	Specifies the interval at which DMMs are sent.	The value is either 1000 or 10000, expressed in milliseconds.
count *count*	Specifies the number of times that DMMs are sent.	The value is an integer ranging from 1 to 60.
packet-size *packet-size*	Specifies the size of the sent packets.	The value is an integer ranging from 64 to 1518, in bytes. The default value is 64.

Usage Guidelines

Usage Scenario

In VLAN scenarios, to implement two-way on-demand frame DM, run the **delay-measure two-way send** command. This command does not take effect in point-to-multipoint link scenarios.

To implement two-way on-demand frame DM for point-to-multipoint links, run the **delay-measure two-way send test-id** command.

Prerequisites

A test instance has been created using the **test-id** command in the MA view.

Precautions

The **delay-measure two-way send test-id** and **delay-measure two-way send** commands are mutually exclusive.

If the configuration changes during on-demand statistics, you can view only the pre-change statistics results. You are advised to run the command for on-demand statistics again for query.

Example

Configure two-way frame DM with the test instance ID of 1, DMM transmission interval of 10s, and measurement times of 60.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 100
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] set service-mode enhanced
Warning: This command will effect forward performance. Continue? [Y/N]:y
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 100

Usage Guidelines

Usage Scenario

This command is applicable to VLANs. You can set the alarm threshold for two-way frame delay measurement on the MEP or RMEP. When the two-way delay exceeds the alarm threshold, an alarm is generated.

Precautions

IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007.

NOTE

Before setting the alarm threshold, you must correctly configure the MD and MA.

Example

Set the alarm threshold for two-way frame delay measurement in the VLAN to 10.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 100
[HUAWEI-md-md1-ma-ma1] delay-measure two-way threshold 10
```

12.9.21 delay-measure two-way trigger if-down

Function

The **delay-measure two-way trigger if-down** command triggers an interface to go ETHOAM down when the delay or delay variation based on a test instance ID exceeds a specified threshold.

The **undo delay-measure two-way trigger if-down** command restores the default configuration.

By default, an interface is not triggered to go ETHOAM down when the delay or delay variation based on a test instance ID exceeds a specified threshold.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

delay-measure two-way { **delay-threshold** | **variation-threshold** } **test-id** *test-id* **trigger if-down**

undo delay-measure two-way { **delay-threshold** | **variation-threshold** } **test-id** *test-id* **trigger if-down**

Parameters

Parameter	Description	Value
delay-threshold	Indicates that an interface is triggered to go ETHOAM down when the delay exceeds a specified threshold.	-
variation-threshold	Indicates that an interface is triggered to go ETHOAM down when the delay variation exceeds a specified threshold.	-
test-id *test-id*	Specifies the ID of a test instance.	The value is an integer that ranges from 1 to 4294967295.

2: Configuration level

Usage Guidelines

Usage Scenario

When no service is bound to the MA, the interface where the MEP resides is an Eth-Trunk interface's primary member interface. To ensure the quality of the primary link, run the **delay-measure two-way trigger if-down** command on the interface where the MEP resides. If the delay or delay variation based on a test instance ID exceeds the threshold configured using the **delay-measure two-way delay-threshold test-id** or **delay-measure two-way variation-threshold test-id** command, the primary link has poor quality. In this case, the interface is triggered to go ETHOAM down, triggering an active/standby Eth-Trunk link switchover.

Prerequisites

A test instance has been created using the **test-id** command in the MA view.

Example

Trigger the Eth-Trunk member interface GE 0/0/1 to go Down when the two-way delay based on a test instance ID of 2 exceeds a specified threshold.

```
<HUAWEI> system-view
[HUAWEI] set service-mode enhanced
Warning: This command will effect forward performance. Continue? [Y/N]:y
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] mep mep-id 8 interface gigabitethernet 0/0/1 outward
[HUAWEI-md-md1-ma-ma1] remote-mep mep-id 9
[HUAWEI-md-md1-ma-ma1] test-id 2 mep 8 remote-mep 9
[HUAWEI] interface eth-trunk 1
[HUAWEI-Eth-Trunk1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] eth-trunk 1
[HUAWEI-GigabitEthernet0/0/1] delay-measure two-way delay-threshold test-id 2 trigger if-down
```

12.9.22 delay-measure two-way variation-threshold test-id

Function

The **delay-measure two-way variation-threshold test-id** command configures variation thresholds for two-way proactive frame delay measurement (DM).

The **undo delay-measure two-way variation-threshold test-id** command deletes the variation thresholds configured for two-way proactive frame DM.

By default, no variation thresholds are configured for two-way proactive frame DM.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

delay-measure two-way variation-threshold test-id *test-id* **upper-limit** *upper-limit* **lower-limit** *lower-limit*

undo delay-measure two-way variation-threshold test-id *test-id* [**upper-limit** *upper-limit* **lower-limit** *lower-limit*]

Parameters

Parameter	Description	Value
test-id	Specifies the ID of a test instance.	The value is an integer ranging from 1 to 4294967295.

Parameter	Description	Value
upper-limit *upper-limit*	Specifies an upper variation threshold for two-way proactive frame DM.	The value is an integer ranging from 0 to 4294967295, in microseconds.
lower-limit *lower-limit*	Specifies a lower variation threshold for two-way proactive frame DM.	The value is an integer ranging from 0 to 4294967295, in microseconds. The lower variation threshold must be less than the upper variation threshold.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure upper and lower variation thresholds for two-way proactive frame DM that monitors link quality, run the **delay-measure two-way variation-threshold test-id** command. After configuring upper and lower variation thresholds, you can obtain data (such as the number of times that a threshold-crossing event occurs) within a sampling period to monitor network performance.

Prerequisites

A test instance has been created using the **test-id** command in the MA view.

Precautions

The configured threshold makes sense only after the proactive measurement is configured.

Example

Set lower and upper variation thresholds for two-way proactive frame DM in VLAN scenarios to 200 microseconds and 400 microseconds, respectively.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 100
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] set service-mode enhanced
Warning: This command will effect forward performance. Continue? [Y/N]:y
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 100
[HUAWEI-md-md1-ma-ma1] mep mep-id 1 interface gigabitethernet 0/0/1 inward
[HUAWEI-md-md1-ma-ma1] remote-mep mep-id 2
```

```
[HUAWEI-md-md1-ma-ma1] mep ccm-send enable
[HUAWEI-md-md1-ma-ma1] remote-mep ccm-receive enable
[HUAWEI-md-md1-ma-ma1] test-id 1 mep 1 remote-mep 2
[HUAWEI-md-md1-ma-ma1] delay-measure two-way variation-threshold test-id 1 upper-limit 400
lower-limit 200
```

12.9.23 display y1731 statistic-type

Function

The **display y1731 statistic-type** command displays performance statistics collected through Y.1731.

Format

display y1731 statistic-type { **oneway-delay** | **twoway-delay** } **md** *md-name* **ma** *ma-name* [**count** *count-value*]

display y1731 statistic-type { **single-loss** | **dual-loss** } **md** *md-name* **ma** *ma-name* [**count** *count-value*] (Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.)

display y1731 statistic-type single-loss test-id *test-id* [**count** *count-value*] (Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.)

display y1731 statistic-type single-synthetic-loss test-id *test-id* [**count** *count-value*] (Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.)

display y1731 statistic-type twoway-delay test-id *test-id* [**count** *count-value*] (Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.)

Parameters

Parameter	Description	Value
dual-loss	Displays statistics about dual-ended frame loss measurement.	-
single-loss	Displays statistics about single-ended frame loss measurement.	-
oneway-delay	Displays statistics about the one-way frame delay.	-
twoway-delay	Displays statistics about the two-way frame delay.	-

Parameter	Description	Value
md *md-name*	Specifies the name of an MD.	The value is a string of 1 to 43 characters without spaces, hyphens (-), and question marks (?). MD names on a device are unique.
ma *ma-name*	Specifies the name of an MA.	The value is a string of characters without spaces, hyphens (-), and question marks (?). The total length of the names of the MA and MD must be within 44 characters. Names of MAs in an MD are unique.
count *count-value*	Specifies the number of statistics entries to be displayed. If the parameter is not specified, the command output displays all the statistics.	The value is an integer in the range from 1 to 60.
test-id *test-id*	Specifies the ID of a test instance.	The value is an integer in the range from 1 to 4294967295.
single-synthetic-loss	Displays statistics about single-ended SLM.	-

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run the **display y1731 statistic-type** command to display performance statistics collected through Y.1731, including single-ended frame loss statistics, dual-ended frame loss statistics, single-ended SLM statistics, one-way frame delay statistics, and two-way frame delay statistics.

Prerequisites

The **cfm enable (system view)** command has been run to enable the CFM function globally.

Example

Display the statistics about the one-way frame delay in the MA **ma1** in the MD **md1**.

```
<HUAWEI> display y1731 statistic-type oneway-delay md md1 ma ma1
Latest one-way delay statistics:
--------------------------------------------------------------------------------
Index    Delay(usec)     Delay variation(usec)
--------------------------------------------------------------------------------
    1         10000                    -
    2         10000                    0
    3         10000                    0
    4         10000                    0
    5         10000                    0
    6         10000                    0
    7         10000                    0

12.9.24 display y1731 test-info

Function

The **display y1731 test-info** command displays information about test instances for Y.1731 statistics collection.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display y1731 test-info [**test-id** *test-id*]

Parameters

Parameter	Description	Value
test-id *test-id*	Displays information about a specified test instance.	The value is an integer ranging from 1 to 4294967295.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view information about test instances for Y.1731 statistics collection, run the **display y1731 test-info** command.

Example

Display information about test instance 1 for Y.1731 statistics collection on a device.

```
<HUAWEI> display y1731 test-info test-id 1
-----------------------------------------------------------
 TestId 1 information:
-----------------------------------------------------------
 MD Name                      : md1
 MA Name                      : ma
 MEP ID                       : 1
 Local Mac                    : xxxx-xxxx-xxxx
 Remote MEP ID                : 2

 Single SLM Receive           : disabled
 Single SLM RecvTimeout       : --
```

Table 12-77 Description of the **display y1731 test-info** command output

Item	Description
TestId 1 information	Information about test instance 1.
MD Name	Name of the MD.
MA Name	Name of the MA.
MEP ID	MEP ID.
Local Mac	Local MAC address.

Item	Description
Remote MEP ID	RMEP ID.
Bind Mac	MAC address of the RMEP.
Send Mac	MAC address carried in frames.
8021p	802.1p priority value specified in a specified test instance. To set the 802.1p priority value specified in a specified test instance, run the **test-id** command.
Uplink 8021p	Priority value of upstream packets. The switch does not support this function.
Downlink 8021p	Priority value of downstream packets. The switch does not support this function.
Single LM	Whether Y.1731 packet sending is enabled for single-ended frame LM. ● enabled ● disabled To enable Y.1731 packet sending for single-ended frame LM, run the **loss-measure single-ended send test-id** or **loss-measure single-ended continual send test-id** command.
Single LM Interval	Interval at which Y.1731 packets are sent for single-ended frame LM. To set the interval at which Y.1731 packets are sent for single-ended frame LM, run the **loss-measure single-ended send test-id** or **loss-measure single-ended continual send test-id** command.
Single LM Count	Number of Y.1731 packets that are to be sent for single-ended frame LM. To set the number of Y.1731 packets sent for single-ended frame LM, run the **loss-measure single-ended send test-id** command.
Single LM Receive	Whether Y.1731 packet receiving is enabled for single-ended frame LM. ● enabled ● disabled To enable SLM frame sending for single-ended SLM, run the **loss-measure single-ended receive test-id** command.

Item	Description
OneWay DM	Whether Y.1731 packet sending is enabled for one-way frame DM. - enabled - disabled The switch does not support one-way frame delay measurement based on test instances.
OneWay DM Interval	Interval at which Y.1731 packets are sent for one-way frame DM. The switch does not support one-way frame delay measurement based on test instances.
OneWay DM Count	Number of Y.1731 packets sent for one-way frame DM. The switch does not support one-way frame delay measurement based on test instances.
OneWay DM Packet Size	Size of Y.1731 packets transmitted for one-way frame DM. The switch does not support one-way frame delay measurement based on test instances.
OneWay DM Receive	Whether Y.1731 packet receiving is enabled for one-way frame DM. - enabled - disabled The switch does not support one-way frame delay measurement based on test instances.
TwoWay DM	Whether Y.1731 packet sending is enabled for two-way frame DM. - enabled - disabled To enable Y.1731 packet sending for two-way frame DM, run the **delay-measure two-way send test-id** or **delay-measure two-way continual send test-id** command.

Item	Description
TwoWay DM Interval	Interval at which Y.1731 packets are sent for two-way frame DM. To set the interval at which Y.1731 packets are sent for two-way frame DM, run the **delay-measure two-way send test-id** or **delay-measure two-way continual send test-id** command.
TwoWay DM Count	Number of Y.1731 packets sent for two-way frame DM. To set the number of Y.1731 packets sent for two-way frame DM, run the **delay-measure two-way send test-id** command.
TwoWay DM Packet Size	Size of Y.1731 packets transmitted for two-way frame DM. To set the size of Y.1731 packets transmitted for two-way frame DM, run the **delay-measure two-way send test-id** or **delay-measure two-way continual send test-id** command.
TwoWay DM Receive	Whether Y.1731 packet receiving is enabled for two-way frame DM. ● enabled ● disabled To enable Y.1731 packet receiving for two-way frame DM, run the **delay-measure two-way receive test-id** command.
Single SLM	Whether Y.1731 packet sending is enabled for single-ended SLM. ● enabled ● disabled To enable Y.1731 packet sending for single-ended SLM, run the **loss-measure single-ended-synthetic send** or **loss-measure single-ended-synthetic continual send** command.
Single SLM Interval	Interval at which SLM frames are sent for single-ended SLM. To set the interval at which SLM frames are sent for single-ended SLM, run the **loss-measure single-ended-synthetic send** or **loss-measure single-ended-synthetic continual send** command.

Item	Description
Single SLM SendingCount	Number of SLM frames to be sent for single-ended SLM within each measurement period. To set the number of SLM frames to be sent for single-ended SLM within each measurement period, run the **loss-measure single-ended-synthetic send** or **loss-measure single-ended-synthetic continual send** command.
Single SLM SendTimeout	Timeout period for the transmit end to receive SLM frames. To set the timeout period for the transmit end to receive SLM frames, run the **loss-measure single-ended-synthetic send** or **loss-measure single-ended-synthetic continual send** command.
Single SLM Receive	Whether SLM frame sending is enabled for single-ended SLM. ● enabled ● disabled To enable SLM frame sending for single-ended SLM, run the **loss-measure single-ended-synthetic receive** command.
Single SLM RecvTimeout	Timeout period for the receive end to receive SLM frames. To set the timeout period for the receive end to receive SLM frames, run the **loss-measure single-ended-synthetic receive** command.

12.9.25 loss-measure dual-ended continual

Function

The **loss-measure dual-ended continual** command enables proactive dual-ended frame loss measurement.

The **undo loss-measure dual-ended continual** command disables proactive dual-ended frame loss measurement.

By default, dual-ended frame loss measurement is disabled.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

loss-measure dual-ended continual mep *mep-id* **remote-mep** *mep-id*

undo loss-measure dual-ended continual [**mep** *mep-id* [**remote-mep** *mep-id*]]

Parameters

Parameter	Description	Value
mep-id *mep-id*	Specifies the ID of a MEP.	The value is an integer in the range from 1 to 8191.
remote-mep *mep-id*	Specifies the ID of an RMEP.	The value is an integer in the range from 1 to 8191.

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The dual-ended frame loss measurement function is service-oriented. You can estimate quality of services based on the calculated packet loss rate.

Dual-ended frame loss measurement is deployed on end-to-end MEPs. In Y.1731, frame loss statistics are collected based on the transmit and receive counters carried in CCMs.

NOTE

The interval for collecting dual-ended frame loss statistics does not need to be configured separately, because it equals the interval at which CCMs are sent.

Prerequisites

The command takes effect only after the following configurations are completed:

- Run the **cfm version standard** command in the system view to specify IEEE Standard 802.1ag-2007 for CFM.
- Run the **cfm enable (system view)** command to enable CFM globally.
- Run the **cfm md** command in the system view to create an MD.
- Run the **ma** command in the MD view to create an MA.
- Run the **mep mep-id** command in the MA view to create an inward-facing MEP.

If **remote-mep** *mep-id* is specified in the **delay-measure one-way continual** command, the following configurations must be completed:

- Run the **remote-mep** command in the MA view to create an RMEP.
- Run the **mep ccm-send enable** command in the MA view to enable the local MEP in the MA to send CCMs.
- Run the **remote-mep ccm-receive enable** command in the MA view to enable the MEP to receive CCMs from the RMEP in the same MA.

Example

Enable dual-ended frame loss measurement in the VLAN scenario.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 10
[HUAWEI-md-md1-ma-ma1] mep mep-id 1 interface GigabitEthernet0/0/1 outward
[HUAWEI-md-md1-ma-ma1] mep ccm-send mep-id 1 enable
[HUAWEI-md-md1-ma-ma1] remote-mep ccm-receive mep-id 2 enable
[HUAWEI-md-md1-ma-ma1] loss-measure dual-ended continual mep 1 remote-mep 2
```

12.9.26 loss-measure single-ended continual send

Function

The **loss-measure single-ended continual send** command enables proactive single-ended frame loss measurement.

The **undo loss-measure single-ended continual send** command disables proactive single-ended frame loss measurement.

By default, proactive single-ended frame loss measurement is disabled.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

loss-measure single-ended continual send mep *mep-id* { **mac** *mac-address* | **remote-mep** *mep-id* } **interval** { **1000** | **10000** | **30000** }

undo loss-measure single-ended continual send [**mep** *mep-id*]

Parameters

Parameter	Description	Value
mep *mep-id*	Specifies the ID of a MEP.	The value is an integer in the range from 1 to 8191.
mac *mac-address*	Specifies the MAC address of an RMEP.	The value is in the format of H-H-H, where H is a hexadecimal number of 1 to 4 digits.

Parameter	Description	Value
remote-mep *mep-id*	Specifies the ID of an RMEP.	The value is an integer in the range from 1 to 8191.
interval	Specifies the interval at which LMMs are sent.	The value is 1000, 10000, or 30000, in milliseconds.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The collection interval can be specified to collect statistics about and analyze packet loss data in a period of time.

NOTE

Single-ended frame loss measurement is implemented for the link between the local MEP and an RMEP identified by an ID or a MAC address.

- If the local MEP has not learned the MAC address of the RMEP, the MAC address of the RMEP must be specified to implement single-ended frame loss measurement.
- If the local MEP has learned the MAC address of the RMEP, the ID of the RMEP can be used to implement single-ended frame loss measurement.

Prerequisites

The command takes effect only after the following configurations are completed:

- Run the **cfm version standard** command in the system view to specify IEEE Standard 802.1ag-2007 for CFM.
- Run the **cfm enable (system view)** command to enable CFM globally.
- Run the **cfm md** command in the system view to create an MD.
- Run the **ma** command in the MD view to create an MA.
- Run the **mep mep-id** command in the MA view to create an inward-facing MEP.

If **remote-mep** *mep-id* is specified in the **delay-measure one-way continual** command, the following configurations must be completed:

- Run the **remote-mep** command in the MA view to create an RMEP.
- Run the **mep ccm-send enable** command in the MA view to enable the local MEP in the MA to send CCMs.
- Run the **remote-mep ccm-receive enable** command in the MA view to enable the MEP to receive CCMs from the RMEP in the same MA.

Example

Enable single-ended frame loss measurement in the VLAN scenario and set the RMEP ID to 2 and interval to 30 seconds.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 10
[HUAWEI-md-md1-ma-ma1] loss-measure single-ended continual send mep 1 remote-mep 2 interval
30000
```

12.9.27 loss-measure single-ended continual send test-id

Function

The **loss-measure single-ended continual send test-id** command enables single-ended frame loss measurement based on the test instance.

The **undo loss-measure single-ended continual send test-id** command disables on-demand single-ended frame loss measurement.

By default, on-demand single-ended frame loss measurement is disabled.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

loss-measure single-ended continual send test-id *test-id* **interval** { **1000** | **10000** | **30000** }

undo loss-measure single-ended continual send [**test-id** *test-id*]

Parameters

Parameter	Description	Value
test-id *test-id*	Specifies the ID of a test instance.	The value is an integer in the range from 1 to 4294967295.
interval	Specifies the interval at which LMMs are sent.	The value is 1000, 10000, or 30000, in milliseconds.

Views

2: Configuration level

Usage Guidelines

Usage Scenario

Statistics based on a test instance are mainly used in the P2MP scenario. You can run this command to collect non-stop packet loss statistics.

Prerequisites

The **test-id** *test-id* command has been run in the MA view to create a test instance.

Example

Enable single-ended frame loss measurement based on test instance 1 in the VLAN scenario and set the interval to 30 seconds.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 10
[HUAWEI-md-md1-ma-ma1] loss-measure single-ended continual send test-id 1 interval 30000
```

12.9.28 loss-measure single-ended receive

Function

The **loss-measure single-ended receive** command enables the remote device to receive LMMs to implement single-ended frame loss measurement.

The **undo loss-measure single-ended receive** command disables the remote device from receiving LMMs.

By default, the remote device is disabled from receiving LMMs in an MA.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

loss-measure single-ended receive mep *mep-id*

undo loss-measure single-ended receive [**mep** *mep-id*]

Parameters

Parameter	Description	Value
mep *mep-id*	Specifies the ID of an MEP.	The value is an integer in the range from 1 to 8191.

2: Configuration level

Usage Guidelines

Usage Scenario

When the packet loss rate is detected on a link to evaluate the link performance, you can run this command to enable the remote device to receive LMMs. This command is used to configure the remote device in the single-ended frame loss measurement in the VLAN scenario.

Prerequisites

The command takes effect only after the following configurations are completed:

- Run the **cfm version standard** command in the system view to specify IEEE Standard 802.1ag-2007 for CFM.
- Run the **cfm enable (system view)** command to enable CFM globally.
- Run the **cfm md** command in the system view to create an MD.
- Run the **ma** command in the MD view to create an MA.
- Run the **mep mep-id** command in the MA view to create an inward-facing MEP.

Example

Configure the remote device to receive LMMs in a VLAN.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 10
[HUAWEI-md-md1-ma-ma1] mep mep-id 1 interface GigabitEthernet0/0/1 outward
[HUAWEI-md-md1-ma-ma1] loss-measure single-ended receive mep 1
```

12.9.29 loss-measure single-ended receive test-id

Function

The **loss-measure single-ended receive test-id** command enables the remote device to receive LMMs based on the test instance to implement single-ended frame loss measurement.

The **undo loss-measure single-ended receive test-id** command disables the remote device from receiving LMMs based on the test instance.

By default, the remote device is disabled from receiving LMMs in an MA.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

loss-measure single-ended receive test-id *test-id*

undo loss-measure single-ended receive [**test-id** *test-id*]

Parameters

Parameter	Description	Value
test-id	Specifies the ID of a test instance.	The value is an integer in the range from 1 to 4294967295.

Usage Scenario

Statistics based on a test instance are mainly used in the P2MP scenario. When the packet loss rate is detected on a link to evaluate the link performance, you can run this command to enable the remote device to receive LMMs.

Prerequisites

The **test-id** *test-id* command has been run in the MA view to create a test instance.

Example

Configure the remote device to receive LMMs based on the test instance.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 10
[HUAWEI-md-md1-ma-ma1] loss-measure single-ended receive test-id 1
```

12.9.30 loss-measure single-ended send

Function

The **loss-measure single-ended send** command enables single-ended frame loss measurement.

By default, single-ended frame loss measurement is disabled.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

loss-measure single-ended send mep *mep-id* [**mac** *mac-address* | **remote-mep** *mep-id*] **interval** { **1000** | **10000** } **count** *count-value*

Parameters

Parameter	Description	Value
mep *mep-id*	Specifies the ID of a MEP.	The value is an integer in the range from 1 to 8191.
mac *mac-address*	Specifies the MAC address of an RMEP.	The value is in the format of H-H-H, where H is a hexadecimal number of 1 to 4 digits.
remote-mep *mep-id*	Specifies the ID of an RMEP.	The value is an integer in the range from 1 to 8191.
interval	Specifies the interval at which LMMs are sent.	The value is 1000 or 10000, in milliseconds.
count *count-value*	Specifies the single-ended frame loss measurement count.	The value is an integer in the range from 1 to 60.

MA view

Default Level

2: Configuration level

Usage Guidelines

When the packet loss rate is detected on a link to evaluate the link performance, you can run this command to enable the remote device to receive LMMs.

NOTE

Single-ended frame loss measurement is implemented for the link between the local MEP and an RMEP identified by an ID or a MAC address.

- If the local MEP has not learned the MAC address of the RMEP, the MAC address of the RMEP must be specified to implement single-ended frame loss measurement.
- If the local MEP has learned the MAC address of the RMEP, the ID of the RMEP can be used to implement single-ended frame loss measurement.

Prerequisites

The command takes effect only after the following configurations are completed:

- Run the **cfm version standard** command in the system view to specify IEEE Standard 802.1ag-2007 for CFM.
- Run the **cfm enable (system view)** command to enable CFM globally.
- Run the **cfm md** command in the system view to create an MD.
- Run the **ma** command in the MD view to create an MA.
- Run the **mep mep-id** command in the MA view to create an inward-facing MEP.

If **remote-mep** *mep-id* is specified in the **delay-measure one-way continual** command, the following configurations must be completed:

- Run the **remote-mep** command in the MA view to create an RMEP.
- Run the **mep ccm-send enable** command in the MA view to enable the local MEP in the MA to send CCMs.
- Run the **remote-mep ccm-receive enable** command in the MA view to enable the MEP to receive CCMs from the RMEP in the same MA.

Example

In the VLAN scenario, enable single-ended frame loss measurement and set the RMEP ID to 2, measurement interval to 10 seconds, and measurement count to 60 times.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 10
[HUAWEI-md-md1-ma-ma1] mep mep-id 1 interface GigabitEthernet0/0/1 outward
[HUAWEI-md-md1-ma-ma1] mep ccm-send mep-id 1 enable
[HUAWEI-md-md1-ma-ma1] remote-mep ccm-receive mep-id 2 enable
[HUAWEI-md-md1-ma-ma1] loss-measure single-ended send mep 1 remote-mep 2 interval 10000
count 60
```

12.9.31 loss-measure single-ended send test-id

Function

The **loss-measure single-ended send test-id** command enables single-ended frame loss measurement based on the test instance.

By default, single-ended frame loss measurement based on the test instance is disabled.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

loss-measure single-ended send test-id *test-id* **interval** { **1000** | **10000** } **count** *count-value*

Parameters

Parameter	Description	Value
test-id	Specifies the ID of a test instance.	The value is an integer in the range from 1 to 4294967295.
interval	Specifies the interval at which LMMs are sent.	The value is 1000 or 10000, in milliseconds.
count *count-value*	Specifies the single-ended frame loss measurement count.	The value is an integer in the range from 1 to 60.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Statistics collection based on the test instance is applicable to the P2MP scenario. You can run this command to check the packet loss on the link periodically or once only.

Prerequisites

The **test-id** *test-id* command has been run in the MA view to create a test instance.

Example

In the VLAN scenario, enable single-ended frame loss measurement based on the test instance 1 and set the measurement interval to 10 seconds and measurement count to 60 times.

```
<HUAWEI> system-view
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 10
[HUAWEI-md-md1-ma-ma1] loss-measure single-ended send test-id 1 interval 10000 count 60
```

12.9.32 loss-measure single-ended-synthetic continual send

Function

The **loss-measure single-ended-synthetic continual send** command enables proactive single-ended synthetic loss measurement (SLM).

The **undo loss-measure single-ended-synthetic continual send** command disables proactive single-ended SLM.

By default, proactive single-ended SLM is disabled.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

loss-measure single-ended-synthetic continual send test-id *test-id* **interval** { **3.3** | **10** | **100** | **1000** | **10000** } [**sending-count** *count-value*] [**time-out** *timeout*] [**packet-size** *packet-size*]

undo loss-measure single-ended-synthetic continual send test-id *test-id*

Parameters

Parameter	Description	Value
test-id *test-id*	Specifies the ID of a test instance.	The value is an integer that ranges from 1 to 4294967295.
interval { **3.3** | **10** | **100** | **1000** | **10000** }	Specifies the interval at which SLM frames are sent.	Enumerated value, in milliseconds: ● 3.3 ● 10 ● 100 ● 1000 ● 10000
sending-count *count-value*	Specifies the times that SLM frames are sent within each measurement period.	The value is an integer ranging from 1 to 1000. The default value is 10.
timeout *timeout*	Specifies the timeout period during which the device waits for a response.	The value is an integer ranging from 1 to 10, in seconds. The default value is 5s.
packet-size *packet-size*	Specifies the size of the SLM frames.	The value is an integer ranging from 64 to 1518, in bytes. The default value is 64.

Usage Guidelines

Usage Scenario

To collect accurate frame loss statistics on a point-to-multipoint network, run the **loss-measure single-ended-synthetic continual send** command to configure proactive single-ended SLM.

Prerequisites

A test instance has been created using the **test-id** command in the MA view.

Example

Configure SLM with **test id** of 1 and statistics collection interval of 10s.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 100
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] set service-mode enhanced
Warning: This command will effect forward performance. Continue? [Y/N]:y
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 100
[HUAWEI-md-md1-ma-ma1] mep mep-id 1 interface gigabitethernet 0/0/1 inward
[HUAWEI-md-md1-ma-ma1] remote-mep mep-id 2
[HUAWEI-md-md1-ma-ma1] test-id 1 mep 1 remote-mep 2
[HUAWEI-md-md1-ma-ma1] loss-measure single-ended-synthetic continual send test-id 1 interval 10
```

12.9.33 loss-measure single-ended-synthetic local-ratio-threshold test-id

Function

The **loss-measure single-ended-synthetic local-ratio-threshold test-id** command configures local packet loss ratio thresholds for single-ended synthetic loss measurement (SLM).

The **undo loss-measure single-ended-synthetic local-ratio-threshold test-id** command deletes the local packet loss ratio thresholds configured for single-ended SLM.

By default, no local packet loss ratio thresholds are configured for single-ended SLM.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

loss-measure single-ended-synthetic local-ratio-threshold test-id *test-id* **upper-limit** *upper-limit* **lower-limit** *lower-limit*

undo loss-measure single-ended-synthetic local-ratio-threshold test-id *test-id* [**upper-limit** *upper-limit* **lower-limit** *lower-limit*]

Parameters

Parameter	Description	Value
test-id	Specifies the ID of a test instance.	The value is an integer that ranges from 1 to 4294967295.
upper-limit *upper-limit*	Specifies an upper local packet loss ratio threshold for single-ended SLM.	The value is a string of 1 to 8 characters in the format of *xxx.xxxx*, in percentages.
lower-limit *lower-limit*	Specifies a lower local packet loss ratio threshold for single-ended SLM.	The value is a string of 1 to 8 characters in the format of *xxx.xxxx*, in percentages. The lower local packet loss ratio threshold must be less than the upper local packet loss ratio threshold.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a point-to-multipoint or multipoint-to-multipoint network, run the **loss-measure single-ended-synthetic local-ratio-threshold test-id** command to configure local packet loss ratio thresholds for single-ended SLM. After configuring upper and lower local packet loss ratio thresholds, you can obtain data (such as the number of times that a threshold-crossing event occurs) within a sampling period to monitor network performance.

Prerequisites

A test instance has been created using the **test-id** command in the MA view.

Precautions

Thresholds can be configured only for proactive single-ended SLM and cannot be configured for on-demand single-ended SLM.

Example

Set lower and upper local packet loss ratio thresholds for single-ended SLM to 10.1111 and 11.1111 respectively for test instance 1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 100
```

```
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] set service-mode enhanced
Warning: This command will effect forward performance. Continue? [Y/N]:y
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 100
[HUAWEI-md-md1-ma-ma1] mep mep-id 1 interface gigabitethernet 0/0/1 inward
[HUAWEI-md-md1-ma-ma1] remote-mep mep-id 2
[HUAWEI-md-md1-ma-ma1] test-id 1 mep 1 remote-mep 2
[HUAWEI-md-md1-ma-ma1] loss-measure single-ended-synthetic local-ratio-threshold test-id 1 upper-
limit 11.1111 lower-limit 10.1111
```

12.9.34 loss-measure single-ended-synthetic receive

Function

The **loss-measure single-ended-synthetic receive** command enables a device to receive synthetic loss measurement (SLM) frames for single-ended SLM.

The **undo loss-measure single-ended-synthetic receive** command disables the device from receiving SLM frames.

By default, no device in a maintenance association (MA) is enabled to receive SLM frames.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

loss-measure single-ended-synthetic receive test-id *test-id* [**time-out** *timeout-value*]

undo loss-measure single-ended-synthetic receive test-id *test-id*

Parameters

Parameter	Description	Value
test-id *test-id*	Specifies the ID of a test instance.	The value is an integer that ranges from 1 to 4294967295.
time-out *timeout-value*	Specifies the timeout period for the receive end to receive SLM frames.	The value is an integer that ranges from 10 to 300, in seconds. The default value is 300.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **loss-measure single-ended-synthetic send** command is run to configure on-demand single-ended SLM or the **loss-measure single-ended-synthetic continual send** command is run to configure proactive single-ended SLM, run the **loss-measure single-ended-synthetic receive** command to enable the device to receive SLM frames.

Prerequisites

A test instance has been created using the **test-id** command in the MA view.

Precautions

If you delete or modify the configuration on the receive end more than once, the statistical data may become incorrect. Therefore, do not delete or modify the statistical task after the configuration is complete.

To modify the configuration, disable the device from receiving SLM frames and then perform reconfiguration.

For a proactive single-ended SLM task, set **time-out** on the receive end to a value greater than the value of **interval** on the transmit end.

Example

Configure the remote end to receive SLM frames, set the value of **test id** to 1, and set the timeout period for the receive end to receive SLM frames to 200s.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 100
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] set service-mode enhanced
Warning: This command will effect forward performance. Continue? [Y/N]:y
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 100
[HUAWEI-md-md1-ma-ma1] mep mep-id 1 interface gigabitethernet 0/0/1 inward
[HUAWEI-md-md1-ma-ma1] remote-mep mep-id 2
[HUAWEI-md-md1-ma-ma1] test-id 1 mep 1 remote-mep 2
[HUAWEI-md-md1-ma-ma1] loss-measure single-ended-synthetic receive test-id 1 time-out 200
```

12.9.35 loss-measure single-ended-synthetic remote-ratio-threshold test-id

Function

The **loss-measure single-ended-synthetic remote-ratio-threshold test-id** command configures remote packet loss ratio thresholds for single-ended synthetic loss measurement (SLM).

The **undo loss-measure single-ended-synthetic remote-ratio-threshold test-id** command deletes the remote packet loss ratio thresholds configured for single-ended SLM.

By default, no remote packet loss ratio thresholds are configured for single-ended SLM.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

loss-measure single-ended-synthetic remote-ratio-threshold test-id *test-id* **upper-limit** *upper-limit* **lower-limit** *lower-limit*

undo loss-measure single-ended-synthetic remote-ratio-threshold test-id *test-id* [**upper-limit** *upper-limit* **lower-limit** *lower-limit*]

Parameters

Parameter	Description	Value
test-id	Specifies the ID of a test instance.	The value is an integer ranging from 1 to 4294967295.
upper-limit *upper-limit*	Specifies an upper remote packet loss ratio threshold for single-ended SLM.	The value is a string of 1 to 8 characters in the format of *xxx.xxxx*, in percentages.
lower-limit *lower-limit*	Specifies a lower remote packet loss ratio threshold for single-ended SLM.	The value is a string of 1 to 8 characters in the format of *xxx.xxxx*, in percentages. The lower remote packet loss ratio threshold must be less than the upper remote packet loss ratio threshold.

Views

Usage Guidelines

Usage Scenario

In a point-to-multipoint or multipoint-to-multipoint scenario, you can run this command to configure remote packet loss ratio thresholds for single-ended SLM. After the thresholds are configured, you can obtain data such as the number of times that a threshold-crossing event occurs.

Prerequisites

A test instance has been created using the **test-id** command in the MA view.

Precautions

Thresholds can be configured only for proactive single-ended SLM and cannot be configured for on-demand single-ended SLM.

Example

Set lower and upper remote packet loss ratio thresholds for single-ended SLM to 10.1111 and 11.1111 respectively for test instance 1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 100
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] set service-mode enhanced
Warning: This command will effect forward performance. Continue? [Y/N]:y
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 100
[HUAWEI-md-md1-ma-ma1] mep mep-id 1 interface gigabitethernet 0/0/1 inward
[HUAWEI-md-md1-ma-ma1] remote-mep mep-id 2
[HUAWEI-md-md1-ma-ma1] test-id 1 mep 1 remote-mep 2
[HUAWEI-md-md1-ma-ma1] loss-measure single-ended-synthetic remote-ratio-threshold test-id 1
upper-limit 11.1111 lower-limit 10.1111
```

12.9.36 loss-measure single-ended-synthetic send

Function

The **loss-measure single-ended-synthetic send** command configures on-demand single-ended synthetic loss measurement (SLM).

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

loss-measure single-ended-synthetic send test-id *test-id* **interval** { **3.3** | **10** | **100** | **1000** | **10000** } [**sending-count** *count-value*] [**time-out** *time-out-value*] [**packet-size** *packet-size*] [**measurement-count** *measurement-count*]

Parameters

Parameter	Description	Value
test-id *test-id*	Specifies the ID of a test instance.	The value is an integer ranging from 1 to 4294967295.

Parameter	Description	Value
interval { **3.3** | **10** | **100** | **1000** | **10000** }	Specifies the interval at which SLM frames are sent.	Enumerated value, in milliseconds: - 3.3 - 10 - 100 - 1000 - 10000
sending-count *count-value*	Specifies the times that SLMs are sent within each measurement period.	The value is an integer ranging from 1 to 1000. The default value is 10.
time-out *time-out-value*	Specifies the timeout period during which the device waits for a reply.	The value is an integer ranging from 1 to 10, in seconds. The default value is 5s.
packet-size *packet-size*	Specifies the size of the sent packet.	The value is an integer ranging from 64 to 1518, in bytes. The default value is 64.
measurement-count *measurement-count*	Specifies the number of measurements.	The value is an integer ranging from 1 to 60. The default value is 1.

Views

MA view

2: Configuration level

Usage Guidelines

Usage Scenario

When implementing frame loss measurement (LM), Maintenance Association End Points (MEPs) exchange ETH-LM frames. However, single-ended frame LM cannot collect accurate frame loss statistics on a point-to-multipoint or multipoint-to-multipoint network. To resolve this issue, configure on-demand single-ended SLM.

Prerequisites

A test instance has been created using the **test-id** command in the MA view.

Precautions

If the configuration changes during on-demand statistics, you can view only the pre-change statistics results. You are advised to run the command for on-demand statistics again for query.

Example

Configure single-ended SLM with the test ID of 1, SLM frame transmission interval of 1s, SLM frame transmission times of 10, and timeout period waiting for a reply of 5s.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 100
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] set service-mode enhanced
Warning: This command will effect forward performance. Continue? [Y/N]:y
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 100
[HUAWEI-md-md1-ma-ma1] mep mep-id 1 interface gigabitethernet 0/0/1 inward
[HUAWEI-md-md1-ma-ma1] remote-mep mep-id 2
[HUAWEI-md-md1-ma-ma1] test-id 1 mep 1 remote-mep 2
[HUAWEI-md-md1-ma-ma1] loss-measure single-ended-synthetic send test-id 1 interval 1000 sending-count 10 time-out 5
```

12.9.37 loss-measure single-ended-synthetic trigger if-down

Function

The **loss-measure single-ended-synthetic trigger if-down** command triggers an interface to go ETHOAM down when the near- or far-end frame loss ratio based on a test instance ID exceeds a specified threshold.

The **undo loss-measure single-ended-synthetic trigger if-down** command restores the default configuration.

By default, an interface is not triggered to go ETHOAM down when the near- or far-end frame loss ratio based on a test instance ID exceeds a specified threshold.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

loss-measure single-ended-synthetic { **local-ratio-threshold** | **remote-ratio-threshold** } **test-id** *test-id* **trigger if-down**

undo loss-measure single-ended-synthetic { **local-ratio-threshold** | **remote-ratio-threshold** } **test-id** *test-id* **trigger if-down**

Parameters

Parameter	Description	Value
local-ratio-threshold	Indicates that an interface is triggered to go ETHOAM down when the near-end frame loss ratio exceeds a specified threshold.	-
remote-ratio-threshold	Indicates that an interface is triggered to go ETHOAM down when the far-end frame loss ratio exceeds a specified threshold.	-
test-id *test-id*	Specifies the ID of a test instance.	The value is an integer that ranges from 1 to 4294967295.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When no service is bound to the MA, the interface where the MEP resides is an Eth-Trunk interface's primary member interface. To ensure the quality of the primary link, run the **loss-measure single-ended-synthetic trigger if-down** command on the interface where the MEP resides. If the near- or far-end frame loss ratio based on a test instance ID exceeds the threshold configured using the **loss-measure single-ended-synthetic local-ratio-threshold test-id** or **loss-measure single-ended-synthetic remote-ratio-threshold test-id** command, the primary link has poor quality. In this case, the interface is triggered to go ETHOAM down, triggering a primary/secondary Eth-Trunk link switchover.

Prerequisites

A test instance has been created using the **test-id** command in the MA view.

Example

Trigger the Eth-Trunk member interface GE 0/0/1 to go ETHOAM down when the near-end frame loss ratio based on a test instance ID of 2 exceeds a specified threshold.

```
<HUAWEI> system-view
[HUAWEI] set service-mode enhanced
Warning: This command will effect forward performance. Continue? [Y/N]:y
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
```

```
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] mep mep-id 8 interface gigabitethernet 0/0/1 outward
[HUAWEI-md-md1-ma-ma1] remote-mep mep-id 9
[HUAWEI-md-md1-ma-ma1] test-id 2 mep 8 remote-mep 9
[HUAWEI] interface eth-trunk 1
[HUAWEI-Eth-Trunk1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] eth-trunk 1
[HUAWEI-GigabitEthernet0/0/1] loss-measure single-ended-synthetic local-ratio-threshold test-id 2
trigger if-down
```

12.9.38 ping mac multicast

Function

The **ping mac multicast** command configures multicast MAC ping in the current MA.

Format

ping mac multicast mep *mep-id* [**-c** *count* | **-p** *priority-value* | **-t** *timeout*] *

Parameters

Parameter	Description	Value
mep *mep-id*	Specifies the ID of a MEP.	The value is an integer ranging from 1 to 8191.
-c *count*	Specifies the number of multicast Loopback Messages (LBMs) to be sent.	The value is an integer ranging from 1 to 4294967295. The default value is 3.
-p *priority-value*	Specifies the priority of the multicast LBM.	The value is an integer ranging from 0 to 7. The default value is the same as the 802.1p priority of the 802.1ag packets which is specified in MA view (**packet-priority**).
-t *timeout*	Specifies the timeout period for waiting for a Loopback Reply (LBR).	The value is an integer that ranges from 1 to 65535, in milliseconds. By default, the value is 5000 milliseconds.

Views

MA view

Default Level

0: Visit level

Usage Guidelines

Usage Scenario

The destination MAC address of multicast MAC ping is a multicast MAC address. Multicast MAC ping provides two functions, that is, acknowledging faults and discovering RMEPs.

- Acknowledging faults: Multicast MAC ping provides the fault acknowledgement function similar to that provided by 802.1ag MAC ping. In a multicast MAC ping test, test packets are sent to test whether the path from the local device to the destination device is reachable. Multicast MAC ping can acknowledge the faults of links between multiple MEPs once.
- Discovering RMEPs: All RMEPs in the MA can be discovered.

  For example, there are three MEPs in an MA: MEP1, MEP2, and MEP3. After multicast MAC ping is configured on MEP1, MEP1 sends multicast LBMs. After MEP2 and MEP3 receive the LBM, they reply with an LBR. The LBR carries the MAC address of MEP2 or MEP3, MEP ID, and delay. Before configuring the **remote-mep** command on MEP1, you can configure multicast MAC ping to detect all RMEPs in an MA.

Prerequisites

A MEP has been created using the **mep mep-id** command.

Precautions

IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007. Before using the **ping mac multicast** command, you must use the **cfm version** command to set the Ethernet CFM version to IEEE Standard 802.1ag-2007.

Example

Create an MD named **md1**, create an MA named **ma1** in the MD, and configure multicast MAC ping in **ma1**.

```
<HUAWEI> system-view
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] mep mep-id 1 interface gigabitethernet 0/0/1 inward
[HUAWEI-md-md1-ma-ma1] ping mac multicast mep 1 -p 6 –c 1 –t 3
Reply from 00e0-fc00-0204 mep id 10: time = 9ms
Reply from 00e0-fc00-0269 mep id 11: time = 11ms
Packets: Sent = 1, Received = 2
Minimum = 9ms, Maximum = 11ms, Average = 10ms
```

Table 12-78 Description of the **ping mac multicast** command output

Item	Description
Reply from	MAC address of the RMEP.
mep id	MEP ID.
time	Delay, in millisecond.

Item	Description
Sent	Number of sent multicast LBMs.
Received	Number of received LBRs.
Minimum	Minimum delay, in millisecond.
Maximum	Maximum delay, in millisecond.
Average	Average delay, in millisecond.

12.9.39 reset y1731 statistic-type

Function

The **reset y1731 statistic-type** command clears statistics collected through Y. 1731.

Format

reset y1731 statistic-type { **oneway-delay** | **twoway-delay** } **md** *md-name* **ma** *ma-name*

reset y1731 statistic-type { **single-loss** | **dual-loss**} **md** *md-name* **ma** *ma-name* (Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.)

reset y1731 statistic-type twoway-delay test-id *test-id* (Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.)

reset y1731 statistic-type single-synthetic-loss test-id *test-id* (Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.)

reset y1731 statistic-type single-loss test-id *test-id* (Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.)

Parameters

Parameter	Description	Value
oneway-delay	Clears statistics about one-way frame delay measurement.	-
twoway-delay	Clears statistics about two-way frame delay measurement.	-

Parameter	Description	Value
single-loss	Clears statistics about single-ended frame loss measurement.	-
dual-loss	Clears statistics about dual-ended frame loss measurement.	-
md *md-name*	Clears statistics about a specified MD.	The MD must exist.
ma *ma-name*	Clears statistics about a specified MA.	The MA must exist.
test-id *test-id*	Clears statistics about a specified test instance.	The test instance ID must exist.
single-synthetic-loss	Clears single-ended SLM statistics.	-

Views

All views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To obtain Y.1731 statistics within a specified period of time, run the **reset y1731 statistic-type** command to delete existing Y.1731 statistics, and then run the **display y1731 statistic-type** command after a period of time.

Precautions

After the **reset y1731 statistic-type** command is executed, statistics are cleared and cannot be restored. Exercise caution when you run the command.

Example

Clear statistics about the one-way frame delay.

```
<HUAWEI> reset y1731 statistic-type oneway-delay md mdname ma maname
```

12.9.40 test-id

Function

The **test-id** command creates a test instance for Y.1731 statistics collection.

The **undo test-id** command deletes a test instance.

By default, no test instance is created in an MA for Y.1731 statistics collection.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

test-id *test-id* **mep** *mep-id* { **remote-mep** *mep-id* } [**8021p** *8021p-value*] [**description** *description*]

undo test-id *test-id*

Parameters

Parameter	Description	Value
test-id *test-id*	Specifies the ID of a test instance.	The value is an integer ranging from 1 to 4294967295.
mep *mep-id*	Specifies the MEP ID.	The value is an integer that ranges from 1 to 8191.
remote-mep *mep-id*	Specifies the RMEP ID.	The value is an integer that ranges from 1 to 8191.
8021p *8021p-value*	Specifies a priority value for packets.	The value is an integer that ranges from 0 to 7.
description *description*	Specifies the description of a test instance.	The value is a string of 1 to 63 case-sensitive characters without spaces.

Views

MA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To implement single-ended SLM, run the **test-id** command to create a test instance.

During two-way frame delay measurement in point-to-multipoint scenarios, you need to run this command to configure a test instance.

During two-way frame delay measurement, if the size or priority of outgoing DMMs needs to be specified or there is the high requirement on the detection accuracy, you can run this command to configure a test instance.

Prerequisites

- A MEP has been created using the **mep mep-id** command in the MA view.
- An RMEP has been created using the **remote-mep** command in the MA view.

Precautions

To configure a test instance, run the **set service-mode** command in the system view to configure the device to work in enhanced (S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S is enhanced-oam) mode before enabling CFM globally.

IEEE 802.1ag has two versions: IEEE 802.1ag Draft 7 and IEEE Standard 802.1ag-2007. This command can be used only on the device running IEEE Standard 802.1ag-2007. Before using the **test-id** command, you must use the **cfm version** command to set the Ethernet CFM version to IEEE Standard 802.1ag-2007.

When you run this command in the same MA view to configure multiple test instances, the RMEPs of the local MEP must be different switches.

Example

Configure test instance 200, and specify the MEP ID as 8 and RMEP ID as 9.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 100
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] set service-mode enhanced
Warning: This command will effect forward performance. Continue? [Y/N]:y
[HUAWEI] cfm enable
[HUAWEI] cfm md md1
[HUAWEI-md-md1] ma ma1
[HUAWEI-md-md1-ma-ma1] map vlan 100
[HUAWEI-md-md1-ma-ma1] mep mep-id 8 interface gigabitethernet 0/0/1 inward
[HUAWEI-md-md1-ma-ma1] remote-mep mep-id 9
[HUAWEI-md-md1-ma-ma1] test-id 200 mep 8 remote-mep 9
```

13 User Access and Authentication Commands

13.1 AAA Configuration Commands

13.1.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

13.1.2 aaa

Function

The **aaa** command displays the AAA view.

Format

aaa

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Using the **aaa** command in the system view, you can enter the AAA view and perform the following security configurations for access users:

- Creating users
- Configuring user levels
- Creating an authentication scheme
- Creating an authorization scheme
- Creating a domain

Example

Access the AAA view.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa]
```

13.1.3 aaa abnormal-offline-record

Function

The **aaa abnormal-offline-record** command enables the device to record users' abnormal logout information.

The **undo aaa abnormal-offline-record** command disables the device from recording users' abnormal logout information.

By default, the device records users' abnormal logout information.

Format

aaa abnormal-offline-record

undo aaa abnormal-offline-record

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

If users abnormally log out, run **aaa abnormal-offline-record** command to enable the record function for fault locating.

After the **undo aaa abnormal-offline-record** command is run, no abnormal logout information is recorded unless the **aaa abnormal-offline-record** command is run.

Example

Enable the device to record users' abnormal logout information.

```
<HUAWEI> system-view
[HUAWEI] aaa abnormal-offline-record
```

Disable the device from recording users' abnormal logout information.

```
<HUAWEI> system-view
[HUAWEI] undo aaa abnormal-offline-record
```

13.1.4 aaa offline-record

Function

The **aaa offline-record** command enables the device to record users' normal logout information.

The **undo aaa offline-record** command disables the device from recording users' normal logout information.

By default, the device is enabled to record user normal logout information.

Format

aaa offline-record

undo aaa offline-record

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

If users fail to get online, run **aaa offline-record** command to enable the record function for fault locating.

After the **undo aaa offline-record** command is run, no logout information is recorded unless the **aaa offline-record** command is run.

Example

Enable the device to record users' normal logout information.

```
<HUAWEI> system-view
[HUAWEI] aaa offline-record
```

Disable the device from recording users' normal logout information.

```
<HUAWEI> system-view
[HUAWEI] undo aaa offline-record
```

13.1.5 aaa online-fail-record

Function

The **aaa online-fail-record** command enables the device to record users' online failures.

The **undo aaa online-fail-record** command disables the device from recording users' online failures.

By default, the device records users' online failures.

Format

aaa online-fail-record

undo aaa online-fail-record

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

If you want to query the login failure records to find out unauthorized users, run the **aaa online-fail-record** command to enable the device to record users' online failures.

After the **undo aaa online-fail-record** command is run, no online failure is recorded unless the **aaa online-fail-record** command is run.

Example

Enable the device to record users' online failures.

```
<HUAWEI> system-view
[HUAWEI] aaa online-fail-record
```

Disable the device from recording users' online failures.

```
<HUAWEI> system-view
[HUAWEI] undo aaa online-fail-record
```

13.1.6 aaa-authen-bypass

Function

The **aaa-authen-bypass** command sets the bypass authentication timeout interval.

The **undo aaa-authen-bypass** command cancels the bypass authentication timeout interval.

By default, no bypass authentication timeout interval is set.

Format

aaa-authen-bypass enable time *time-value*

undo aaa-authen-bypass enable

Parameters

Parameter	Description	Value
enable	Enables remote bypass authentication.	-
time *time-value*	Specifies the bypass authentication timeout interval.	The value is an integer that ranges from 1 to 1440, in minutes.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

This command applies to the scenarios that require fast authentication response. When a user in a user domain where multiple authentication modes (for example, RADIUS authentication and local authentication) are configured, bypass authentication is enabled, and the bypass authentication timeout interval is configured, the user will be authenticated using the local authentication mode and the bypass authentication timer is enabled simultaneously if the RADIUS server does not respond to the authentication request. When other users in the same domain are authenticated during the configured bypass authentication timeout interval, the users are directly authenticated using the local authentication mode, so that the users can be authenticated without waiting until the RADIUS server responds to their authentication requests, accelerating the authentication response.

Precautions

When only one authentication mode is configured in a user domain and the bypass authentication timer is enabled, other users in the same domain are directly considered to fail the authentication during the bypass authentication timeout interval.

Example

Set the bypass authentication timeout interval to 3 minutes.

```
<HUAWEI> system-view
[HUAWEI] aaa-authen-bypass enable time 3
```

13.1.7 aaa-author-bypass

Function

The **aaa-author-bypass** command sets the bypass authorization timeout interval.

The **undo aaa-author-bypass** command cancels the bypass authorization timeout interval.

By default, no bypass authorization timeout interval is set.

Format

aaa-author-bypass enable time *time-value*

undo aaa-author-bypass enable

Parameters

Parameter	Description	Value
enable	Enables remote bypass authorization.	-
time *time-value*	Specifies the bypass authorization timeout interval.	The value is an integer that ranges from 1 to 1440, in minutes.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

This command applies to the scenarios that require fast authorization response. When a user in a user domain where multiple authorization modes (for example, HWTACACS authorization and local authorization) are configured, bypass authorization is enabled, and the bypass authorization timeout interval is configured, the user will be authorized using the local authorization mode and the bypass authorization timer is enabled simultaneously if the HWTACACS server does not respond to the authorization request. When other users in the same domain are authorized during the configured bypass authorization timeout interval, the users are directly authorized using the local authorization mode, so that the users can be authorized without waiting until the HWTACACS server responds to their authorization requests, accelerating the authorization response.

Precautions

When only one authorization mode is configured in a user domain and the bypass authorization timer is enabled, other users in the same domain are directly considered to fail the authorization during the bypass authorization timeout interval.

Example

Set the bypass authorization timeout interval to 3 minutes.

```
<HUAWEI> system-view
[HUAWEI] aaa-author-bypass enable time 3
```

13.1.8 aaa-author-cmd-bypass

Function

The **aaa-author-cmd-bypass** command sets the command-line bypass authorization timeout interval.

The **undo aaa-author-cmd-bypass** command cancels the command-line bypass authorization timeout interval.

By default, no command-line bypass authorization timeout interval is set.

Format

aaa-author-cmd-bypass enable time *time-value*

undo aaa-author-cmd-bypass enable

Parameters

Parameter	Description	Value
enable	Enables remote command-line bypass authorization.	-
time *time-value*	Specifies the command-line bypass authorization timeout interval.	The value is an integer that ranges from 1 to 1440, in minutes.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

This command applies to the scenarios that require fast command-line authorization response. When a user in a user domain where multiple command-line authorization modes (for example, HWTACACS authorization and local authorization) are configured, command-line bypass authorization is enabled, and the command-line bypass authorization timeout interval is configured, the user will be authorized using the local authorization mode and the command-line bypass authorization timer is enabled simultaneously if the HWTACACS server does not respond to the command-line authorization request. When other users in the same domain are authorized during the configured command-line bypass authorization timeout interval, the users are directly authorized using the local authorization mode, so that the users can be authorized without waiting until the

HWTACACS server responds to their authorization requests, accelerating the authorization response.

Precautions

When only one command-line authorization mode is configured in a user domain and the command-line bypass authorization timer is enabled, other users in the same domain are directly considered to fail the command-line authorization during the command-line bypass authorization timeout interval.

Example

Set the command-line bypass authorization timeout interval to 3 minutes.

```
<HUAWEI> system-view
[HUAWEI] aaa-author-cmd-bypass enable time 3
```

13.1.9 aaa-author session-timeout invalid-value enable

Function

The **aaa-author session-timeout invalid-value enable** command prevents a device from disconnecting or reauthenticating users when the RADIUS server delivers session-timeout with value 0.

The **undo aaa-author session-timeout invalid-value enable** command restores the default setting.

By default, when the RADIUS server delivers session-timeout with value 0, this attribute does not take effect.

Format

aaa-author session-timeout invalid-value enable

undo aaa-author session-timeout invalid-value enable

Parameters

None

Views

AAA view

Default Level

3: Management level

Usage Guidelines

When the RADIUS server delivers session-timeout with value 0:

- If the **aaa-author session-timeout invalid-value enable** command is not configured, the session-timeout attribute delivered by the server does not take effect and the period for disconnecting or reauthenticating users depends on the device configuration.

- If the **aaa-author session-timeout invalid-value enable** command is configured, the session-timeout attribute delivered by the server takes effect and the device does not disconnect or reauthenticate users.

You can run the **dot1x timer reauthenticate-period** *reauthenticate-period-value* or **mac-authen timer reauthenticate-period** *reauthenticate-period-value* command to configure the period for disconnecting or reauthenticating users on the device.

Example

Prevent the device from disconnecting or reauthenticating users when the RADIUS server delivers session-timeout with value 0.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] aaa-author session-timeout invalid-value enable
```

13.1.10 aaa-quiet administrator except-list

Function

The **aaa-quiet administrator except-list** command configures a user to access the network using a specified IP address when the user account is locked.

The **undo aaa-quiet administrator except-list** command restores the default setting.

By default, a user cannot access the network when the account is locked.

Format

aaa-quiet administrator except-list { *ipv4-address* | *ipv6-address* } &<1-32>

undo aaa-quiet administrator except-list

Parameters

Parameter	Description	Value
ipv4-address	Specifies an IPv4 address. A user can access the network using this IPv4 address when the user account is locked.	The value must be a valid unicast address in dotted decimal notation.

Parameter	Description	Value
ipv6-address	Specifies an IPv6 address. A user can access the network using this IPv6 address when the user account is locked.	The total length of the value is 128 bits, which are divided into eight groups. Each group contains four hexadecimal digits. The value is in the format of X:X:X:X:X:X:X:X.

Views

AAA view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In AAA view, after the function of locking the account of an AAA local authentication user or AAA remote authentication user is configured using the **local-aaa-user wrong-password** or **administrator remote authen-fail** command, if a user consecutively enters an incorrect password and the number of times that the user enters an incorrect password reaches the allowed maximum number of times, the user account is locked and the user cannot access the network when the account is locked. To facilitate maintenance and management, you can run the **aaa-quiet administrator except-list** command to configure the user to access the network using a specified IP address when the user account is locked.

Precautions

- This function takes effect only for the administrators.
- A maximum of 64 IPv4 and IPv6 addresses can be configured.

Example

Configure a user to access the network using the specified IP address 10.1.1.1 when the user account is locked.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] aaa-quiet administrator except-list 10.1.1.1
```

13.1.11 access-limit user-name max-num

Function

The **access-limit user-name max-num** command configures the maximum number of users who are allowed to access the network using the same user name.

The **undo access-limit user-name max-num** command restores the default setting.

By default, the number of users who are allowed to access the network using the same user name is not limited, and is determined by the maximum number of access users supported by the device.

Format

access-limit user-name max-num *number*

undo access-limit user-name max-num

Parameters

Parameter	Description	Value
number	Specifies the maximum number of users who are allowed to access the network using the same user name.	The value is an integer and is determined by the maximum number of access users supported by the device.

Views

Service scheme view

Default Level

3: Management level

Usage Guidelines

By default, the number of users who are allowed to access the network using the same user name is not limited. To limit the number of users who are allowed to access the network using a user name, run the **access-limit user-name max-num** command. For example, the bandwidth share mode is configured for all terminal users in a small office network access scenario. To facilitate maintenance, the server delivers the same user name to replace the user names entered by terminal users. The number of access users needs to be limited based on the user name to ensure the network access experience of all terminal users.

For RADIUS authentication users, configurations for limiting the number of access users based on the user name are carried in the HW-UserName-Access-Limit (26-18) attribute.

NOTE

Only users who are successfully authenticated support the configurations for limiting the number of access users based on the same user name, and pre-connection users do not support such configurations.

This command does not take effect in inter-AC roaming scenarios.

Example

In the service scheme **s1**, set the maximum number of users who are allowed to access the network using the same user name to 15.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] service-scheme s1
[HUAWEI-aaa-service-s1] access-limit user-name max-num 15
```

13.1.12 accounting dual-stack separate

Function

The **accounting dual-stack separate** command enables separate statistics collection or separate rate limiting of IPv4 and IPv6 user traffic.

The **undo accounting dual-stack separate** command disables separate statistics collection or separate rate limiting of IPv4 and IPv6 user traffic.

By default, the device does not distinguish between IPv4 and IPv6 user traffic when collecting traffic statistics or rate limiting IPv4 and IPv6 user traffic.

NOTE

This command is supported only on the following switch models:

S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, S6730S-S, S6735-S, S6720-EI, S6720S-EI

Format

accounting dual-stack separate

undo accounting dual-stack separate

Parameters

None

Views

AAA domain view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To collect statistics about IPv4 and IPv6 user traffic separately or perform accounting for IPv4 and IPv6 users separately based on traffic, run the **statistic enable (AAA domain view)** command to enable traffic statistics collection, and then run the **accounting dual-stack separate** command to enable separate traffic statistics collection for IPv4 and IPv6 users.

If you want to separately limit the rate of IPv4 and IPv6 users based on traffic, authorize CAR to the users, and then run the **accounting dual-stack separate** command to enable separate rate limiting for IPv4 and IPv6 users.

Precautions

You are advised to configure this function before users go online. If this function is configured after users go online, separate traffic statistic collection or rate limiting may be inaccurate. You are advised to collect traffic statistics or limit the rate again after users go offline.

Example

Enable separate statistics collection or separate rate limiting of IPv4 and IPv6 user traffic.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] domain example
[HUAWEI-aaa-domain-example] accounting dual-stack separate
Warning: This operation may cause online users' traffic statistics inaccurate, Re-online is recommended
after this operation, continue?[Y/N]y
```

13.1.13 accounting interim-fail

Function

The **accounting interim-fail** command sets the maximum number of real-time accounting failures and configures a policy used after the number of real-time accounting failures exceeds the maximum.

The **undo accounting interim-fail** command restores the default maximum number of real-time accounting failures and the default policy.

By default, the maximum number of real-time accounting failures is 3 and the device keeps users online after the number of real-time accounting failures exceeds the maximum.

Format

accounting interim-fail [**max-times** *times*] { **offline** | **online** }

undo accounting interim-fail

Parameters

Parameter	Description	Value
max-times *times*	Specifies the maximum number of real-time accounting failures. If the maximum number of real-time accounting failures is reached and the next accounting request still has no response, the device considers that accounting fails and takes a policy for users.	The value is an integer that ranges from 1 to 255. The default value is 3.
offline	Disconnects users if real-time accounting fails.	-
online	Keeps users online if real-time accounting fails.	-

Views

Accounting scheme view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After the real-time accounting function takes effect, the device sends real-time accounting requests to an accounting server, and the accounting server responds to the accounting requests. If the network is unstable, for example, a jitter occurs, the device may not receive response packets. As a result, accounting is interrupted for a short period of time. To reduce or prevent accounting interruption, run the **accounting interim-fail** command to set the maximum number of real-time accounting failures. The device considers that real-time accounting fails only after the number of consecutive real-time accounting failures exceeds the maximum.

Choose one of the following policies to be applied after the maximum number of real-time accounting failures is reached:

- **online**: To prevent users from being affected by network faults, use the **online** policy to allow paid users to go online.
- **offline**: To stop providing services when accounting fails, use the **offline** policy to force paid users to go offline.

Prerequisites

The real-time accounting function has been enabled by using the **accounting realtime** command.

Precautions

The **accounting interim-fail** command does not take effect for online users, but takes effect for the users who go online after the command is executed.

Example

In the accounting scheme **scheme1**, set the maximum number of real-time accounting failures to 5 and use the **offline** policy.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] accounting-scheme scheme1
[HUAWEI-aaa-accounting-scheme1] accounting realtime 3
[HUAWEI-aaa-accounting-scheme1] accounting interim-fail max-times 5 offline
```

13.1.14 accounting realtime

Function

The **accounting realtime** command enables the real-time accounting function and sets the interval for real-time accounting in an accounting scheme.

The **undo accounting realtime** command disables the real-time accounting function.

By default, the device performs accounting based on user online duration, the real-time accounting function is disabled.

Format

accounting realtime *interval*

undo accounting realtime

Parameters

Parameter	Description	Value
interval	Specifies the interval for real-time accounting.	The value is an integer that ranges from 0 to 65535, in minutes. When the value is set to 0, real-time accounting is disabled. The default value is 0.

Views

Accounting scheme view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

This command applies to the users who are charged based on online duration. If a user goes offline unexpectedly, the accounting server cannot receive the accounting-stop packet, so it keeps charging the user while they are not receiving a service. To solve the problem, configure the real-time accounting function on the device. After the real-time accounting function is configured, the device periodically sends real-time accounting packets to the accounting server. After receiving the real-time accounting packets, the accounting server charges the user. If the device detects that the user goes offline, it stops sending real-time accounting packets and the accounting server stops accounting. The result of real-time accounting is precise.

Precautions

- When the accounting interval is set using both the **accounting realtime** command and the Acct-Interim-Interval attribute, if the Acct-Interim-Interval value range is 60-3932100, the interval set by Acct-Interim-Interval has a higher priority. Otherwise, the interval set by the **accounting realtime** command takes effect.
- If an accounting scheme is applied to a domain, the **accounting realtime** command does not affect online users, but only takes effect for the users who go online after the command is executed.
- If *interval* is set to 0 and the IP address of the client is changed, the device still sends a real-time accounting packet carrying the changed IP address information to the RADIUS server.
- A short interval for real-time accounting requires high performance of the device and accounting server. If there are more than 1000 users, setting a long interval for real-time accounting is recommended. The following table lists the suggested real-time accounting intervals for different user quantities.

Table 13-1 Real-time accounting interval for different user quantities

User Quantity	Interval for Real-Time Accounting (Minutes)
1-99	3
100-499	6
500-999	12
≥ 1000	≥ 15

Example

In the accounting scheme **scheme1**, enable the real-time accounting function and set the interval for real-time accounting to 6 minutes.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] accounting-scheme scheme1
[HUAWEI-aaa-accounting-scheme1] accounting realtime 6
```

13.1.15 accounting start-fail

Function

The **accounting start-fail** command configures a policy for accounting-start failures.

The **undo accounting start-fail** command restores the default policy for accounting-start failures.

By default, users cannot go online if accounting-start fails. That is, the **offline** policy is used.

Format

accounting start-fail { **offline** | **online** }

undo accounting start-fail

Parameters

Parameter	Description	Value
offline	Rejects users' online requests if accounting-start fails.	-
online	Allows users to go online if accounting-start fails.	-

Views

Accounting scheme view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If a user goes online after an accounting scheme is applied, the device sends an accounting-start packet to an accounting server. When the network is working properly, the accounting server responds to the accounting-start packet. If a fault occurs on the network, the device may not receive the response packet from the accounting server. As a result, accounting fails. The device provides the following policies for accounting failures:

- **online**: To prevent users from being affected by network faults, use the **online** policy to allow paid users to go online.
- **offline**: To stop providing services when accounting fails, use the **offline** policy to force paid users to go offline.

Precautions

The command takes effect only when the accounting mode configured using the **accounting-mode** command is HWTACACS or RADIUS.

Example

In the accounting scheme **scheme1**, use the **online** policy for accounting-start failures.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] accounting-scheme scheme1
[HUAWEI-aaa-accounting-scheme1] accounting start-fail online
```

13.1.16 accounting-mode

Function

The **accounting-mode** command configures an accounting mode in an accounting scheme.

The **undo accounting-mode** command restores the default accounting mode in an accounting scheme.

By default, the accounting mode is **none**.

Format

accounting-mode { **hwtacacs** | **none** | **radius** | **haca** }

undo accounting-mode

Parameters

Parameter	Description	Value
hwtacacs	Indicates that accounting is performed by an HWTACACS server.	-
none	Indicates non-accounting.	-
radius	Indicates that accounting is performed by a RADIUS server.	-

Parameter	Description	Value
haca	Indicates that accounting is performed by an HACA server. **NOTE** Only the following switch models support HACA: S200, S1730S-S1 S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5720S-LI, S500, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H and S6720S-S	-

Views

Accounting scheme view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Enterprises or carriers need to generate revenue by charging users who are accessing the Internet.

When a user goes online, accounting starts after the user is authenticated and authorized. When the user goes offline, accounting stops. The client sends the account packet containing the user's online duration to the accounting server.

To charge users, set the accounting mode to RADIUS or HWTACACS. Generally, the accounting mode is consistent with the authentication mode. If you do not need to charge users, set the accounting mode to none.

Precautions

The device does not support local accounting. When the authentication scheme configured using the **authentication-mode** command defines local authentication, you need to run the **accounting-mode none** command to configure non-accounting or run the **accounting start-fail** command to configure a policy for accounting-start failures.

Follow-up Procedure

Apply the accounting scheme to a domain to enable the device to charge the users in the domain using the **domain** command in the AAA view.

Example

Set the accounting mode to RADIUS in the accounting scheme **scheme1**.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] accounting-scheme scheme1
[HUAWEI-aaa-accounting-scheme1] accounting-mode radius
```

13.1.17 accounting-scheme (AAA domain view)

Function

The **accounting-scheme** command applies an accounting scheme to a domain.

The **undo accounting-scheme** command restores the default accounting scheme of a domain.

By default, the accounting scheme named **default** is applied to a domain. In this default accounting scheme, non-accounting is used and the real-time accounting function is disabled.

Format

accounting-scheme *accounting-scheme-name*

undo accounting-scheme

Parameters

Parameter	Description	Value
accounting-scheme-name	Specifies the name of an accounting scheme.	The accounting scheme must already exist.

Views

AAA domain view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To charge users in a domain, create an accounting scheme and perform configurations in the accounting scheme, for example, set the accounting mode and policy for accounting-start failures. Run the **accounting-scheme** command in the AAA domain view to apply the accounting scheme to the domain.

Prerequisites

An accounting scheme has been created and configured using the **accounting-scheme** command. For example, the accounting mode and policy for accounting-start failures have been configured.

Example

Apply the accounting scheme **account1** to the domain **isp1**.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] accounting-scheme account1
[HUAWEI-aaa-accounting-account1] quit
[HUAWEI-aaa] domain isp1
[HUAWEI-aaa-domain-isp1] accounting-scheme account1
```

Restore the default accounting scheme of the domain **isp2**.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] domain isp2
[HUAWEI-aaa-domain-isp2] undo accounting-scheme
```

13.1.18 accounting-scheme (AAA view)

Function

The **accounting-scheme** command creates an accounting scheme and displays the accounting scheme view.

The **undo accounting-scheme** command deletes an accounting scheme.

By default, there is an accounting scheme named **default** in the system. This default accounting scheme can be modified but cannot be deleted. In this default accounting scheme, non-accounting is used and the real-time accounting function is disabled.

Format

accounting-scheme *accounting-scheme-name*

undo accounting-scheme *accounting-scheme-name*

Parameters

Parameter	Description	Value
accounting-scheme-name	Specifies the name of an accounting scheme.	The value is a string of 1 to 32 case-sensitive characters. It cannot contain spaces or the following symbols: / \ : * ? " < > | @ ' %. The value cannot be - or --.

Views

AAA view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To charge users in a domain, create and configure an accounting scheme, for example, the accounting mode and policy for accounting-start failures. Run the **accounting-scheme** command in the AAA domain view to apply the accounting scheme to the domain.

Follow-up Procedure

After an accounting scheme is created:

- Run the **accounting interim-fail** command to set the maximum number of real-time accounting failures and configure a policy used after a real-time accounting failure.
- Run the **accounting realtime** command to enable the real-time accounting function and set the interval for real-time accounting in an accounting scheme.
- Run the **accounting start-fail** command to configure a policy for accounting-start failures.
- Run the **accounting-mode** command to configure an accounting mode in an accounting scheme.

After an accounting scheme is configured, run the **accounting-scheme** command in the AAA domain view to apply the accounting scheme to a domain.

Precautions

If the configured accounting scheme does not exist, the **accounting-scheme** command in the AAA view creates an accounting scheme and displays the accounting scheme view. If the configured accounting scheme already exists, the **accounting-scheme** command in the AAA view displays the accounting scheme view directly.

To delete an accounting scheme applied to a domain, run the **undo accounting-scheme (AAA domain view)** command.

Example

Create an accounting scheme named **scheme1**.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] accounting-scheme scheme1
[HUAWEI-aaa-accounting-scheme1]
```

Enter the default accounting scheme view.

```
<HUAWEI> system-view
[HUAWEI] aaa
```

```
[HUAWEI-aaa] accounting-scheme default
[HUAWEI-aaa-accounting-default]
```

13.1.19 access-user remote authen-fail

Function

The **access-user remote authen-fail** command enables the account locking function for access users who fail remote authentication.

The **undo access-user remote authen-fail** command disables the account locking function for access users who fail remote authentication.

By default, the account locking function is disabled for access users who fail remote authentication.

Format

access-user remote authen-fail retry-interval *retry-interval* **retry-time** *retry-time* **block-time** *block-time*

undo access-user remote authen-fail

Parameters

Parameter	Description	Value
retry-interval *retry-interval*	Specifies the authentication retry interval after a remote authentication failure.	The value is an integer in the range from 5 to 65535, in minutes.
retry-time *retry-time*	Specifies the maximum number of consecutive authentication failures.	The value is an integer in the range from 3 to 65535.
block-time *block-time*	Specifies the account locking period.	The value is an integer in the range from 5 to 65535, in minutes.

Views

AAA view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To ensure account and password security, enable the account locking function for access users who fail remote authentication. If a user reaches the incorrect account or password attempt limit within the specified authentication retry period, the user is locked and will be automatically unlocked after a certain period.

Precautions

- This command takes effect only for remotely authenticated access users.
- When an active/standby switchover is performed, the originally locked account is automatically unlocked.
- After you run the **undo access-user remote authen-fail** command to disable the account locking function for access users who fail remote authentication, the locked account is automatically unlocked.
- If a remote authentication user does not reach the consecutive authentication attempt limit configured using the **access-user remote authen-fail** command, the user is not locked. If you run the **access-user remote authen-fail** command to change the consecutive authentication attempt limit to be less than the number of consecutive authentication failures, the user has one chance to be authenticated.

Example

Enable the account locking function for access users who fail remote authentication, and set the authentication retry interval to 5 minutes, maximum number of consecutive authentication failures to 3, and account locking period to 5 minutes.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] access-user remote authen-fail retry-interval 5 retry-time 3 block-time 5
```

13.1.20 administrator remote authen-fail

Function

The **administrator remote authen-fail** command enables the account locking function for administrators who fail remote authentication.

The **undo administrator remote authen-fail** command disables the account locking function for administrators who fail remote authentication.

By default, the account locking function is enabled for administrators who fail remote authentication, the authentication retry interval is 5 minutes, the maximum number of consecutive authentication failures is 30, and the account locking period is 5 minutes.

Format

administrator remote authen-fail retry-interval *retry-interval* **retry-time** *retry-time* **block-time** *block-time*

undo administrator remote authen-fail

Parameters

Parameter	Description	Value
retry-interval *retry-interval*	Specifies the authentication retry interval after a remote authentication failure.	The value is an integer in the range from 5 to 65535, in minutes.
retry-time *retry-time*	Specifies the maximum number of consecutive authentication failures.	The value is an integer in the range from 3 to 65535.
block-time *block-time*	Specifies the account locking period.	The value is an integer in the range from 5 to 65535, in minutes.

Views

AAA view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To ensure account and password security of administrators, enable the account locking function for administrators who fail remote authentication. If an administrator enters incorrect account and password more than the maximum number of consecutive authentication failures within the given period, the account is locked. After a certain period, the account is unlocked.

Precautions

- This command takes effect only for remotely authenticated administrators.
- When an active/standby switchover is performed, the originally locked account is automatically unlocked.
- After you run the **undo administrator remote authen-fail** command to disable the account locking function for administrators that fail remote authentication, the locked account is automatically unlocked.
- If a remote authentication user does not reach the consecutive authentication attempt limit configured using the **administrator remote authen-fail** command, the user is not locked. If you run the **administrator remote authen-fail** command to change the consecutive authentication attempt limit to be less than the number of consecutive authentication failures, the user has one chance to be authenticated.

Example

Enable the account locking function for administrators who fail remote authentication, and set the authentication retry interval to 5 minutes, maximum number of consecutive authentication failures to 3, and account locking period to 5 minutes.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] administrator remote authen-fail retry-interval 5 retry-time 3 block-time 5
```

13.1.21 admin-user privilege level

Function

The **admin-user privilege level** command configures a user as an administrator to log in to the device and sets the user privilege level.

The **undo admin-user privilege level** command cancels the default user privilege level.

By default, the user privilege level is not specified.

Format

admin-user privilege level *level*

undo admin-user privilege level

Parameters

Parameter	Description	Value
level	Specifies a user privilege level. A larger value indicates a higher user privilege level. After logging in to the device, a user can run only the commands at the same or lower privilege levels.	The value is an integer that ranges from 0 to 15.

Views

Service scheme view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The device provides hierarchical management of commands. A command has a privilege level, and a user can run only the commands at the same or lower privilege levels. By using the **admin-user privilege level** command to set the user privilege level, the device controls commands used by users.

By default, commands are classified into the following privilege levels:

- Level 0 (visit level): Commands at level 0 include diagnosis commands such as ping and tracert commands and commands that are used to access a remote device such as the STelnet client. Commands at level 0 cannot be used to save configuration files.
- Level 1 (monitoring level): Commands at level 1 are used for system maintenance, including display commands. Commands at level 1 cannot be used to save configuration files.
- Level 2 (configuration level): Commands at level 2 are used for service configuration, including routing commands and commands at each network layer to provide network services for users.
- Level 3 (management level): Commands at level 3 are used for basic operations of the system to support services, including file system, FTP, Trivial File Transfer Protocol (TFTP), configuration file switching commands, slave board control commands, user management commands, command level configuration commands, and debugging commands.

To manage users in a refined manner, upgrade command privilege levels to levels 0 to 15. You can run the **command-privilege level** command to upgrade command privilege levels in a batch. You can also run the **command-privilege level rearrange** command to increase privilege levels.

- If non-authentication is used, the administrator privilege level is specified using the **user privilege** command in the VTY interface view.
- If local authentication is used, the user privilege level of the administrator is the local user privilege level configured using the **local-user privilege level** command.
- If remote authentication is performed, the administrator privilege level can be set in the following ways, in descending order of priority:
  a. Using the user privilege level sent by an authentication server to the device after authentication has succeeded
  b. Running the **admin-user privilege level** command to set the administrator privilege level in a service scheme
  c. Running the **user privilege** command to set the user privilege level in VTY mode
- If both remote authentication and local authentication are configured and remote authentication is performed before local authentication, the administrator privilege level is that used in remote authentication. If local authentication is performed because the remote server does not respond, the administrator privilege level is the local user privilege level configured using the **local-user privilege level** command.

The device can update the configuration in a domain dynamically. After a service scheme is applied to a domain, you can directly modify the user privilege level in the service scheme but cannot unbind the service scheme from the domain. To delete the service scheme, run the **undo service-scheme (AAA domain view)** command.

Follow-up Procedure

Run the **display service-scheme** command to view the user privilege level in a service scheme.

Example

Configure a user as an administrator to log in to the device and set the administrator privilege level to 15.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] service-scheme svcscheme1
[HUAWEI-aaa-service-svcscheme1] admin-user privilege level 15
```

13.1.22 assignment

Function

The **assignment** command configures the VLAN assignment algorithm in a VLAN pool.

The **undo assignment** command restores the default VLAN assignment algorithm in a VLAN pool.

By default, the VLAN assignment algorithm is **hash** in a VLAN pool.

Format

assignment { **even** | **hash** }

undo assignment

Parameters

Parameter	Description	Value
even	Sets the VLAN assignment algorithm to **even**.	-
hash	Sets the VLAN assignment algorithm to **hash**.	-

Views

VLAN pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

- When the VLAN assignment algorithm is set to **even**, service VLANs are assigned to users from the VLAN pool based on the order in which users go online. Address pools mapping the service VLANs evenly assign IP addresses to users. If a user goes online many times, it obtains different IP addresses.
- When the VLAN assignment algorithm is set to **hash**, VLANs are assigned to users from the VLAN pool based on the hash result of their MAC addresses. As long as the VLANs in the VLAN pool do not change, the users obtain fixed VLAN. A user is preferentially assigned the same IP address when going online at different times.

Precautions

For the **even** VLAN assignment algorithm, the aging time of IP addresses is set large on the DHCP server. A user is assigned different IP addresses when going online at different times. As a result, a user may occupy many IP addresses, which wastes IP addresses. Additionally, frequent IP address changes may lower user experience.

Configuration Impact

The VLAN assignment algorithm configuration affects only newly connected users, but not those that have been connected to the network.

Example

Set the VLAN assignment algorithm to **even** in the VLAN pool **test**.

```
<HUAWEI> system-view
[HUAWEI] vlan pool test
[HUAWEI-vlan-pool-test] assignment even
```

13.1.23 authentication-mode (authentication scheme view)

Function

The **authentication-mode** command configures an authentication mode for an authentication scheme.

The **undo authentication-mode** command restores the default authentication mode in an authentication scheme.

By default, local authentication is used. The names of local users are case-insensitive.

Format

authentication-mode { **hwtacacs** | [**local** | **local-case**] | **radius** | **haca** } * [**none**]

authentication-mode none

undo authentication-mode

NOTE

Only the following switch models support HACA:

S200, S1730S-S1

S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5720S-LI, S500, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H and S6720S-S

Parameters

Parameter	Description	Value
hwtacacs	Authenticates users using an HWTACACS server. To perform HWTACACS authentication, configure an HWTACACS authentication server in an HWTACACS server template.	-
local	Authenticates users locally and sets local user names to case-insensitive.	-
local-case	Authenticates users locally and sets local user names to case-sensitive.	-
radius	Authenticates users using a RADIUS server. To perform RADIUS authentication, configure a RADIUS authentication server in a RADIUS server template.	-
haca	Authenticates users using a Huawei Agile Cloud Authentication (HACA) server.	-
none	Indicates non-authentication. That is, users access the network without being authenticated.	-

Views

Authentication scheme view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To authenticate users, configure an authentication mode in an authentication scheme.

If multiple authentication modes are configured in an authentication scheme, the authentication modes are used according to the sequence in which they were configured.

- In the sequence of local authentication followed by remote authentication:

  If a login account is not created locally but exists on the remote server, the authentication mode is changed from local authentication to remote authentication.

  If a login account is created locally and on the remote server, and local authentication fails because the password is incorrect, remote authentication will not be performed.

- In the sequence of remote authentication followed by local authentication:

  If a login account is created locally but not on the remote server, remote authentication fails and local authentication will not be performed.

  A user is authenticated using the local authentication mode only when the remote server is Down or does not respond to the user's authentication request.

  NOTE

  Normally, if the remote server is Down or does not respond, local authentication is used. If a large number of users need to go online through the device, the device may be unable to process responses from the server in a timely manner. As a result, the AAA module of the device cannot receive responses from the server until the protection timer expires. These users then cannot go online and cannot be authenticated using local authentication. In this case, reconnect these offline users to the device.

You can configure multiple authentication modes in an authentication scheme to reduce authentication failure possibilities.

- After the **authentication-mode radius local** command is used, the device cannot complete RADIUS authentication if it fails to connect to the RADIUS authentication server. In this case, the device starts local authentication.
- After the **authentication-mode local radius** command is used, if the entered user name exists on the device but the entered password is incorrect, the user fails the authentication; if the entered user name does not exist on the device, the user is redirected to the RADIUS authentication mode and is authenticated based on user information on the RADIUS server.

NOTE

- When both RADIUS authentication and non-authentication are configured, if the user fails the RADIUS authentication, non-authentication cannot be used. As a result, a user fails to log in.
- If you run the **authentication-mode** command to configure non-authentication and run the **authentication-mode (user interface view)** command to configure AAA authentication, the device does not allow administrators to log in from the user interface view.
- If none authentication is configured or none authentication is configured as the backup authentication mode, you need to run the **accounting start-fail online** or **accounting-mode none** command in the accounting scheme view to prevent users from going offline due to accounting failures.

Precautions

If non-authentication is configured using the **authentication-mode** command, users can pass the authentication using any user name or password. Therefore, to protect the device and improve network security, you are advised to enable authentication, allowing only authenticated users to access the device or network.

It is not recommended that HACA authentication be configured together with another authentication (except non-authentication). Otherwise, the two configured authentication modes cannot take effect simultaneously. For example, if the **authentication-mode haca radius** command is configured, users can log in after passing HACA authentication; if users fail HACA authentication, RADIUS authentication will not be performed on them.

Example

Configure the authentication scheme named **scheme1** to use RADIUS authentication.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] authentication-scheme scheme1
[HUAWEI-aaa-authen-scheme1] authentication-mode radius
```

13.1.24 authentication-scheme (AAA domain view)

Function

The **authentication-scheme** command applies an authentication scheme to a domain.

The **undo authentication-scheme** command restores the default configuration of the authentication scheme in a domain.

By default, the authentication scheme named **radius** is applied to the **default** domain, the authentication scheme named **default** is applied to the **default_admin** domain, and the authentication scheme named **radius** is applied to other domains.

Format

authentication-scheme *scheme-name*

undo authentication-scheme

Parameters

Parameter	Description	Value
scheme-name	Specifies the name of an authentication scheme.	The value must be an existing authentication scheme name.

Views

AAA domain view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To authenticate users in a domain, run the **authentication-scheme (AAA domain view)** command to apply an authentication scheme to a domain.

Prerequisites

An authentication scheme has been created and configured with required parameters, for example, the authentication mode and authentication mode for upgrading user levels.

Example

Apply the authentication scheme named **scheme1** to a domain named **domain1**.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] domain domain1
[HUAWEI-aaa-domain-domain1] authentication-scheme scheme1
```

13.1.25 authentication-scheme (AAA view)

Function

The **authentication-scheme** command creates an authentication scheme and displays its view.

The **undo authentication-scheme** command deletes an authentication scheme.

By default, the default authentication scheme is used. This default authentication scheme can be modified but cannot be deleted. In the default authentication scheme:

- Local authentication is used.
- The **offline** policy is used for authentication failures.

By default, the system also provides the authentication scheme **radius**. The **radius** authentication scheme can be modified, but cannot be deleted. In the **radius** authentication scheme:

- RADIUS authentication is used.
- The **offline** policy is used for authentication failures.

Format

authentication-scheme *scheme-name*

undo authentication-scheme *scheme-name*

Parameters

Parameter	Description	Value
scheme-name	Specifies the name of an authentication scheme.	The value is a string of 1 to 32 case-sensitive characters. It cannot contain spaces or the following symbols: / \ : * ? " < > | @ ' %. The value cannot be - or --.

Views

AAA view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To authenticate users, run the **authentication-scheme** command to create an authentication scheme. Creating an authentication scheme is necessary before performing authentication-relevant configurations.

Follow-up Procedure

After an authentication scheme is created, run the **authentication-mode (authentication scheme view)** command to configure an authentication mode in an authentication scheme.

After an authentication scheme is configured, run the **authentication-scheme (AAA domain view)** command to apply the authentication scheme to a domain.

Precautions

If the configured authentication scheme does not exist, the **authentication-scheme** command creates an authentication scheme and displays the authentication scheme view. If the configured authentication scheme already exists, the **authentication-scheme** command directly displays the authentication scheme view.

To delete an authentication scheme applied to a domain, run the **undo authentication-scheme (AAA domain view)** command.

Example

Create an authentication scheme named **newscheme**.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] authentication-scheme newscheme
[HUAWEI-aaa-authen-newscheme]
```

Access the default authentication scheme view.

```
<HUAWEI> system-view
[HUAWEI] aaa
```

```
[HUAWEI-aaa] authentication-scheme default
[HUAWEI-aaa-authen-default]
```

13.1.26 authentication-super

Function

The **authentication-super** command configures an authentication mode for upgrading user levels in an authentication scheme.

The **undo authentication-super** command restores the default authentication mode for upgrading user levels in an authentication scheme.

By default, the **super** mode is used. That is, local authentication is used.

Format

authentication-super { **hwtacacs** | **radius** | **super** } * [**none**]

authentication-super none

undo authentication-super

Parameters

Parameter	Description	Value
hwtacacs	Uses HWTACACS authentication to upgrade user levels.	-
radius	Uses RADIUS authentication to upgrade user levels.	-
super	Uses local authentication to upgrade user levels.	-
none	Indicates that user levels can be upgraded without authentication.	-

Views

Authentication scheme view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If users in a domain need to upgrade their levels, the device requests the users to enter the password to authenticate the users. If AAA authentication has been configured using the **authentication-mode (user interface view)** command, run the **authentication-super** command to configure an authentication mode for upgrading user levels.

When you use the **super** command to switch a user level to a lower level or the same level, no authentication is required. When you use the **super** command to switch a user level to a higher level, authentication is required. The user can be granted rights only after being authenticated.

- If **super** is used and the local authentication is specified, run the **local-user** command in the AAA view to create a local user and set parameters for the local user.
- If **hwtacacs** is used and the HWTACACS authentication is specified, perform configurations relevant to HWTACACS authentication.
- If **radius** is used and the RADIUS authentication is specified, perform configurations relevant to RADIUS authentication.
- If **radius** is specified, the RADIUS authentication mode is used to upgrade the user level. The user name to be sent is $enab+user level. Ensure that the user has been configured on the server.
- If **none** is used, no authentication is required.

Precautions

If multiple authentication modes are configured in an authentication scheme, these authentication modes are used in the sequence in which they were configured. The device uses another authentication mode only when it does not receive any response in the current authentication. The device does not switch to another authentication mode if the user fails to pass one authentication mode.

Example

Set the authentication mode to HWTACACS authentication in the authentication scheme **scheme1**.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] authentication-scheme scheme1
[HUAWEI-aaa-authen-scheme1] authentication-super hwtacacs
```

13.1.27 authentication-type radius chap access-type admin

Function

The **authentication-type radius chap access-type admin** command replaces PAP authentication with CHAP authentication when RADIUS authentication is performed on administrators.

The **undo authentication-type radius chap access-type admin** command restores PAP authentication when RADIUS authentication is performed on administrators.

By default, PAP authentication is used when RADIUS authentication is performed on administrators.

Format

authentication-type radius chap access-type admin [**ftp** | **ssh** | **telnet** | **terminal** | **http**] *

undo authentication-type radius chap access-type admin

Parameters

Parameter	Description	Value
ftp	Replaces PAP authentication with CHAP authentication when RADIUS authentication is performed on administrators who access the device using FTP.	-
ssh	Replaces PAP authentication with CHAP authentication when RADIUS authentication is performed on administrators who access the device using SSH.	-
telnet	Replaces PAP authentication with CHAP authentication when RADIUS authentication is performed on administrators who access the device using Telnet.	-
terminal	Replaces PAP authentication with CHAP authentication when RADIUS authentication is performed on administrators who access the device using a terminal.	-

Parameter	Description	Value
http	Replaces PAP authentication with CHAP authentication when RADIUS authentication is performed on administrators who access the device using a web management system.	-

Views

Authentication scheme view

Default Level

3: Management level

Usage Guidelines

CHAP is ciphertext authentication protocol. During CHAP authentication, the NAS device sends the user name, encrypted password, and 16-byte random code to the RADIUS server. The RADIUS server searches for the database according to the user name and obtains the password that is the same as the encrypted password at the user side. The RADIUS server then encrypts the received 16-byte random code and compares the result with the password. If they are the same, the user is authenticated. If they are different, the user fails to be authenticated. In addition, if the user is authenticated, the RADIUS server generates a 16-byte random code to challenge the user. CHAP is more secure and reliable than PAP.

If no parameter is specified when you run the **authentication-type radius chap access-type admin** command, the configuration takes effect on the administrators who access the device using FTP, SSH, Telnet, Terminal, and HTTP.

When the device is connected to the RADIUS server that supports CHAP authentication, this function needs to be configured.

Example

Replace PAP authentication with CHAP authentication when RADIUS authentication is performed on administrators who access the device using FTP.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] authentication-scheme scheme1
[HUAWEI-aaa-authen-scheme1] authentication-type radius chap access-type admin ftp
```

13.1.28 authorization-cmd

Function

The **authorization-cmd** command configures command-specific authorization for an administrator of a specific level. After command-specific authorization is enabled and an administrator of a specific privilege level logs in to the device, the commands that the administrator enters can be executed only after being authorized by the HWTACACS server.

The **undo authorization-cmd** command disables command-specific authorization for an administrator of a specific privilege level.

By default, the command-specific authorization is disabled. That is, an administrator of any level can execute only commands of or below its privilege level after logging in to the device.

Format

authorization-cmd *privilege-level* **hwtacacs** [**local**] [**none**]

undo authorization-cmd *privilege-level*

Parameters

Parameter	Description	Value
privilege-level	Specified the administrator privilege level.	The value is an integer that ranges from 0 to 15.
hwtacacs	Indicates HWTACACS authorization.	-
local	Indicates local authorization.	-
none	Indicates that command line authorization is directly performed for a user if the HWTACACS server does not respond to the authorization request of the user.	-

Views

Authorization scheme view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After being authorized, the users at a certain privilege level can run the commands of the same or lower privilege levels. Command line authorization can be configured to implement minimum user rights control. When command line authorization is enabled, each command entered by users can be executed only after being authorized. After command line authorization is enabled for users at a certain privilege level, the commands run by the users at that privilege level must be authorized by an HWTACACS server.

Precautions

- You are advised to configure local authorization as a backup of command line authorization. If command line authorization cannot be performed because of a failure on an HWTACACS server, the device starts local authorization.
- After the **authorization-cmd** command is executed, command line authorization does not take effect immediately. Command line authorization takes effect only when an authorization scheme containing command line authorization is applied to administrator view correctly.
- Commands whose privilege levels are higher than the administrator privilege level cannot be authorized and fail to be executed.
- When configuring the **authorization-cmd** *privilege-level* **hwtacacs local** command, you must create a local account. The device then performs authentication based on the local account configuration.

NOTICE

After an authorization scheme containing command line authorization is applied to administrator view, if you run the **undo authorization-cmd** command, an online administrator at a certain privilege level cannot run any commands except for the **quit** command. The administrator needs to log in again.

Example

Configure command line authorization for administrators at the privilege level 2.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] authorization-scheme scheme1
[HUAWEI-aaa-author-scheme1] authorization-cmd 2 hwtacacs
```

13.1.29 authorization-info check-fail policy

Function

The **authorization-info check-fail policy** command determines whether the device allows users to go online after the authorization information check fails.

The **undo authorization-info check-fail policy** command restores the default configuration.

By default, the device allows users to go online after the authorization information check fails.

Format

authorization-info check-fail policy { **online** | **offline** }

undo authorization-info check-fail policy

Parameters

Parameter	Description	Value
online	Indicates that the device allows users to go online after the authorization information check fails.	-
offline	Indicates that the device prohibits users from going online after the authorization information check fails.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

The device supports user authorization through the ACL, UCL Group, User Group and VLAN delivered from the RADIUS server. If the ACL, UCL Group, User Group and VLAN delivered from the RADIUS server are not configured on the device, the authorization information check fails on the device.

You can use this command to configure the users to go online and the authorization information delivered by the RADIUS server does not take effect.

Example

Configure the device to allow users to go online after the authorization information check fails.

```
<HUAWEI> system-view
[HUAWEI] authorization-info check-fail policy online
```

13.1.30 authorization-mode

Function

The **authorization-mode** command configures an authorization mode for an authorization scheme.

The **undo authorization-mode** command restores the default authorization mode in an authorization scheme.

By default, local authorization is used. The names of local users are case-insensitive.

Format

authorization-mode { **hwtacacs** | **if-authenticated** | { **local** | **local-case** } } * [**none**]

authorization-mode none

undo authorization-mode

Parameters

Parameter	Description	Value
hwtacacs	Indicates that the user is authorized by an HWTACACS server.	-
if-authenticated	Indicates that only the user who succeeds in authentication is authorized. The configuration of if-authenticated authorization does not take effect in RADIUS authentication.	-
local	Authenticates users locally and sets local user names to case-insensitive.	-
local-case	Authenticates users locally and sets local user names to case-sensitive.	-
none	Indicates non-authorization.	-

Views

Authorization scheme view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To authorize users, configure an authorization mode in an authorization scheme.

You can configure multiple authorization modes in an authorization scheme to reduce the chance of authorization failures.

After the **authorization-mode hwtacacs local** command is used, if it fails to connect to the HWTACACS authentication server and HWTACACS authorization cannot be performed, the device starts local authorization.

Precautions

- If multiple authorization modes are used in an authorization scheme, the **if-authenticated** mode or **none** mode must be used as the last authorization mode.
- If the authorization mode is set to **if-authenticated** or **none**, the local authentication administrator does not inherit the level configured using the **local-user privilege level** command after login. The administrator first inherits the level configured using the **admin-user privilege level** command in the service scheme bound to the domain. If the level is not configured in the domain, the administrator inherits the level configured using the **user privilege** command in the VTY view.

  By default, users who log in to a device in the VTY view of the console interface are at level 15 and users who log in to a device in other VTY views are at level 0.
- If multiple authorization modes are configured in an authorization scheme, the authorization modes are used according to the sequence in which they were configured. The device uses another authorization mode only when it does not receive any response in the current authorization mode.

Example

Configure the authorization scheme named **scheme1** to apply HWTACACS authorization.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] authorization-scheme scheme1
[HUAWEI-aaa-author-scheme1] authorization-mode hwtacacs
```

13.1.31 authorization-modify mode

Function

The **authorization-modify mode** command configures the update mode for user authorization information delivered by the authorization server.

The **undo authorization-modify mode** command restores the default update mode for user authorization information delivered by the authorization server.

By default, the update mode of user authorization information delivered by the authorization server is **overlay**. That is, the new user authorization information overwrites all existing user authorization information.

Format

authorization-modify mode { **modify** | **overlay** }

undo authorization-modify mode

Parameters

Parameter	Description	Value
modify	Indicates the **modify** mode.	-
overlay	Indicates the **overlay** mode.	-

Views

AAA view

Default Level

3: Management level

Usage Guidelines

The authorization server can deliver all or part of user authorization information, such as the ACL rule and dynamic VLAN.

You can run the **authorization-modify mode** command to configure one of the following update modes for user authorization information delivered by the authorization server:

- **modify**: modification mode indicating that new user authorization information overwrites only existing user authorization information of the same type.
- **overlay**: overwriting mode indicating that new user authorization information overwrites all existing user authorization information.

If the authorization server has delivered ACL 3001 to a user, and the administrator needs to deliver new authorization information:

- In the **modify** mode, if the new authorization information is ACL 3002, the authorization information of the user is ACL 3002. If the new authorization information is VLAN 100, the authorization information of the user is ACL 3001 and VLAN 100.
- In the **overlay** mode, no matter whether the new authorization information is ACL 3002 or VLAN 100, the authorization information of the user is the new ACL or VLAN.

This command takes effect for only the authorization information delivered by the RADIUS server.

After a user group or service scheme is authorized to a user on the device and a certain attribute configured in the user group or service scheme is modified on the server, if other configured attributes need to be modified, the authorization information on the server must contain the previously modified attribute. Otherwise, the original attribute value in the user group or service scheme will be restored. For example, to modify an attribute in a user group:

1. The device authorizes the user group configured with the VLAN and ACL attributes to a user.
2. To modify the VLAN attribute, authorize the new VLAN attribute to the user through the RADIUS server.
3. To modify the ACL attribute after the VLAN attribute is modified, you must authorize the modified VLAN attribute and new ACL attribute through the RADIUS server. Otherwise, the original VLAN attribute in the user group will be restored.

NOTE

For user re-authentication:

- If the Session-Timeout attribute is delivered during RADIUS CoA authorization, the original re-authentication timer is deleted and the timer carried by the Session-Timeout attribute is started.
- If the Session-Timeout attribute is not delivered during RADIUS CoA authorization:
  - When the **modify** mode is used, the original re-authentication timer is not deleted; instead, the timer is suspended during user authorization and continues to take effect after the authorization completes.
  - When the **overlay** mode is used:

    If the original re-authentication timer is locally configured, the original re-authentication timer is not deleted; instead, the timer is suspended during user authorization and continues to take effect after the authorization completes.

    If the original timer is delivered by the server, the original timer is deleted and re-authentication is performed depending on whether the local re-authentication timer is configured on the device.

Example

Set the update mode of user authorization information delivered by the authorization server to **modify**.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] authorization-modify mode modify
```

13.1.32 authorization-scheme (AAA domain view)

Function

The **authorization-scheme** command applies an authorization scheme to a domain.

The **undo authorization-scheme** command unbinds an authorization scheme from a domain.

By default, no authorization scheme is applied to a domain.

Format

authorization-scheme *authorization-scheme-name*

undo authorization-scheme

Parameters

Parameter	Description	Value
authorization-scheme-name	Specifies the name of an authorization scheme.	The authorization scheme must already exist.

Views

AAA domain view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

RADIUS integrates authentication and authorization; therefore, RADIUS authorization and authentication must be used together. HWTACACS separates authentication from authorization; therefore, you can configure another authorization type even if HWTACACS authentication, local authentication, or non-authentication is used.

To authorize users in a domain, run the **authorization-scheme (AAA domain view)** command.

Prerequisites

An authorization scheme has been created and configured with required parameters, for example, the authorization mode and command line authorization.

Example

Apply the authorization scheme **author1** to the domain **isp1**.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] authorization-scheme author1
[HUAWEI-aaa-author-author1] quit
[HUAWEI-aaa] domain isp1
[HUAWEI-aaa-domain-isp1] authorization-scheme author1
```

13.1.33 authorization-scheme (AAA view)

Function

The **authorization-scheme** command creates an authorization scheme and enters the authorization scheme view, or directly enters an existing authorization scheme view.

The **undo authorization-scheme** command deletes an authorization scheme.

By default, the default authorization scheme is used. This default authorization scheme can be modified but cannot be deleted. In the default authorization scheme, local authorization is used and command line authorization is disabled.

Format

authorization-scheme *authorization-scheme-name*

undo authorization-scheme *authorization-scheme-name*

Parameters

Parameter	Description	Value
authorization-scheme-name	Specifies the name of an authorization scheme.	The value is a string of 1 to 32 case-sensitive characters. It cannot contain spaces or the following symbols: / \ : * ? " < > | @ ' %. The value cannot be - or --.

Views

AAA view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

RADIUS integrates authentication and authorization; therefore, RADIUS authorization and authentication must be used together. HWTACACS separates authentication from authorization; therefore, you can configure another authorization type even if HWTACACS authentication, local authentication, or non-authentication is used. You must run the **authorization-scheme** command to create an authorization scheme before performing authorization-relevant configurations, for example, setting the authorization mode and command line authorization function.

Follow-up Procedure

After an authorization scheme is created:

- Run the **authorization-mode** command to configure an authorization mode in an authorization scheme.
- Run the **authorization-cmd** command to configure command line authorization for users at a certain level.

After an authorization scheme is configured, run the **authorization-scheme (AAA domain view)** command to apply the authorization scheme to a domain.

Precautions

- If the configured authorization scheme does not exist, the **authorization-scheme (AAA view)** command creates an authorization scheme and displays the authorization scheme view.
- If the configured authorization scheme already exists, the **authorization-scheme (AAA view)** command directly displays the authorization scheme view.

To delete the authorization scheme applied to a domain, run the **undo authorization-scheme (AAA domain view)** command.

Example

Create an authorization scheme named **scheme0**.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] authorization-scheme scheme0
[HUAWEI-aaa-author-scheme0]
```

Enter the default authorization scheme view.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] authorization-scheme default
[HUAWEI-aaa-author-default]
```

13.1.34 cmd recording-scheme

Function

The **cmd recording-scheme** command applies a policy in a recording scheme to record the commands executed on the device.

The **undo cmd recording-scheme** command deletes a policy from a recording scheme.

By default, the commands that are used on the device are not recorded.

Format

cmd recording-scheme *recording-scheme-name*

undo cmd recording-scheme

Parameters

Parameter	Description	Value
recording-scheme-name	Specifies the name of a recording scheme.	The recording scheme must already exist.

Views

AAA view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

During the device configuration, incorrect operations may result in network faults. After the **cmd recording-scheme** command is executed, you can view records of the commands executed on the device to locate the network faults.

Prerequisites

A recording scheme has been created by using the **recording-scheme** command and a recording mode has been configured by using the **recording-mode hwtacacs** command.

Example

Configure a policy in the recording scheme **scheme0** to record the commands executed on the device.

```
<HUAWEI> system-view
[HUAWEI] hwtacacs-server template hw1
[HUAWEI-hwtacacs-hw1] quit
[HUAWEI] aaa
[HUAWEI-aaa] recording-scheme scheme0
[HUAWEI-aaa-recording-scheme0] recording-mode hwtacacs hw1
[HUAWEI-aaa-recording-scheme0] quit
[HUAWEI-aaa] cmd recording-scheme scheme0
```

13.1.35 cut access-user

Function

The **cut access-user** command terminates one or multiple access user connections, also forcibly disconnecting online users.

Format

cut access-user { **domain** *domain-name* | **interface** *interface-type interface-number* [**vlan** *vlan-id* [**qinq** *qinq-vlan-id*]] | **ip-address** *ip-address* [**vpn-instance** *vpn-instance-name*] | **mac-address** *mac-address* | **service-scheme** *service-scheme-name* | **access-slot** *slot-id* | **user-id** *begin-number* [*end-number*] | **username** *user-name* }

cut access-user ssid *ssid-name* (This command is only supported by the S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.)

cut access-user access-type admin [**ftp** | **ssh** | **telnet** | **terminal** | **web**] [**username** *user-name*]

Parameters

Parameter	Description	Value
domain *domain-name*	Disconnects sessions in a specified domain.	The value must be the name of an existing domain.
interface *interface-type interface-number*	Disconnects sessions on a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
vlan *vlan-id* [**qinq** *qinq-vlan-id*]	Disconnects sessions in a specified VLAN. - *vlan-id* specifies the ID of a VLAN. In QinQ applications, this parameter specifies the inner VLAN ID. - *qinq-vlan-id* specifies the outer VLAN ID.	The values of *vlan-id* and *qinq-vlan-id* are integers that range from 1 to 4094.
ip-address *ip-address*	Disconnects sessions initiated by a specified IP address.	The value is in dotted decimal notation.
vpn-instance *vpn-instance-name*	Indicates the name of the VPN instance that the specified IP address belongs to.	The value must be an existing VPN instance name.
mac-address *mac-address*	Disconnects sessions initiated by a specified MAC address.	The value is in H-H-H format. An H contains 4 hexadecimal digits.
service-scheme *service-scheme-name*	Terminates connections based on the service scheme.	The value must be the name of an existing service scheme.
access-slot *slot-id*	Disconnects sessions on a specified device.	The value range depends on the model of the device.
ssid *ssid-name*	Disconnects sessions initiated by a service set identifier (SSID) for a service set.	The SSID must already exist. **NOTE** SSID is supported only in the NAC unified mode.
user-id *begin-number* [*end-number*]	Disconnects sessions of a specified user.	The user-id must exist on the device.

Parameter	Description	Value
username *user-name*	Disconnects sessions of a user with a specified user name.	The value must be the name of an existing user.
access-type	Displays information about the users using the specified authentication mode.	-
admin [**ftp** | **ssh** | **telnet** | **terminal** | **web**]	Displays information about the administrators using the specified authentication mode. ● **ftp**: FTP user ● **ssh**: SSH user ● **telnet**: Telnet user ● **terminal**: Terminal user ● **web**: Web user	-

Usage Guidelines

Usage Scenario

Performing some configurations, such as AAA, on the device, requires that no users be online. You can run the **cut access-user** command to disconnect sessions.

Precautions

- The **cut access-user** command interrupts all services of the user whose session is torn down.
- For administrators, lower-level users cannot tear down the connections of higher-level users.
- If the character string of the user name contains spaces (for example, a b), you can run the **display access-user username "a b"** command to view online users.
- If the character string of the user name contains spaces and quotation marks ("") simultaneously, you cannot use the user name to view online users. In this case, you can run the **display access-user | include** *username* command to view the user ID of the online user, and then run the **display access-user**

user-id *user-id* command to view the user. Alternatively, you can run the **cut access-user user-id** *user-id* command to force the user to go offline.

Example

Tear down the session initiated by the IP address 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] cut access-user ip-address 10.1.1.1
```

13.1.36 display aaa

Function

The **display aaa** command displays information about normal logout, abnormal logout, and login failures.

Format

display aaa { **offline-record** | **abnormal-offline-record** | **online-fail-record** } { **all** | **reverse-order** | **domain** *domain-name* | **interface** *interface-type interface-number* [**vlan** *vlan-id* [**qinq** *qinq-vlan-id*]] | **ip-address** *ip-address* [**vpn-instance** *vpn-instance-name*] | **mac-address** *mac-address* | **access-slot** *slot-number* | **time** *start-time end-time* [**date** *start-date end-date*] | **username** *user-name* [**time** *start-time end-time* [**date** *start-date end-date*]] } [**brief**]

Parameters

Parameter	Description	Value
offline-record	Displays normal logout records.	-
abnormal-offline-record	Displays abnormal logout records.	-
online-fail-record	Displays login failure records.	-
all	Displays all login and logout records.	-
reverse-order	Displays the records in order of newest to oldest.	-
domain *domain-name*	Specifies the name of a domain.	The value is a string of 1 to 64 case-insensitive characters, excluding spaces, *, ?, and ".
interface *interface-type interface-number*	Specifies the type and number of an interface.	-

Parameter	Description	Value
vlan *vlan-id*	Specifies the inner VLAN ID.	The value is an integer that ranges from 1 to 4094.
qinq *qinq-vlan-id*	Specifies the outer VLAN ID.	The value is an integer that ranges from 1 to 4094.
ip-address *ip-address*	Specifies an IP address.	The value is in dotted decimal notation.
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
mac-address *mac-address*	Specifies a MAC address.	The value is in H-H-H format. An H is a 4-digit hexadecimal number.
access-slot *slot-number*	Specifies a slot ID.	The value is an integer. The value range depends on the model of the device.
username *user-name*	Specifies a user.	The value must be an existing user.
time *start-time end-time*	Specifies a time range.	The format is HH:MM:SS, indicating hour:minute:second.
date *start-date end-date*	Specifies a date.	The format is YYYY/MM/DD. YYYY is the year, MM is the month, and DD is the day.
brief	Displays brief login and logout information.	-

1: Monitoring level

Usage Guidelines

Usage Scenario

This command allows you to view information about user normal logouts, abnormal logouts, and login failures based on the domain name, interface, IP address, VPN instance, MAC address, or slot ID.

Precautions

Only letters, digits, and special characters can be displayed for **username**.

When the value of **username** contains special characters or characters in other languages except English, the device displays dots (.) for these characters. If there are more than three such consecutive characters, three dots (.) are displayed. Here, the special characters are the ASCII codes smaller than 32 (space) or larger than 126 (~).

NOTE

For the meanings, causes, and handling suggestions of abnormal user logins and logouts, see "**Common Causes of Access Authentication**" in the *Huawei S Series Campus Switches Troubleshooting Guide*.

Example

Display information about normal user logouts in the domain **rds**.

```
<HUAWEI> display aaa offline-record domain rds
 -------------------------------------------------------------------
  User name             : test@rds
  Domain name           : rds
  User MAC              : 00e0-fc01-b67c
  User access type      : 802.1x

Table 13-2 Description of the **display aaa** command output

Item	Description
User name	User name.
Domain name	Domain of a user.

Item	Description
User MAC or MAC	MAC address of a user.
User access type	Access type of a user: - 802.1x indicates that the user accesses the network through 802.1X. - API indicates that the user accesses the network through the API. - FTP indicates that the user accesses the network through FTP. - Telnet indicates that the user accesses the network through Telnet. - Terminal indicates that the user accesses the network through terminal. - SSH indicates that the user accesses the network through SSH. - x25-pad indicates that the user accesses the network through x25-pad. - HTTP indicates that the user accesses the network through HTTP. - Web indicates that the user accesses the network through web. For the related command, see **local-user service-type**.
User access interface	Access interface of a user.
Qinq vlan/User vlan	VLAN that a user belongs to. - In QinQ application, QinQvlan indicates the outer VLAN ID and Uservlan indicates the inner VLAN ID. - For a common VLAN, Uservlan indicates the VLAN ID, and QinQvlan is 0.
User IP address or IP address	IP address of a user.
User IPV6 address	IPv6 address of a user.
User ID	Index of a user.
User login time	Time when a user goes online.
User offline time	Time when a user goes offline.

Item	Description
User offline reason, User online fail reason, or Reason	Reason why a user fails to go online or offline. The common reasons are as follows: ● The value "EAPOL user request" indicates that an 802.1X user requests to go offline. ● The value "PPP user request" indicates that a PPP user requests to go offline. ● The value "Web user request" indicates that a web user requests to go offline. ● The value "AAA cut command" indicates that a user is deleted using command line. ● The value "Session time out" indicates that a session times out. ● The value "Idle cut" indicates that a user is disconnected because the user does not perform any operation within a specified period. ● The value "PPP authentication fail" indicates a PPP authentication failure. ● The value "STA disassociation" indicates that a STA is disassociated. ● The value "STA disassociation(delay offline)" indicates that the STA disassociation is delayed. ● The value "console reset or disable port" indicates that the management interface is Down. ● The value "Interface net down" indicates that an interface is Down. ● The value "Local authentication reject" indicates that the local authentication password is incorrect. ● The value "AS detect fail" indicates that an AS detection failure occurs on an access device in the policy association scenario. ● The value "AS smooth fail" indicates that an AS smoothing

Item	Description
	failure occurs on an access device in the policy association scenario. - The value "AS configuration changed on interface" indicates that the user goes offline because the configuration of an AS interface on an access device changes in the policy association scenario. - The value "IP address conflict" indicates that IP addresses conflict. - The value "Add FPI item timeout(LPU)" indicates that the LPU authorization times out. - The value "EAPOL client timeout" indicates that the client times out to respond. - The value "low RSSI" indicates that the wireless signal strength is weak. - The value "No authentication server configured" indicates that no authentication server is configured. - The value "No radius-server template bound" indicates that no RADIUS server template is bound. - The value "No tacacs-server template bound" indicates that no TACACS server template is bound. - The value "No accounting server configured" indicates that no accounting server is configured. - The value "Accounting server no response" indicates that the accounting server does not respond. - The value "EAPOL client restart associate" indicates that the 802.1X client re-triggers an association. - The value "Users with low priorities go offline" indicates that users go offline because their priorities are low. - The value "Resources are insufficient" indicates that

Item	Description
	resources of the device are insufficient. - The value "Local Authentication user block" indicates that the local user is locked. - The value "Roaming is prohibited" indicates that user roaming is forbidden. - The value "AP fault" indicates that a wireless user is forced offline due to AP disconnection. - The value "Remote user is blocked" indicates that the remotely authenticated user is locked. - The value "Not support authorization with car" indicates that upstream CAR authorization is not supported for the user group. - The value "Not support authorization with user-group" indicates that re-mark authorization is not supported for the user group. - The value "Radius authentication reject" indicates that the RADIUS server responds with an Access-Reject packet. - The value "Data flow or online time exceed threshold" indicates that the online duration or used traffic of the user reaches the threshold. - The value "AS access interface down" indicates that the interface connecting an access device to a user goes Down in an SVF or policy association scenario. - The value "Server response times out" indicates that the server does not respond due to timeout. - The value "The shared keys on the device and Portal server are different" indicates that the shared key configured on the device is different from that configured on the Portal server.

Item	Description
	● "The acl locally delivered by AAA is invalid or does not exist": The ACL delivered by AAA is invalid or does not exist. ● "The description of the acl sent by Radius is incorrect": The description of the ACL delivered by RADIUS is incorrect. ● "The Rediect ACL delivered by AAA is incorrectly checked": The redirect ACL delivered by AAA is incorrect. ● "AAA gets service scheme error": AAA failed to obtain SERVICE_SCHEME. ● "AAA get author info error": AAA failed to obtain authentication information. ● "AAA check author vlan error": AAA failed to check the authorized VLAN. ● The value "AAA authorization dynamic vlan error" indicates that the dynamic VLAN authorized by AAA is incorrect. ● The value "SAM failed to deliver authorized VLAN" indicates that SAM failed to deliver the authorized VLAN. ● "SAM failed to deliver QOS": SAM failed to deliver QoS. ● "SAM failed to deliver port mac limit": SAM failed to deliver the port MAC limit. ● "SAM failed to deliver vm car": SAM failed to deliver VM CAR. ● "User flow detect fail": User traffic detection fails.

Item	Description
Authen reply message	Authentication response message. If the Access-Reject packet returned by the RADIUS server carries this field, this field is filled with the message carried in the Access-Reject packet. The length of this field cannot exceed 32 bytes. Otherwise, the message "Authentication fail,user is blocked" or "Authentication fail" is displayed.
User name to server	User name sent by the device to the server.
AP ID	ID of the AP that a wireless user associates with.
Radio ID	ID of the radio that a wireless user associates with.
AP MAC	MAC address of the AP that a wireless user associates with.
SSID	SSID that a wireless user associates with.
Conflict IP address/Conflict IPv6 address	Conflicting IPv4 or IPv6 address.

13.1.37 display aaa configuration

Function

The **display aaa configuration** command displays the AAA configurations, for example, the domain, authentication scheme, authorization scheme, and accounting scheme.

Format

display aaa configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

AAA configurations are limited by system specifications. Before performing AAA configurations, run the **display aaa configuration** command to check whether there are sufficient resources.

Example

Display the AAA summary.

```
<HUAWEI> display aaa configuration
  Domain Name Delimiter                    : @
  Domainname parse direction               : Left to right
  Domainname location                      : After-delimiter
  Administrator user default domain        : default_admin
  Normal user default domain               : default
  Domain                                   : total: 32      used: 5
  Authentication-scheme                    : total: 33      used: 4
  Accounting-scheme                        : total: 32      used: 3
  Authorization-scheme                     : total: 32      used: 2
  Service-scheme                           : total: 32      used: 0
  Recording-scheme                         : total: 64      used: 0
  Local-user                               : total: 1000    used: 1
  Local-user block retry-interval          : 5 Min(s)
  Local-user block retry-time              : 3
  Local-user block time                    : 5 Min(s)
  Remote-admin-user block retry-interval   : 5 Min(s)
  Remote-admin-user block retry-time       : 30
  Remote-admin-user block time             : 5 Min(s)
  Session timeout invalid enable           : No
  Navigator first login state              : No
```

Table 13-3 Description of the **display aaa configuration** command output

Item	Description
Domain Name Delimiter	Domain name delimiter, which can be any of the following characters: \ / : < > | @ ' %. The default domain name delimiter is @. To configure a domain name delimiter, run the **domain-name-delimiter** command.
Domain	Number of domains. ● total: indicates the total number of domains that can be created. ● used: indicates the number of domains that have been created.
Domainname parse direction	Parsing direction of the domain name. ● Left to right ● Right to left To configure this parameter, run the **domainname-parse-direction** command.

Item	Description
Domainname location	Domain name location. - After-delimiter: The domain name is placed behind the domain name delimiter. - Before-delimiter: The domain name is placed before the domain name delimiter. To configure this parameter, run the **domain-location** command.
Administrator user default domain	Domain name of administrator users.
Normal user default domain	Domain name of normal users.
Authentication-scheme	Number of authentication schemes. - total: indicates the total number of authentication schemes that can be created. - used: indicates the number of authentication schemes that have been created.
Accounting-scheme	Number of accounting schemes. - total: indicates the total number of accounting schemes that can be created. - used: indicates the number of accounting schemes that have been created.
Authorization-scheme	Number of authorization schemes. - total: indicates the total number of authorization schemes that can be created. - used: indicates the number of authorization schemes that have been created.
Service-scheme	Number of service schemes. - total: indicates the total number of service schemes that can be created. - used: indicates the number of service schemes that have been created.
Recording-scheme	Number of recording schemes. - total: indicates the total number of recording schemes that can be created. - used: indicates the number of recording schemes that have been created.

Item	Description
Local-user	Number of local users. - total: indicates the total number of local users that can be created. - used: indicates the number of local users that have been created.
Local-user block retry-interval	Authentication retry interval of a local account. To configure this parameter, run the **local-aaa-user wrong-password** command.
Local-user block retry-time	Maximum number of consecutive authentication failures for a local account. To configure this parameter, run the **local-aaa-user wrong-password** command.
Local-user block time	Locking time of a local account. To configure this parameter, run the **local-aaa-user wrong-password** command.
Remote-access-user block retry-interval	Authentication retry interval for access users who fail remote authentication. To configure this parameter, run the **access-user remote authen-fail** command.
Remote-access-user block retry-time	Maximum number of consecutive authentication failures for access users. To configure this parameter, run the **access-user remote authen-fail** command.
Remote-access-user block time	Locking time for access users who fail remote authentication. To configure this parameter, run the **access-user remote authen-fail** command.
Remote-admin-user block retry-interval	Authentication retry interval for administrators who fail remote authentication. To configure this parameter, run the **administrator remote authen-fail** command.
Remote-admin-user block retry-time	Maximum number of consecutive authentication failures for administrator. To configure this parameter, run the **administrator remote authen-fail** command.
Remote-admin-user block time	Locking period for administrators who fail remote authentication. To configure this parameter, run the **administrator remote authen-fail** command.

Item	Description
Session timeout invalid enable	- Yes: The device will not disconnect or reauthenticate users when the RADIUS server delivers session-timeout with value 0. - No: The device will disconnect or reauthenticate users when the RADIUS server delivers session-timeout with value 0. To configure this parameter, run the **aaa-author session-timeout invalid-value enable** command.
Navigator first login state	Indicates the first login status of the factory device.

13.1.38 display aaa statistics offline-reason

Function

The **display aaa statistics offline-reason** command displays the reasons why users go offline.

Format

display aaa statistics offline-reason

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display aaa statistics offline-reason** command helps you know the reason why a user goes offline. You can locate network faults according to the command output.

Example

Display reasons why users go offline.

```
<HUAWEI> display aaa statistics offline-reason
 19  User request to offline                                                    :2
 87  AAA cut command                                                              :1
```

Table 13-4 Description of the display aaa statistics offline-reason command output

Item	Description
19/87	Reason code.
User request to offline	A user requested to go offline.
2/1	Number of times users go offline.
AAA cut command	A user is disconnected by the **cut access-user** command.

13.1.39 display aaa-quiet administrator except-list

Function

The **display aaa-quiet administrator except-list** command displays IP addresses that a user can use to access the network when the user account is locked.

Format

display aaa-quiet administrator except-list

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

After a user is configured to access the network using a specified IP address when the user account is locked using the **aaa-quiet administrator except-list** command, you can run the **display aaa-quiet administrator except-list** command to check information about the specified IP addresses.

Example

Display IP addresses that a user can use to access the network when the user account is locked.

```
<HUAWEI> display aaa-quiet administrator except-list
--------------------------------------------------------------------------------
 Admin silent whitelist
--------------------------------------------------------------------------------
```

```
10.2.2.1
10.2.2.2
--------------------------------------------------------------------------------
Total: 2, printed: 2
```

Table 13-5 Description of the **display aaa-quiet administrator except-list** command output

Item	Description
Admin silent whitelist	IP addresses configured in a whitelist.

13.1.40 display access-user (all views)

Function

The **display access-user** command displays information about online users (including access users and administrators).

Format

display access-user [**domain** *domain-name* | **interface** *interface-type interface-number* [**vlan** *vlan-id* [**qinq** *qinq-vlan-id*]] | **ip-address** *ip-address* [**vpn-instance** *vpn-instance-name*] | **ipv6-address** *ipv6-address* | **access-slot** *slot-id* | **wired** | **wireless**] [**detail**]

display access-user username *user-name* [**detail**]

display access-user ssid *ssid-name* (This command is supported only on the S5731-H, S5731S-H, S5732-H, S6730S-H and S6730-H.)

display access-user [**mac-address** *mac-address* | **service-scheme** *service-scheme-name* | **user-id** *user-id*]

display access-user statistics

display access-user access-type admin [**ftp** | **ssh** | **telnet** | **terminal** | **web**] [**username** *user-name*]

NOTE

Only the S5731-H, S5731S-H, S6730S-H, S5732-H, and S6730-H support the **wireless** parameter.

Parameters

Parameter	Description	Value
domain *domain-name*	Displays information about users in a specified domain.	The domain name must already exist.

Parameter	Description	Value
interface *interface-type interface-number*	Displays information about users on a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
vlan *vlan-id* [**qinq** *qinq-vlan-id*]	Displays information about users in a VLAN. - *vlan-id* specifies the ID of a VLAN. In QinQ applications, this parameter specifies the inner VLAN ID. - *qinq-vlan-id* specifies the outer VLAN ID. In the authorized ISP VLAN scenario, you can view the user information only when the specified VLAN ID is the ISP VLAN ID.	The values of *vlan-id* and *qinq-vlan-id* are integers that range from 1 to 4094.
ip-address *ip-address*	Displays information about the user with a specified IP address. **NOTE** For NAC or static users, details about the users are displayed. For other users, brief information about the users is displayed.	The value of *ip-address* is in dotted decimal notation.
vpn-instance *vpn-instance-name*	Indicates the name of the VPN instance that the specified IP address belongs to.	The value must be an existing VPN instance name.
ipv6-address *ipv6-address*	Displays information about the user with a specified IPv6 address.	The value consists of 128 bits, which are classified into 8 groups. Each group contains 4 hexadecimal digits in the format X:X:X:X:X:X:X:X.
mac-address *mac-address*	Displays information about the user with a specified MAC address.	The value is in H-H-H format. An H contains four hexadecimal digits.

Parameter	Description	Value
service-scheme *service-scheme-name*	Displays information about the user with a specified service scheme.	The service scheme must already exist.
access-slot *slot-id*	Displays information about users connecting to a specified device.	The value range depends on the model of the device.
ssid *ssid-name*	Specifies the SSID for a service set.	The SSID must already exist. **NOTE** SSID is supported only in the NAC unified mode.
username *user-name*	Displays information about the user with a user name.	The user name must already exist.
statistics	Displays user statistics on the device. - Historical wireless user statistics: displays historical wireless user statistics on the device. - Current online user statistics: displays current user statistics on the device.	The keyword **statistics** is supported only in the NAC unified mode.
user-id *user-id*	Displays information about sessions of a specified user. If this parameter is specified, detailed information about the user is displayed.	The user-id must exist on the device.
detail	Displays detailed information about users.	-
access-type	Displays information about the users using the specified authentication mode.	-

Parameter	Description	Value
admin [**ftp** | **ssh** | **telnet** | **terminal** | **web**]	Displays information about the administrators using the specified authentication mode. ● **ftp**: FTP user ● **ssh**: SSH user ● **telnet**: Telnet user ● **terminal**: Terminal user ● **web**: Web user	-
wired	Displays information about wired users.	-
wireless	Displays information about wireless users.	-

Usage Guidelines

Usage Scenario

This command displays information about user sessions on the device.

Precautions

Administrators with low privilege levels cannot view information about administrators with high privilege levels.

If the character string of the user name contains spaces (for example, a b), you can run the **display access-user username "a b"** command to view online users.

If the character string of the user name contains spaces and quotation marks ("") simultaneously, you cannot use the user name to view online users. In this case, you can run the **display access-user | include** *username* command to view the user ID of the online user, and then run the **display access-user user-id** *user-id* command to view the user. Alternatively, you can run the **cut access-user user-id** *user-id* command to disconnect the user.

When displaying VPN user entries based on user IP address, you must set the **vpn-instance** *vpn-instance-name* parameter to specify the VPN instance to which the IP address belongs.

If **user-id** is specified, detailed information about the specified user is displayed. If **user-id** is not specified, brief information about all online users is displayed, including the user ID, user name, IP address, and MAC address of each user.

Only letters, digits, and special characters can be displayed for **username**.

When the value of **username** contains special characters or characters in other languages except English, the device displays dots (.) for these characters. If there are more than three such consecutive characters, three dots (.) are displayed. Here, the special characters are the ASCII codes smaller than 32 (space) or larger than 126 (~).

When you run the **display access-user** command without specifying any parameter to view user information and the value of **username** is longer than 20 characters, the device displays up to three dots (.) for the characters following the 19th character; that is, only 22 characters are displayed. When you run the **display access-user** command with parameters specified to view detailed information about the user table, all the characters of **username** are displayed, and the rule for converting special characters remains unchanged.

When **interface** is specified, the device displays the connection information of online wired users on the interface.

When querying user information based on interfaces, MAC addresses, or VLANs, the device only displays information about 802.1X, Portal, or MAC address authentication users.

Example

Display information about user sessions on the device.

```
<HUAWEI> display access-user
 ------------------------------------------------------------------------------------------
 UserID Username                    IP address                MAC           Status
 ------------------------------------------------------------------------------------------
 1      normal@local                -                         xxxx-xxxx-xxxx    Success
 62     005500000001                192.168.1.121             xxxx-xxxx-xxx1    Open
 32675  fztest                      -                         xxxx-xxxx-xxx2    Success
 16019  b002404                     192.168.1.2               xxxx-xxxx-xxx3    Success
 ------------------------------------------------------------------------------------------
 Total: 4, printed: 4
```

NOTE

If you specify the **include** or **exclude** parameter in the command, the values of **Total** and **printed** are still the total number of users.

Display information about the user with the user ID 1.

```
<HUAWEI> display access-user user-id 1
Basic:
  User ID                         : 1
  User name                       : normal
